

Networking in One Day!

Developers Guide, API, Production and Deployment

NetBurner 3.5.0

NetBurner, Inc. 5-Apr-2024

1 NetBurner 3.5.0	1
1.1 Welcome to NetBurner Version 3!	1
1.2 Who Is This Guide For?	1
1.3 Recommended Starting Point for New Developers	2
1.4 Documentation Overview	2
1.4.1 The NetBurner Application Programming Interface (API)	2
1.4.2 Device Discovery and Configuration	3
1.4.3 The NBEclipse Getting Started Guide	3
1.4.4 Migration Guides	3
1.4.5 Example Programs	3
1.4.6 Programmers Guide	4
1.4.7 Platform References	4
1.4.8 System Diagnostics	4
1.4.9 Utilities	4
1.4.10 Production and Deployment	4
1.4.11 Location of Original Factory Program	5
1.4.12 Experienced NetBurner Customers	5
2 Build System	7
2.1 Introduction	7
2.2 GCC Compiler Flags	7
2.2.1 Generic	7
2.2.2 Architecture-Specific Compiler Flags	9
2.2.2.1 ARM Cortex-M7	9
2.2.2.2 ARM Cortex-M0+	9
2.2.2.3 ColdFire	9
2.2.3 CPU-Specific Compiler Flags	9
2.2.3.1 SAME70	9
2.2.3.2 MIMXRT11xx, MIMXRT10xx	10
2.2.3.3 SAMD20	10
2.2.3.4 MCF5441X	10
2.2.4 Platform-Specific Compiler Flags	10
2.2.4.1 MODM7AE70	10
2.2.4.2 SBE70LC	11
2.2.4.3 SOMRT1061	11
2.2.4.4 MOD5441X	11
2.2.4.5 NANO54415	11
2.2.4.6 SB800EX	11
2.3 Linker Flags	11
2.3.1 Generic	11
2.3.2 Architecture-Specific Linker Flags	12
2.3.3 CPU-Specific Linker Flags	12

2.3.3.1 SAME70	12
2.3.3.2 MIMXRT11xx, MIMXRT10xx	12
2.3.3.3 SAMD20	12
2.3.3.4 MCF5441X	13
2.3.4 Platform-Specific Linker Flags	13
2.4 Pack Binary	13
2.4.1 Generic	13
2.4.2 Architecture-Specific	13
2.4.3 CPU-Specific	13
2.4.3.1 MCF5441X	13
2.4.3.2 SAMD20	14
2.4.3.3 SAME70	14
2.4.3.4 MIMXRT11xx, MIMXRT10xx	14
2.4.4 Platform-Specific	14
2.4.4.1 MODM7AE70	14
2.4.4.2 SBE70LC	14
2.4.4.3 SOMRT1061	14
2.4.4.4 MOD5441X	15
2.4.4.5 NANO54415	15
2.4.4.6 SB800EX	15
3 Command Line Tools	17
3.1 Introduction	17
3.2 Command Line Summary	17
3.3 Command Line Environment Variables	17
3.4 Create a New Project From an Example	18
3.4.1 Edit the makefile	19
3.4.2 Edit main.cpp	19
3.5 Modifying System Files with Overload	20
3.5.1 Predef.h and predef-overload.h	20
3.5.2 Important Overload Rules	20
3.6 GNU Debugger (GDB)	21
3.6.1 Example GDB Session	21
3.7 Addr2line	24
3.7.1 ColdFire platforms	24
3.7.2 ARM platforms	24
4 Device Discovery and Configuration	25
4.1 Introduction	25
4.1.1 Device Discovery Methods:	25
4.1.2 Device Configuration methods:	25
4.2 Configuration Procedure	26
4.2.1 Configuration Settings	28

4.2.1.1 Config	28
4.2.1.2 Update Application	28
4.2.1.3 Config → Sys	28
4.2.1.4 Config → Sys → BOOT	28
4.2.1.5 Config → Sys → Netlf	29
4.2.1.6 Config → Sys → Netlf → Ethernet0	29
4.2.1.7 Config → Sys → Netlf → Ethernet0 → IPv4	29
4.2.1.8 Config → Sys → Netlf → Ethernet0 → IPv6	30
4.3 The JSON Object	31
4.3.1 Developer Notes	32
4.4 Configuration Security	33
4.5 Serial Port Configuration	33
5 Migration Guides	41
5.1 Release 2.x to 3.x Overview	41
5.1.1 Hardware	42
5.1.2 Configuration	42
5.1.3 RTOS	42
5.1.4 TCP	43
5.1.5 Network Interfaces	43
5.1.6 SSL/TLS	43
5.1.7 System Initialization	43
5.1.8 NBEclipse	43
5.1.9 GCC	44
5.2 Release 2.x to 3.x Porting Guide	44
5.2.1 Device Configuration	44
5.2.2 Configuration Procedure	44
5.2.3 Recommended Examples	45
5.2.4 Configuration Security	45
5.2.4.1 Cautions When Using the Jumper Recover Procedure on a Device	46
5.2.5 Device Application Updates	46
5.2.6 Eclipse and Development Tools Updates	46
5.2.7 SSL/TLS	47
5.2.8 Notes on Porting From Previous Revisions	47
5.2.9 Porting I2C From MCF52xx Based Products to MODM7AE70	48
5.3 Upgrade 5441x Platforms to 3.x	50
5.3.1 Introduction	50
5.3.2 5441x Product Models Numbers	50
5.3.3 3.x Update Procedures	50
5.3.3.1 Procedure For a New 5441x Device Running The NetBurner Factory App	51
5.3.3.2 Procedure Using the 2.x to 3.x Conversion Application: xxxx-3p0-Update_APP.s19	51
5.3.3.3 Procedure Using Alternate Boot Monitor	51

5.3.4 Procedure to Revert Back to 2.x	52
5.3.4.1 Serial Port Procedure	52
5.3.4.2 Hardware Reset Jumper Procedure	52
5.3.5 Note on IPSetup utility and 3.x Devices	53
6 NBEclipse	55
6.1 Getting Started Guide	55
6.1.1 Introduction	55
6.1.1.1 How to Use This Guide	55
6.1.1.2 Source Code for Example Programs	56
6.1.1.3 Hardware Setup	56
6.1.1.4 Software Installation	56
6.1.1.5 Upgrading From a Previous Installation	56
6.1.1.6 Java Installation	56
6.1.1.7 Debug Port	57
6.1.2 Platform Overview	57
6.1.2.1 NetBurner Development Platform Choices	57
6.1.3 Project Management	57
6.1.3.1 NBEclipse Key Points	58
6.1.4 Creating Projects and Importing Files	58
6.1.4.1 Create a New Project	59
6.1.4.2 Select the NetBurner Project Type	59
6.1.4.3 Specify Project Name and Executable Option	60
6.1.4.4 Project Configurations	61
6.1.4.5 Select Your NetBurner Target Device	62
6.1.4.6 Application Wizard	64
6.1.4.7 New Project Created	65
6.1.4.8 Import Example Source Files to the Project SRC Folder	66
6.1.4.9 Open your main.cpp source file	70
6.1.4.10 Project Import Complete	71
6.1.4.11 Download the Application to Your Device	73
6.1.4.12 View the Device Web Page	76
6.1.4.13 View Serial Port Status Messages with MTTTY	77
6.1.5 Debugger	78
6.1.5.1 Starting a Debug Session	78
6.1.6 Rebuilding Projects & Libraries	81
6.1.6.1 Rebuild Project Source Files	81
6.1.6.2 Rebuild Library Files	82
6.1.7 Overload Directory	83
6.2 Add a Library to a Project	90
6.3 Change The IP Targeted By A Project	91
7 PC Tools and Utilities	93

7.1 Multi-threaded TTY Serial Terminal (MTTTY)	93
7.1.1 MTTTY FAQ	94
7.2 Wget	94
7.3 NBUupdate	95
7.4 Smart Traps	95
7.4.1 Trap Information	96
7.4.2 Register Information	97
7.4.3 RTOS Information	97
7.4.4 Task Information	97
7.5 Task Scan	97
7.5.1 TaskScan FAQ	98
7.6 WinAddr2Line	99
7.6.1 Using WinAddr2Line	100
7.7 IPSetup	100
7.8 AutoUpdate	100
7.9 Virtual Comm Port	101
7.10 CompHtml	101
7.11 CompCode	101
7.12 flashpack	101
8 Platform References	103
8.1 MODM7AE70 Platform Reference	103
8.1.1 Introduction	103
8.1.2 MODM7AE70 Processor Information	103
8.1.3 Datasheet	103
8.1.4 Development Board Schematic	103
8.1.5 Memory Operation	104
8.1.6 Memory Map	104
8.1.7 External Bus Interface	104
8.2 MOD54415, MOD54417 Platform Reference	104
8.2.1 Introduction	104
8.2.2 MCF5441x Processor Information	105
8.2.3 Datasheet	105
8.2.4 Development Board Schematic	105
8.2.5 Memory Operation	105
8.2.6 Memory Map	106
8.3 NANO54415 Platform Reference	106
8.3.1 Introduction	106
8.3.2 MCF54415 Processor Information	106
8.3.3 Datasheet	106
8.3.4 Development Board Schematic	107
8.3.5 Memory Operation	107

8.3.6 Processor Runtime Memory Map	107
8.3.7 Application SPI Flash Memory	108
8.4 SB800EX Platform Reference	108
8.4.1 Introduction	108
8.4.2 MCF54415 Processor Information	108
8.4.3 Datasheet	108
8.4.4 Memory Operation	108
8.4.5 Processor Runtime Memory Map	109
8.4.6 Application SPI Flash Memory	109
8.5 SBE70LC Platform Reference	110
8.5.1 Introduction	110
8.5.2 SBE70LC Processor Information	110
8.5.3 Datasheet	110
8.5.4 Development Board Schematic	110
8.5.5 Memory Operation	110
8.5.6 Memory Map	110
8.6 SOMRT1061 Platform Reference	111
8.6.1 Introduction	111
8.6.2 Datasheet	111
8.6.3 Development Board Schematic	111
8.6.4 SOMRT1061 Platform General Information	111
8.6.4.1 The 8MB of Flash uses a Flash File System and is used for all storage purposes:	111
8.6.4.2 External Memory Bus	112
8.6.5 Boot Sequence	112
8.7 Recovery: MODM7AE70, SBE70LC	112
8.7.1 Introduction	112
8.7.2 Repeating Traps or Resets	112
8.7.2.1 Step 1: Abort to the Configuration Server	113
8.7.2.2 Step 2: Download a New Application	113
8.7.3 Unresponsive Device or No Serial Port Access	113
8.7.3.1 Recovery Jumper Locations	114
8.8 Recovery: MOD5441x, NANO54415, SB800EX	116
8.8.1 Step 1: Abort to the Alternate Boot Monitor	116
8.8.2 Recovery Jumper Locations	117
8.8.2.1 NANO54415	117
8.8.2.2 MOD5441x	117
8.8.2.3 SB800EX	118
8.8.3 Step 2: Download a New Application	119
8.8.3.1 Network	119
8.8.3.2 Serial Port	119
8.9 Recovery: SOMRT1061	120
8.9.1 Introduction	120

8.9.2 Boot Components and Features Overview	120
8.9.3 Boot Sequence Overview	120
8.9.3.1 Normal Boot	120
8.9.3.2 Incorrect Network Settings	120
8.9.3.3 Application Starts, But Traps After Application Initialization	121
8.9.3.4 Application Starts, But Traps Before Application Initialization	121
8.9.4 Procedure to Abort to the Configuration Server	121
8.9.5 Uploading a New Application	121
8.9.5.1 Web Page Upload	121
8.9.5.2 NBUpdate	121
8.9.5.3 Serial Console Interface	121
8.9.6 Procedures to Abort to the Alternate Boot Monitor	122
8.9.6.1 No Valid Application	122
8.9.6.2 Configuration Server Access Operational	122
8.9.6.3 Application Traps Before UserMain() Starts	122
8.9.7 Hardware Jumper Recovery	122
8.9.7.1 Recovery Jumper Operation	122
8.9.7.2 Procedure	123
8.9.7.3 Recovery Jumper Location	123
8.10 ARM Cache Management	124
8.10.1 Details	124
8.10.2 Instructions	124
8.10.2.1 Turning cache on/off	124
8.10.2.2 Declaring static objects non cachable	124
8.10.2.3 Cleaning Cache	124
8.10.2.4 Invalidating Cache	124
9 Production & Deployment	125
9.1 Production Releases and Customer Deployment	125
9.2 Finding a Device on a Network	125
9.3 Application Programming	125
9.3.1 Configuration Web Page	126
9.3.2 nbupdate Utility	126
9.3.3 wget Utility	126
9.3.3.1 Program an Application	126
9.3.3.2 Read The Configuration	127
9.3.3.3 Program New Configuration Settings	127
9.4 Customer Configuration	127
10 Programmers Guide	129
10.1 Introduction	129
10.1.1 Source Code for Example Programs	130
10.1.2 Tools and Library Version Information	130

10.1.3 Application Wizard Project	130
10.2 Config Server Programming Guide	131
10.2.1 Introduction	131
10.2.2 Configuration Parameters	131
10.2.2.1 Config	131
10.2.2.2 Config.AppData	132
10.2.2.3 Config.Sys	132
10.2.3 The Configuration Web Interface	134
10.2.4 Serial Configuration Interface	135
10.2.5 Creating a Custom Web Interface	136
10.2.6 Configuration API Examples	136
10.3 Custom Branding	136
10.4 IPv4/IPv6 Dual Stack Guide	137
10.4.1 Obtaining IPv6 addresses	137
10.4.1.1 Link-Local	137
10.4.1.2 Router Auto-Configuration	137
10.4.1.3 DHCPv6	137
10.4.1.4 Static IP Addresses	137
10.4.2 IPADDR Class	137
10.4.3 IPADDR Member Functions	138
10.4.3.1 Setting IP Address Values with Member Functions	138
10.4.3.2 Member functions to set an IP address:	138
10.4.3.3 Setting IP Address Values with Static Functions	138
10.4.3.4 Reading and Checking IP Address Values	139
10.4.3.5 Output an IP Address	139
10.4.4 Domain Name Service (DNS)	139
10.4.5 Note for OSX Users	140
10.5 EDFS Programming Guide	140
10.5.1 Example Programs	140
10.5.2 Reference Manuals for the EDFS API	140
10.5.3 Supported Hardware Platforms	140
10.5.4 Debug Port	141
10.5.5 Flash Card Hardware Interface Design	141
10.5.5.1 Flash Card Hardware Interface Design	141
10.5.6 EDFS-FAT File System Operation	143
10.5.6.1 EDFS-FAT File System Operation	143
10.5.7 EDFS-STD File System with On-chip Flash	145
10.5.7.1 Using the EDFS-STD File System with On-chip Flash	145
10.6 File Descriptors	148
10.6.1 Creating Custom I/O Drivers Using File Descriptors	148
10.6.2 Using File Descriptors to Pend on Multiple Events	149
10.7 HTML Processing	149

10.7.1 Introduction	149
10.7.2 Dynamic Content	150
10.7.3 HTML Tags	150
10.7.3.1 Configuration System Tags	150
10.7.3.2 The CPPCALL Tag	151
10.7.3.3 The VARIABLE Tag	153
10.7.3.4 The INCLUDE Tag and htmlvar.h Header File	153
10.7.3.5 The VARIABLE() Tag With Parameters	154
10.7.3.6 Extending the VARIABLE Tag	154
10.7.3.7 The CONFIGVALUE Tag	154
10.7.4 HTTP GET Request Handler	154
10.7.5 HTTP Form POST Handler	156
10.8 Interrupt Handling	159
10.8.1 Overview	159
10.8.2 Recommended Interrupt Functions	159
10.8.3 Functions That Cannot Be Called in an ISR	159
10.8.3.1 All nbrtos init and pend functions (all OsxxPendNoWait functions are okay):	159
10.8.3.2 I/O functions:	160
10.8.3.3 Memory management functions:	160
10.8.4 MODM7AE70 and SBE70LC Platforms (SAME70)	160
10.8.4.1 Configure the interrupt request (IRQ) priority for a PIO pin	160
10.8.4.2 Configure the interrupt request (IRQ) priority for a PIO port	161
10.8.4.3 Set up an interrupt request (IRQ) pin	161
10.8.4.4 Enable the interrupt for the given PinIO	161
10.8.4.5 Disable the interrupt for the given PinIO	162
10.8.5 MOD54415, MOD54417, NANO54415 and SB800EX Platforms (MCF5441x)	162
10.8.5.1 INTERRUPT() Macro	162
10.8.5.2 SetIncC() function (Set Interrupt Controller)	163
10.8.5.3 Example, OneWire Interrupt Configuration	164
10.8.6 SOMRT1061 Platform	164
10.9 JSON Lexer	164
10.9.1 Using the JSON Lexer Interface	164
10.9.2 Earthquake Example	166
10.9.2.1 Source Code	166
10.9.2.2 Earthquake Summary Serial Output	167
10.9.2.3 JSON Data Parsed From Web Site	167
10.10 NetBurner RTOS	175
10.10.1 What is a Preemptive RTOS?	176
10.10.2 Preemptive Operation, Priorities and Blocking	176
10.10.2.1 RTOS Blocking Functions	176
10.10.2.2 I/O Functions That Can Block	176
10.10.2.3 Network Functions That Can Block	176

10.10.2.4 Functions That Can Enable a Task To Be "Ready To Run"	176
10.10.2.5 System Task Priorities	177
10.10.3 Task Creation	177
10.10.4 Protecting Shared Data	178
10.10.5 Semaphore	180
10.10.6 Queues	180
10.10.7 FIFO	180
10.10.8 Critical Section	180
10.10.9 OS Flags	180
10.11 Network Protocols	181
10.11.1 TCP vs UDP	181
10.11.1.1 TCP	182
10.11.2 TCP Server	182
10.11.2.1 NetBurner TCP Server Basics	182
10.11.2.2 Simple TCP Server Example	183
10.11.2.3 Advanced TCP Server for Multiple Connections	184
10.11.3 TCP Client	186
10.11.3.1 Application Source Code	187
10.11.4 UDP Class	191
10.11.4.1 Receiving UDP Packets Using the UDP Class	191
10.11.4.2 Sending a UDP Packet Using the UDP Class	191
10.11.4.3 UDP Send/Receive Example with UDP Class	192
10.11.5 UDP Sockets	193
10.11.5.1 Receiving UDP Packets using UDP Sockets	194
10.11.5.2 Sending UDP Packets using UDP Sockets	194
10.11.5.3 UDP Send/Receive Example Using Sockets	194
10.12 SSL/TLS Programming Guide	195
10.12.1 Quick Start	196
10.12.2 SSL/TLS Fundamentals	196
10.12.3 Certificate Issuer Decision Matrix	200
10.12.4 SSL/TLS Instructions	202
10.12.4.1 Automatic Onboard Trusted Certificate Creation with an ACME CA	202
10.12.4.2 Automatic Onboard Self-Signed Certificate Creation	203
10.12.4.3 Manual Private CA Certificate Creation	203
10.12.4.4 Obtaining Certificates via a third-party Certificate Authority	203
10.12.4.5 Manual Certificate Installation	204
10.12.4.6 Testing Your Certificates	204
10.12.4.7 Creating a Certificate Authority List	205
10.12.5 SSL/TLS Troubleshooting	205
10.12.5.1 Troubleshooting Browser Warnings	205
10.13 SSH Programming Guide	206
10.13.1 SSH Overview	206

10.13.1.1 Supported Key Types, Sizes, and Formats	206
10.13.1.2 Migrating from NNDK 3.3.5 and earlier to 3.3.6 or later	206
10.13.1.3 Onboard Generated Keys	208
10.13.1.4 Order of Key Use	208
10.13.1.5 User Authorization	208
10.14 Web Server	208
10.14.1 Basic Web Server	208
10.14.2 Dynamic Web Content	209
10.14.2.1 Dynamic Content Using the CPPCALL Tag	210
10.14.2.2 Displaying Variables Using the VARIABLE Tag	210
10.14.2.3 Linking to Variables Using the INCLUDE Tag and htmlvar.h Header File	211
10.14.2.4 Function Callbacks With Variables Using the VARIABLE Tag	211
10.14.2.5 Extending the VARIABLE tag for User Defined Types	211
11 System Diagnostics	213
11.1 Introduction	213
11.2 Configuration Server Page with Diagnostics Enabled	213
11.3 System Configuration Web Page Display	214
11.4 Adding Your Own Diagnostic Information	217
12 Example Applications	219
12.1 Example Applications Main Page	219
12.2 AES	221
12.3 Board Lock	222
12.3.1 Key Blob	222
12.3.2 Sign Board	222
12.3.3 Check Lock	222
12.4 Clear Configuration Flash	223
12.5 Clear User Parameter Flash	223
12.6 Configuration	223
12.6.1 Application Data	223
12.6.1.1 Basic Config Variables	223
12.6.1.2 Config Class	224
12.6.1.3 Nesting Config Objects	224
12.6.2 Config and System Params	225
12.6.2.1 Modify Boot	225
12.6.2.2 Modify Ethernet Interface	225
12.6.2.3 Show Configuration	225
12.6.3 Config Web Interfaces	225
12.6.3.1 Basic Web Config	226
12.6.3.2 Basic Web Config with SSL/TLS	226
12.6.3.3 Config Tags	226
12.6.3.4 Custom Web Config	227

12.6.3.5 Custom Web System Config	227
12.6.4 Detached Config Object	228
12.7 DNS Device Name	228
12.8 DHCP	228
12.8.1 DHCP Client - Change IP Address	229
12.8.2 DHCP Client - Test DHCP	229
12.8.2.1 Example of advanced DHCP functionality	229
12.8.3 DHCP Server (DHCPD)	229
12.8.4 DHCP Client - Change IP Address Via Webpage	229
12.9 DNS Client	230
12.10 Embedded Flash File System (EFFS)	230
12.10.1 FAT File System (EFFS-FAT)	230
12.10.1.1 Application Update	231
12.10.1.2 Basic	231
12.10.1.3 FTP	231
12.10.1.4 HTTP	231
12.10.1.5 HTML Variables	233

Index**1799**

Chapter 1

NetBurner 3.5.0

1.1 Welcome to NetBurner Version 3!

This documentation package details the capabilities of your NetBurner Development Software and Tools. If you are viewing this document from your development tools installation, the latest version is available at www.netburner.com. There is also a pdf version of this document at [PDF Version](#)

Note

Version 3 is used as a development platform on all ARM based devices, as well as MOD5441x, NANO54415 and SB800EX devices. If you have an earlier ColdFire based device please refer to the version 2 development tools.

1.2 Who Is This Guide For?

NetBurner devices come in two forms:

- Devices pre-programmed with factory applications that can be used without any custom programming on the device itself. Serial to Ethernet devices are a good example of this.
- If you wish to customize any device, we provide development tools that enable you to create custom applications.

This guide is intended for software developers to create custom applications to run on NetBurner devices. If you are using a device that does not require custom programming, please refer to that device's product page for documentation and any appropriate software utilities.

1.3 Recommended Starting Point for New Developers

Your NetBurner development system is pre-programmed with a factory application. If connected to a network with Internet access and a DHCP server, you can open a web browser, go to discover.netburner.com, and access your device immediately; both the application web page and configuration interface.

If you are connected directly, such as a laptop with a direct Ethernet connection, or on a network without a DHCP server and Internet access, please see the procedure below:

- Configure the development kit device/hardware (if necessary) as described in the Quick Start Guide.
- Connect both your development computer and your NetBurner device to a network with Internet access. Internet access is not required for development, but will make the initial configuration of the device easier.
- If using a development kit with a USB interface, connect it from the development board to your computer. It will provide both power and a console/debug serial port. To view status and debug information, run a serial terminal program such as the included MTTY, although any serial terminal application should work.
- Your NetBurner device will be running a pre-programmed factory application. Open a web browser and type "discover.netburner.com" to identify your device. Links on the web page are available to go directly to the device's web page and configuration page.

Note

If you do not have an Internet connection, you can use a utility such as `localdiscover`. Please refer to the Device Discovery and Configuration section of this guide.

- Refer to the NBEclipse Getting Started Guide section of this document to learn how to create, build and download applications. If you prefer to use command line tools, they are available as well.
- Select one of the examples from the "`\nburn\examples`" folder. Create a project and download per the NBEclipse Guide.
- Refer to the Programmers Guide and NetBurner API documents for additional information.

Note

NBEclipse provides auto-complete functionality by pressing `ctrl-space`. This makes accessing the API functions much easier.

1.4 Documentation Overview

1.4.1 The NetBurner Application Programming Interface (API)

Description of the functions and capabilities in the NetBurner Library API. These functions include:

- Real-Time Operating System
- TCP/IP Stack
- Peripherals, such as SPI, I2C, 1-Wire, UARTs, ADC, DAC, Timers, etc
- Description of objects, classes and structures
- Function error codes

1.4.2 Device Discovery and Configuration

How to locate your NetBurner device as well as configure system parameters.

1.4.3 The NBEclipse Getting Started Guide

Describes how to create projects and build applications.

1.4.4 Migration Guides

Information for those moving from tools revision 2.x to 3.x.

1.4.5 Example Programs

Well over 100 example programs on everything from web servers, TCP, UDP, Configuration to hardware peripherals. The examples are described in this guide, and located in the "\nburn\examples" folder of your installation.

Note

NBEclipse provides an easy example import feature when you create a new project.

Interesting Starting Examples:

- ShowInterfaces: Displays all available network interface information on a web page and serial port
- SimpleHtml: Minimal web server
- IPADDR-IP Address: IPADDR object operations for assignment and display
- PlatformSpecific folder: Unique peripherals for each hardware platform, such as timers, ADC, DAC and unique I2C and SPI peripherals
- RTOS folder: How to use the various system RTOS capabilities

1.4.6 Programmers Guide

Textbook style guide on how to use the various features of your device and networking.

- Device configuration and the Configuration Server
- HTML Processing and Web Server
- NetBurner Real-Time Operating System (NBRTOS)
- Network Protocols such as TCP and UDP
- Security using SSL/TLS
- Embedded Flash File System (EFFS)

1.4.7 Platform References

The Platform References of this guide provide hardware information such as memory maps and device recovery should your application crash in a way that is not easily reset. Schematics for your NetBurner devices are located in the `\nburn\docs\NetBurner\platform` folder.

1.4.8 System Diagnostics

Information on how to enable and use built-in device diagnostics as well as customizing to add your own.

1.4.9 Utilities

Tools and Utilities that are run on a client computer, such as discover, configuration, and application updates.

1.4.10 Production and Deployment

Creating a great application and end product is just part of what needs to be done for a successful product. NetBurner provides deployment information and utilities that you can use in your production environment to program and configure modules in volume, as well as offer to your end customers.

1.4.11 Location of Original Factory Program

If at any time you wish to restore the original factory program that was running on your device, the pre-built application image is located in the `\nburn\platform\ folder. For example, \nburn\platform\MODM7AE70\original. This path assumes a default install to a folder named nburn.`

1.4.12 Experienced NetBurner Customers

A significant change you will notice is how the device configuration is accomplished using a web interface. Please refer to the Migration Guide for a detailed description of the differences between release version 3 and previous releases.

Chapter 2

Build System

2.1 Introduction

The Build System section contains information on subjects such as the GCC Compiler and Build Environment.

2.2 GCC Compiler Flags

Compiler flags can be added or modified in both NBEclipse and command line makefiles.

2.2.1 Generic

Language	Mode	Flag	Description
C/C++	R, D	<code>-gdwarf-2</code>	Adds dwarf-2 debug symbols to the binary. This makes it easier to resolve symbols in gdb.
C/C++	R, D	<code>-Wall</code>	Enables all warnings.
C/C++	R, D	<code>-Werror=return-type</code>	Treats warnings as errors for functions that are missing a return statement.
C/C++	R, D	<code>-Wno-unused</code>	Suppresses warnings for unused variables.
C/C++	R, D	<code>-falign-functions=4</code>	Aligns functions to 4-byte boundaries for improved performance.
C/C++	R	<code>-O2</code>	Enables level 2 optimization for improved performance.
C/C++	D	<code>-O0</code>	Disables optimization for debugging.

Language	Mode	Flag	Description

2.2.2 Architecture-Specific Compiler Flags

2.2.2.1 ARM Cortex-M7

Language	Mode	Flag	Description
C/C++	R, D	<code>-fasynchronous-unwind-tables</code>	Enables asynchronous unwind tables
C/C++	R, D	<code>-D_C11_SOURCE</code>	Defines the <code>_C11_SOURCE</code> macro.
C/C++	R, D	<code>-DCORTEX_M7</code>	Defines the <code>CORTEX_M7</code> macro.

2.2.2.2 ARM Cortex-M0+

Language	Mode	Flag	Description
C/C++	R, D	<code>-fasynchronous-unwind-tables</code>	Enables asynchronous unwind tables
C/C++	D	<code>-fomit-frame-pointer</code>	Omit frame pointer for improved performance.
C/C++	R, D	<code>-D_C11_SOURCE</code>	Defines the <code>_C11_SOURCE</code> macro.
C/C++	R, D	<code>-DCORTEX_M0PLUS</code>	Defines the <code>CORTEX_M0PLUS</code> macro.

2.2.2.3 ColdFire

Language	Mode	Flag	Description
C/C++	R, D	<code>-fno-omit-frame-pointer</code>	Do not omit frame pointer for improved debugging.
C/C++	R, D	<code>-fasynchronous-unwind-tables</code>	Enables asynchronous unwind tables
C/C++	R, D	<code>-DCOLDFIRE</code>	Defines the <code>COLDFIRE</code> macro.
Assembler	D	<code>--defsym _DEBUG=1</code>	Defines the <code>_DEBUG</code> symbol.

2.2.3 CPU-Specific Compiler Flags

2.2.3.1 SAME70

Language	Mode	Flag	Description
C/C++	R, D	<code>-mcpu=cortex-m7</code>	Specifies the CPU architecture.
C/C++	R, D	<code>-mthumb</code>	Specifies the Thumb instruction set.

Language	Mode	Flag	Description
C/C++	R, D	-mfpv5=fpv5-d16	Specifies the floating-point unit.
C/C++	R, D	-mfloat-abi=\$(ABI_OPT)	Specifies the floating-point ABI. Defaults to softfp
C/C++	R, D	-D\$(CPU)	Defines the \$(CPU) macro.
C++	R, D	-fno-use-cxa-atexit	Disables the use of <code>__cxa_atexit</code>
C++	R, D	-falign-functions=4	Aligns functions to 4-byte boundaries for improved performance.

2.2.3.2 MIMXRT11xx, MIMXRT10xx

Language	Mode	Flag	Description
C/C++	R, D	-mcpu=cortex-m7	Specifies the CPU architecture.
C/C++	R, D	-mthumb	Specifies the Thumb instruction set.
C/C++	R, D	-mfpv5=fpv5-d16	Specifies the floating-point unit.
C/C++	R, D	-mfloat-abi=\$(ABI_OPT)	Specifies the floating-point ABI. Defaults to softfp
C/C++	R, D	-D\$(CPU)	Defines the \$(CPU) macro.
C++	R, D	-fno-use-cxa-atexit	Disables the use of <code>__cxa_atexit</code>
C++	R, D	-falign-functions=8	Aligns functions to 8-byte boundaries for improved performance.

2.2.3.3 SAMD20

Language	Mode	Flag	Description
C/C++	R, D	-mcpu=cortex-m0plus	Specifies the CPU architecture.
C/C++	R, D	-mthumb	Specifies the Thumb instruction set.
C++	R	-fno-use-cxa-atexit	Disables the use of <code>__cxa_atexit</code>
C++	R	-falign-functions=4	Aligns functions to 4-byte boundaries for improved performance.

2.2.3.4 MCF5441X

Language	Mode	Flag	Description
C/C++	R, D	-D\$(CPU)	Defines the \$(CPU) macro.
C/C++	R, D	-mcpu=54415	Specifies the CPU architecture.

2.2.4 Platform-Specific Compiler Flags

2.2.4.1 MODM7AE70

Language	Mode	Flag	Description
C/C++	R, D	-D__SAME70Q21__	Defines the <code>__SAME70Q21__</code> macro.
C/C++	R, D	-DMODM7AE70	Defines the <code>MODM7AE70</code> macro.

2.2.4.2 SBE70LC

Language	Mode	Flag	Description
C/C++	R, D	-D__SAME70Q21↔ __	Defines the __SAME70Q21__ macro.
C/C++	R, D	-DSBE70LC	Defines the SBE70LC macro.

2.2.4.3 SOMRT1061

Language	Mode	Flag	Description
C/C++	R, D	-D__MIMXRT106xx↔ __	Defines the __MIMXRT106xx__ macro.
C/C++	R, D	-D__MIMXRT1061_↔ _	Defines the __MIMXRT1061__ macro.
C/C++	R, D	-DSOMRT1061	Defines the SOMRT1061 macro.

2.2.4.4 MOD5441X

Language	Mode	Flag	Description
C/C++	R, D	-DMOD5441X	Defines the MOD5441X macro.

2.2.4.5 NANO54415

Language	Mode	Flag	Description
C/C++	R, D	-DNANO54415	Defines the NANO54415 macro.

2.2.4.6 SB800EX

Language	Mode	Flag	Description
C/C++	R, D	-DSB800EX	Defines the SB800EX macro.

2.3 Linker Flags

2.3.1 Generic

Flag	Description
\$ (CPUFLAG)	Specifies the CPU architecture flag.
-Wl, -n	Disables linking to dyn
-T\$(NNDK_ROOT)/platform/\$(PLATFORM)/liblinker.scrip	Specifies the linker script.

Flag	Description
<code>-Wl, -R\$(NNDK_ROOT)/platform/\$(PLATFORM)</code>	Specifies the linker script.
<code>-Wl, -Map=\$(@:.elf=.map)</code>	Generates a map file.
<code>-Wl, --cref</code>	Generates a cross-reference table.
<code>-Wl, --gc-sections</code>	Removes unused sections to reduce the size of the binary.
<code>-Wl, --start-group, \$(NBLIBS) \$(XTRALIB) -lstdc++ -lc -Wl, --end-group</code>	Specifies the libraries to link.

2.3.2 Architecture-Specific Linker Flags

None

2.3.3 CPU-Specific Linker Flags

2.3.3.1 SAME70

Flag	Description
<code>-nostartfiles</code>	Disables linking to the default startup files.
<code>-mfloat-abi=\$(ABI_OPT)</code>	Specifies the floating-point ABI. Defaults to softfp
<code>-Wl--thumb-entry=Reset_Handler</code>	Specifies the entry point.
<code>-Wl--thumb-entry=_start_</code>	Specifies the entry point. (SOMRT1061)

2.3.3.2 MIMXRT11xx, MIMXRT10xx

Flag	Description
<code>-nostartfiles</code>	Disables linking to the default startup files.
<code>-mfloat-abi=\$(ABI_OPT)</code>	Specifies the floating-point ABI. Defaults to softfp
<code>-Wl--thumb-entry=Reset_Handler</code>	Specifies the entry point.

2.3.3.3 SAMD20

Flag	Description
<code>-nostartfiles</code>	Disables linking to the default startup files.
<code>-Wl--thumb-entry=Reset_Handler</code>	Specifies the entry point.

2.3.3.4 MCF5441X

None

2.3.4 Platform-Specific Linker Flags

None

2.4 Pack Binary

2.4.1 Generic

None

2.4.2 Architecture-Specific

None

2.4.3 CPU-Specific

2.4.3.1 MCF5441X

Executable	I/O	Flag	Description
m68k-elf-objcopy	.elf -> .s19	-O srec	Converts the elf file to s19
m68k-elf-objcopy	.elf -> .s19	-Wl,--gc-sections	Removes unused sections to reduce the size of the binary.
m68k-elf-objcopy	.elf -> .s19	--strip-all	Removes all symbols from the binary.
compcode	.s19 -> _APP.s19	-M \$(^↵ :.s19=.map)	Specifies the map file.
compcode	.s19 -> _APP.s19	-R	Print report.
compcode	.s19 -> _APP.s19	-P\$(PLATFORM)	Specifies the platform.
NetBurner, Inc. © Apr-2024	.s19 -> .bin	-O binary	Converts the s19 file to binary
compcode	.s19 -> .bin	-M \$(^↵ :.s19=.map)	Specifies the map file.

2.4.3.2 SAMD20

Executable	I/O	Flag	Description
nbfspack	.elf -> .bin	-output-target bin	Converts the elf file to binary

2.4.3.3 SAME70

Executable	I/O	Flag	Description
arm-none-eabi-size	.elf -> .bin		Displays the size of the binary.
nbfspack	.elf -> .bin	-output-target bin	Converts the elf file to binary
nbfspack	.elf -> .bin	-S	Show build statistics.
nbfspack	.elf -> .bin	-P \$(PLATFORM)	Specifies the platform.

2.4.3.4 MIMXRT11xx, MIMXRT10xx

Executable	I/O	Flag	Description
nbfspack	.elf -> .bin	-output-target bin	Converts the elf file to binary

2.4.4 Platform-Specific

2.4.4.1 MODM7AE70

Executable	I/O	Flag	Description
nbfspack	.elf -> .bin	-C	Compress program sections
nbfspack	.elf -> .bin	-cflag S:3	.
nbfspack	.elf -> .bin	-cflag S:0	.
nbfspack	.elf -> .bin	-cflag S:1	.

2.4.4.2 SBE70LC

Executable	I/O	Flag	Description
nbfspack	.elf -> .bin	-C	Compress program sections
nbfspack	.elf -> .bin	-cflag S:3	.
nbfspack	.elf -> .bin	-cflag S:0	.
nbfspack	.elf -> .bin	-cflag S:1	.

2.4.4.3 SOMRT1061

None

2.4.4.4 MOD5441X

Executable	I/O	Flag	Description
compcode	.s19 -> .bin	0xC0040000 0xC1FC0000	Application address range.

2.4.4.5 NANO54415

Executable	I/O	Flag	Description
compcode	.s19 -> .bin	0x04000 0x800000	Application address range.

2.4.4.6 SB800EX

Executable	I/O	Flag	Description
compcode	.s19 -> .bin	0x04000 0x800000	Application address range.

Chapter 3

Command Line Tools

3.1 Introduction

As an alternative to NBEclipse, you can use the command line tools to build your NetBurner projects. In fact, all the example programs are built and tested internally with command line tools. You will find a makefile in each example folder, so any of the examples can be used as a demonstration of how to use command line tools. Windows, Mac and Linux are supported. The command line tools can also be used to invoke the NetBurner tools from the development environment of your choice.

3.2 Command Line Summary

Command	Description
make	Build a project using the makefile in the project directory
make -j	Make using multiple cores to speed up the process
make load	Build project and load into device
make -j load	Build project with multiple cores and load into device
make clean	Delete a project's libraries and object files

Note

The command you will use 99% of the time is: "make -j load". If you have build errors that are difficult to track down, doing a single core "make" will cause the build to stop at the first error.

3.3 Command Line Environment Variables

There are a number of environment variables that can be set to effect the command line build when you do a make. For example, you can specify the target device IP address in which to download the application with a make -j load.

On the command line, typing "set <variable>" will display the current value. Typing "set <variable>=<value>" will set the environment variable. For example, "set DEVIP" will display the current target IP address. Typing "set DEVIP=10.1.1.1" will set DEVIP to the specified IP address.

Command	Description
DEVIP	Causes a make with the "load" parameter to download to the specified IP address
PLATFORM	Specifies the NetBurner platform to build for
NNDK_ROOT	Specifies the location of your NetBurner development tools installation
TOOLCHAINPATH	Specifies the location of the GCC tools path, such as the compiler

For example, to reference a standard NetBurner tools installation (also see "\nburn\setenv.bat" for an example):

```
set NNDK_ROOT=c:/nburn
set PLATFORM=MODM7AE70
set DEVIP=192.168.1.66
set TOOLCHAINPATH=c:/nburn/gcc/bin
```

3.4 Create a New Project From an Example

The easiest way to create a new project is to copy an existing one and modify it:

- Open a command prompt at the location where you keep your projects, such as \NetBurner\Projects
- Create a folder for your project, lets use HelloWorld as an example
- Move to the HelloWorld folder
- Copy an example, such as \nburn\examples\web\SimpleHtml

- At this point your project structure will look like:

```
\NetBurner\Projects
  \- HelloWorld
     \- html
        |- index.html
     \- src
        |- main.cpp
     | makefile
```

- Run "make -j" to build the project. The "-j" options uses multiple cores for the build
- When the build completes, an obj folder is created with the object files and .bin application image file↵: \NetBurner\Projects\HelloWorld\obj\release\SimpleHtml.bin (and also .s19 for SREC platforms).

```
\NetBurner\Projects
  \- HelloWorld
     \- html
        |- index.html
     \- obj
        \- release
           |- SimpleHtml.bin
     \- src
        |- main.cpp
     | makefile
```

- To load the application into your device, use the "make -j load" command.

There are many files and folders under the obj folder, including the compiled libraries and object files.

Note

Each project has its own build of the libraries and system files. That way if any changes need to be made (which is rare), it can be done on a per-project basis. This will be discussed in the overload section of this document.

We named our project HelloWorld, but are running SimpleHtml at this point. To customize the project:

- Edit the makefile to change the application image file name to HelloWorld
- Edit main.cpp to change the application name to HelloWorld
- Run "make -j load" to build and load the application into the device

3.4.1 Edit the makefile

The example makefile is shown below:

```
NAME = SimpleHtml

CPP_SRC = src/main.cpp

CREATEDTARGS += src/htmldata.cpp
CPP_SRC += src/htmldata.cpp
src/htmldata.cpp : $(wildcard html/*.*)
    comphtml html -osrc/htmldata.cpp

include $(NNDK_ROOT)/make/boilerplate.mk
```

Changing the NAME from SimpleHtml to HelloWorld will create the image file as HelloWorld.bin (and .s19)

The CPP_SRC is a list of all .cpp files to build. In this case there is only one, but if there were more it would look like:

```
CPP_SRC = src/main.cpp \
        += src/file2.cpp \
        += src/file3.cpp \
        += src/file4.cpp
```

If you have .c source files you can add them with C_SRC in the same manor.

The html related lines auto-generate a cpp file from the code in the project's html directory.

The final line calls the boilerplate makefile which includes the platform specific make instructions. While you can drill down into the details, this type of makefile structure makes creating projects much easier since you only need to list the source files of your project.

3.4.2 Edit main.cpp

A fully functional application with the web server enables is actually very few lines of code:

```
#include <init.h>
#include <nbrtos.h>
#include <system.h>

const char *AppName = "Simple HTML Example";

void UserMain(void *pd)
{
    init();
    StartHttp(); // Initialize network stack
    WaitForActiveNetwork(); // Start web server, default port 80

    iprintf("Web Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());
    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

This example just initializes the system, starts the web server, prints out some information, and loops forever with a 1 second delay. Changing the AppName to HelloWorld will change the name that shows up in the find and configuration utilities.

3.5 Modifying System Files with Overload

There can be instances in which you need to modify a NetBurner system file. This is accomplished using the Overload feature. NBEclipse creates an overload folder automatically, but with command line it must be created manually.

Note

The overload example is located in `\nburn\examples\Overload`

Adding an overload folder to our HelloWorld project:

```
\NetBurner\Projects
  \- HelloWorld
    \- html
      |- index.html
    \- obj
      \- release
        |- SimpleHtml.bin
    \- overload
    \- src
      |- main.cpp
    | makefile
```

Once you know which file you want to overload, the path in the overload folder must exactly match the system file path. For example, if we want to overload the `predef.h` include file located in the `\nburn\nbrtos\include` folder:

```
\NetBurner\Projects
  \- HelloWorld
    \- html
      |- index.html
    \- obj
      \- release
        |- SimpleHtml.bin
    \- overload
      \- nbrtos
        \- include
          |- predef.h
    \- src
      |- main.cpp
    | makefile
```

Now the project's `predef.h` will be used along with any changes made to it.

3.5.1 Predef.h and predef-overload.h

These are unique and powerful files used to change base-level system options. We recommend overloading items in here sparingly and using `predef-overload.h` whenever possible since the `predef.h` file changes between NNDK releases and it can be hard to track what overloads you need to keep when they're all mixed together with the defaults.

So, just follow the above directions using a blank `predef-overload.h` file containing only the predef constants you want to change.

3.5.2 Important Overload Rules

- The first time a file is added to the overload folder, a "make clean" is required. From that point on, any modifications to that file will automatically handle building all necessary system files.

If a system include folder is overloaded, this folder should be added to your project include paths. Right click on the project and select project properties. Under C/C++ Build->Settings, select GNU C++ Compiler->Includes and add the overload include folder. If utilizing C code, then GNU C Compiler->Includes should also be added.

3.6 GNU Debugger (GDB)

To load an application and start GDB from the command line:

- Build and load a debug build of the application `make loaddebug -j`.
- Start GDB:
 - For ARM devices such as the SOMRT1061, MODM7AE70 and SBE70LC: `arm-eabi-gdb -se obj/debug/<elf.file>`
 - For MOD5441X, NANO54415, and SB800EX platforms: `m68k-elf-gdb -se obj/debug/<elf.file>`
- Connect to the target device with: `target remote <ipaddress>:2159`

To end the GDB session and leave the target running use `detach`. To end the GDB session use `quit`. The GDB command reference is located here: <http://www.gnu.org/software/gdb/documentation/>.

3.6.1 Example GDB Session

An GDB session running the SimpleHtml example on a MOD54417 is shown below. The example has been modified to add some variables that do simple counting.

```
void UserMain(void *pd)
{
    init(); // Initialize network stack
    StartHttp(); // Start web server, default port 80
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    iprintf("Web Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());

    uint32_t i = 0;
    uint32_t j = 0;
    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND);
        i++;
        j = j + 1;
        iprintf("i: %ld, j: %ld\r\n", i, j);
    }
}
```

Load the application. Note that the DEVIP environment variable is set to the device's IP address 10.1.1.169. The application will begin execution and wait for GDB to connect.

```
C:\NetBurner\projects\SimpleHtml>make loaddebug -j
C:/nburn/pcbin/nbupdate obj/debug/DBSimpleHtml.bin 10.1.1.169
uriReq: http://10.1.1.169:20034/appupdate.htm

urlStr: http://10.1.1.169:20034/appupdate.htm
200

C:\NetBurner\projects\SimpleHtml>
```

Start GDB:

```
C:\NetBurner\projects\SimpleHtml>m68k-elf-gdb -se obj/debug/DBSimpleHtml.elf
GNU gdb (GDB) 8.2
Copyright (C) 2018 Free Software Foundation, Inc.
License GPLv3+: GNU GPL version 3 or later <http://gnu.org/licenses/gpl.html>
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law.
Type "show copying" and "show warranty" for details.
This GDB was configured as "--host=i686-w64-mingw32 --target=m68k-unknown-elf".
Type "show configuration" for configuration details.
For bug reporting instructions, please see:
<http://www.gnu.org/software/gdb/bugs/>.
Find the GDB manual and other documentation resources online at:
  <http://www.gnu.org/software/gdb/documentation/>.

For help, type "help".
Type "apropos word" to search for commands related to "word"...
Reading symbols from obj/debug/DBSimpleHtml.elf...done.
(gdb)
```

Connect to the MOD54417 target on port 2159. This will pause the application at whatever line of code it happens to be on. For simple examples that will typically be the NBRtos idle task.

```
(gdb) target remote 10.1.1.169:2159
Remote debugging using 10.1.1.169:2159
OSTaskIdle (data=0x0) at C:/nburn/arch/coldfire/source/nbrtosmain.cpp:425
425         asm ( " NOP" );
(gdb)
```

At this point you can do whatever type of GDB commands you wish. To set a break point at the `i++`; at line 29 of `main.cpp` and use the `continue` command to execute until the break point is reached:

```
(gdb) break main.cpp:29
Breakpoint 1 at 0x40009282: file src/main.cpp, line 29.
(gdb) info break
Num   Type           Disp Enb Address      What
1     breakpoint      keep y   0x40009282 in UserMain(void*) at src/main.cpp:29
(gdb) continue
Continuing.
[Switching to Thread 2]

Thread 2 hit Breakpoint 1, UserMain (pd=0x0) at src/main.cpp:29
29         i++;
(gdb)
```

The `list` command can be used to view the source code around the breakpoint:

```

Thread 2 hit Breakpoint 1, UserMain (pd=0x0) at src/main.cpp:29
29             i++;
(gdb) list
24             uint32_t i = 0;
25             uint32_t j = 0;
26             while (1)
27             {
28                 OSTimeDly(TICKS_PER_SECOND);
29                 i++;
30                 j = j + 1;
31                 iprintf("i: %ld, j: %ld\r\n", i, j);
32             }
33         }
(gdb)
\code

\latexonly \end{tcolorbox} \endlatexonly

\n
Now view the variables with print, as well as all local variables:

\latexonly \begin{tcolorbox} \endlatexonly

\code
(gdb) print i
$1 = 2
(gdb) info local
i = 2
j = 2
(gdb)

```

Use `next` to go to the next line without stepping into a function (the `step` command steps into a function). GDB commands can typically use just the first letter, in this case `n`:

```

(gdb) n
30             j = j + 1;
(gdb) info local
i = 3
j = 2
(gdb)

```

To make changes to your code use the `detach` command so that the application can resume and will be ready for your next code download:

```

(gdb) detach
Detaching from program: C:\NetBurner\projects\SimpleHtml\obj\debug\DBSimpleHtml.elf, Remote target
Ending remote debugging.
[Inferior 1 (Remote target) detached]
(gdb)

```

To exit GDB, use the `quit` command:

```

(gdb) quit
C:\NetBurner\projects\SimpleHtml>

```

3.7 Addr2line

Note

On Windows and ColdFire-based modules, you can use [WinAddr2Line](#) instead.

To get line numbers and function names from trap memory addresses, you can use `addr2line` on the command line like this:

```
addr2line -ifCe Release/YourProject.elf 00001111 11112222
```

Replace "addr2line" with the path to the appropriate program below, and replace the numbers with memory addresses you want to find.

3.7.1 ColdFire platforms

For ColdFire based platforms, use `m68k-elf-addr2line`. This is distributed in the `\nburn\gcc\bin\` folder.

3.7.2 ARM platforms

For ARM-based platforms, use `arm-unknown-eabi-addr2line`. This is distributed in the `\nburn\gcc\bin\` folder.

Chapter 4

Device Discovery and Configuration

4.1 Introduction

Device discovery and configuration can be accomplished in a number of ways, including methods that are platform independent, including Windows, macOS, Linux, tablets and mobile phones.

Note

Please refer to the [Production & Deployment](#) section of this document for methods and utilities designed to program and configure devices in a production environment.

4.1.1 Device Discovery Methods:

- If the device and computer have Internet access, open a web browser and go to 'discover.netburner.com'.
- Use the localdiscover utility located in `\nburn\pcbin\localdiscover`. This is a multi-platform utility written in Golang for Windows, macOS and Linux. The compiled version can be distributed to your customers, but not the Golang source code.
- Use the Python find utility, located in `\nburn\pctools\find`.
- Use the debug/console serial port.

4.1.2 Device Configuration methods:

- Interactively using a web browser to access the device's Configuration Server
- Sending a JSON object and a utility such as wget (See [Production & Deployment](#))
- The device's serial interface to the Configuration Server

The primary configuration method is through the device's Configuration Web Server. By utilizing a web server, a device can be configured from any platform or operating system. The underlying configuration mechanism is handled through a JavaScript Object Notation (JSON) object. This will be described in more detail later, but the important point is that it provides a simple interface that can be used by non-embedded developers (e.g. web developers) to interact and configure the device. The implementation is also designed to enable you to add any application specific information to be stored and accessed in the same manor, such as calibration values, set points, etc.

You are also able to create your own configuration web interface that will appear in place of the default interface. In this way you can organize and present data in the appropriate way for your customers, as well as add your own custom logo, images and descriptions. Examples are provided.

4.2 Configuration Procedure

- Connect your NetBurner device to a network with Internet access.
- Open a web browser on your host computer and go to `discover.netburner.com`. You will see a list of devices on your network. (If the device does not have Internet access, use the `localdiscover` utility instead).

All system and application settings can now be viewed and/or modified by navigating the tree structure.

Using `discover.netburner.com`:

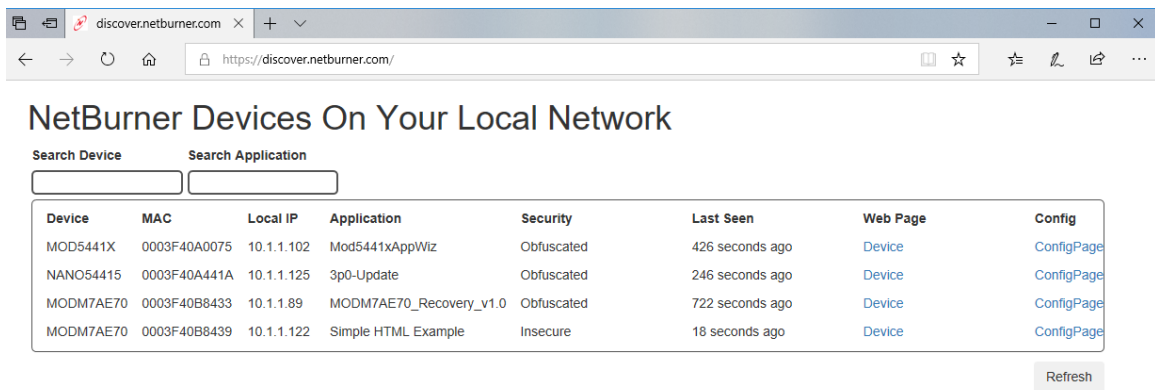

Figure 4.1 Discover using `discover.netburner.com`

Using `localdiscover` utility:

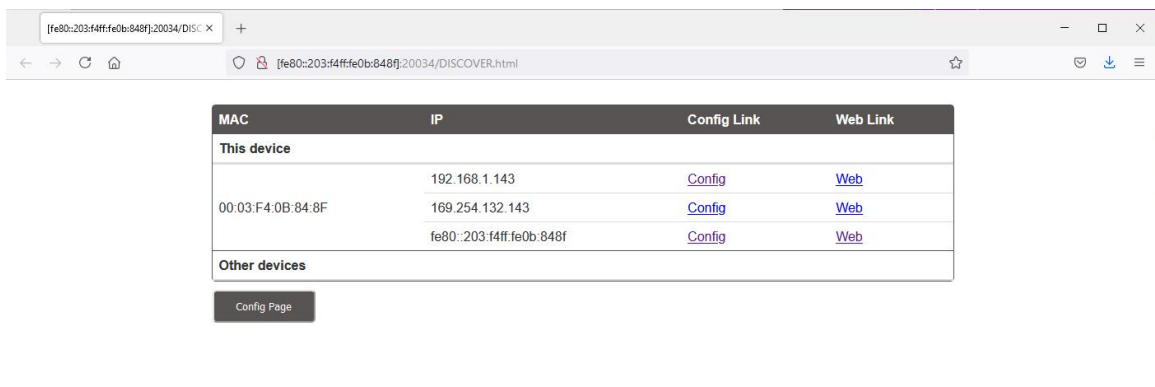

Figure 4.2 LocalDiscover Utility

The "Device" link will take you to the device application web page. The "ConfigPage" link will take you to the device configuration web page, as shown below:

The screenshot shows a web browser window with the address bar displaying "10.1.1.73:20034/ROOT.html". The page features a navigation menu on the left with sections for "Config", "AppData", and "Sys". The "Sys" section is expanded to show "Boot" and "NetIf" settings. The "Boot" section includes fields for Abort (A), BootBaud (115200), BootDelay (2), BootQuiet (checkbox), BootUart (0), Password, SerialConfig (DuringBoot), and User. The "NetIf" section is expanded to show "Ethernet0" settings, including DeviceName, DhcpDiscoverSec (1), DiscoveryObfuscate (checked), DiscoveryReportInterval (900), and DiscoveryReportUrl (discover.netburner.com/Devi). Below these are sections for IPv4, IPv6, MAC (00:03:F4:0B:83:F5), Platform (MODM7AE70), Version (8), and Reboot (checked). On the right side, there is a "NetBurner" logo and a vertical stack of buttons: "Exapand All", "Collapse All", "Update Record", "Raw Config Page", and "NB Discover". At the bottom, there is an "Update Application" section with a file input field and "Choose File" and "Send File" buttons.

Figure 4.3 Configuration Web Page

4.2.1 Configuration Settings

4.2.1.1 Config

Top level configuration leaf containing System (Sys) and Application Data (AppData) configuration leaves. AppData will only be populated if an application uses the configuration system for storage/configuration of application specific items, as opposed to common system configuration settings.

Setting	Description
Version	Configuration system write counter. Increments each time new values are saved.
Reboot	Check this option to reboot the system once new values are saved

4.2.1.2 Update Application

A new application can be programmed into the device by choosing an image file and selecting the "Send File" button. Note that the Reboot checkbox should normally be checked so that the device reboots and runs the new application that was sent.

4.2.1.3 Config → Sys

System settings

Setting	Description
Application	Name of running application.
Platform	Name of hardware platform, such as MOD54415

4.2.1.4 Config → Sys → BOOT

Boot settings.

Setting	Description
Abort	Character or string to send to the boot serial port to abort the application boot process and enter the Serial Port Configuration interface. Default is 'A'.
BootBaud	Boot serial port baud rate. Default is 115200, N, 8, 1.
BootDelay	Number of seconds to delay starting the application. This is the time available to send the Abort character or string. Default is 2 seconds. DO NOT SET TO 0.
BootQuiet	At power-up the boot serial port will send the message: "Waiting 2 seconds to boot..." Enabling quiet boot will disable this message. Default is off.
BootUart	Designated boot UART number. Varies by platform, but typically default is 0.

Setting	Description
User	Optional user name for password protection of the web page interface.
Password	Optional password to access the web page configuration interface.
SerialConfig	Boot options for the Serial Port Configuration interface: <ul style="list-style-type: none"> - During Boot (default) - Always Enabled - Pause after boot - Disabled

Note

The password can be reset through the Serial Port Configuration interface.

4.2.1.5 Config → Sys → NetIf

The NetIf section contains settings for all available network interfaces. For example, if the system has a single Ethernet interface, there will be a section named `Ethernet0`. If there are two Ethernet interfaces, the second will be `Ethernet1`. If a Wifi interface is available it will be listed as well.

4.2.1.6 Config → Sys → NetIf → Ethernet0

Settings for each Ethernet interface

Setting	Description
DeviceName	Interface name used for DNS and NetBIOS
DhcpDiscoverSec	Number of seconds after boot to wait before sending a DHCP Discover message. Default is 1.
DiscoveryObfuscate	Send data to Discover Server obfuscated rather than plain text for security. Default is enabled.
DiscoveryReportInterval	How often to report to Discovery Server in seconds. Default is 900.
DiscoveryReportUrl	Name of Discover Server. Default is: <code>discover.netburner.com/Device↔Post</code> .
MAC	MAC address
SupressDefault	Disable Ping and UDP Echo ports. Default is not suppressed.
VlanTag	Virtual Network tag number. Default is 0

4.2.1.7 Config → Sys → NetIf → Ethernet0 → IPv4

IPv4 network interface settings.

Setting	Description
ActiveAddr	Current IP address.
ActiveDNS1	Current DNS1 address.
ActiveDNS2	Current DNS2 address.
ActiveGate	Current Gateway address.
ActiveMask	Current IP Mask.
AutoIPAddr	Auto IP address.
AutoIPEn	Enable AutoIP feature. Default is enabled.
EnableMacmDNS	Enable device access by name in the format: <code>nburnxxxxxx.local</code> , where <code>xxxxxx</code> is the last 6 digits of the MAC address. Default is disabled.
LocalName	Specify device access by name in the <code>.local</code> format. For example: <code>mydevice.local</code> .
Mode	IP Address Mode: <ul style="list-style-type: none"> - DHCP (default) - DHCP with fallback to static - Static - Disabled
StaticAddr	Static IP address.
StaticDNS1	Static DNS1 address.
StaticDNS2	Static DNS2 address.
StaticGate	Static Gateway address.
StaticMask	Static IP Mask.

DHCP With Fallback Details

After boot, the first [DHCP](#) Discover message will be sent once the network link is active. Note that if the network link is not active, such as when a network cable is not connected, [DHCP](#) will not start, and the fallback to a static address will not occur.

Once [DHCP](#) starts it will attempt to get the IP settings from a [DHCP](#) server. If not successful, it will retry 4 more times at 8, 16, 23, and 64 seconds. If not successful, then the fallback to static IP address settings will occur.

For custom applications, the retries can be modified in the [DHCP](#) Client header file (may be moved to `constants.h` in a future release). The defaults are shown below:

```
#define DEFAULTTIMEOUT (4)
#define DEFAULTRETRY (5)
```

4.2.1.8 Config → Sys → NetIf → Ethernet0 → IPv6

IPv6 network interface settings main leaf. Note: refer to [DHCP With Fallback Details](#) section above.

Setting	Description
Mode	IP Address Mode: <ul style="list-style-type: none"> - DHCP (default) - DHCP with fallback to static - Static - Disabled
StaticAddr	Static IP address.
StaticDNS1	Static DNS1 address.
StaticDNS2	Static DNS2 address.

Config → Sys → NetIf → Ethernet0 → IPv6 → ActiveAddr

Displays a list of active addresses. The number will depend on the network architecture. All devices should have at least a link local address with prefix fe80::. Other addresses can be assigned from a DHCPv6 server and routers on the network. The example below shows link local, DHCPv6 and a router.

```
0 fe80::203:f4ff:fe07:386b
1 2600:1700:410:190f:203:f4ff:fe07:386b
2 2600:1700:410:190f::2000
```

Config → Sys → NetIf → Ethernet0 → IPv6 → ActiveDNS

Displays a list of active DNS server addresses. The number will depend on the network architecture. All devices should have at least a link local address with prefix fe80::. Other addresses can be assigned from a DHCPv6 server and routers on the network. The example below shows link local, DHCPv6 and a router.

```
0 fe80::203:f4ff:fe07:386b
1 2600:1700:410:190f:203:f4ff:fe07:386b
2 2600:1700:410:190f::2000
```

Config → Sys → NetIf → Ethernet0 → IPv6 → ActiveDNS

Displays a list of active DNS servers.

Config → Sys → NetIf → Ethernet0 → IPv6 → Route

Displays a list of active router addresses.

4.3 The JSON Object

It is not necessary to understand the underlying JSON implementation, but for those that are interested a sample JSON object is shown below. It identifies each configuration field, which can range from a string, boolean, or a selection of values. For developers, the programmers guide and examples provide the operational details.

Warning

If you do decided to use any of the JSON configuration methods, you must first download a JSON object from your specific device. Under no circumstances should you use the example below as you actual device will likely be different in some respects.

The root of the object is Config. The next levels are AppData and Sys. AppData is available for your application to store information. Sys is used for the system configuration such as IP settings.

```
{
  "Config":{
    "AppData":{},
    "Sys":{
      "Application":"Simple HTML Example",
      "Boot":{
        "Abort":"A",
        "BootBaud":115200,
        "BootDelay":2,
        "BootQuiet":false,
        "BootUart":0,
        "Password":"",
        "SerialConfig":{
          "Choices":"DuringBoot, AlwaysEnabled, PauseAfterBoot, Disabled", "Value":"DuringBoot"
        },
        "User":""
      },
      "NetIf":{
        "Ethernet0":{
          "DeviceName":"",
          "DhcpDiscoverSec":1,
          "DiscoveryObfuscate":true,
          "DiscoveryReportInterval":900,
          "DiscoveryReportUrl":"discover.netburner.com/DevicePost",
          "IPv4":{
            "ActiveAddr":"10.1.1.73",
            "ActiveDNS1":"10.1.1.1",
            "ActiveDNS2":"0.0.0.0",
            "ActiveGate":"10.1.1.1",
            "ActiveMask":"255.255.252.0",
            "AutoIPAddr":"169.254.131.245",
            "AutoIPEn":true,
            "Mode":{
              "Choices":"DHCP,DHCP w Fallback,Static,Disabled", "Value":"DHCP"
            },
            "StaticAddr":"0.0.0.0",
            "StaticDNS1":"0.0.0.0",
            "StaticDNS2":"0.0.0.0",
            "StaticGate":"0.0.0.0",
            "StaticMask":"0.0.0.0"
          },
          "IPv6":{
            "ActiveAddr":["2602:306:b8e9:c83f::14c0","2602:306:b8e9:c83f:203:f4ff:fe0b:83f5","fe80::203:f4ff:fe0b:83f5"],
            "ActiveDNS":["2602:306:b8e9:c83f:208:a2ff:fe0c:b081","2602:306:b8e9:c83f:208:a2ff:fe0c:b081"],
            "ActiveRoute":["fe80::1:1"],
            "Mode":{
              "Choices":"DHCP,DHCP w Fallback,Static,Disabled", "Value":"DHCP"
            },
            "StaticAddr":"::",
            "StaticDNS1":"::",
            "StaticDNS2":"::"
          },
          "MAC":"00:03:F4:0B:83:F5"
        },
        "Platform":"MODM7AE70"
      },
      "Version":8,
      "Reboot":false
    }
  }
}
```

4.3.1 Developer Notes

If you were writing a web interface and need only the data under Ethernet in the tree, it can be accessed by: <http://10.1.1.71:20034/UI.html?CONFIG/SYS/NETIF/Ethernet>

To obtain just the IP address: `http://10.1.1.71:20034/UI.html?CONFIG/SYS/NETIF/↔Ethernet/IPv4/ActiveAddr`

Recommended Examples: The following examples are recommended to begin evaluating the platform. They are located in the `\nburn\examples` directory.

- ShowInterfaces
- `\Configuration\Web\BasicWebConfig`

4.4 Configuration Security

One of the features of NetBurner 3.0 is that each device is configured through its own configuration web interface. Data sent and received through the network interface has three options for security:

- Open: No security, plain text
- Obfuscated: Encrypted, but without TLS and a secure certificate and private key
- Secure: Encrypted with TLS and a certificate and private key

4.5 Serial Port Configuration

If enabled, the Configuration Server can be accessed through the device serial port. The configuration tree is exactly the same as what you see on the web interface and in the JSON object. For example, the Ethernet0 settings are located at `Config > Sys > NetIf > Ethernet0`.

The serial port interface is located on UART0 by default. It can be modified and enabled/disabled in the `Config > Sys > Boot` level of the Configuration Server.

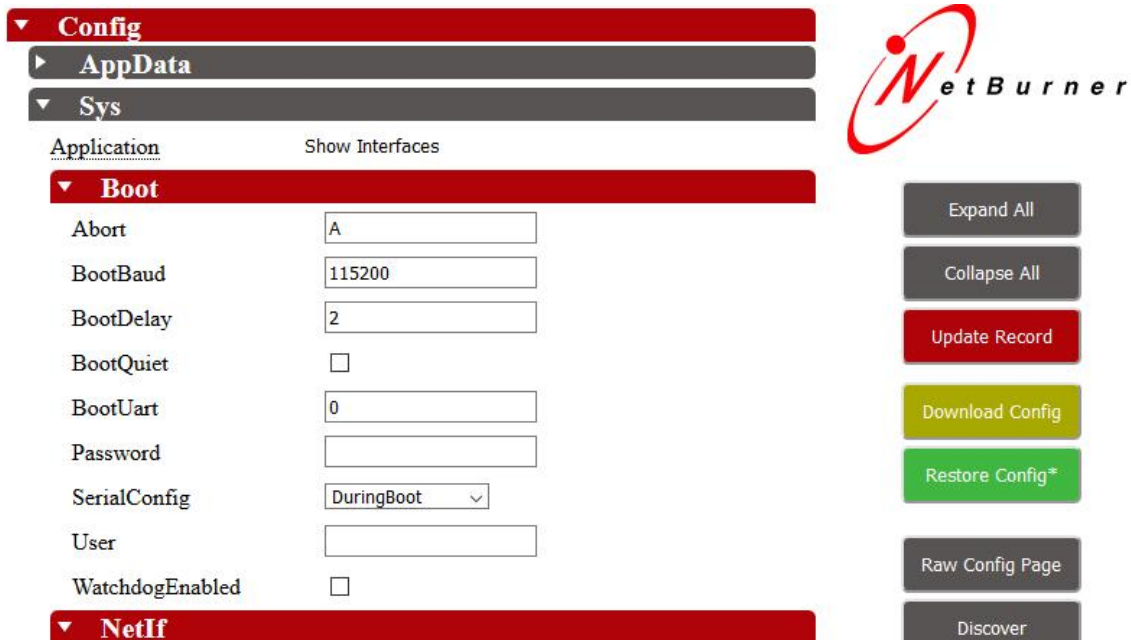

Figure 4.4 Config Boot Level

To access the serial port configuration:

- Connect a cable to the serial port selected as the BootUart
- Run a serial terminal program such as MTTTY
- Reset the device, and type a 'A' when prompted to Abort the boot sequence

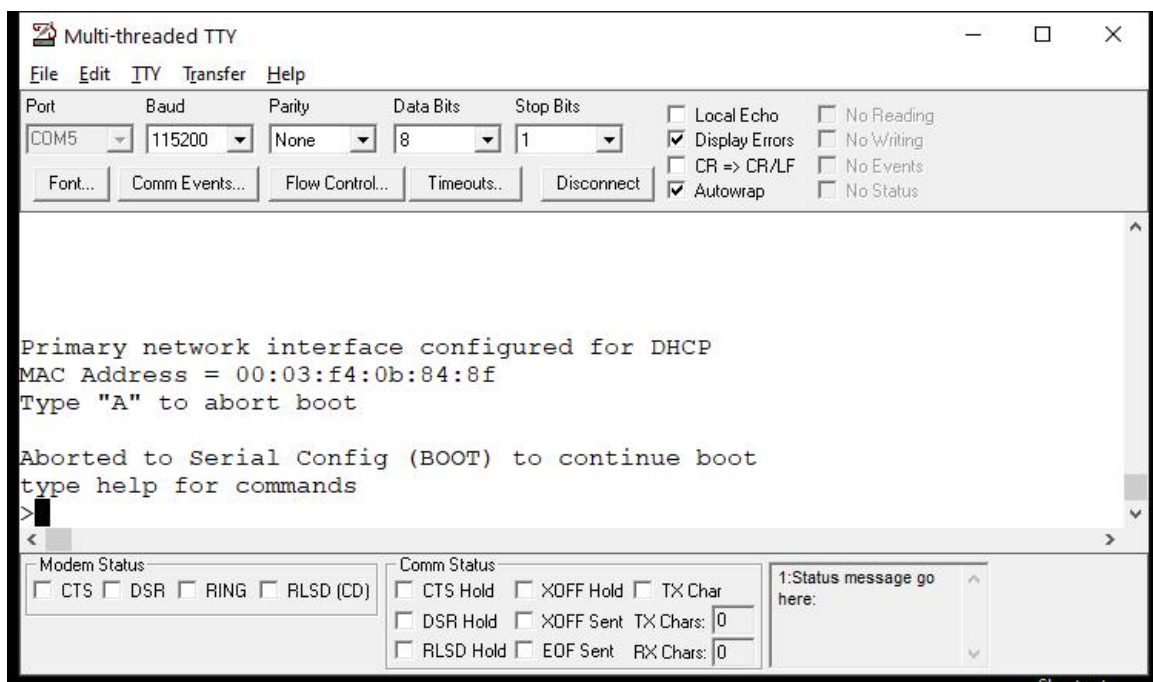

Figure 4.5 Abort Boot Sequence

You are now in the serial configuration mode as indicated by the '>' character. Typing "help" will display the help menu.

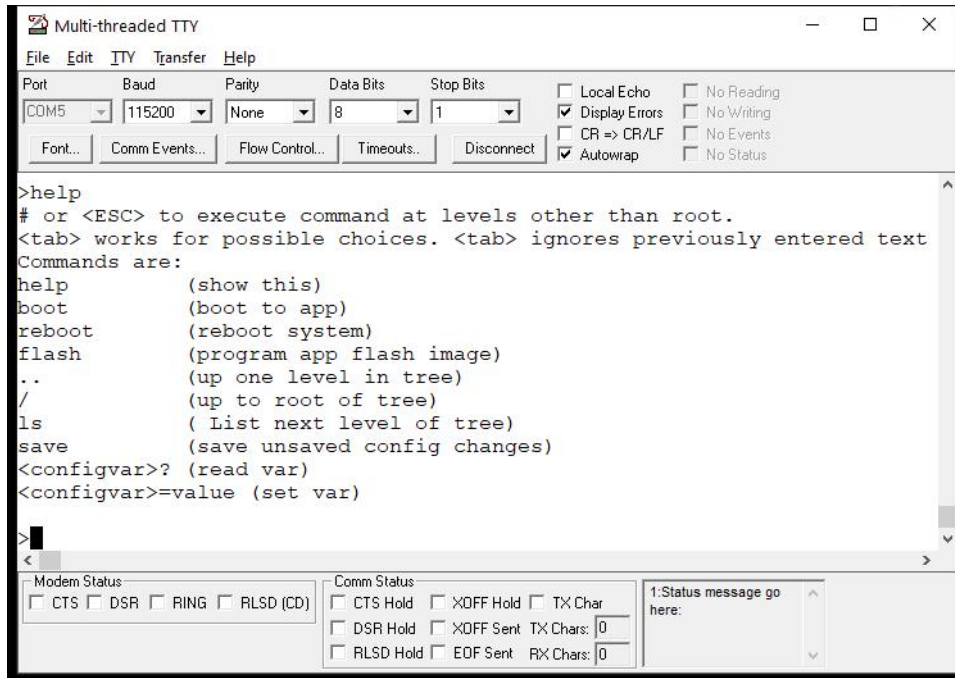

Figure 4.6 Serial Help Menu

If we type the "ls" command we can see the next level of the tree is `Config`, since we are at the root level. In this example we will set the Static IP values. Note that to change from `DHCP` to static, we must also change the `Mode` option from `DHCP` to `Static`. To navigate to the next level you type in the name of that level. For example, to go to the `Config` level:

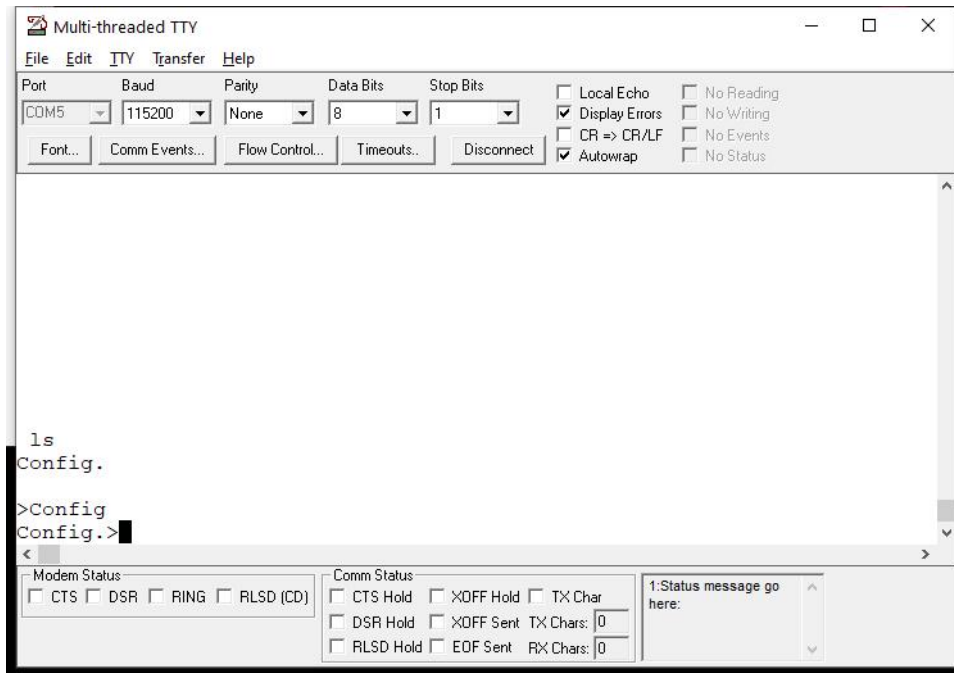

Figure 4.7 Config Level

The prompt will show the current location, in this case `Config>`. In the same manner to navigate to the IPv4 settings the level names are typed into the terminal. Note that tabbed auto-completion is also available.

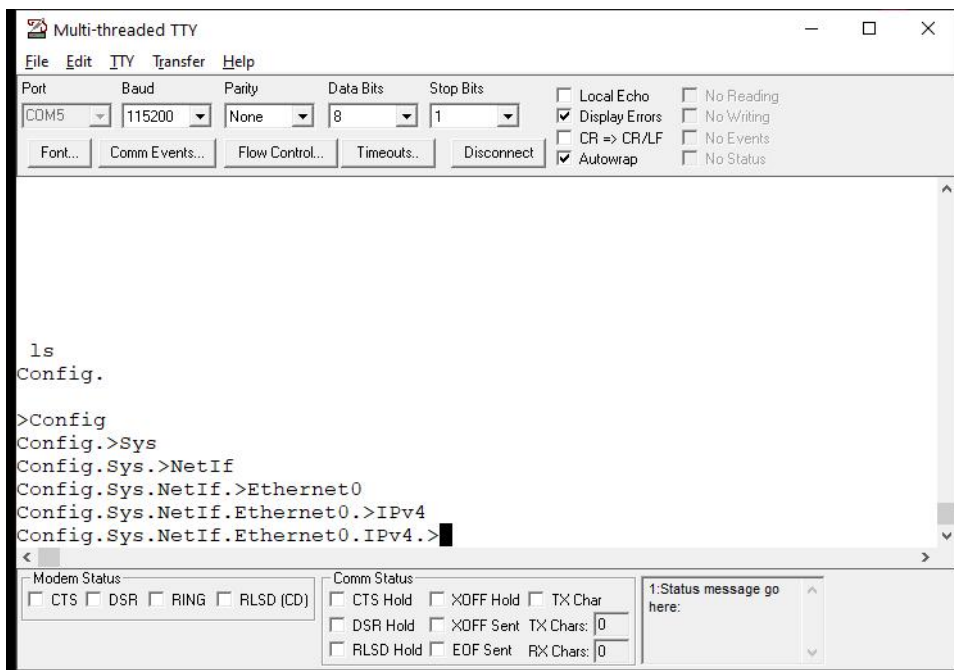

Figure 4.8 IPv4 Level

At any level, typing a "?" will display the current values of that level and all levels beneath in the JSON object format. For example:

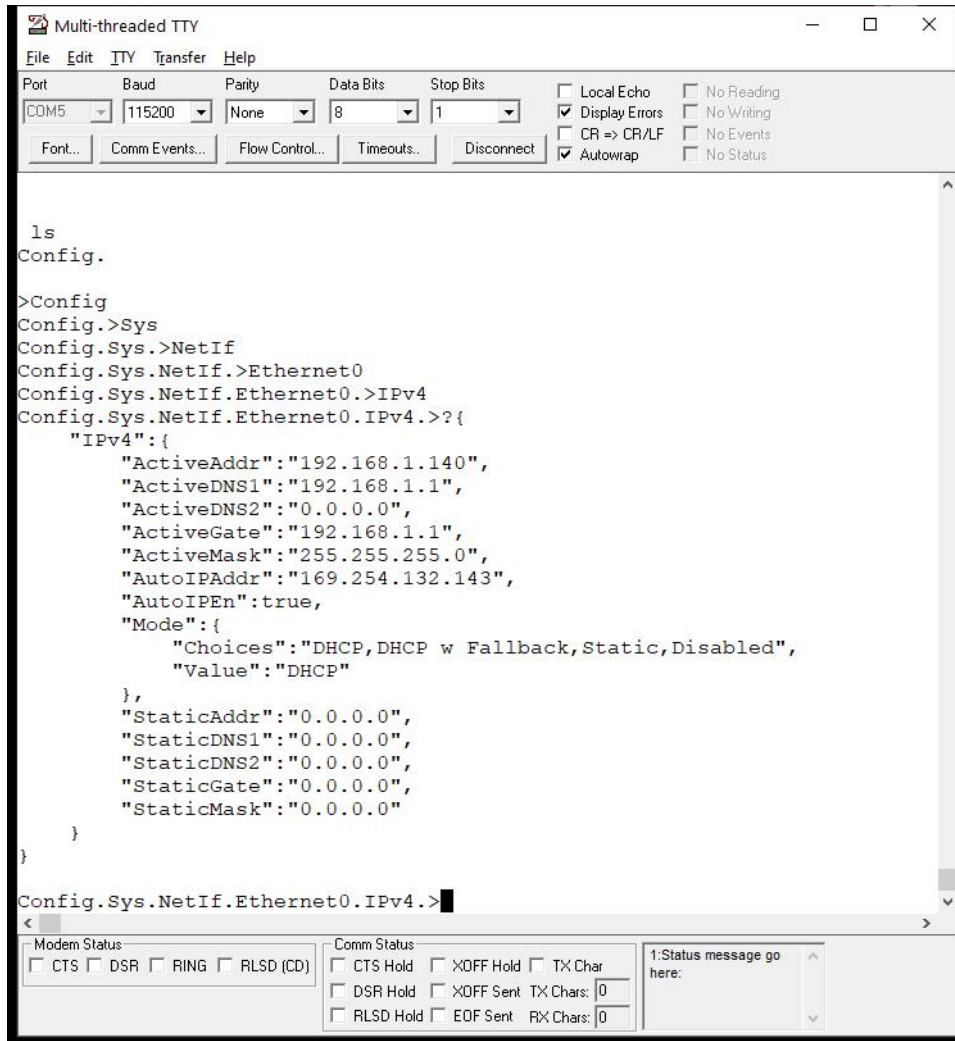

Figure 4.9 Display IPv4 Level

In this example we are interested in the static IP settings. There are two choices to set them: from the IPv4 level by including the name of the next level and the value, or by going down to each level individually and entering just the value. In this case we will stay at the IPv4 level and include the name of the static item we want to set. To set the StaticAddr type: StaticAddr="10.1.1.99". We will also type a "?" to see the changed value:

```

Multi-threaded TTY
File Edit ITY Transfer Help
Port COM5 Baud 115200 Parity None Data Bits 8 Stop Bits 1
Local Echo No Reading
Display Errors No Writing
CR => CR/LF No Events
Autowrap No Status

"StaticDNS1":"0.0.0.0",
"StaticDNS2":"0.0.0.0",
"StaticGate":"0.0.0.0",
"StaticMask":"0.0.0.0"
}
}
Config.Sys.NetIf.Ethernet0.IPv4.>StaticAddr="10.1.1.99"
Value Set #save to save here and now.
Config.Sys.NetIf.Ethernet0.IPv4. (unsaved)>?{
  "IPv4":{
    "ActiveAddr":"192.168.1.140",
    "ActiveDNS1":"192.168.1.1",
    "ActiveDNS2":"0.0.0.0",
    "ActiveGate":"192.168.1.1",
    "ActiveMask":"255.255.255.0",
    "AutoIPAddr":"169.254.132.143",
    "AutoIPEn":true,
    "Mode":{
      "Choices":"DHCP,DHCP w Fallback,Static,Disabled",
      "Value":"DHCP"
    },
    "StaticAddr":"10.1.1.99",
    "StaticDNS1":"0.0.0.0",
    "StaticDNS2":"0.0.0.0",
    "StaticGate":"0.0.0.0",
    "StaticMask":"0.0.0.0"
  }
}
Config.Sys.NetIf.Ethernet0.IPv4. (unsaved)>
Modem Status: CTS DSR RING RLSD (CD)
Comm Status: CTS Hold XOFF Hold TX Char
DSR Hold XOFF Sent TX Chars: 0
RLSD Hold EOF Sent RX Chars: 0
1:Status message go here:

```

Figure 4.10 Set StaticAddr Value

In the same manor we will set the Mask, Gateway and DNS. To set the Mode we will need to either include the Mode level in the setting string or go to the Mode level, since the setting is a Choices selection and not a simple string like the static IP settings. To accomplish this from the IPv4 level type: `Mode.Choices="Static"`. If you navigate the to Mode level, the command would be: `Choices="Static"`. At this point the unsaved settings are:

Figure 4.11 Static Summary

Warning

From the settings display you can see that the `Mode` selector control has two settings: `Choices` and `Value`. The `Choices` are values that appear in the web page selector control and you do not want to modify them. Only modify the `Value` to one of the `Choices` values.

To store the modified values in the Configuration Record in Flash memory, type `#save`. This will store the values, but the IP settings will not take effect until the device is rebooted.

Chapter 5

Migration Guides

There are currently three NetBurner development tool branches:

- 2.7.x, IPv4 only for all products except ARM.
- 2.9.x, IPv4/IPv6 dual stack for all products except ARM. This release will continue to be fully supported for ColdFire devices.
- 3.x, Latest release including IoT enhancements. Supports 5441x (MOD5441x, NANO54415, SB800EX) and ARM (MODM7AE70) platforms.

Note

If you are updating from a 2.7.x release to a 2.9.x release, please see the IPv6 guide in the `\nburn\docs` folder.

The following sections will describe the migration path in more detail.

- [Release 2.x to 3.x Overview](#)
- [Release 2.x to 3.x Porting Guide](#)
- [Upgrade 5441x Platforms to 3.x](#)

5.1 Release 2.x to 3.x Overview

When developing NetBurner 3.x we incorporated customer requests to enable the use of the latest ARM base processors, security protocols, and IoT capabilities. For existing customers we have done our best to balance the additional capabilities with ease of migration.

5.1.1 Hardware

- Support for ARM processors, starting with the 300MHz M7.
- Support for NXP/Freescale 5441x based products: MOD54415, MOD54417, SB800EX, NANO54415. For other NetBurner platforms we will fully maintain the 2.9.x branch.
- Applications easily scale from single chip solutions to large memory platforms.

5.1.2 Configuration

A new configuration and update system has been created:

- Updates, discovery and configuration are now platform independent and do not require any computer OS specific utilities.
- Devices can be discovered by going to "discover.netburner.com" in a web browser.
- Applications can be updated from a web browser, the nbupdate utility, NBEclipse, WGET, or the serial interface.
- Configuration can now be done with a JSON object. These objects can be saved or uploaded, making configuration in a production environment much easier and faster.
- Developers can easily create their own configuration objects.
- The IPSetup windows utility can be used to locate a device, but not configure it.

5.1.3 RTOS

The low level code of the RTOS has been modified to support new features including:

- Increased the number of tasks from 64 to a user defined value.
- OS functions are now managed as C++ objects.

5.1.4 TCP

- Increased the maximum number of sockets from 32 to a user defined value. A Maximum value over 256 may have an impact on performance.

5.1.5 Network Interfaces

- Many new interfaces supported
- Access to interfaces now requires looking at an Interface Object, rather than global variables such as ETHERNETIP. This was needed to support additional interfaces, a larger number of interfaces, and IPv6 capability.

5.1.6 SSL/TLS

- Updated to the latest protocols and ciphers (2.9.x also has the SSL/TLS updates).
- The process for generating compiled-in certificates has been made easier, but is slightly different.
- Devices can now generate certificates.

5.1.7 System Initialization

- A new function, `init()`, is now used to initialize stack, all interfaces, and network debugging.

5.1.8 NBEclipse

- Updated to Oxygen
- Can generate makefiles that can be used on command line builds.

5.1.9 GCC

- Updated to 8.1

5.2 Release 2.x to 3.x Porting Guide

5.2.1 Device Configuration

Previously device configuration was accomplished with IPSetup, a windows based program. In 3.x there are a number of ways to configure the device that are independent of the host computer type. The primary method is through the device's own configuration web server. In this way the device can be configured by a web browser on any platform. There is also a serial interface configuration method.

- Can be configured by any web browser, and applications can be programmed into the device. *Note:* Autoupdate and IPSetup are no longer used to download applications or configure the device. However, you can still use IPSetup to discover a device's IP address.
- Devices can be found by typing `discover.netburner.com` in the web browser URL field.
- The underlying configuration mechanism is handled through a JavaScript Object Notation (JSON) object. This will be described in more detail later, but the important point is that it provides a simple interface that can be used by non-embedded developers (e.g. web developers) to interact and configure the device. The implementation is also designed to enable you to add any application specific information to be stored and accessed in the same manor, such as calibration values, set points, etc.
- You are able to create your own configuration web interface that will appear in place of the default interface. In this way you can organize and present data in the appropriate way for your customers, as well as add your own custom logo, images and descriptions. Examples are provided.

5.2.2 Configuration Procedure

- Connect your NetBurner device to a network with Internet access.
- Open a web browser on your host computer and go to `discover.netburner.com`. You will see a list of devices on your network. 
- The "Device" link will take you to the device's web page. The "ConfigPage" link will take you to the device's configuration web page as shown below: 

A sample JSON object is shown below:

```
{
  "Config":{
    "AppData":{},
    "Sys":{
      "Application":"Simple HTML Example",
      "Boot":{
        "Abort":"A",
        "BootBaud":115200,
        "BootDelay":2,
        "BootQuiet":false,
        "BootUart":0,
        "Password":"",
        "SerialConfig":{
          "Choices":"DuringBoot, AlwaysEnabled, PauseAfterBoot, Disabled", "Value":"DuringBoot"
        },
        "User":""
      },
    },
    "NetIf":{
      "Ethernet0":{
```

```

"DeviceName": "",
"DhcpDiscoverSec": 1,
"DiscoveryObfuscate": true,
"DiscoveryReportInterval": 900,
"DiscoveryReportUrl": "discover.netburner.com/DevicePost",
"IPv4": {
  "ActiveAddr": "10.1.1.73",
  "ActiveDNS1": "10.1.1.1",
  "ActiveDNS2": "0.0.0.0",
  "ActiveGate": "10.1.1.1",
  "ActiveMask": "255.255.252.0",
  "AutoIPAddr": "169.254.131.245",
  "AutoIPEn": true,
  "Mode": {
    "Choices": "DHCP,DHCP w Fallback,Static,Disabled", "Value": "DHCP"
  },
  "StaticAddr": "0.0.0.0",
  "StaticDNS1": "0.0.0.0",
  "StaticDNS2": "0.0.0.0",
  "StaticGate": "0.0.0.0",
  "StaticMask": "0.0.0.0"
},
"IPv6": {
  "ActiveAddr": ["2602:306:b8e9:c83f::14c0", "2602:306:b8e9:c83f:203:f4ff:fe0b:83f5", "fe80::203:f4ff:fe0b:83f5"],

```

If you were writing a web interface and need only the data under Ethernet in the tree, it can be accessed by: <http://10.1.1.71:20034/UI.html?CONFIG/SYS/NETIF/Ethernet>

To obtain just the IP address: <http://10.1.1.71:20034/UI.html?CONFIG/SYS/NETIF/Ethernet/IPv4/ActiveAddr>

5.2.3 Recommended Examples

The following examples are recommended to begin evaluating the platform. They are located in the `\nburn\examples` directory.

- ShowInterfaces
- \Configuration\Web\BasicWebConfig

5.2.4 Configuration Security

One of the features of NetBurner 3.0 is that each device is configured through its own configuration web interface. Data sent and received through the network interface has three options for security:

- Open: No security, plain text
- Obfuscated: Encrypted, but without TLS and a secure certificate and private key
- Secure: Encrypted with TLS and a certificate and private key

Each NetBurner device generates a default certificate and private key, which is stored in its internal flash memory, which can be used to secure the connection as a self-signed certificate. You can also use the device's private key to create your own externally self-signed certificate, or have a certificate issued by a recognized third party. The externally signed certificate can then be installed by overwriting the device's default key.

5.2.4.1 Cautions When Using the Jumper Recover Procedure on a Device

Each device has a location to insert a shorting jumper to reset the module in the event of a catastrophic software problem, such as downloading an application image that corrupts flash memory or crashes. This recovery procedure will erase all of flash memory and download a recovery image. A new private key and certificate will then be generated. In such a case, any external self-signed or third party certificates will no longer be valid since the private key will have changed. A new certificate will have to be created from the new private key.

5.2.5 Device Application Updates

Note

The AutoUpdate utility is no longer used for download application to your device.

You will notice there is an Update Application on the web page. Application are now uploaded using the web interface. Alternatively, there is a windows executable that can be run from the command line in `\nburn\pcbin\nbupdate.exe`. Application images are now `.bin` files, they are no longer `.s19` files. If building in NBEclipse the `.bin` file will be located in your workspace project's release folder. The format using `nbupdate.exe` is as follows: `nbupdate <application .bin file> <device IP>`

5.2.6 Eclipse and Development Tools Updates

Summary of new and improved features:

- Eclipse has been updated to the Oxygen version. It also takes advantage of multiple processor cores on the host computer to greatly speed up compile times. *Note:* if using the command line to build you can use `make -j` to use multiple cores.
- GCC has been updated to version 8.1.
- Each project now has its own NetBurner library. Now any system changes you make will be specific to the project, and each project can have its own modifications.
- The makefile implementation is now identical for NBEclipse and command line builds.

5.2.7 SSL/TLS

Improvements include:

- Moving from NetBurnerSSL to wolfSSL
- Support for a much broader range of ciphers
- Support for DER encoded certificates
- Support for server-side peer verification
- Support for onboard certificate generation
- Substantial improvements to SSL stability
- Support for client side certificate authority lists
- A cleaner interface for using certificate authority lists, as well as the ability to dynamically alter them during runtime
- Faster key generation for onboard certificate generation
- Lays the groundwork for future improvements
 - TLS v1.3
 - FIPS 140 Ready
 - DTLS

5.2.8 Notes on Porting From Previous Revisions

- Big endian vs. little endian. The ColdFire processors have a big endian architecture, while ARM processors are little endian. If you have code that manipulates 16-bit or 32-bit numbers that rely on a big endian format you will need to ensure it works for both types.
- The typical startup sequence of function calls: `IntializeStack()`, `GetDhcpIfNecessary`, `EnableAutoUpdate()`, etc have been replaced with a single call: `init()` which is declared in the header file `init.h`. You will need to remove header files such as:

```
#include <startnet.h>
#include <autoupdate.h>
#include <dhcpcclient.h>
#include <NetworkDebug.h>
```
- The real-time operating system has been modified to increase performance and capabilities. The header file `ucos.h` is now `nbrtos.h`. Any RTOS function calls that had UCOS in related names have been modified to reflect this.
- `UCOS_ENTER_CRITICAL` has been replaced with `NBRTOS_ENTER_CRITICAL`.
- The `StartHTTP()` function is now `StartHttp()` and `StartHttps()`.
- Callbacks have been added to replace the `MyDoGet()` and `MyDoPost()` functions. See [HTML Processing](#) for examples on usage.
- A new function has been added to wait for an active network connection, meaning the device has link. A typical startup sequence will be:

```
init();
WaitForActiveNetwork(TICKS_PER_SECOND * 10);
StartHttp(); // or StartHttps();
```

- Types such as `WORD`, `DWORD`, etc have been replaced with `uint16_t`, `int16_t`, `uint32_t`, `int32_t`, etc.
- Registering a name with a **DHCP** server is no longer done by assigning a string to `extern const char pDHCPOfferName`. It is now set by assigning a name to the configuration tree JSON object element: `CONFIG:SYS:NETIF:Ethernet:DeviceName`.
- Runtime calls to the network interface such as `EthernetIP()` have been removed. Please refer to the `ShowInterfaces` example for methods to obtain runtime interface data.

5.2.9 Porting I2C From MCF52xx Based Products to MODM7AE70

Applicable Platforms:

- MOD5234
- MOD5270
- MOD5272
- MOD5282
- PK70EX
- SB70
- SB70LC
- SB72

MCF52xx platforms have a single **I2C** peripheral, therefore the **I2C** driver API knew which signal pins to use and the set of functions to send/receive data only had to consider a single peripheral. ARM based platforms have many **I2C** peripherals, so a different type of driver/API is required. For example, with just a single **I2C** peripheral, an `I2CSend()` function is all that is needed. If there are many **I2C** peripherals, the driver must be able to send on any of them. This applies to all **I2C** functions: read, write, status, error detection, etc.

The most robust and scalable implementation is to use **I2C** peripheral C++ objects. You do not need to be a C++ programmer to use these objects in your application, other than to understand the format to call a member function of the object instead of a global C function call. For example, if in C you had a global function named `GetI2CStatus()`, it would now be a member function of a specific **I2C** object/peripheral and the call would be `MyI2CObject.GetI2CStatus()`. This method enables your application to handle multiple **I2C** peripherals, and the status function knows which peripheral to use because it operates on the object. Note that since the status function is called as a member function of the object, it is common to take that into consideration in the member function name, so it would likely be `MyI2CObject.GetStatus()`.

In this way you can easily handle multiple **I2C** peripherals: `MyI2CObject1`, `MyI2CObject2`, `MyI2CObject3`, etc. Your application code does not need to manage and continuously check for which peripheral is being used, such as having a C style array of **I2C** peripherals.

The **I2C** driver for MCF52xx devices in the NNDK 2.x tools has the interface listed below. Note that there is a bit of C++ even in the old driver in terms of the function prototypes. You are likely calling some of these functions without any parameters, or with less than all the parameters listed. In C++ default parameters are specified in the function prototype with the '=' sign. So you can call `I2CInit()` with no parameters in your application, and the default parameters in the function prototype will be used.

```

void I2CInit( BYTE slave_Addr = 0x08, BYTE freqdiv = 0x3C )

BYTE I2CSend( BYTE val, DWORD ticks_to_wait = I2C_RX_TX_TIMEOUT )
BYTE I2CSendBuf( BYTE addr, PBYTE buf, int num, bool stop = true )

BYTE I2CRead( PBYTE val, DWORD ticks_to_wait = I2C_RX_TX_TIMEOUT )
BYTE I2CReadBuf( BYTE addr, PBYTE buf, int num, bool stop = true )

BYTE I2CStart( BYTE addr, bool Read_Not_Write, DWORD ticks_to_wait = I2C_RX_TX_TIMEOUT )
BYTE I2CStop( DWORD ticks_to_wait = I2C_RX_TX_TIMEOUT )
BYTE I2CRestart( BYTE addr, bool Read_Not_Write, DWORD ticks_to_wait = I2C_RX_TX_TIMEOUT )

void I2CResetPeripheral()

bool I2CRXAvail()
DWORD I2CTXAvail()
BYTE I2CGetByte()

```

The **I2C** implementation in the 3.x tools for ARM platform uses the **I2CDevice** Class. For example, on the MODM7AE70, an **I2C** object to select an **I2C** peripheral to interface with an EEPROM can be declared as (code taken from the **I2C Pic Kit** example):

```

#define I2C_MODULE_NUM 0 // use I2C0/TW0
#define I2C_EEPROM_ADDRESS (0xA0 >> 1) // Microchip 24LC0B EEPROM, 2Kbit (256 x 8)
I2CDevice EepromDevice(i2c[I2C_MODULE_NUM], I2C_EEPROM_ADDRESS);

```

The declaration of the **I2CDevice** creates an **I2C** object for **I2C** peripheral module 0 at the specified EEPROM **I2C** address. Creating the object also handles the initialization, so the equivalent of **I2CInit()** is not needed. Once we have created the object, all we need to do is call the member functions to control it in the format: `EepromDevice.<member function>`. For example, to send/write a single byte value of 0x60 to address 0x01 of the EEPROM: `EepromDevice.writeReg8(0x01, 0x60)`; Note that in ARM terms, the **I2C** addresses are referred to as registers. `writeReg8()` refers to 8-bits.

You will also note that the return values use the C++ operator `::`. Whereas the 2.x driver returned an unsigned 8-bit value (BYTE), the 3.x driver returns a typed value of `Result_t`. Using typed values will result in more robust application code since the compiler can detect when a return value is used incorrectly. the "I2C::" result types are (be sure to view the latest information in the 3.x NetBurner API manual):

```

I2C_RES_ACK      Acknowledged
I2C_RES_NACK     Not acknowledged
I2C_RES_ARB_LST Arbitration listening
I2C_RES_BUSY    Bus is busy
I2C_RES_ARG     Bad argument

```

The corresponding functions to the MCF52xx **I2CDevice** driver are below. This is the recommended driver.

```

// Constructor to create object, also initializes the I2C peripheral. The pInterface
// parameter will be i2c[0], i2c[1] or i2c[2], representing the 3 I2C peripherals.
// The optional 3rd parameter is normally left as a default. It can be used to set the
// number of register address byte to send, from 0 to 3.
// Example: I2Cdevice EepromDevice(i2c[0], address);
I2CDevice(I2C & pInterface, uint8_t deviceAddress, uint8_t numAddressBytes = 1)

```

```

Result_t writeReg8(uint32_t reg, uint8_t dat)
Result_t writeRegN(uint32_t reg, uint8_t *buf, uint32_t blen)

```

```

Result_t readReg8(uint32_t reg, uint8_t &dat)
Result_t readRegN(uint32_t reg, uint8_t *buf, uint32_t blen)

```

Start, Stop and Restart are taken care of in the `writeRegN` and `readRegN` functions. In situations in which a restart was used for sending more than 1 byte as an address, the `numAddressBytes` parameter in the **I2CDevice** constructor can be used.

```

void resetBus()
void setup(uint32_t busSpeed) // change bus speed

```

If you wish to have more manual control over the **I2C** transactions, you can create an **I2C** object instead of an **I2CDevice** object:

```

// Create an I2C peripheral object. The module parameter for the MODM7AE70 can be 0, 1 or 2.
I2C(int module)

```

```

Result_t writeReg8(uint8_t devAddr, uint32_t reg, uint8_t data)
Result_t writeRegN(uint8_t devAddr, uint32_t reg, uint8_t *buf, uint32_t blen)

```

```

Result_t readReg8(uint8_t devAddr, uint32_t reg, uint8_t &data)
Result_t readRegN(uint8_t devAddr, uint32_t reg, uint8_t *buf, uint32_t blen)

```

```

void setup(uint32_t busSpeed)

```

```

Result_t DoTransaction(I2CTxn_t *pTransaction, bool bRepeatedStart = false);

```

```

void resetBus()

```

In NNDK 3.x there is also a third option. ARM refers to the [I2C](#) as a two-wire interface, or a wire interface in general. A [WireIntf](#) class is available for even more manual control. It was written for those familiar with Arduino drivers, but can be used for more detailed control in general. Please refer to the NNDK 3.x documentation for details.

5.3 Upgrade 5441x Platforms to 3.x

5.3.1 Introduction

The ColdFire 5441x platforms were created before NetBurner 3.x, but they can be easily upgraded. The primary difference is in the device configuration. For reverse compatibility with prior tool sets, all 5441x devices are shipped with a factory application built with the 2.x release so they work with the IPSetup and AutoUpdate utilities. Once you download an application created in NetBurner 3.x, the device will then have the advantages of the 3.x features. The upgrade procedure consists of first loading a conversion application as described below. Thereafter you can load 3.x applications directly.

5.3.2 5441x Product Models Numbers

- MOD54415
- MOD54417
- NANO54415
- SB800EX

5.3.3 3.x Update Procedures

There are 3 procedures that can be used depending on the production date of your 5441x device. For reverse compatibility all 5441x devices ship from the factory running a 2.x application. All are described in more detail in the following sections.

1. For devices manufactured January 2022 or later, the 2.x factory application can process 2.x or 3.x application images, so download your 3.x application using the AutoUpdate utility.
2. For devices manufactured prior to January 2022, use the AutoUpdate utility to download a 2.x to 3.x conversion application.
3. For devices manufactured January 2022 or later, abort to the Alternate Monitor and download either a 2.x or 3.x application. Note that this procedure is also used to revert back to a 2.x compatible device.

Attention

Once a device is running a 3.x application, you will no longer use the 2.x utilities IPSetup and AutoUpdate. Instead, you will use the methods described in the Device Discovery and Configuration section of this manual.

Attention

The NetBurner development tools for 5441x platforms produce both S-Record (.s19) and binary (.bin) application images. The 2.x compatible AutoUpdate utility mentioned in the migration section only uses .s19 files. The preferred file format going forward for all 3.x applications is the .bin format.

5.3.3.1 Procedure For a New 5441x Device Running The NetBurner Factory App

New devices from the factory are programmed with a 2.x factory application to be compatible with older designs. The application can process both 2.x and 3.x applications. The procedure is to identify the device and download a 3.x application.

- Connect the NetBurner device to the network and verify you can see the device's IP address with the Auto↔ Update utility.
- Select your 3.x application and update.

5.3.3.2 Procedure Using the 2.x to 3.x Conversion Application: xxxx-3p0-Update_APP.s19

This procedure can be used for a 5441x device that is currently running any 2.x application. The procedure is to identify the device, download a 2.x to 3.x conversion application, then download any 3.x application.

- Connect the NetBurner device to the network and verify you can see the device's IP address with the Auto↔ Update utility.
- Use the Autoupdate utility to download the appropriate conversion application image for your particular platform, located in the folder: \nburn\platform\\original\. For example, a MOD5441x application name would be: "MOD5441X-3p0-Update_APP.s19".
- You will now be able to create and download 3.x applications on the device.

5.3.3.3 Procedure Using Alternate Boot Monitor

As of April 2021, the Alternate Boot Monitor has the ability to process a 3.x image file (older revisions must use the previous procedure by loading the conversion application). Alternate Boot Monitor revisions must be the revision shown below or later:

Platform	Revision
MOD5441x	1.11
NANO54415	1.05
SB800EX	1.05

- Connect to the debug/console port of the device with a serial terminal such as MTTY
- Reset or power cycle the device (or use the recovery jumper)
- Press the 'A' key to abort when prompted (or use the recovery jumper)
- Use the AutoUpdate utility to download your 3.x application image

Note

If you have a device with an earlier Alternate Boot Monitor revision and wish to update it (the Alternate Boot Monitor), please contact NetBurner Support at <https://support.netburner.com>.

5.3.4 Procedure to Revert Back to 2.x

If you wish to revert back to 2.x, there are two methods to abort the boot sequence and enter the Alternate Boot Monitor:

1. Using the serial port interface
2. Using the hardware reset jumper

5.3.4.1 Serial Port Procedure

- Connect to the RS-232 debug/console port of the device with a serial terminal such as MTTY
- Reset or power cycle the device
- Press the 'A' key to abort when prompted to abort to the Alternate Boot Monitor
- Use the AutoUpdate utility to download your 2.x application image

5.3.4.2 Hardware Reset Jumper Procedure

- Insert the hardware reset jumper
- Reset or power cycle the device to abort to the Alternate Boot Monitor
- Use the AutoUpdate utility to download your 2.x application image

5.3.5 Note on IPSetup utility and 3.x Devices

The windows IPSetup utility will still identify the IP address of a 3.x device. However, it cannot configure the device. The IPSetup device window designates these devices with a prefix of NEWCONFIG.

Figure 5.1 IPSetup with 3.x Application

Chapter 6

NBEclipse

There are three different ways to develop with the NetBurner Tools:

1. Install NBEclipse, which provides project management, a make system, and an editing environment.
2. From the command line using the make utility. Each example in the `\nburn\examples` folder provides an example makefile.
3. Use your own editing environment, and have that environment call the makefile for the project.

The documents in this section will describe how to use the NBEclipse environment and command line.

[Getting Started Guide](#)

[Add a Library to a Project](#)

[Change The IP Targeted By A Project](#)

[pageNBEclipse-ChangeCompcodeSettings](#)

6.1 Getting Started Guide

6.1.1 Introduction

6.1.1.1 How to Use This Guide

The goal of the NetBurner Eclipse Getting Started Guide is to familiarize new users with the NetBurner Eclipse (NBEclipse) interface and basic operation. NBEclipse is based on the standard Eclipse release with additional features to support development with NetBurner hardware, such as the ability to locate your NetBurner device on the network, and download an application to the device's flash memory. Topics include:

- How to create a new project
- Import, compile, and execute example programs
- Debug an example program
- Use the application wizard to create a new program
- Various tips on useful features of the NBEclipse environment

6.1.1.2 Source Code for Example Programs

Source code for the examples in this document are located in the `\nburn\examples` directory of your NetBurner tools installation.

6.1.1.3 Hardware Setup

This document assumes you have a working hardware platform on which you can run the examples. Your NetBurner development kit hardware is pre-programmed with an example application at the factory. Before executing the examples in this document, it would be a good idea to connect your NetBurner device to your computer and verify you have serial and network communication with the device as described in the NNDK Quick Start Guide.

6.1.1.4 Software Installation

NetBurner software tools run on Microsoft Windows and OSX. When you receive your development kit there will be a bright red card with a keycode. Register this keycode at <https://support.netburner.com> to download the development tools.

6.1.1.5 Upgrading From a Previous Installation

Do not install over an existing version when upgrading from a previous version of the NetBurner tools. The upgrade requires that you either rename or uninstall the existing installation directory. The recommended procedure is as follows:

1. Backup any existing projects you want to save, especially if they are in the NetBurner tools installation directory.
2. Rename the existing tools installation folder. For example, if upgrading from revision 2.8.8, rename `\nburn` to `\nburn2p8p8`, then install the new version to `\nburn`. This way you can always get back to the previous installation and environment by renaming `\nburn2p8p8` to `\nburn`.

6.1.1.6 Java Installation

NBEclipse requires the 64-bit Java Runtime Environment (JRE) revision 1.8 or higher. If there is no JRE installed, then you will receive an error message when starting NBEclipse stating that it cannot find the JRE executable. The JRE is free from <http://java.sun.com>. Download either the Java SE (Standard Edition) Development Kit (JDK) or Runtime Environment and follow the installation prompts. You may need to restart your computer after installation is complete.

Note

NBEclipse tools version prior to 3.0 require the 32-bit JRE.

6.1.1.7 Debug Port

Throughout this guide, we will refer to the "serial debug port". The serial debug port is one of the RS-232 ports that can be used to interact with your NetBurner device in the example programs. Stdout, stdin, and stderr are mapped to the debug port by default, so when you use functions like printf(), scanf(), gets(), they read and write to the serial debug port. Mapping of the stdio is configurable, as you can disable the serial debug port and use it as a general purpose UART, or reassign the stdio file descriptors to use other serial or network interfaces. Debugging in NBEclipse on network-enabled platforms will occur through the Ethernet connection, while debugging on non-network platforms will use the serial port.

6.1.2 Platform Overview

6.1.2.1 NetBurner Development Platform Choices

Your NetBurner Network Development Kit provides two options for development:

1. NBEclipse Integrated Development Environment (IDE)
2. Command line tools using the GNU make utility.

The choice of what platform you wish to use depends on personal preferences. The command line tools use makefiles, which are included for every example program and can be used as a starting point for your own makefiles. The make utility can also be invoked from within other IDEs and code editors such as Microsoft Visual Studio.

6.1.3 Project Management

The following points are useful to users who have not used a similar type of project manager. There are three primary methods to maintain and build a project:

1. Use NBEclipse to manage the project with the project files located in the NBEclipse workspace. This is the recommended method.
2. Use NBEclipse to manage the project with the project files located in an existing directory outside the NBEclipse workspace.
3. Configure NBEclipse to use an external makefile that you maintain.

6.1.3.1 NBEclipse Key Points

1. NBEclipse uses a "workspace" in which projects are created and source files are copied.
2. All source code files must reside in the project's "src" folder.
3. If using the web server, all HTML and associated files must reside in the project's "html" folder.
4. All recognized files in a project directory will be compiled. Recognized files have extensions of .c, .cpp, and .s (.s is an assembly language file).
5. The Project Explorer tab on the left side of the NBEclipse IDE is a navigation window like a file browser, it is not a file project manager. All recognized files will be built as part of the application. If you have non-project related files in your project directory and wish to see only the project files in the tab, you can select a filter to display only source code files.
6. To download an application to your NetBurner device, select "Run as NetBurner Application" from the project's Build Targets folder.
7. Application build output files such as .o, .elf, .map, .bin and .s19, and .bin will be written to project sub-directories named "Release" and "Debug" that correspond to the type of build executed. The .bin and .s19 files are the application image files.
8. The keyboard shortcut `<ctrl> b` will build the active project.
9. The keyboard combination of `<ctrl> <space>` invokes function auto-complete.

6.1.4 Creating Projects and Importing Files

This is the most common type of project creation. It will be used to build and run example programs, and is a good starting point for your own projects. By "empty project" we are referring to creating a project without running the Application Wizard to auto-generate a minimal application. After we create the project we will use the project import feature to import source code files from an example into the project.

1. Create an empty project.
2. Import source files by right-clicking on the project name and using the Import feature from the drop down menu.
3. Build the application and download to your NetBurner device.

6.1.4.1 Create a New Project

From the main menu, select **File->New->Project**:

Figure 6.1 Create a New Project

6.1.4.2 Select the NetBurner Project Type

Select the NetBurner project type, then select Next:

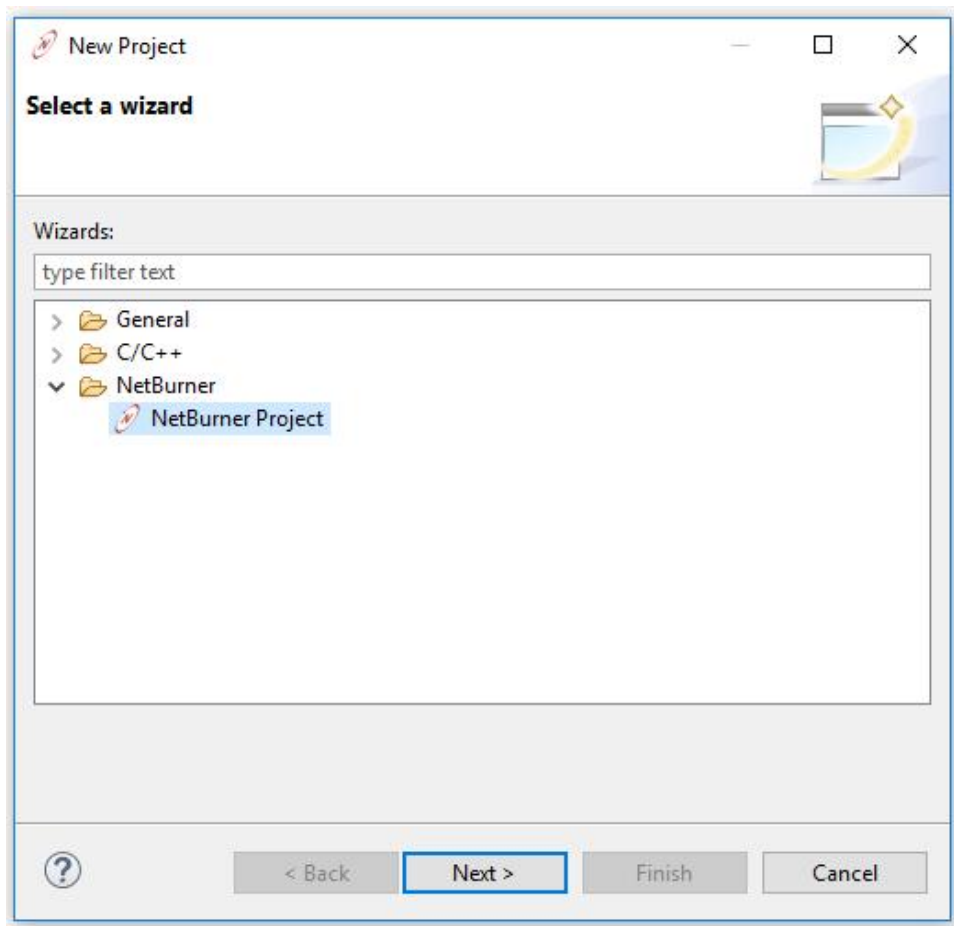

Figure 6.2 Select Product Type

6.1.4.3 Specify Project Name and Executable Option

Enter your project name in the Project Name field (it is best not to use spaces with gcc tool chains). In this example we entered "SimplHtml", since that is the example we will import. Make sure the Executable is set to: "NetBurner C++ Project".

Warning

Be sure to select NetBurner Device Executable, do not select the C/C++ option.

Note

You can create a project in a directory outside of your workspace by unchecking the Use Default Location checkbox, and using the Browse button to select the directory containing the source files.

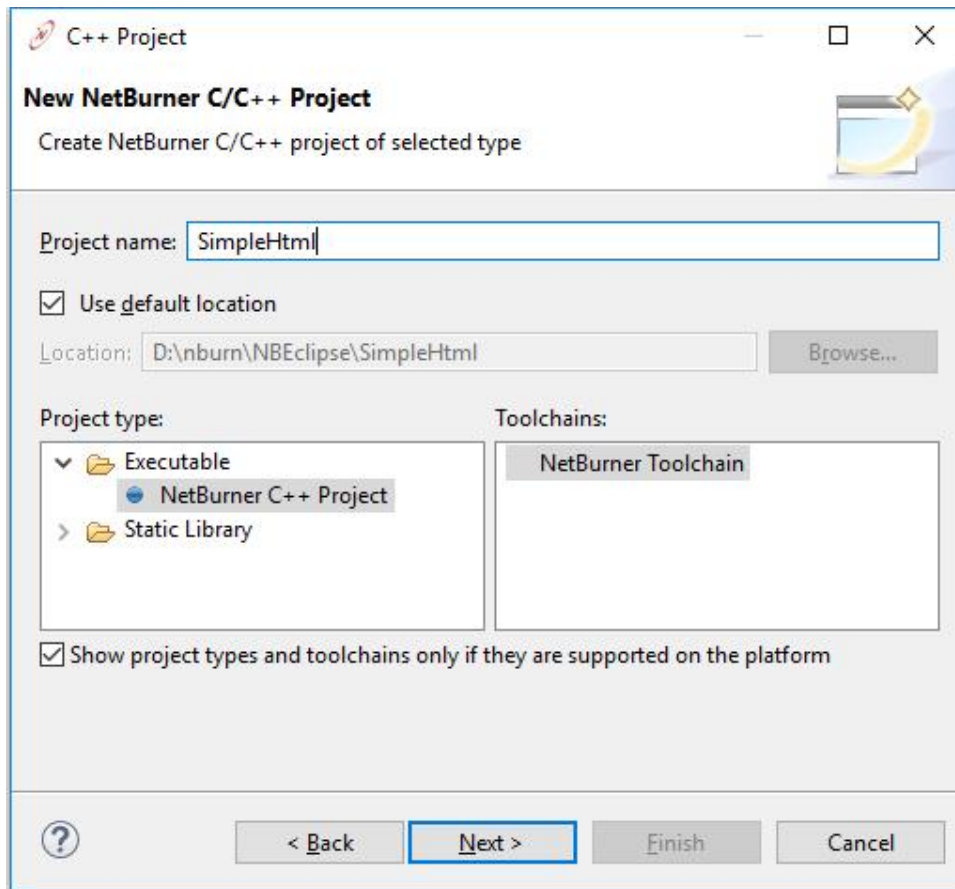

Figure 6.3 Select NetBurner Device Executable

6.1.4.4 Project Configurations

The default options for the project configurations are both Release and Debug. Leave the defaults and select Next.

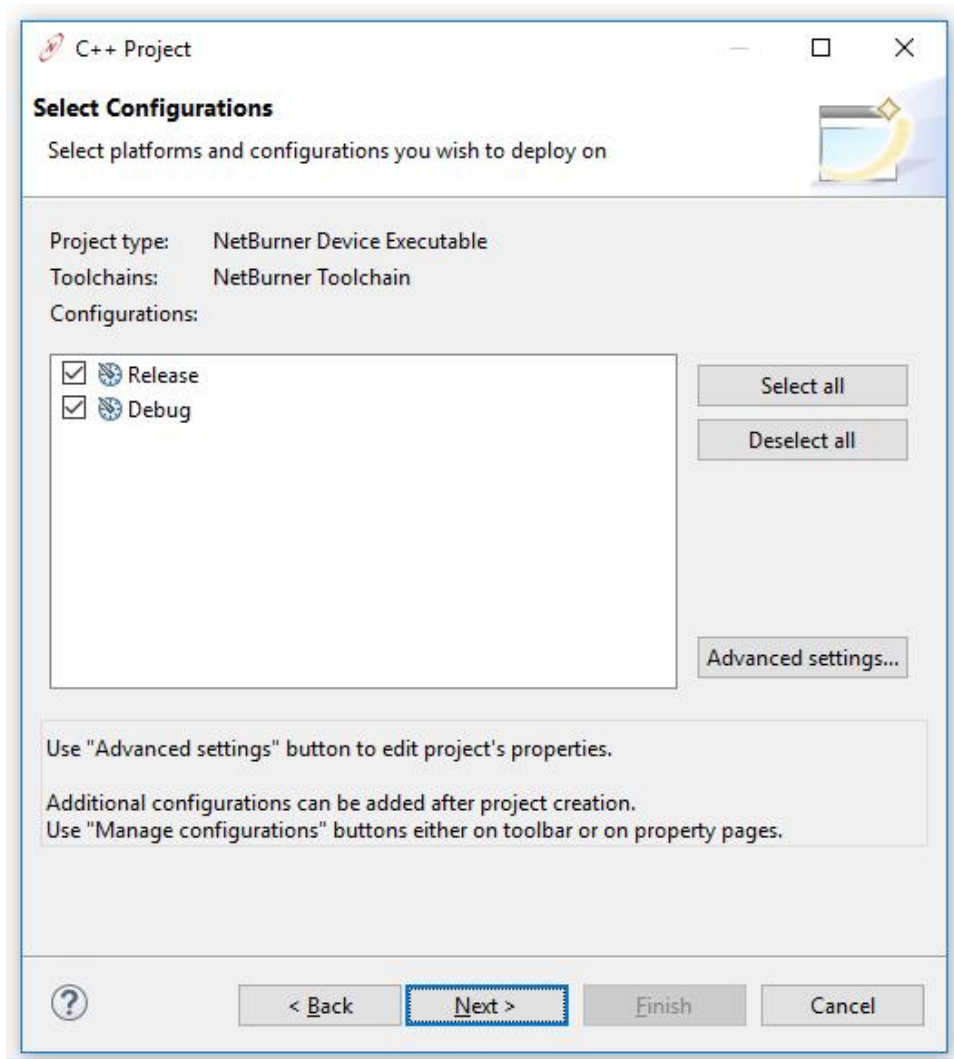

Figure 6.4 Project Configurations

6.1.4.5 Select Your NetBurner Target Device

There are two ways to select your target NetBurner device:

1. Click on the Search button to bring up a list of NetBurner devices on your network (device must be operational).
2. Manually: Click on the Target Platform drop down box to select your platform, then type in the IP address.

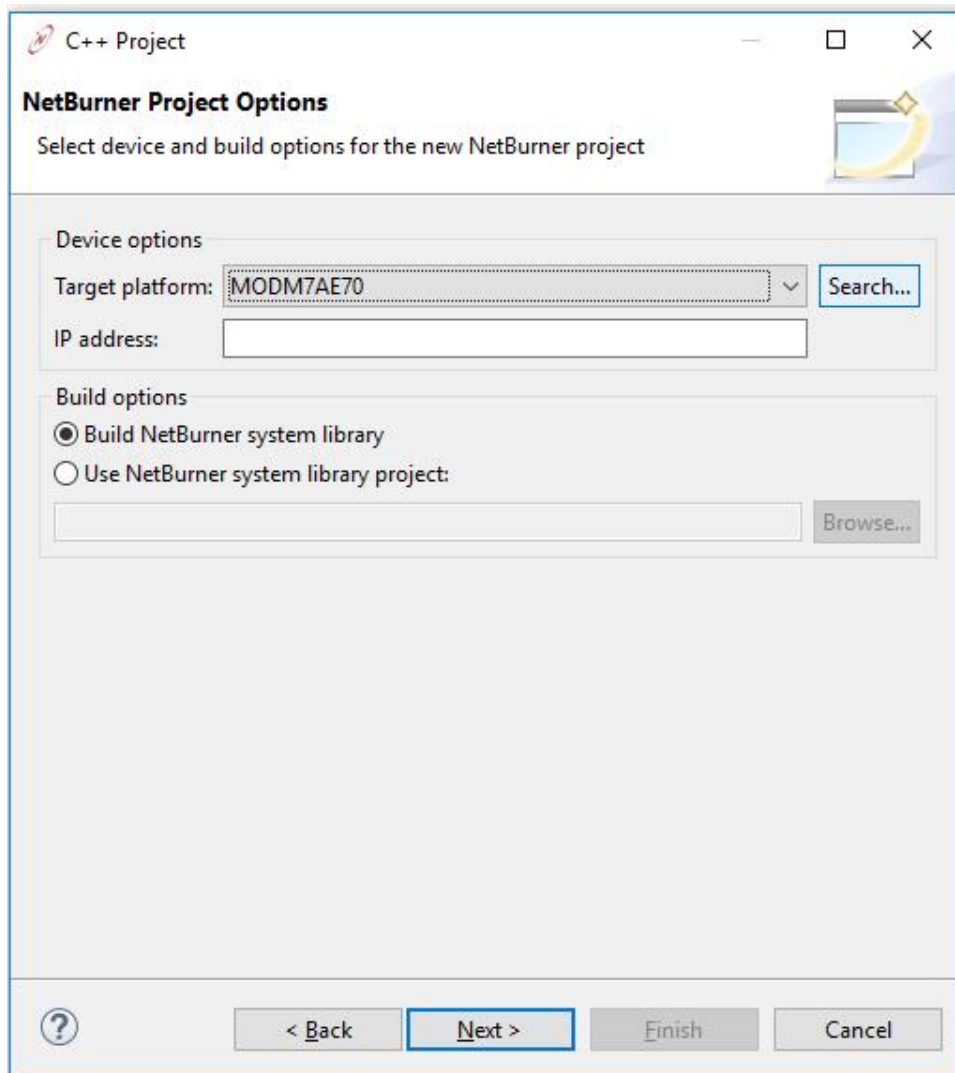

Figure 6.5 Search for devices

When using the Search feature, select the device in the list that corresponds to the MAC address printed on the label of your NetBurner device. In the image below we can see the device type, MODM7AE70, its MAC address, and its IP address. It will then fill in the platform and IP address for you. When done select Next.

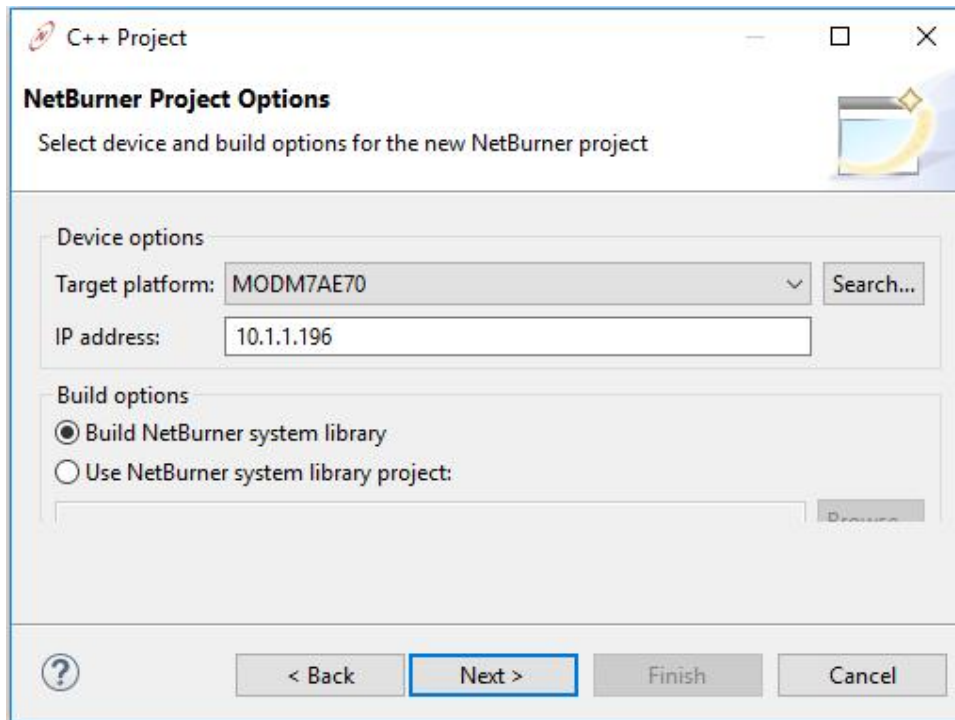

Figure 6.6 Successful search entry

6.1.4.6 Application Wizard

Since we are creating an empty project and will be importing our own source files we do not want to select any items here. However, if you wish to generate a minimal application using the Application Wizard, select both Standard Initialization and Web Server. This will generate a main.cpp source file to use as a starting point for your application.

Select Finish to complete the project creation.

Figure 6.7 Skip Application Wizard code generation

6.1.4.7 New Project Created

You will now see your new project in the Project Explorer pane. At this point we have a project, but still need to import our source files (if you did not use the Application Wizard).

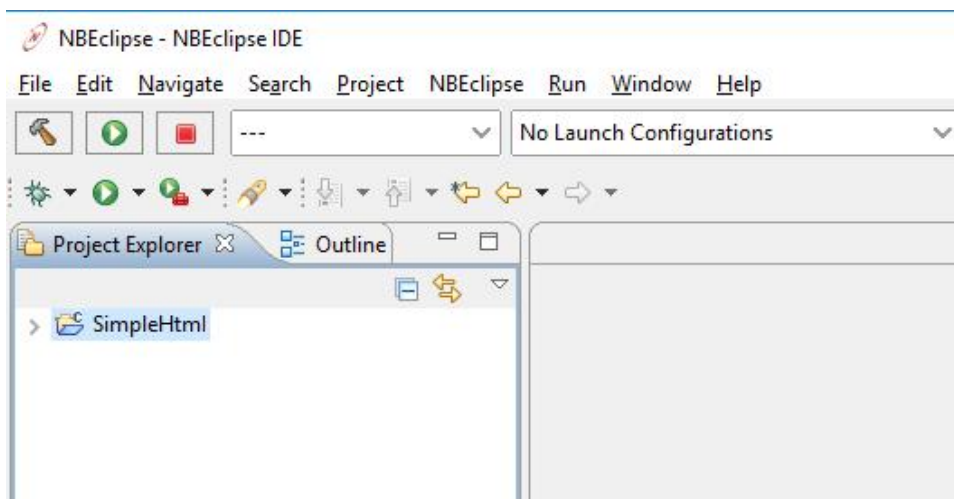

Figure 6.8 A new project has been created

6.1.4.8 Import Example Source Files to the Project SRC Folder

The next step is to import the source files of an example. NBEclipse uses a make utility to manage projects, and will attempt to build all source files in your project directory. Do not import non-source code files, such as .o, .elf, .map, .mk, auto-generated htmldata.cpp files, etc. NBEclipse will store all output files similar to these in project subdirectories named "Release" and "Debug" corresponding to the build type performed.

For this demonstration we will use "`\\nburn\examples\Web\SimpleHtml`". The first step is to right-click on your project in the NBEclipse Project Explorer pane:

Figure 6.9 Select Import

Next select the General->File System, then select Next:

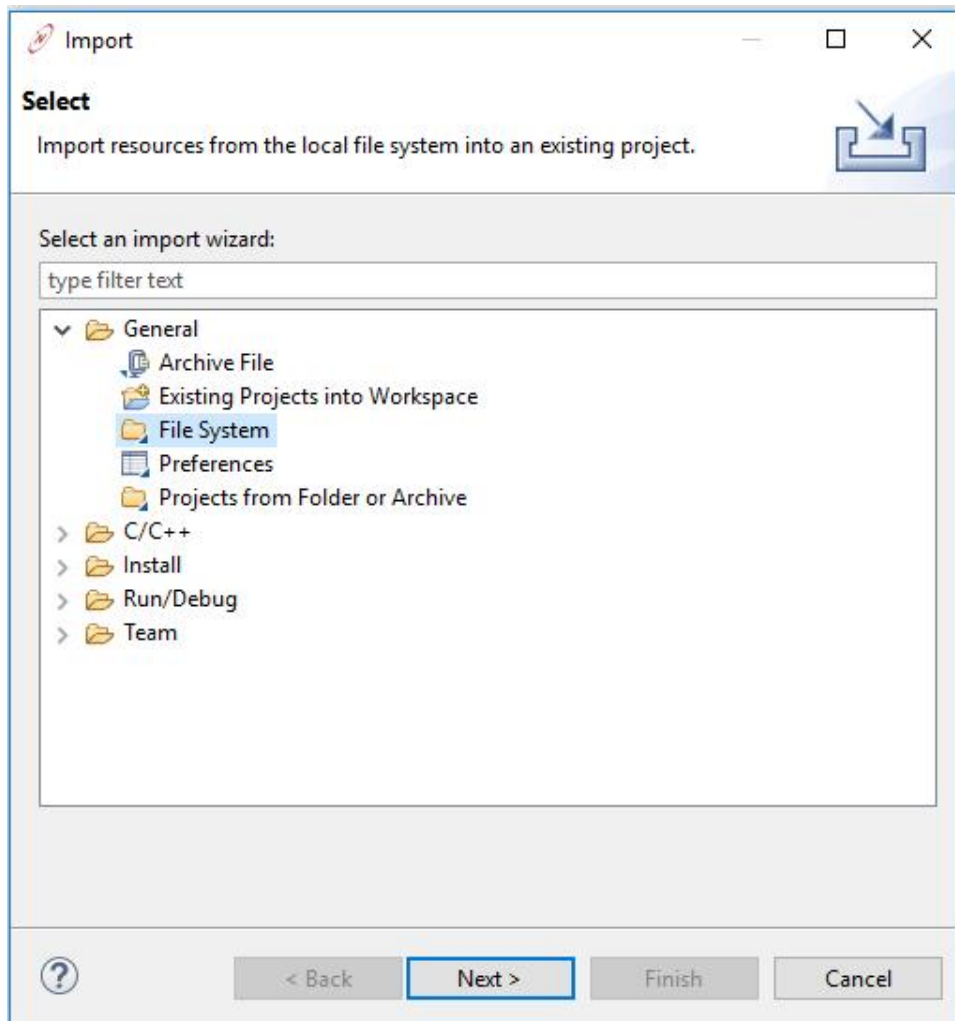

Figure 6.10 Select File System

Select the Browse button to bring up a file selection window, navigate to `\nburn\examples\Web\SimpleHtml`, and select the OK button:

Figure 6.11 Select the Simple HTML Example

Once back at the File System dialog box, click on the ">" symbol next to the SimpleHtml name to open the tree structure. You can see that there is a folder named src and a folder named html. We want the files in both folders, so select the checkbox next to the name "SimpleHtml", which will select all folders underneath it. Note: the makefile you see is only used for command line builds, but it does no harm to import it as well.

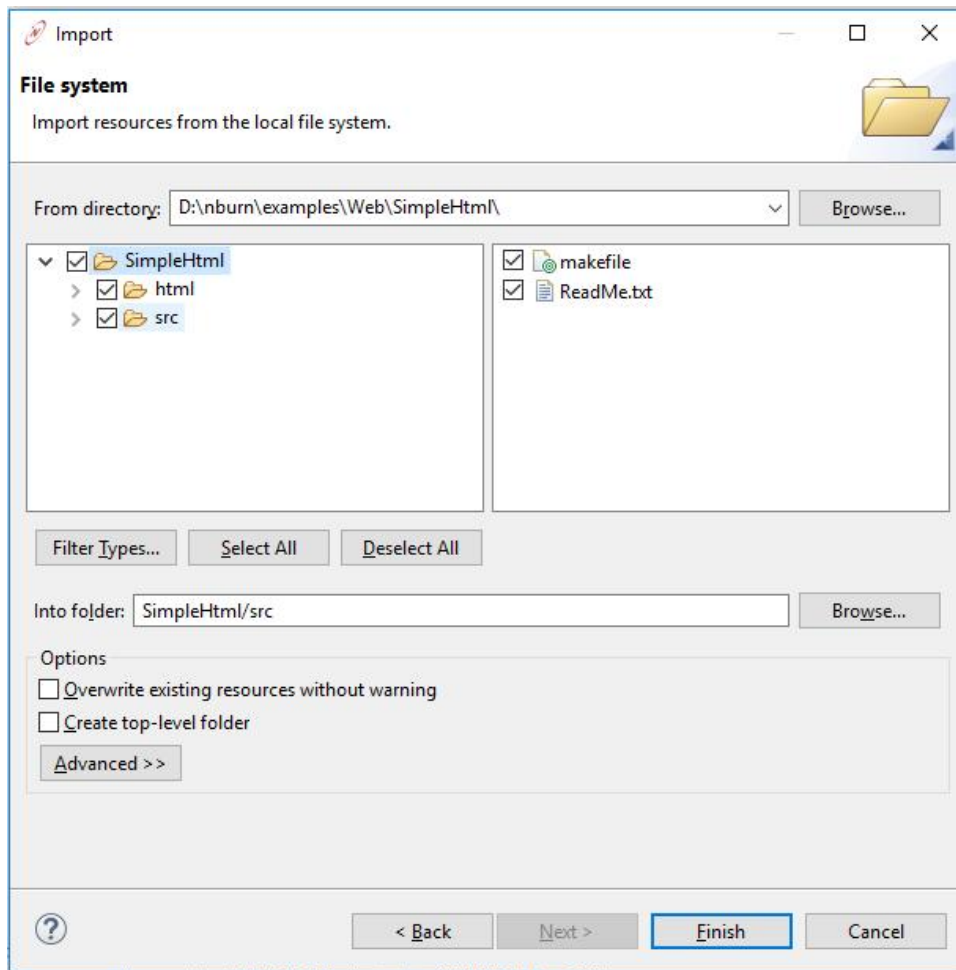

Figure 6.12 Select all SimpleHtml files for import

Select Finish, which will import the files and automatically build the project. You can view the status of the build process in the console window, located in the lower right corner of your screen. In the Project Explorer, click on the ">" symbol next to SimpleHtml. Some important items of note:

- Build Targets has two functions: downloading code to your device, and rebuilding the system libraries if needed.
- The src folder contains all your source code files, such as main.cpp.
- The html folder contains all your web based code.
- The overload directory is used to override any system library files. See the example in `\nburn\examples\OverloadDirectory` for more details.

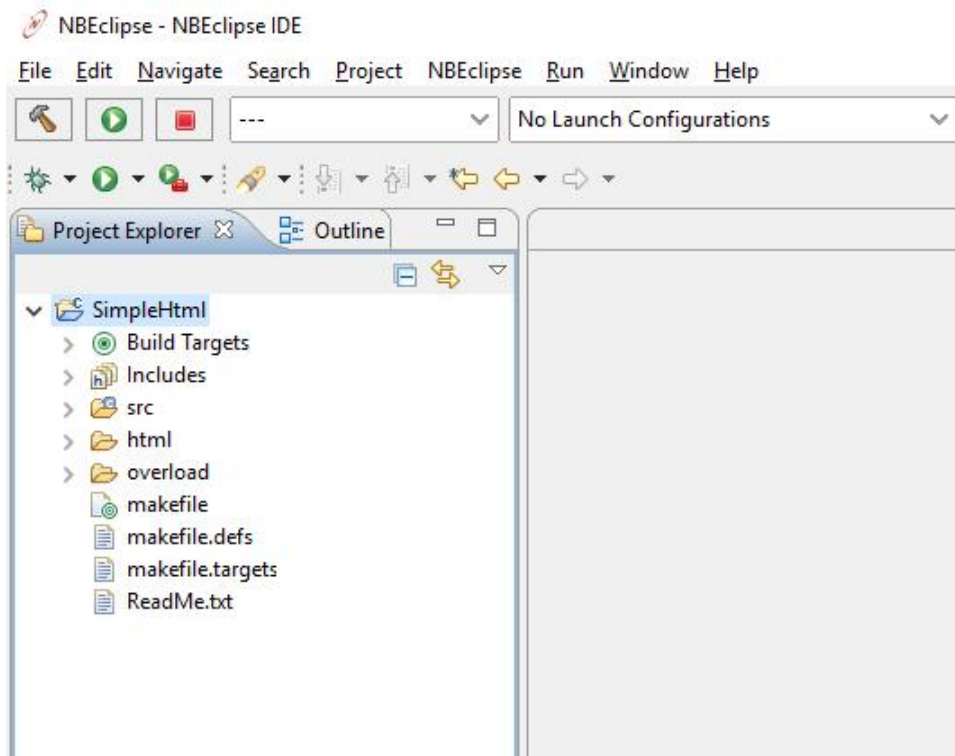

Figure 6.13 Import complete

6.1.4.9 Open your main.cpp source file

Clicking on the ">" symbol next to the src folder, you can open main.cpp in the editor

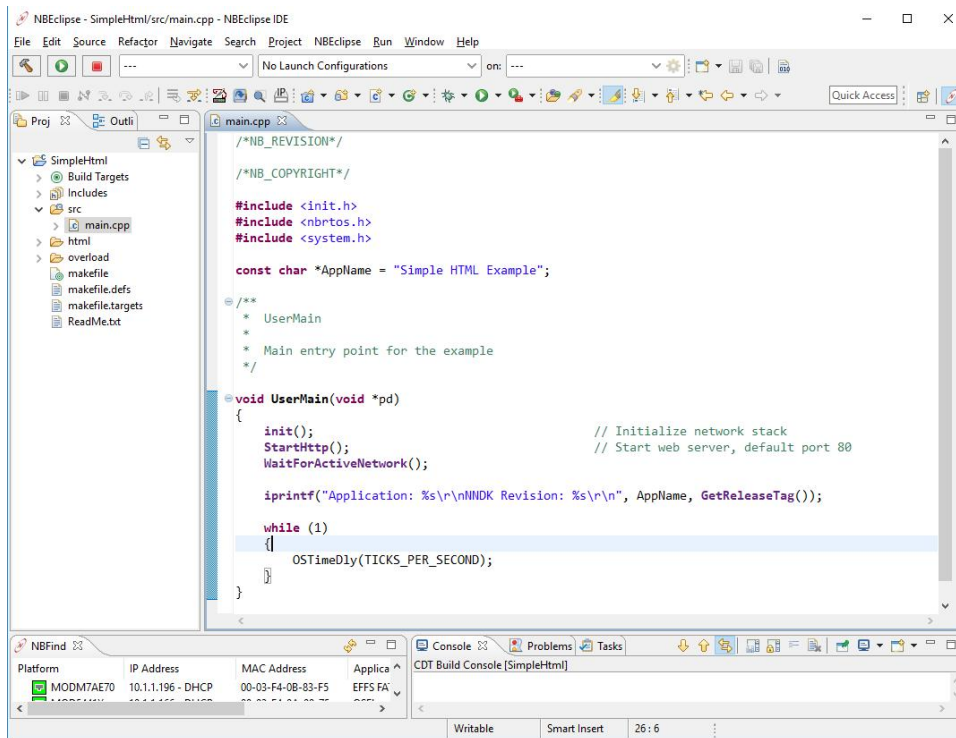

Figure 6.14 Open main.cpp

6.1.4.10 Project Import Complete

At this point you have a project complete with source code files. You can use the editor to modify both src and html files. If you wish to open a html file in text mode to do things like add dynamic content tags such as CPPCALL, VARIABLE, etc, right-click on the html file and use the Open With option to select the text editor:

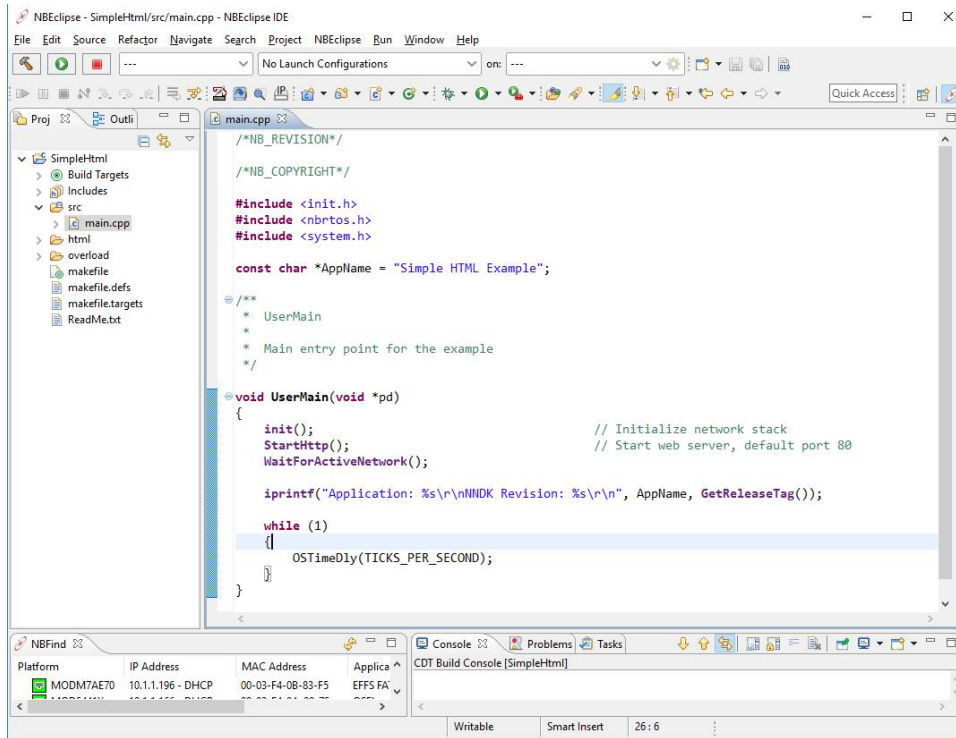

Figure 6.15 Open HTML files in text mode

By default, any time you modify and save a source file, the system will automatically build the application. If you prefer to turn off the auto-build option, to build the project: from the main menu select Project->Build Project, or use the `<ctrl> b` keyboard shortcut.

Figure 6.16 Build the Project

6.1.4.11 Download the Application to Your Device

Now that an application image has been built, the next step is to download the binary image to your NetBurner device. NBEclipse can simultaneously handle multiple NetBurner hardware platforms of the same or different types. For example, multiple MODM7AE70 core modules, or a mix with some MOD54415 modules. Targeting a project to a specific hardware device, is accomplished by creating a Run Configuration for release mode project builds, or a Debug Configuration for project debug builds. An important part of such a configuration is associating the device's IP address with the project so NBEclipse knows where to download the project's binary image.

When you create a new project and select the download option for the first time, NBEclipse will create a Run Configuration for you (Run and Debug Configurations can also be created manually). First select your project by left clicking on it in the Project Window:

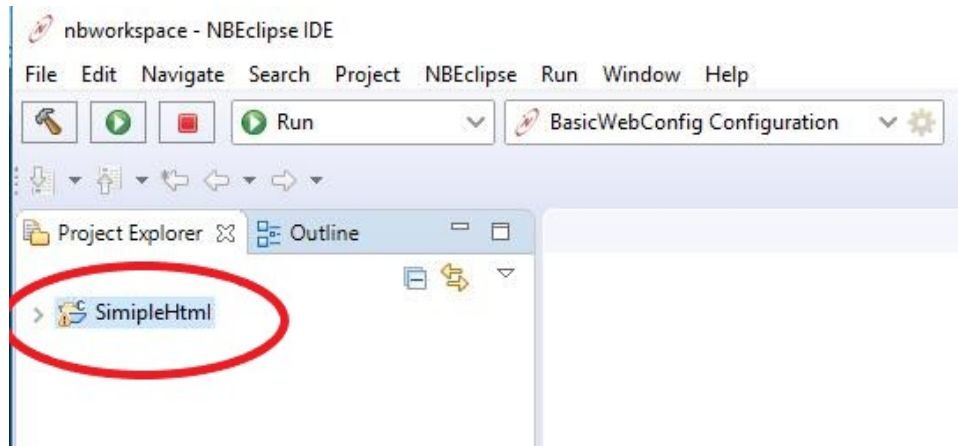

Figure 6.17 Select Project

Then click on the Run button in the upper right corner of NBEclipse:

Figure 6.18 Select Run Button

The Run As dialog box will appear. Select NetBurner Application, which will run the application on the remote system: When you click the OK button, NBEclipse will download the binary image to the remote device and reboot it.

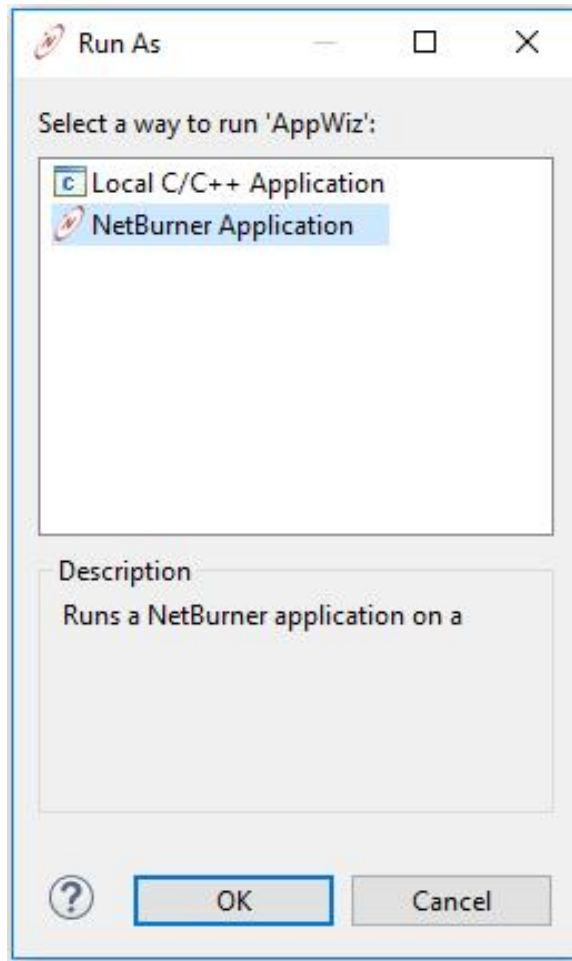

Figure 6.19 Select Run Application

The application should now be running on the device. If you do not remember the IP address of the device, you can find it using the "Find" window in the lower left of NBEclipse. In the screenshot below there are 3 devices. The device running SimpleHtml has IP address 10.1.1.196.

Figure 6.20 Find Device IP

6.1.4.12 View the Device Web Page

Opening a web browser and typing 10.1.1.196 in the URL field:

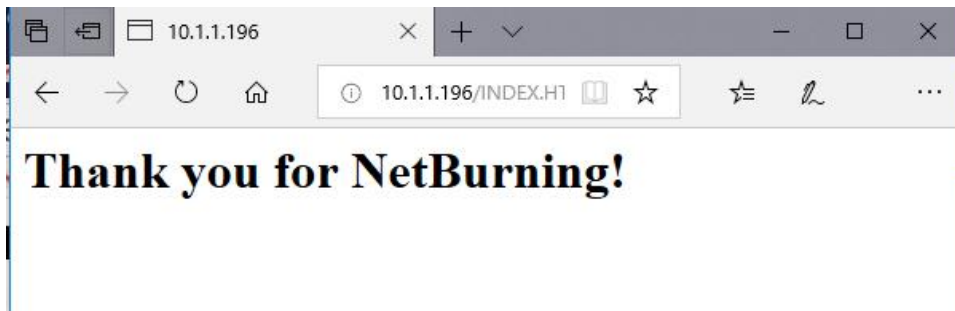

Figure 6.21 HTML Page

If you now look at the upper left side of NBEclipse, you will see the configuration set to Run, and the project set to SimpleHtml for the configuration.

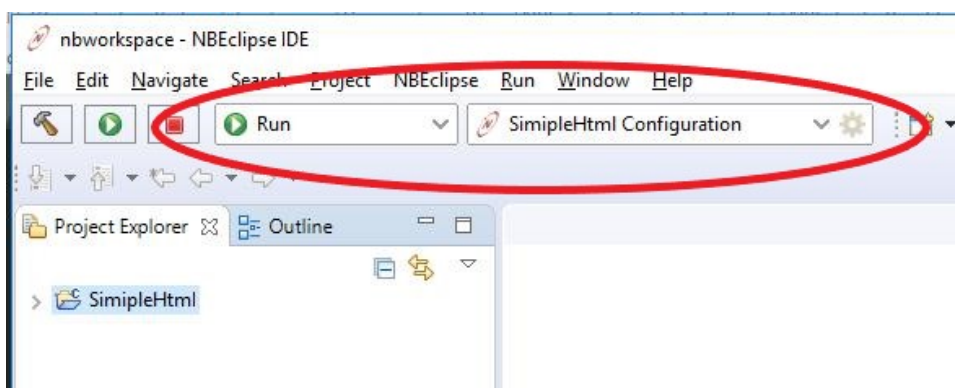

Figure 6.22 Run Configuration

6.1.4.13 View Serial Port Status Messages with MTTY

All NetBurner examples make use of the debug/console serial port to provide status messages. You will need to have a serial connection to your device either through USB or the DB9 on the development board, depending on your hardware configuration. You can then use the MTTY serial terminal application to view the serial output. To open MTTY:

Figure 6.23 Open MTTY

When the device boots the SimpleHtml application you will see:

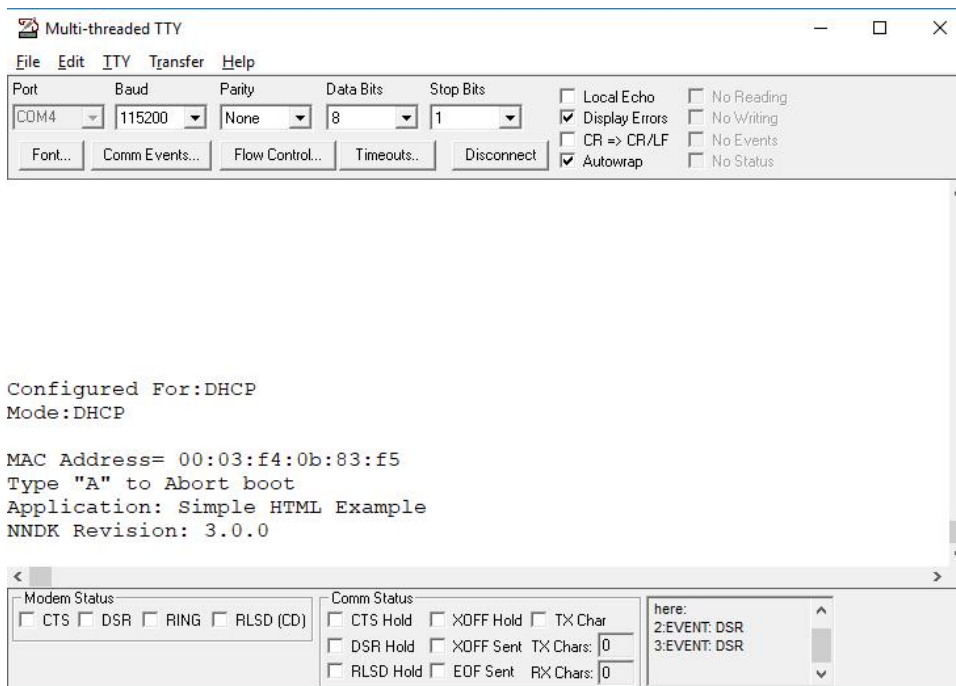

Figure 6.24 MTTY Output

6.1.5 Debugger

In the previous section we created and ran a project in release mode. To use a debugger, the application must be built in debug mode. All debuggers require the code be built in a different manor than a release build:

- Code optimization is disabled
 - If the platform uses external SDRAM with the internal SRAM acceleration for stacks, buffers and variables, it is disabled
- NBEclipse uses a network debugger. This means that an application must be able to at least boot through network initialization so the NBEclipse agent can connect to the GDB stub on the target device.

6.1.5.1 Starting a Debug Session

We will pick up right where we left off for the SimpleHtml example project in the previous section. First, lets open main.cpp and add a variable. UserMain() is shown below:

```
void UserMain(void *pd)
{
    init(); // Initialize network stack
    StartHttp(); // Start web server, default port 80
    WaitForActiveNetwork();

    iprintf("Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());

    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

Add two lines of code to create an integer and increment it:

```
int i = 0; and i++;
```

So UserMain() becomes:

```
void UserMain(void *pd)
{
    init(); // Initialize network stack
    StartHttp(); // Start web server, default port 80
    WaitForActiveNetwork();

    iprintf("Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());

    int i = 0; // <--- Declare variable
    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND);
        i++; // <--- Increment variable
    }
}
```

Previously for the Run Configuration and download we clicked on the green play button in the upper right corner of NBEclipse. This time we will click on the debug button, which is next to it on the left:

Figure 6.25 Select Debug Configuration

It will take a few seconds for the debugger to connect, and the NBEclipse Perspective will change from the NetBurner perspective to the Debug perspective:

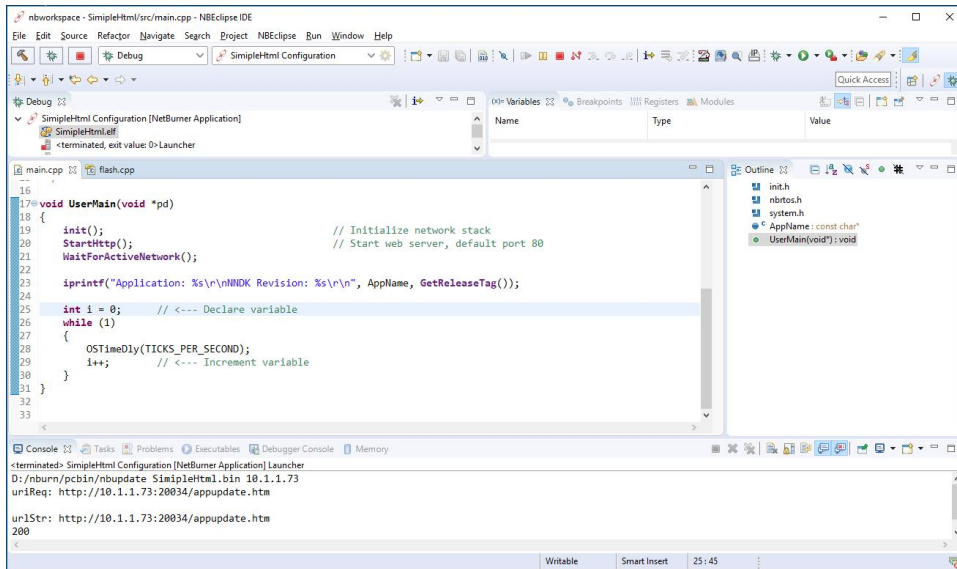

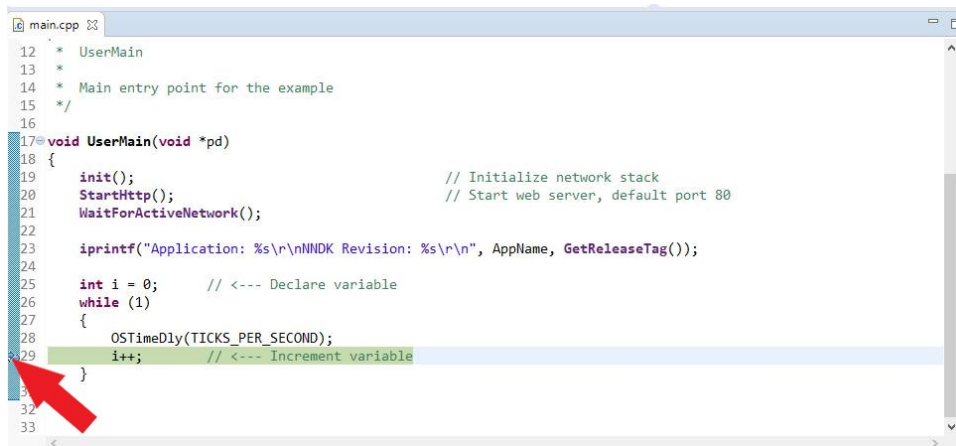

Figure 6.26 Debug Perspective

At this point the code is running. To set a breakpoint on our new variable, double click to the left of the line of code. In this example it is just to the left of line 29:

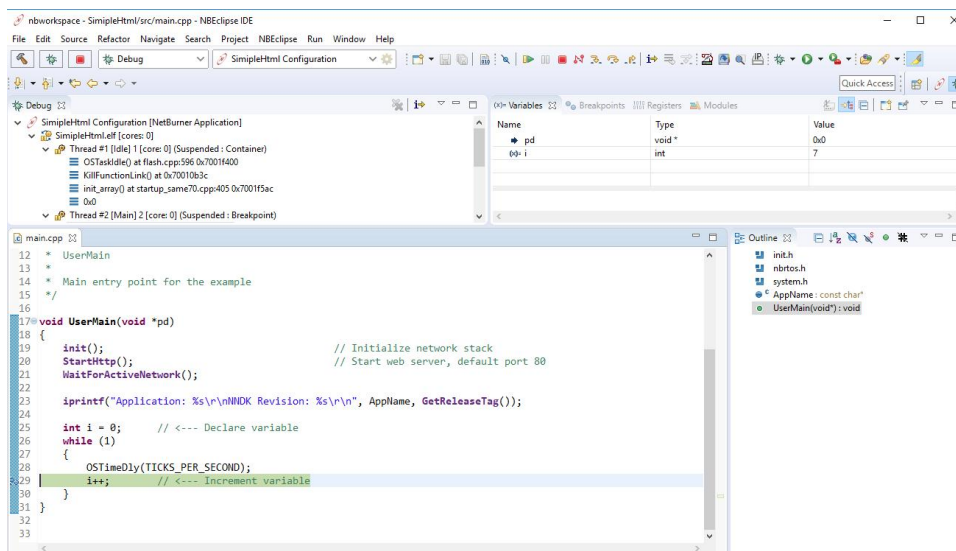

```

12 * UserMain
13 *
14 * Main entry point for the example
15 */
16
17 void UserMain(void *pd)
18 {
19     init(); // Initialize network stack
20     StartHttp(); // Start web server, default port 80
21     WaitForActiveNetwork();
22
23     iprintf("Application: %s\r\nMNDK Revision: %s\r\n", AppName, GetReleaseTag());
24
25     int i = 0; // <--- Declare variable
26     while (1)
27     {
28         OSTimeDly(TICKS_PER_SECOND);
29         i++; // <--- Increment variable
30     }
31 }
32
33

```

Figure 6.27 Set Breakpoint

The screen shot below shows the program stopped at line 29. The Variables window in the upper right shows the variable 'i', which has incremented 7 times so far.

Name	Type	Value
pd	void *	0x0
i	int	7

```

12 * UserMain
13 *
14 * Main entry point for the example
15 */
16
17 void UserMain(void *pd)
18 {
19     init(); // Initialize network stack
20     StartHttp(); // Start web server, default port 80
21     WaitForActiveNetwork();
22
23     iprintf("Application: %s\r\nMNDK Revision: %s\r\n", AppName, GetReleaseTag());
24
25     int i = 0; // <--- Declare variable
26     while (1)
27     {
28         OSTimeDly(TICKS_PER_SECOND);
29         i++; // <--- Increment variable
30     }
31 }
32
33

```

Figure 6.28 Stopped at Breakpoint

The debugger operations are controlled with the tool bar at the top of the screen. If you hover the cursor over the icon the tool tip will describe what it does. Common features are:

- Resume: Available when stopped at a breakpoint. Selecting it will resume the application and stop at the next breakpoint.
- Terminate: Disconnects the debugger from the target device. The device will resume execution without any breakpoints.

- Disconnect: Identical to Terminate.
- Step Into: Single step into a function call.
- Step Over: Single step to the next line of code in the current function.
- Step Return: Execute until current function returns.
Notes on debugging:
- You can switch between the Debug perspective and NetBurner perspective using the NetBurner and Debug icons in the upper right corner of the screen.
- You can edit and build your application from either perspective.
- Hovering the cursor over variables, macros and functions in the source code window will display information on that item.
- The upper left window displays the RTOS task stack.
- It is recommended to terminate a debug session before starting a new one.
- The three icons at the top left of the screen: build, debug and stop, are not used by either perspective.

6.1.6 Rebuilding Projects & Libraries

6.1.6.1 Rebuild Project Source Files

A project "clean" will rebuild all of the project's source code files. It does not affect the library system files associated with the project. From the Project Explorer pane, right-click on your project, then select Clean Project:

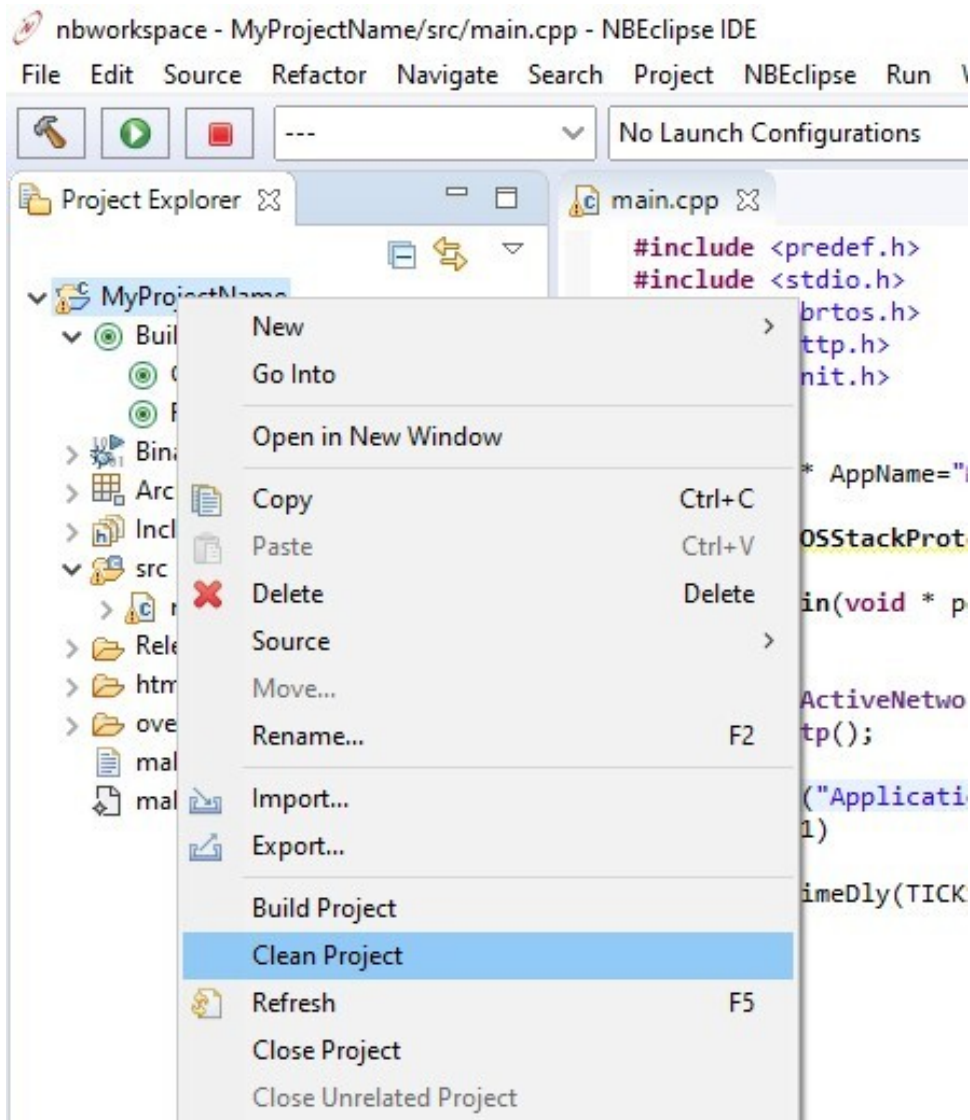

Figure 6.29 Rebuild project files

6.1.6.2 Rebuild Library Files

This is normally not necessary, but there are cases in which the user may want to rebuild the NetBurner system library files. For example, if the user made changes to system source files or added a system source file to a project's overload directory. In these cases, it's recommended to rebuild the NetBurner system library files followed by "cleaning" the project's source files.

To force a rebuild of the NetBurner library files associated with a project, double-click on Clean Project Library in the Build Targets tree:

Figure 6.30 Rebuild a project library

6.1.7 Overload Directory

The overload directory, located inside a project, is used to override any system file by including local copies of system source or header files. This allows the user to isolate system file changes to a specific project. The overload directory provides an alternative to modifying the original system files, which would affect all projects.

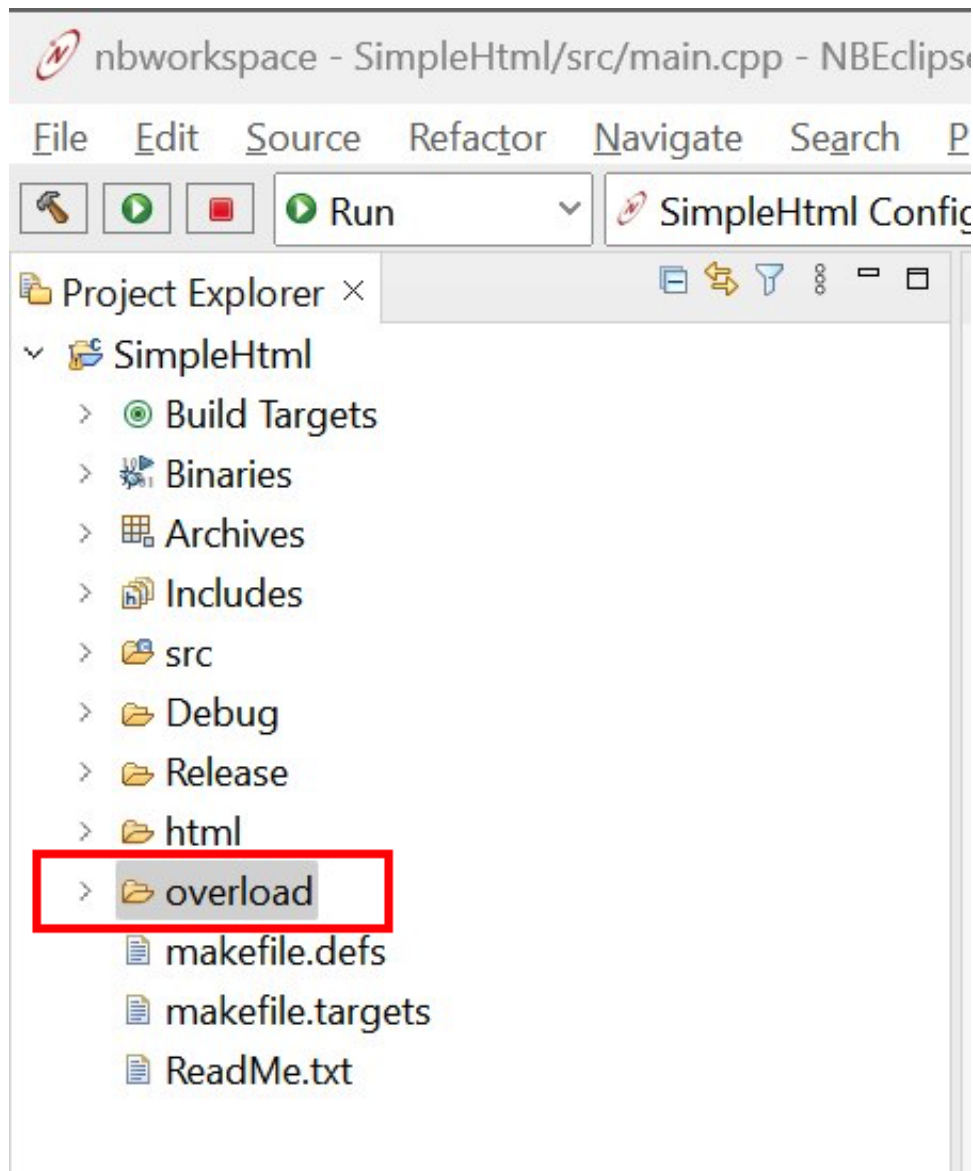

Figure 6.31 Project's Overload Directory

To use this feature, the file to be overloaded should be placed in the overload directory under a directory structure that matches the file's location relative to the NNDK install directory.

To demonstrate the usage and configuration of the overload directory, we will show an example. Let's say the user wants to overload the system's timezone structure so that they can change the name of a timezone. Perhaps the user is deploying their device in a non-English speaking country and would like to change the language used for timezone names. The timezone names are defined in a system file located in the following directory:

```
/nburn/nbrtos/source/timezones.cpp
```

Therefore, the directory structure is replicated inside the overload directory with the following structure:

```
<project root>/overload/nbrtos/source/timezones.cpp
```

The directory structure can be created by right-clicking the overload directory and selecting New->Folder. The overload directory must have a matching directory structure to the path of the system file to be overloaded. For this example, the overload directory should look like the following:

Figure 6.32 Project's Overload Directory Structure

Next, the modified source file must be placed in the correct path in the overload directory. The file can be drag and dropped in place. Alternatively, the file can be imported into the overload directory by right-clicking the overload directory and navigating to Import->General->File System and navigating to the source file. After adding timezone.cpp, our overload example would look like the following:

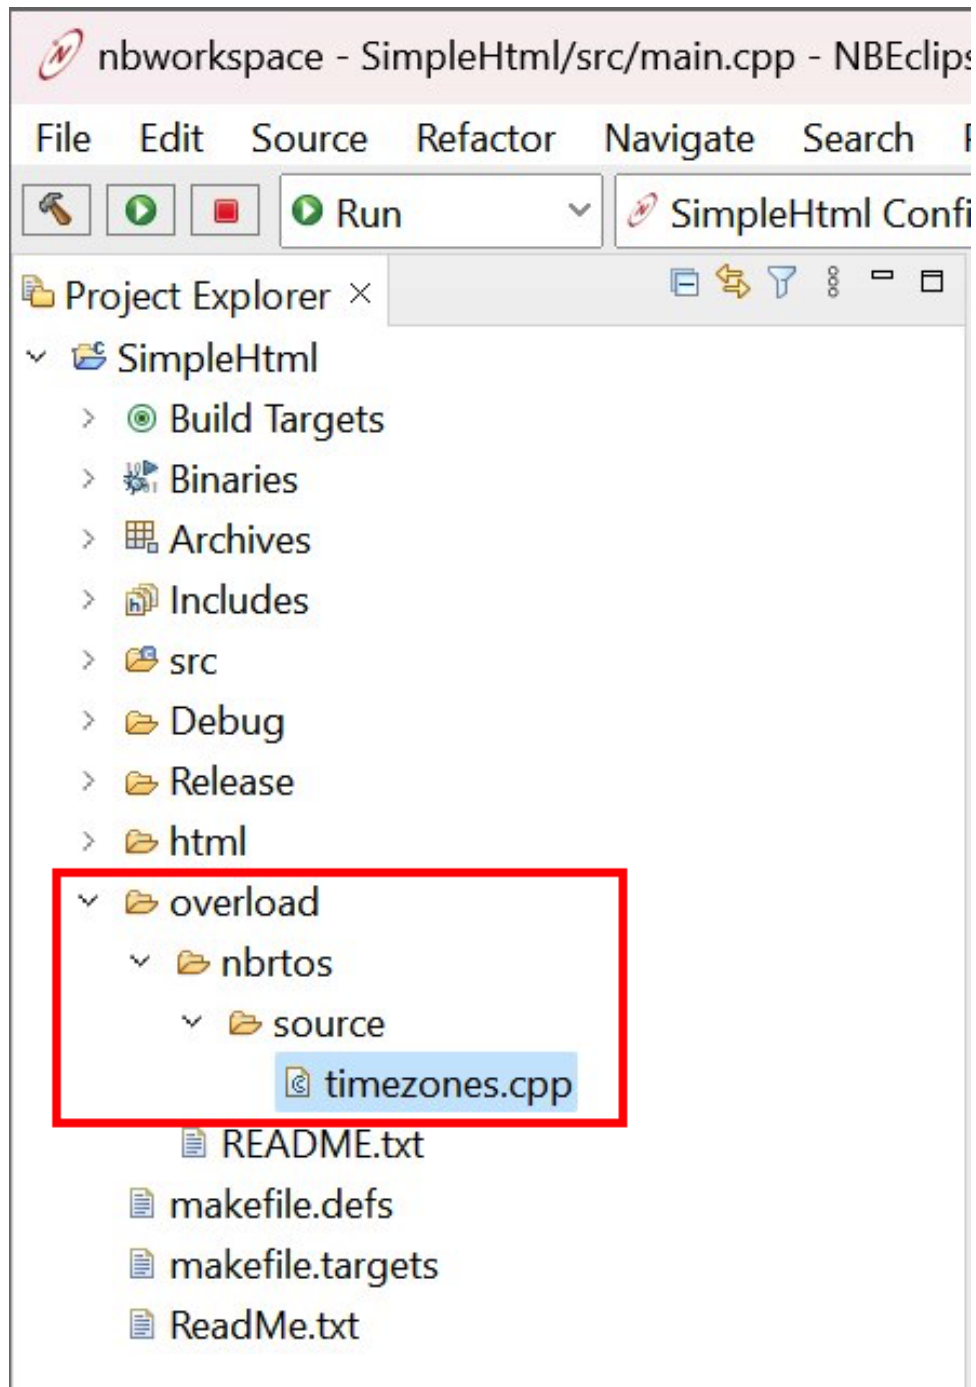

Figure 6.33 Overload Source File Added

Next, the project properties must be configured so that the C++ compiler knows to include the path to the overloaded source file. This can be done by right-clicking the project and selecting "Properties" as shown in the image below.

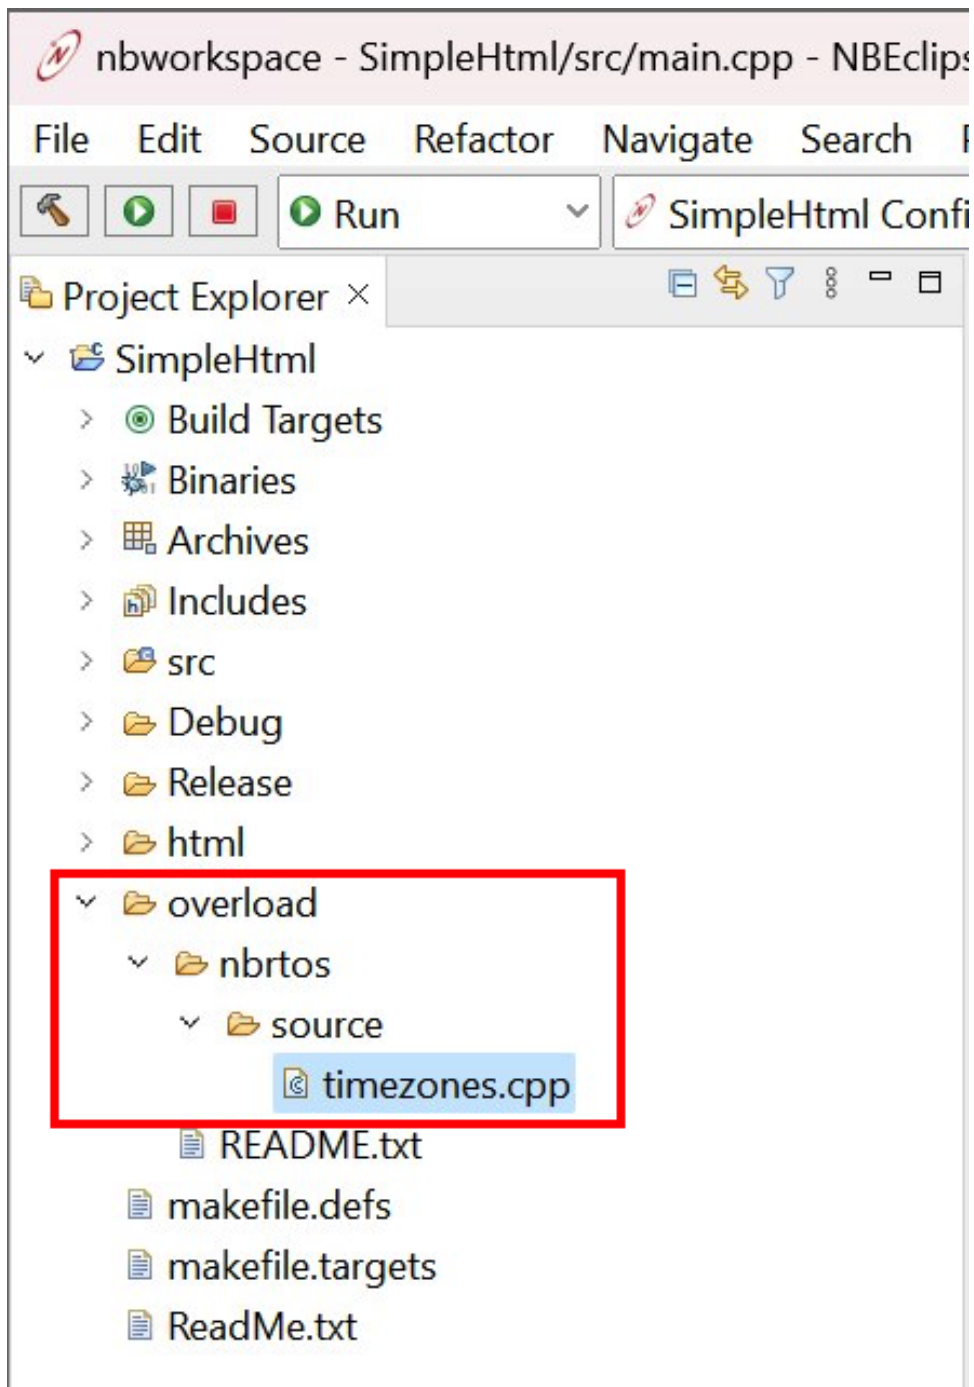

Figure 6.34 Project Properties

Navigate to C/C++ Build->Settings, select GNU C++ Compiler->Includes.

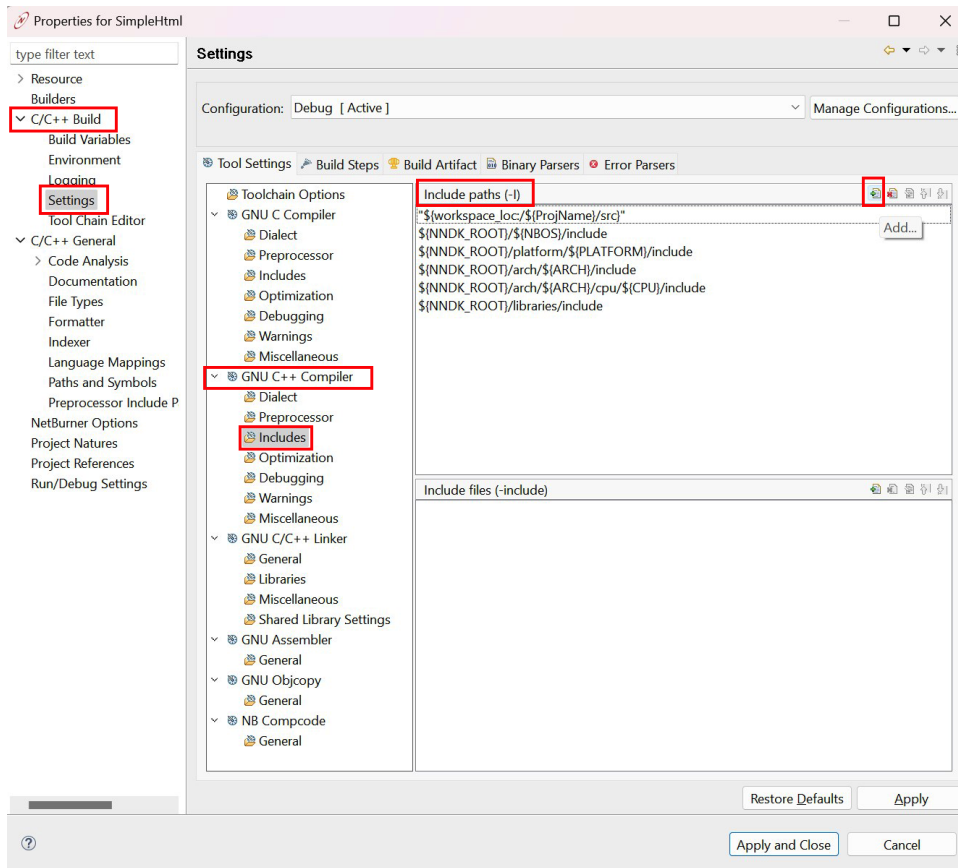

Figure 6.35 Overload Include Paths

Add the overload directory path to the "Include Paths" list by selecting the "+" logo. If utilizing C code, then the path to the overload directory should be added to GNU C Compiler->Includes as well.

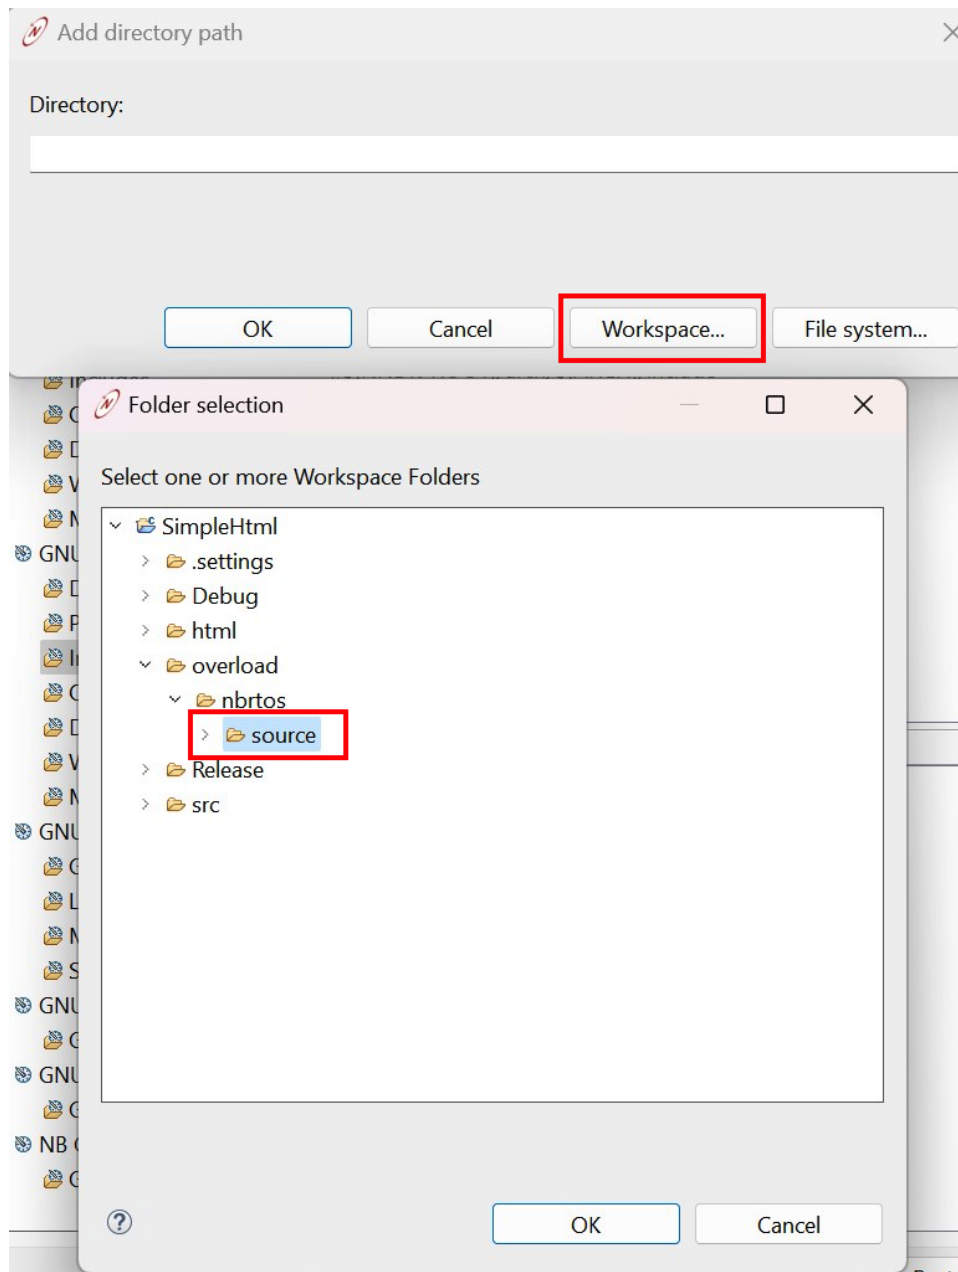

Figure 6.36 Overload Include Path Selection

After adding the overload directory path to the list of "Include Paths," the list should look like the following↔
:

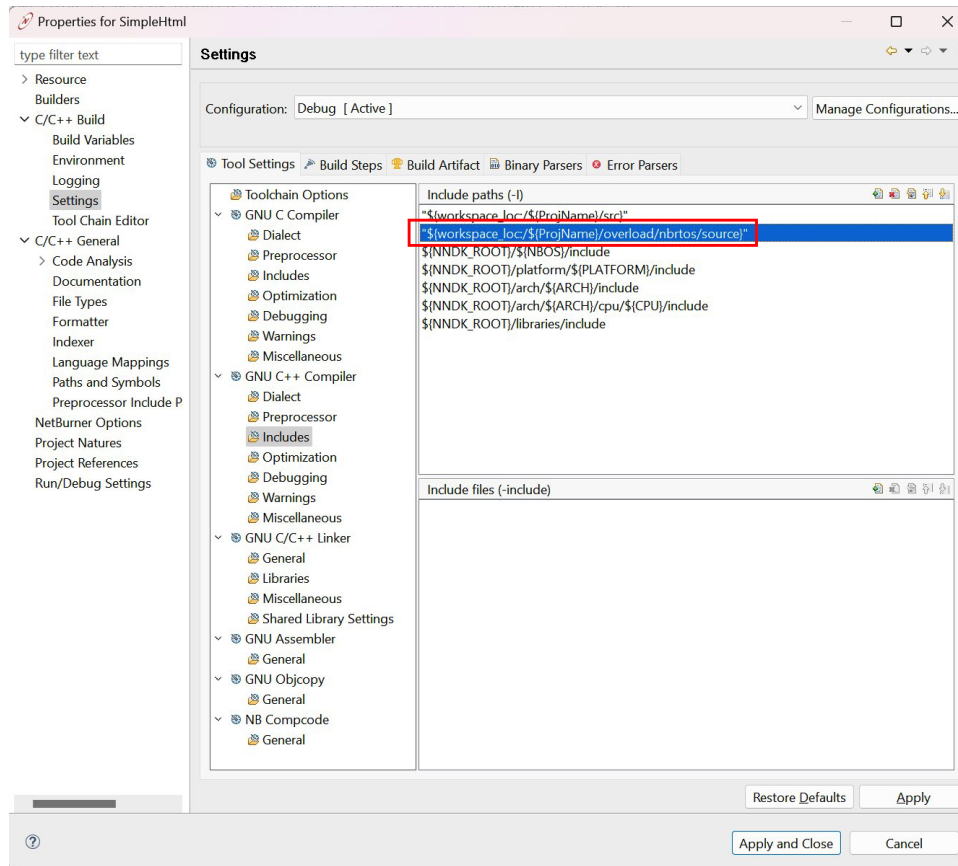

Figure 6.37 Overload Directory Path Added to Include Paths List

Select "Apply and Close" to apply the modifications.

Last, we need to rebuild the NetBurner system files then clean the project files (the order of operations matters). For instructions on doing so, see [Rebuilding Projects & Libraries](#). From this point on, modifying the overloaded source file, `timezone.cpp`, will automatically re-build the necessary files in the NetBurner system files when the project builds.

6.2 Add a Library to a Project

NBEclipse includes the most common libraries by default. However, there are times you will need to tell the build system to include additional libraries, such as if your application uses the Embedded Flash File System (EFFS) for flash memory cards, in which case you need to add the `FatFile` library.

Note: If you are building a project that uses EFFS functions, and have not added the `FatFile` library, you will see many link errors for functions that start with `f_` and `fm_`.

To add a library:

- In NBEclipse, right-click on your project, and select "Properties".
- Select "C/C++ Builds -> Settings" on the left-hand side.
- Select "GNU C/C++ Linker -> Libraries" under the "Tool Settings".

- In the "Libraries" list box, add "FatFile" by using the add icon in top-right corner of the list.
- In the "Libraries Search Path" list box, add the path to the library. For example, for MOD5441x device, the path is: `\nburn\platform\MOD5441X\original\lib`. Note: the naming convention for gcc is as follows: the name of the library is actually `libFatFile.a`, but in the Libraries entry box you only use what comes after "lib" and do not use the `.a` suffix. In this case, we just use "FatFile".

Note

The other common library to add is the EDFS-STD library: `StdFile`. EDFS-FAT is a FAT32 library for flash memory cards. EDFS-STD is used to create a file system in the flash memory chip on the device.

6.3 Change The IP Targeted By A Project

If the IP of your device changes (for example, if you unplug it and it is assigned a different IP when you plug it back in), you will need to tell the build system to target a different IP.

To change the targeted IP:

- In NBEclipse, click on "Project" from the top menu, then click "Properties".
- In the left-hand panel of the Properties menu, click "NetBurner Options".
- Change the targeted IP address in the right-hand side of the panel.

Chapter 7

PC Tools and Utilities

This guide describes the PC tools and utilities that run as stand-alone programs, as well as automatically as part of the NetBurner development tools suite. The executable version of the tools are located in `\nburn\pcbin`, and the source code is located in `\nburn\pctools`.

7.1 Multi-threaded TTY Serial Terminal (MTTTY)

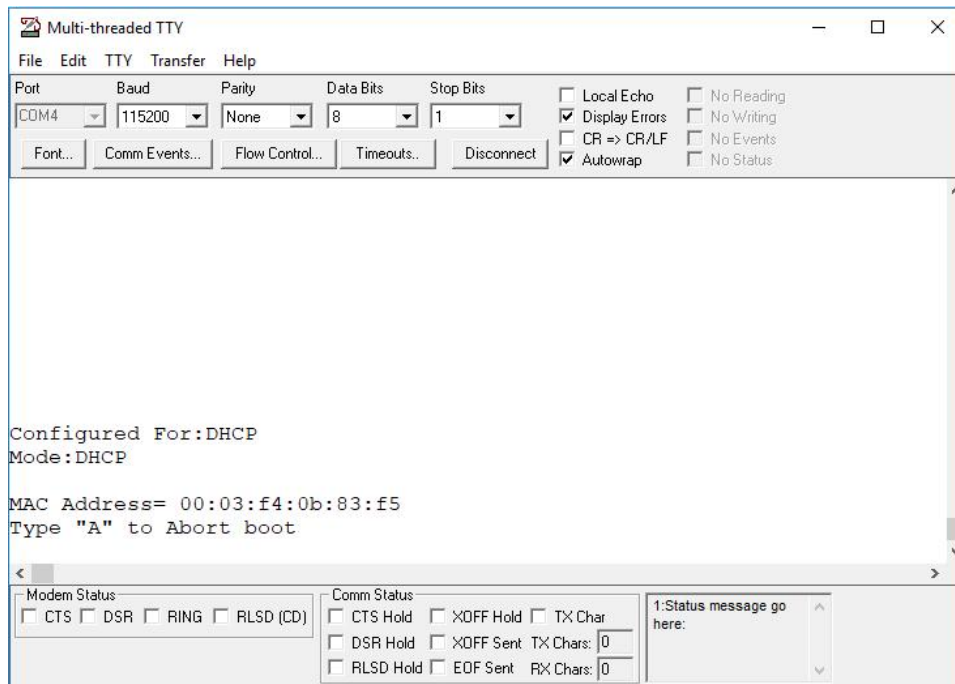

Multi-Threaded TTY (MTTTY) is a serial terminal utility that you can use to communicate with the RS-232 serial ports on your NetBurner device or development kit. It is multi-threaded in that you can run multiple instances of MTTTY for each serial port.

MTTTY is commonly used for:

- Displaying status messages sent from the NetBurner device, such as when using `iprintf()`
- As a serial interface to any application

MTTTY can be started from:

- Inside NBEclipse by clicking on the MTTTY icon
- From the Windows NetBurner program group
- From a command line. The path is: `\nburn\pcbin\mttty.exe`

7.1.1 MTTY FAQ

- The default serial port used for stdio for NetBurner devices is UART0.
- The DB9 connector pinout on NetBurner development boards will have the RS-232 rx and tx signals reversed, so that a null-modem adapter is not required and you can use a straight-through serial cable.
- The DB9 connector pinout on NetBurner Serial-To-Ethernet devices, such as the SB700EX and SB800EX, will be identical to a standard PC type pinout, so a null-modem adapter will be required. (The serial cable that comes with the NetBurner development kits for these specific devices is a null-modem cable)

7.2 Wget

Primary method to program an application into a NetBurner device by posting the application file to the device's config server. It is used automatically by both NBEclipse and the Makefile command line tools. The default flags to call wget are as follows: `wget -nv -O- --progress=dot:micro --post-file=<file name> <Device IP>:20034/appupdate.htm`

Wget also supports loading code onto a device that has been protected by username/password authentication. On the command line, the device username and password are configured by setting the environment flags NBUSER and NBPASSWORD. For example, in a make load, set the username and password as follows: `make load NBUSER=foo NBPASSWORD=bar`. In NBEclipse, username and password are set via the project options. Right click on a project and select Properties. Username and password text input boxes can be found under NetBurner Options. Finally, if manually utilizing wget, use the following wget flags to set a username and password: `--user=foo --password=bar`.

7.3 NBUpdate

Alternative method used to program an application into a NetBurner device by posting the application file to the device's config server. It is invoked as part of the make system for NetBurner development kit NBEclipse and command line builds. It can be replaced with WGET. The format is `nbupdate <file name> <device IP>`

7.4 Smart Traps

While smart traps is not a specific PC application, the interface is accomplished by running the MTTTY serial terminal. During software development it is possible for a software developer to download an application with a coding error severe enough to cause an application to crash. Common causes of a system crash are: task stack overflow, indexing an array out of bounds and bad pointer assignments. When a system crash occurs a device will usually recover by a reboot of the system. The purpose of the SmartTrap utility is to provide more information about the system when the crash occurred to assist with debugging the problem. Smart traps are automatically enabled by the `init()` function. Note that smart traps are disabled when building an application in debug mode.

- SmartTraps are commonly used for debugging an application crash
- SmartTraps are used in conjunction with the MTTTY serial terminal program. The SmartTraps information will be displayed on the debug serial port

Figure 7.1 Example Smart Traps Output

The output has four sections. It is beyond the scope of this document to go into detail on each of the processor registers, please refer to the processor manual for more information, located in the `\nburn\docs` directory of your development tools installation.

7.4.1 Trap Information

This section displays the processor status and error registers. The most significant is the Faulted PC, with is the Program Counter register indicating the area where the fault occurred. In this example the program counter value at the time a trap was detected is `0x02000152`.

7.4.2 Register Information

This section displays the processor's Address and Data registers.

7.4.3 RTOS Information

Identifies the RTOS Task Control Block and the current running task. The priority number is in hexadecimal. Traps caused by stack overflows may corrupt this section of the report.

7.4.4 Task Information

This is a very useful section of the report. It identifies each task, as well as its current state, wait time, and call stack. If you look at the Main task, you can see 6 entries with 0x02000152 (the faulted pc) at the left, and 0 at the right. The value of 0 is the start of the call stack. Each hexadecimal address between those two numbers represents each function that was called.

Each address can be related to the corresponding line number in the source code by using the WinAddr2Line utility. By selecting the .elf file location and each address in the call stack you can determine the calling sequence starting from 0 on the right and moving to the left. The last line signifies the end of the SmartTrap output. Since the boot monitor is configured to "boot to application", the device reboots after the trap occurs.

7.5 Task Scan

TaskScan is a network connected debugging tool that can be used to view the RTOS tasks and status of your running NetBurner application. This tool is unique in that it is active in the release build of your code, rather than the debug build which is compiled without optimization. It is very useful to determine such things as why a specific task is not running the way you had anticipated, if it is waiting on other tasks, and its call stack. TaskScan is only active when the PC program generates a request, so it will not impact your release code execution speed otherwise.

The `init()` function will automatically include `taskmon.h` and call `EnableTaskMonitor()`. TaskScan requires that you have the Executable and Linking Format (ELF) file for the specific application that is running on your NetBurner device. The .elf file is created by the compiler each time you build your application. It contains information TaskScan needs to link the application executable to the source code and task information. For example, if you have a project named MyProject, a file named MyProject.elf will be created.

TaskScan is commonly used for:

- Determining which tasks are running, their state and call stack.
- Looking for blocked tasks.

TaskScan can be started from:

- From the Windows NetBurner program group
- From a command line. The path is: `\nburn\pcbin\taskscan.exe`

7.5.1 TaskScan FAQ

- You must have a valid IP address and mask that can communicate with your PC that is running TaskScan
 - TaskScan essentially takes a snapshot picture of what your application is doing at the time you press the Scan button. It does not otherwise impact the application
 - You must have the exact .elf file used to create the application that is running on your NetBurner device to get valid information
- After starting the Task Scan application use the Browse button to locate your project's elf file, and the Find button to locate the IP address.

Figure 7.2 Starting Task Scan

Then select the Scan button:

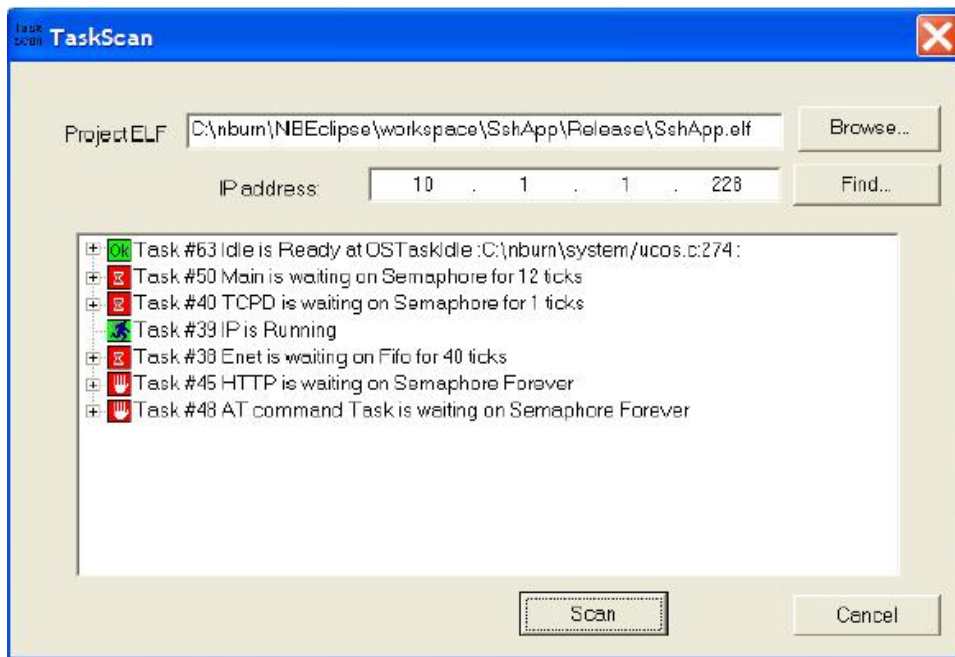

Figure 7.3 Scan Results

Icon	Description
 Green OK	Task is ready to run
 Green Running Man	Task is currently running
 Red Hour Glass	Task is waiting for the specified number of time ticks
 Red Hand	Task is waiting/blocked without a timeout parameter

Figure 7.4 Task Scan Icons

7.6 WinAddr2Line

WinAddr2Line only works for ColdFire-based platforms. For ARM, see [Addr2line](#)

Utility to determine the source code location for a specified memory address and .elf file. This application is typically used in conjunction with the SmartTraps utility when debugging an application that is crashing.

WinAddr2Line is commonly used for:

- Determining the source code address using a faulted program counter memory address from SmartTraps.
- If the cause of a crash is severe memory corruption due to bad pointers, it is possible for the Faulted Program Counter to be pointing to an address in which not code exists. In this case WinAddr2Line will not be able to provide a source code reference because no source code exists at that location.

WinAddr2Line can be started from:

- NBEclipse main tool bar
- The Windows NetBurner program group.
- The command line. The path is: \nburn\pcbin\winaddr2line.exe.

7.6.1 Using WinAddr2Line

- Use the Browse button to select the .elf file for your application and type in the hexadecimal memory address, usually obtained by SmartTraps as the Faulted PC.
- Click on the Decode button.

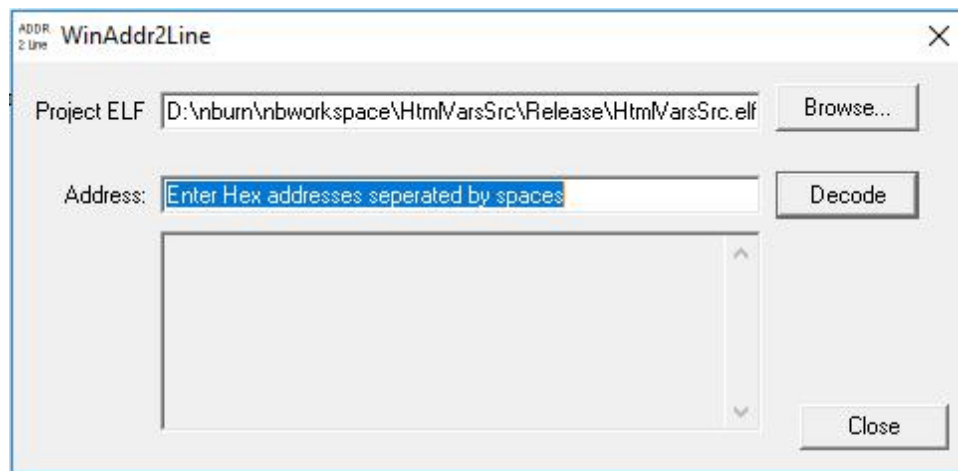

Figure 7.5 Select file and enter address in hexadecimal

7.7 IPSetup

The Windows IPSetup utility was used for network configuration in releases prior to 3.x. Network configuration is now down through the network configuration server on the NetBurner device. See [Device Discovery and Configuration](#) and [Config Server Programming Guide](#) for documentation on the 3.x network configuration system.

7.8 AutoUpdate

Autoupdate was used for loading applications to a device in releases prior to 3.x. Updating code is now done through the configuration server, nbupdate utility, or WGET.

7.9 Virtual Comm Port

The virtual comm port driver for Windows creates a virtual serial port and associates it with a network IP address and port number. It is typically used for legacy Windows applications without the ability to communicate over a network.

7.10 CompHtml

This utility is used by the NetBurner make system. It takes the contents of a project's html directory, implements the NetBurner dynamic web content scheme, callbacks, variables, access priorities, and mime types, and creates a file named `htmldata.cpp`.

7.11 CompCode

This utility is used by the NetBurner make system for 5441x platforms. It processes a `.s19` file into a compressed binary with checksum and header.

7.12 flashpack

This utility is used by the NetBurner make system for ARM platforms. It processes the `application.elf` file into a compressed binary with checksum and header.

Chapter 8

Platform References

This section provides the hardware reference information for your NetBurner platform, including memory maps, boot monitor and module recovery procedures in the event you download an application that is crashing the device.

- [MODM7AE70 Platform Reference](#)

- [ARM Cache Management](#)

8.1 MODM7AE70 Platform Reference

8.1.1 Introduction

This document provides the memory map and locations of reference materials for those who wish to add additional hardware to their NetBurner device.

8.1.2 MODM7AE70 Processor Information

The MODM7AE70 uses the Microchip ARM SAME70 microprocessor. The reference manual and datasheet provide in-depth information on the processor, including register settings, bus configuration and timing information. It is located in the `<nburn_install>\docs\Arm` directory of your NetBurner installation.

8.1.3 Datasheet

The datasheet for the MODM7AE70 module includes information on connectors, signal names, and operational parameters. It is located on the MODM7AE70 product page: [MODM7AE70 Datasheet](#).

8.1.4 Development Board Schematic

The MOD-DEV-70CR development board schematic is located in the `<nburn_install>\docs\NetBurner\platform\Schematics` directory. This schematic can be used for design ideas in your own hardware implementation for power, RS-232, RS-485, and SD Flash card implementation.

8.1.5 Memory Operation

The MODM7AE70 uses 3 types of memory:

- 2MB Flash memory for non-volatile system configuration storage, user application storage, the application in a compressed format, and the optional EFFS-STD file system (note this is different from the EFFS-FAT flash card file system).
- 8MB SDRAM containing the uncompressed application as well as any application data.
- 384KB on-chip SRAM located in the SAME70 microprocessor.

At power-up the application is decompressed from Flash memory to SDRAM and execution begins. If the application is continuously trapping the device can be recovered using the jumper recovery method as described in the Recover section, or if you have serial communication enabled the boot sequence can be aborted by sending the appropriate serial command when prompted after a power cycle.

8.1.6 Memory Map

Region	Size	Address Range	Description
Boot Loader	6k	0x00400000 to 0x004017FF	Initial boot and application extraction
Config Record	10k	0x00401800 to 0x00403FFF	System and User Configuration Data Flash
Cert. Storage	8k	0x00404000 to 0x00405FFF	Optional Security certificate storage
User Flash	8k	0x00406000 to 0x00407FFF	Unstructured binary User Flash Storage
App Flash	1.97M	0x00408000 to 0x005FFFFFFF	Compressed Application and opt file system
Vector Table	-	0x20400000 to 0x2040013F	SRAM - Interrupt Vector Table
Fast App RAM	384k	0x20400180 to 0x2045FFFF	SRAM - Fast Application RAM
Backup RAM	1k	0x40074000 to 0x400743FF	Low power backup RAM
External Bus	-	0x60000000 to 0x60FFFFFFF	Chip Select 0
External Bus	16M	0x61000000 to 0x61FFFFFFF	Chip Select 1
External Bus	16M	0x62000000 to 0x62FFFFFFF	Chip Select 2
External Bus	16M	0x63000000 to 0x63FFFFFFF	Chip Select 3
App RAM	8M	0x70000000 to 0x707FFFFFFF	SDRAM - Standard Application RAM where code is decompressed and variables are allocated
QSPI XIP	-	0x80000000 to 0x80FFFFFFF	QSPI (User add-on) - For utilizing memory Mapped Quad SPI memories

8.1.7 External Bus Interface

The MODM7AE70 provides 17 address lines (A0-A16) and a 16-bit data bus line (D0-D15). The data and address lines shared with the SDRAM are buffered to the module's P1 header pins. Please refer to the MODM7AE70 schematic and datasheet for connector and signal locations. The Microchip SAME70 datasheet, section 33 on External Bus Interface (EBI) and section 34 on Static Memory Controller (SMC), provide details on peripheral functionality and configuration.

8.2 MOD54415, MOD54417 Platform Reference

8.2.1 Introduction

This document provides the memory map and locations of reference materials for those who wish to add additional hardware to their NetBurner device. The MOD54415 and MOD54417 are very similar. The difference is the

MOD54417 provides two hardware network interfaces. The designation MOD5441x in this document applies to both modules.

8.2.2 MCF5441x Processor Information

The MOD54415 uses the NXP MCF54415 microprocessor, and the MOD54417 uses the MCF54417 microprocessor. The NXP MCF5441x reference manual and datasheet provide in-depth information on both processors and is located in the `<nburn_install>\docs\NXP` directory of your NetBurner Network Development Kit installation.

8.2.3 Datasheet

The datasheet for the MOD5441x module can be found on the NetBurner website: [MOD5441x Datasheet](#). The datasheet is the primary control document for connector pin-outs and signal functions.

8.2.4 Development Board Schematic

The MOD-DEV-70CR development board schematic is located in the `<nburn_install>\docs\NetBurner\platform\Schematics` directory. This schematic can be used for design ideas in your own hardware implementation for power, RS-232, RS-485, and SD Flash card implementation.

8.2.5 Memory Operation

The MOD5441x uses 4 types of memory:

- A 4MB write protected serial SPI Flash chip containing the Boot Monitor and Alternate Boot monitor. This provides a recovery method should events such as a bad application that causes continuous traps, or application Flash memory corruption.
- A 32MB parallel Flash chip containing non-volatile system configuration storage, user application storage, the application in a compressed format, and the optional EFFS-STD file system (note this is different from the EFFS-FAT flash card file system).
- A 64MB DDR2 Memory chip that contains the uncompressed application as well as any application data.
- 64KB on-chip SRAM located on the MCF5441x microprocessor.

Note

The reference to "2.x" is there for customers migrating from the NetBurner 2.x development tools. 2.x System Configuration is not used when running 3.x applications.

4MB SPI Boot Flash	32MB Parallel Flash	64MB DDR2 RAM
Boot Monitor	2.x System Configuration	Application (decompressed)
Alternate Boot Monitor	User Parameters	System Stack
	Application (compressed)	
	3.x System Configuration	

The Boot Monitor executes at power-up and attempts to decompress the application into DDR2 RAM and begin execution. If the application is corrupted or does not exist, it will attempt to run the Alternate Boot Monitor. If the Alternate Boot Monitor cannot be run, the system will remain in the Boot Monitor. The Alternate Boot Monitor provides network communication to enable an application download, and is the normal recovery method should

unrecoverable application errors occur. The Boot Monitor only provides serial communication.

8.2.6 Memory Map

The MOD5441x provides 16 address lines (A0-A15) and a 16-bit data bus (D16-D31) running in mode 2. An address bus latch is included on the MOD5441x so external latch is not required for this mode. If you are adding peripherals to your NetBurner device's address/data bus, you can choose unused memory locations from the table below. Once a range has been selected, you will need to configure the appropriate chip select address and option registers in the MCF5451x processor. Please refer to the chip select sections of the NXP MCF5441x processor manual for details on the register configuration. Unlike many ColdFire processors, you are not free to use any unused address for chip selects. The range is restricted. In this table we have used "undefined" for restricted ranges and "unused" for ranges that are valid for additional chip selects. Please see the MCF5441x Manual Section 20.3.1 and the Note above Figure 20-1 for additional details.

Memory Region	Address Range	Description
Undefined	0x00000000 to 0x01FFFFFF	Undefined area to catch null pointers
Unused	0x02000000 to 0x3FFFFFFF	Available to applications
DDR2 RAM	0x40000000 to 0x43FFFFFF	64MB of DDR2 RAM
VBR	0x40000000 to 0x400003FF	1kB processor vector base register
RAMBAR	0x80000000 to 0x8000FFFF	64kB Processor internal SRAM
Parallel Flash	0xC0000000 to 0xC1FFFFFF	32MB parallel flash memory
System Config	0xC0000000 to 0xC001FFFF	128kB system configuration flash sector
2.x Config Rec	0xC0000000 to 0xC0000400	1kB 2.x configuration storage
3.x Certificate	0xC0000400 to 0xC0002400	8kB 3.x certificate storage
3.x System Config.	0xC0002400 to 0xC001FFFF	119kB 3.x system configuration
User Params	0xC0020000 to 0xC003FFFF	128kB user parameter storage
Application Code	0xC0040000 to 0xC1FFFFFF	Compressed application code
Unused	0xC2000000 to 0xDFFFFFFF	Available to applications
IPSBAR	0xE0000000 to 0xFFFFFFFF	Processor internal device registers - accessible using the SIM structure defined in sim5441x.h

8.3 NANO54415 Platform Reference

8.3.1 Introduction

This document provides the memory map and locations of reference materials for those who wish to add additional hardware to their NetBurner device.

8.3.2 MCF54415 Processor Information

The NANO54415 uses the NXP MCF54415 microprocessor. The reference manual and datasheet provide in-depth information on the microprocessor, including register settings, bus configuration and timing information. It is located in the `<nburn_install>\docs\NXP` directory of your NetBurner installation.

8.3.3 Datasheet

The datasheet for the NANO54415 module includes information on connectors, signal names, and operational parameters. It is located on the NANO54415 product page: [NANO54415 Datasheet](#).

8.3.4 Development Board Schematic

The NANO54415 development board schematic is located in the <nburn_install>\docs\NetBurner\Platform\Schematics directory. This schematic can be used for design ideas in your own hardware implementation for power, RS-232, RS-485, and SD Flash card implementation.

8.3.5 Memory Operation

The NANO54415 uses 4 types of memory:

- A 4MB write protected serial SPI Flash chip containing the Boot Monitor and Alternate Boot monitor. This provides a recovery method should events such as a bad application that causes continuous traps, or application Flash memory corruption.
- A 8MB serial SPI Flash chip containing non-volatile system configuration storage, user application storage, the application in a compressed format, and the optional EFFS-STD file system (note this is different from the EFFS-FAT flash card file system).
- A 64MB DDR2 memory chip that contains the uncompressed application as well as any application data.
- 64KB on-chip SRAM located on the MCF54415 microprocessor.

The Boot Monitor executes at power-up and attempts to decompress the application into DDR2 RAM and begin execution. If the application is corrupted or does not exist, it will attempt to run the Alternate Boot Monitor. If the Alternate Boot Monitor cannot be run, the system will remain in the Boot Monitor. The Alternate Boot Monitor provides network communication to enable an application download, and is the normal recovery method should unrecoverable application errors occur. The Boot Monitor only provides serial communication.

Note

The reference to "2.x" is there for customers migrating from the NetBurner 2.x development tools. 2.x System Configuration is not used when running 3.x applications.

4MB SPI Boot Flash	8MB SPI Flash	64MB DDR2 RAM
Boot Monitor	2.x System Configuration	Application (decompressed)
Alternate Boot Monitor	User Parameters	System Stack
	Application (compressed)	
	3.x System Configuration	

8.3.6 Processor Runtime Memory Map

The runtime memory map for the location of the microprocessors onboard SRAM and DDR2 RAM is shown below:

Memory Region	Address Range	Description
Undefined	0x00000000 to 0x01FFFFFF	Undefined area to detect null pointers
DDR2 RAM	0x40000000 to 0x43FFFFFF	64MB of DDR2 RAM
VBR	0x40000000 to 0x400003FF	1kB Processor Vector Base Register
RAMBAR	0x80000000 to 0x8000FFFF	64kB Processor internal SRAM
IPSBAR	0xE0000000 to 0xFFFFFFFF	Processor internal device registers

8.3.7 Application SPI Flash Memory

There is a total of 8MB SPI Flash memory used to store the compressed application and non-volatile parameters. Read/write operations are only accessible through system API functions. The memory does not appear in the microprocessor's address map.

SPI Address	Description
0x000000	8kB 2.x System Configuration Record storage
0x002000	8kB User Parameter Storage
0x004000	7.9MB Compressed Application Code
0x7EE000	8kB 3.x Reserved System Configuration Storage
0x7F0000	64kB 3.x System Configuration

8.4 SB800EX Platform Reference

8.4.1 Introduction

This document provides the memory map and locations of reference materials for those who wish to add additional hardware to their NetBurner device.

8.4.2 MCF54415 Processor Information

The SB800EX uses the NXP MCF54415 microprocessor. The reference manual and datasheet provide in-depth information on the microprocessor, including register settings, bus configuration and timing information. It is located in the `<nburn_install>\docs\NXP` directory of your NetBurner installation.

8.4.3 Datasheet

The datasheet for the SB800EX module includes information on connectors, signal names, and operational parameters. It is located on the SB800EX product page: [SB800EX Datasheet](#).

8.4.4 Memory Operation

The SB800EX uses 4 types of memory:

- A 4MB write protected serial SPI Flash chip containing the Boot Monitor and Alternate Boot monitor. This provides a recovery method should events such as a bad application that causes continuous traps, or application Flash memory corruption.
- An 8MB serial SPI Flash chip containing non-volatile system configuration storage, user application storage, the application in a compressed format, and the optional EFFS-STD file system (note this is different from the EFFS-FAT flash card file system).
- A 64MB DDR2 memory chip that contains the uncompressed application as well as any application data.
- 64K on-chip SRAM located on the MCF54415 microprocessor.

The Boot Monitor executes at power-up and attempts to decompress the application into DDR2 RAM and begin execution. If the application is corrupted or does not exist, it will attempt to run the Alternate Boot Monitor. If the Alternate Boot Monitor cannot be run, the system will remain in the Boot Monitor. The Alternate Boot Monitor provides network communication to enable an application download, and is the normal recovery method should unrecoverable application errors occur. The Boot Monitor only provides serial communication.

Note

The reference to "2.x" is there for customers migrating from the NetBurner 2.x development tools. 2.x System Configuration is not used when running 3.x applications.

4MB SPI Boot Flash	8MB SPI Flash	64MB DDR2 RAM
Boot Monitor	2.x System Configuration	Application (decompressed)
Alternate Boot Monitor	User Parameters	System Stack
	Application (compressed)	
	3.x System Configuration	

8.4.5 Processor Runtime Memory Map

The runtime memory map for the location of the microprocessors onboard SRAM and DDR2 RAM is shown below:

Memory Region	Address Range	Description
Undefined	0x00000000 to 0x01FFFFFF	Undefined area to detect null pointers
DDR2 RAM	0x40000000 to 0x43FFFFFF	64MB of DDR2 RAM
VBR	0x40000000 to 0x400003FF	1kB Processor Vector Base Register
RAMBAR	0x80000000 to 0x8000FFFF	64kB Processor internal SRAM
IPSBAR	0xE0000000 to 0xFFFFFFFF	Processor internal device registers

8.4.6 Application SPI Flash Memory

There is a total of 8MB SPI Flash memory used to store the compressed application and non-volatile parameters. Read/write operations are only accessible through system API functions. The memory does not appear in the microprocessor's address map.

SPI Address	Description
0x000000	8kB 2.x System Configuration Record storage
0x002000	8kB User Parameter Storage
0x004000	7.9MB Compressed Application Code
0x7EE000	8kB 3.x Reserved System Configuration Storage
0x7F0000	64kB 3.x System Configuration

8.5 SBE70LC Platform Reference

8.5.1 Introduction

This document provides the memory map and locations of reference materials for those who wish to add additional hardware to their NetBurner device.

8.5.2 SBE70LC Processor Information

The SBE70LC uses the Microchip ARM SAME70 microprocessor. The reference manual and datasheet provide in-depth information on the processor, including register settings, bus configuration and timing information. It is located in the `<nburn_install>\docs\Arm` directory of your NetBurner installation.

8.5.3 Datasheet

The datasheet for the SBE70LC module includes information on connectors, signal names, and operational parameters. It is located on the SBE70LC product page: [SBE70LC Datasheet](#).

8.5.4 Development Board Schematic

The SB70LC-ADPT-100 development board schematic is located in the `<nburn_install>\docs\NetBurner\platform\Schematics` directory. This schematic can be used for design ideas in your own hardware implementation for power, RS-232, RS-485, and SD Flash card implementation.

8.5.5 Memory Operation

The SBE70LC uses 3 types of memory:

- 2MB Flash memory for non-volatile system configuration storage, user application storage, the application in a compressed format, and the optional EDFS-STD file system (note this is different from the EDFS-FAT flash card file system).
- 8MB SDRAM containing the uncompressed application as well as any application data.
- 384KB on-chip SRAM located in the SAME70 microprocessor.

At power-up the application is decompressed from Flash memory to SDRAM and execution begins. If the application is continuously trapping the device can be recovered using the jumper recovery method as described in the Recover section, or if you have serial communication enabled the boot sequence can be aborted by sending the appropriate serial command when prompted after a power cycle.

8.5.6 Memory Map

Region	Size	Address Range	Description
Boot Loader	6k	0x00400000 to 0x004017FF	Initial boot and application extraction
Config Record	10k	0x00401800 to 0x00403FFF	System and User Configuration Data Flash
Cert. Storage	8k	0x00404000 to 0x00405FFF	Optional Security certificate storage
User Flash	8k	0x00406000 to 0x00407FFF	Unstructured binary User Flash Storage
App Flash	1.97M	0x00408000 to 0x005FFFFFFF	Compressed Application and opt file system
Vector Table	-	0x20400000 to 0x2040013F	SRAM - Interrupt Vector Table
Fast App RAM	384k	0x20400180 to 0x2045FFFF	SRAM - Fast Application RAM
Backup RAM	1k	0x40074000 to 0x400743FF	Low power backup RAM
External Bus	-	0x60000000 to 0x60FFFFFFF	Chip Select 0
External Bus	16M	0x61000000 to 0x61FFFFFFF	Chip Select 1
External Bus	16M	0x62000000 to 0x62FFFFFFF	Chip Select 2

Region	Size	Address Range	Description
External Bus	16M	0x63000000 to 0x63FFFFFF	Chip Select 3
App RAM	8M	0x70000000 to 0x707FFFFFFF	SDRAM - Standard Application RAM where code is decompressed and variables are allocated
QSPI XIP	-	0x80000000 to 0x80FFFFFF	QSPI (User add-on) - For utilizing memory Mapped Quad SPI memories

8.6 SOMRT1061 Platform Reference

8.6.1 Introduction

This document provides the memory map and locations of reference materials for those who wish to add additional hardware to their NetBurner device.

8.6.2 Datasheet

The datasheet for the SOMRT1061 module includes information on connectors, signal names, and operational parameters. It is located on the SOMRT1061 product page: [SOMRT1061 Product Page](#).

8.6.3 Development Board Schematic

The DEV-SOMRT1061 development board schematic is located in the `<nburn_install>\docs\NetBurner\platform\Schematics` directory. This schematic can be used for design ideas in your own hardware implementation for power, RS-232, RS-485, and SD Flash card implementation.

8.6.4 SOMRT1061 Platform General Information

The SOMRT1061 uses the NXP i.MX RT1061 microcontroller. The reference manual and datasheet provide in-depth information on the processor, including register settings, bus configuration and timing information. The reference manual is located in the `<nburn_install>\docs\NXP` directory of your NetBurner installation.

- i.MX RT1061 running at 528MHz (ind temp)
- 8MB SPI Flash (stores compressed application image)
- 32MB PSRAM
- 1MB onboard SRAM:
 - 128k ITCM single cycle instruction fetch memory,
 - 128K DTCM single cycle data fetch memory
 - 768k general purpose fast SRAM

8.6.4.1 The 8MB of Flash uses a Flash File System and is used for all storage purposes:

- Sectors are 8k
- The standard NetBurner configuration, certificate and user flash operate transparently through the file system.

- First sector reserved for file partition table. Note: If you need direct flash access, please contact NetBurner support.
- You can add a secondary Flash File System as demonstrated in the EFFS-STD examples. Multiple partitions are supported. Please refer to the documentation and examples, such as the EFFS-STD multiple partition (multi-part) example.
- Application space varies by use case, but is typically 7.5MB for the compressed application. Items that can reduce the 8MB total space include: file system overhead, certificates, configuration data, secondary file system.

8.6.4.2 External Memory Bus

- Chip selects configurable anywhere in the external bus range

8.6.5 Boot Sequence

At power-up or reset, the application is decompressed from Flash memory to PSRAM, verified by checksum, and execution begins. If the checksum fails or the application crashes, the device will reboot to the Configuration Server to facilitate a recovery by downloading a new application.

If the application causes an issue in which continuous traps occur, or the state of the system is such the Configuration Server cannot run, a recovery hardware jumper procedure can be used to reset the device.

Note

It is always a good idea to have a serial port terminal connected to the boot/debug serial port to view status messages, or use the 'A' to abort the boot sequence command when prompted to abort application execution and boot to the Configuration Server.

8.7 Recovery: MODM7AE70, SBE70LC

8.7.1 Introduction

Applicable Hardware Platforms: MODM7AE70 and SBE70LC.

Device recovery in the event of an errant application running on the device is an important part of the development process. This document describes recovery procedures for a device stuck in a repeating trap/reset condition, or a totally unresponsive device.

8.7.2 Repeating Traps or Resets

The easiest method of recovery is to abort the user application boot process and run only the Configuration Server. The Configuration server will enable a new application to be downloaded using:

- The Configuration Server web page at `<device IP>:20034`
- The nbupdate utility
- The wget utility
- The device serial port

8.7.2.1 Step 1: Abort to the Configuration Server

1. Run a serial terminal such as MTTTY and connect to the device serial port.
2. Power cycle the module.
3. Press "A" when the message, `Type "A" to Abort boot` is displayed. Note that "A" is the default abort command, but the command is configurable in the Configuration Server settings. If the abort command is different, use that command instead of "A".
4. Wait for the `>` prompt to display.

The Configuration Server is now active on both network and the device serial port.

8.7.2.2 Step 2: Download a New Application

At this point a new application can be downloaded through the device web page, nbupdate or serial port.

8.7.2.2.1 Web Page

1. Locate the device using `discover.netburner.com`, the `localdiscover` utility, or open a web browser and type the device address in the URL field: `<device IP>:20034`. For example, `192.168.1.10:20034`.
2. In the Update Application section, select the new `.bin` file to download and select the Send File button.

8.7.2.2.2 NBUpdate

1. Open a command prompt.
2. Type `nbupdate <file name> <device IP>`

8.7.2.2.3 Serial Port

Note

MTTTY is a serial terminal program. You should be able to use any serial terminal program of your choice. When starting the download the binary file must be sent as text or raw data.

Warning

The `.bin` file is a binary file. You must have serial software flow control disabled. If using MTTTY, from the main menu select `TTY > Flow Control` and uncheck both `Xon/Xoff Input Control` and `Xon/Xoff Input Control`. Otherwise the data stream will be corrupted.

1. At the `>` prompt, type `fla` into the serial prompt and then hit enter.
2. At the message 'Begin Download', start the file download (if using MTTTY, type the F5 key).
3. When the file window opens, navigate to the `.bin` application file that you want to load.
4. Hit 'Open', and the application will start the load process.

8.7.3 Unresponsive Device or No Serial Port Access

In a situation in which the device is completely unresponsive and aborting to the Configuration Server is not possible, or if there is no access to the device serial port, shorting two hole locations on the device PCB (also called "jumper recovery") will reset it to a factory default state. The PCB hole locations are 0.1 inches apart so that a shorting jumper can be used. This procedure will erase flash memory including the configuration and application. The device will then be ready to receive a new application using any of the procedures described in the download a New Application section.

1. Power off the device.

2. Short the jumper recovery PCB locations with a shorting jumper or wire.
3. Power on the device.
4. Wait for the device to finish erasing the flash and loading the default application. Progress is indicated by the two blinking LEDs on the device (D1 and D2). When the LEDs stop blinking the reset is complete. For the SBE70LC, the jumper should be removed after 2 seconds. If it is left inserted for 30 seconds or more, it will continually reset.
5. Remove the short jumper or wire.

8.7.3.1 Recovery Jumper Locations

8.7.3.1.1 MODM7AE70

The reset jumper location is labeled "Recovery", located on the end of the board opposite the RJ-45 connector.

Figure 8.1 MODM7AE70 Recovery Jumper Location

8.7.3.1.2 SBE70LC

The reset jumper location is labeled "JP6", located on the end of the board opposite the RJ-45 connector.

Figure 8.2 SBE70LC Recovery Jumper Location

8.8 Recovery: MOD5441x, NANO54415, SB800EX

NetBurner 5441x based devices include: MOD54415, MOD54417, NANO54415 and the SB800EX. These devices have a Recovery Jumper. This is a 2 hole pin location on the circuit board. When shorted during the boot process, the device will boot to the Alternate Boot Monitor rather than the application. If the configuration section of flash has been corrupted, it will also use a safe default version instead of what is in flash memory.

8.8.1 Step 1: Abort to the Alternate Boot Monitor

There is the primary boot monitor, accessible by entering the 'A' (0x41) character immediately on boot. This should allow you to recover the module normally. If for some reason that fails, or you cannot enter the 'A' character, the

have a secondary boot monitor to allow the user to recover from (virtually) all software or configuration faults. The procedure is:

1. Power off the module.
2. Short the 2 pins at the alternate boot jumper location (see below).
3. Power on the module.
4. Wait for the module to finish boot and enter the monitor.
5. Remove the short on the alternate boot jumper location.

8.8.2 Recovery Jumper Locations

8.8.2.1 NANO54415

The boot jumper is a pair of circular pads located near the middle line of the board near the connector.

Figure 8.3 NANO54415 Recovery Jumper Location

8.8.2.2 MOD5441x

The boot jumper is the unpopulated header 'TP1', located near the Ethernet jack.

Figure 8.4 MOD5441x Recovery Jumper Location

8.8.2.3 SB800EX

The boot jumper is the unpopulated header 'JP1', located near the center of the board.

Figure 8.5 SB800EX Recovery Jumper Location

8.8.3 Step 2: Download a New Application

Once the Alternate Boot Monitor is running you should be able to locate your device using:

8.8.3.1 Network

The 5441x devices predate the NetBurner 3.x Development Tools and network recovery requires the use of the AutoUpdate utility. Run the AutoUpdate utility and select the device and new application to download. AutoUpdate requires `_APP.s19` file format. The original, factory application is a safe application to load on to a device that needs to be recovered. It can be found in the `platform\<<PLATFORM>\original` directory.

8.8.3.2 Serial Port

Note

MTTTY is a serial terminal program. You should be able to use any serial terminal program of your choice. When starting the download the binary file must be sent as text or raw data.

Warning

The `.bin` file is a binary file. You must have serial software flow control disabled. If using MTTY, from the main menu select `TTY > Flow Control` and uncheck both `Xon/Xoff Input Control` and `Xon/Xoff Input Control`. Otherwise the data stream will be corrupted.

1. At the `NB>` prompt type `fla` then hit enter.
2. At the message 'Begin Download', start the file download (if using MTTY, type the `F5` key).
3. When the file window opens, navigate to the `.bin` application file that you want to load.
4. Hit 'Open', and the application will start the load process.

Once the download is complete the device will reboot and run the new application.

8.9 Recovery: SOMRT1061

8.9.1 Introduction

Applicable Hardware Platforms: SOMRT1061

Device recovery in the event of an errant application running on the device is an important part of the development process. This document describes recovery procedures for a device stuck in a repeating trap/reset condition, or a totally unresponsive device.

8.9.2 Boot Components and Features Overview

An overview of the key components and features of the boot process are listed below. The remainder of this article will provide further details and usage on each.

- **Boot Monitor.** Executes at power-up or reset. Decompresses Application, performs system verification and jumps to application to begin execution.
- **Application.** Your custom program/application that runs when things are working properly.
- **Configuration Server.** Runs as part of the Application. For recovery, the boot sequence can be aborted in the initialization process (the `init()` function in `UserMain()` will not return), enabling you to change configuration parameters or upload a new application. Note that the application must be able to boot and run to the `init()` function to use this feature. The Configuration Server can be accessed through the web server interface or the serial console port. A new application can be uploaded to the device through any of the following:
 - Configuration Server web page at `<device IP>:20034`
 - `nbupdate` utility
 - `wget` utility
 - serial console interface
- **Alternate Boot Monitor.** Used as part of a recovery method when aborting to the Configuration Server is not possible. There are two use cases:
 - If you can abort to the Configuration Monitor but are unable to load a new application for some reason, you can issue the command "ABOOT" through the serial console and the device will reboot to the Alternate Boot Monitor without having to use the jumper recovery procedure. You can then issue the "Erase All" command to erase Flash memory.
 - If there is no application programmed into the device, it will boot to the Alternate Boot Monitor.
 - If the application is crashing before `UserMain()` starts, such as a crashing global constructor, you will need to boot to the Alternate Boot Monitor with the recovery jumper procedure described later in this article.

8.9.3 Boot Sequence Overview

8.9.3.1 Normal Boot

For a properly running application. Boot Monitor starts, decompresses application to RAM, performs system checks, then jumps to the start of the application.

8.9.3.2 Incorrect Network Settings

Symptom:** The application boots and runs, but the network IP settings are such that the device cannot communicate. Resolution:** Abort to the **Configuration Server** and modify network settings with serial console interface.

8.9.3.3 Application Starts, But Traps After Application Initialization

Symptom:** The application boots and can run to the point of initialization (the `init()` function in `UserMain()`), but traps afterwards.

Resolution:** Abort to the **Configuration Server** and upload corrected application.

8.9.3.4 Application Starts, But Traps Before Application Initialization

Symptom:** The application traps immediately upon boot. The Configuration Server is not accessible.

Resolution:** Abort to the **Alternate Boot Monitor** and upload corrected application. Access through the serial console interface or telnet.

8.9.4 Procedure to Abort to the Configuration Server

Abort the boot sequence and run the Configuration Server, accessible on the web interface and serial console interface.

- Run a serial terminal such as MTTY and connect to the device serial console interface.
- Reset or power cycle the module.
- Press the "A" key when the message: `Type "A" to Abort` is displayed. Note that "A" is the default abort command, but the command is configurable in the Configuration Server settings. If the abort command is different, use that command instead of "A".
- At the `>` prompt you can now type serial console commands, or use the web interface if you have network connectivity.
- A new application can be uploaded as described in the Uploading a New Application section.

8.9.5 Uploading a New Application

The following application update methods can be used from the Configuration Server or Alternate Boot Monitor.

8.9.5.1 Web Page Upload

- Locate the device using `discover.netburner.com`, the `localdiscover` utility, or open a web browser and type the device address in the URL field: `<device IP>:20034`. For example, `192.168.1.10:20034`.
- In the Update Application section, select the new `.bin` file to download and select the Send File button.

8.9.5.2 NBUdate

- Open a command prompt.
- Type `nupdate <file name> <device IP>`

8.9.5.3 Serial Console Interface

Note

MTTTY is a serial terminal program. You should be able to use any serial terminal program of your choice. When starting the download the binary file must be sent as text or raw data.

Warning

The .bin file is a binary file. You must have serial software flow control disabled. If using MTTTY, from the main menu select `TTY > Flow Control` and uncheck both `Xon/Xoff Input Control` and `Xon/Xoff Input Control`. Otherwise the data stream will be corrupted.

- At the `>` prompt, type `fla` into the serial prompt and then hit enter.
- At the message 'Begin Download', start the file download (if using MTTTY, type the `F5` key).
- When the file window opens, navigate to the .bin application file that you want to load.
- Hit 'Open', and the application will start the load process.

8.9.6 Procedures to Abort to the Alternate Boot Monitor

There are three instances in which the Alternate Boot Monitor is needed for device recovery. A new application can be uploaded as described in the [Uploading a New Application](#) section.

8.9.6.1 No Valid Application

If no application had been programmed into the device, or the checksum verification fails when an application is decompressed from Flash to RAM, the Boot Monitor will automatically jump to the Alternate Boot Monitor.

8.9.6.2 Configuration Server Access Operational

If the Configuration Server can run but code updates are not working correctly, the "ABOOT" command can be used on the Serial Console Interface to invoke the Alternate Boot Monitor without having to perform the jumper recovery procedure.

8.9.6.3 Application Traps Before UserMain() Starts

If the application is crashing before `UserMain()` starts, such as a crashing global constructor, access to the Configuration Server is not possible as it is part of the application. Your only choice will be to access the Alternate Boot monitor with the recovery jumper. Please see the [recovery jumper procedure](#) section.

8.9.7 Hardware Jumper Recovery

In a situation in which the device is completely unresponsive, continually trapping prior to the "Type A to Abort" prompt, or if there is no access to the device's serial console interface, shorting the recovery pad to ground on the device (referred to as "jumper recovery") can be used to abort the boot process and run the Alternate Boot Monitor. The device will then be ready to receive a new application using any of the procedures described in the [download a New Application](#) section.

8.9.7.1 Recovery Jumper Operation

The recovery pad can be shorted with a jumper in two ways:

- **Short Hold:** Boot to Configuration Server. Loads existing configuration and mount file system. Remove shorting jumper right after reset or power-on. The device should now be running the Configuration Server which can be accessed via the serial console interface or web interface.

- **Long Hold:** Boot to Alternate Boot Monitor. Do not load existing configuration or mount file system. Hold shorting jumper in place throughout the entire boot process until the Alternate Boot Monitor command prompt appears in the serial console interface or the network LEDs on the RJ-45 jack become active. Application Flash is not accessible except for the `Erase All` command in the Alternate Boot Monitor. After erasing Flash memory, the next time the device boots it will reset to factory defaults.

Note

A Long Hold will initialize the device to factory default settings, such as network configuration set to [DHCP](#), AutoIP enabled and Local Discovery enabled.

8.9.7.2 Procedure

- Power off the device.
- Short the jumper recovery pad to the nearby ground pad or some other accessible ground location with a shorting jumper or wire.
- Reset or power on the device.
- Hold shorting jumper in place for either a Short Hold or Long Hold.
- Remove the jumper or wire.

8.9.7.3 Recovery Jumper Location

The recovery pad and ground pad are located on the corner of the module between P2 and P3. Using a pair of tweezers may be easiest for shorting the two pads. Alternatively, the recovery pad can be shorted to any ground pin to achieve the same result, which may be easier, especially if using the DEV-SOMRT1061 development board.

Figure 8.6 SOMRT1061 Recovery Jumper Location

8.10 ARM Cache Management

When using some features like DMA or otherwise experiencing cache coherency issues and instability, you may want to disable memory caching.

8.10.1 Details

What happens if memory changes a region AND there is a delayed write to the same region? Who wins? Is this an issue for things like ethernet where both CPU and DMA hardware can both change an area? Whoever writes to RAM later wins: For example if the CPU has the address in the cache and writes to it, and then the Hardware writes to it, then the CPU evicts the cache line and flushes, the CPU wins. If the CPU writes to the RAM first, then the Hardware writes to it, the Hardware wins. Either way, this will be a poorly defined system that will fail in real operations.

Whenever DMA is expected to write to memory, the CPU shall not write to that region. Whenever the CPU needs to read data that DMA has written, unless the region is known to be non-cached, the code shall issue a cache invalidation for the region in question.

Whenever the CPU writes to a region that is cached and needs DMA to read a coherent state of the memory, the software shall issue a cache cleaning for the region in question.

8.10.2 Instructions

8.10.2.1 Turning cache on/off

- `SCB_EnableDCache();`
- `SCB_DisableDCache();`
- `SCB_EnableICache();`
- `SCB_DisableICache();`

8.10.2.2 Declaring static objects non cacheable

Non cacheable objects only live in On Chip FlexRAM which is SRAM. PSRAM is all cached.

To declare a variable as non-cached, use the variable tag `DO_NOT_CACHE`, akin to `FAST_USER_VAR: uint32_t foo DO_NOT_CACHE;`

Note

You cannot assign a static value to non-cached objects.

8.10.2.3 Cleaning Cache

(Making sure all cache -> memory transactions are complete)

- For whole cache:

```
asm("dsb");
SCB_CleanDCache();
```
- For a defined region of memory:

```
asm("dsb");
SCB_CleanDCache_by_Addr(<start address>, <buffer size>);
```

8.10.2.4 Invalidating Cache

(Making sure memory changes make it to cache)

- For whole cache.

```
asm("dsb");
SCB_InvalidatedDCache();
```
- For a defined region of memory:

```
asm("dsb");
SCB_InvalidatedDCache_by_Addr(<start address>, <buffer size>);
```

Chapter 9

Production & Deployment

9.1 Production Releases and Customer Deployment

Once product development is complete, there are a number of choices for device location and configuration:

- How to find the device on a network
- How to program the application into devices in production
- How to configure devices in production
- How Customers can change configuration settings

Note

Utility source code is located in `\nburn\pctools`, and built versions are in `\nburn\pbin`. You may modify or rebrand these utilities and distribute to your end customers, so long as they are only run with NetBurner target hardware.

9.2 Finding a Device on a Network

A device can be located the following ways:

- If the device and computer have Internet access, open a web browser and go to discover.netburner.com
- Use the `localdiscover` utility. This is a multi-platform utility written in Golang for Windows, macOS and Linux. The compiled version can be distributed to your customers, but not the Golang source code.
- The Python `find` utility, located in `\nburn\pctools\find`.
- Use the debug/console serial port

9.3 Application Programming

Applications are programmed into flash memory by sending an application image to the device's configuration server, located at its IP address on port 20034. This can be done in a number of ways, all of which are multi-platform (Windows, macOS, and Linux):

- A web browser from the device's configuration server web page
- The nbupdate command-line utility
- The WGET command-line utility
- A serial port using the serial command processor

9.3.1 Configuration Web Page

To send a file from a web browser, enter the URL of your device. The URL format is "<ip address>:<port number>", such as: "10.1.1.100:20034". Once at the web page, browse for the application image file and select "Update".

9.3.2 nbupdate Utility

nbupdate is a multi-platform command-line utility written by NetBurner. The format is: `nbupdate <filename> <ip address>`. For example, `nbupdate myApp.bin 10.1.1.196`, or `nbupdate myApp.s19 10.1.1.196`.

If the environment variable DEVIP is set the IP address parameter is not required. For example, `SET DEVIP=10.1.1.196`. Now you can call nbupdate with only the application file name. To determine the current setting of DEVIP, type "SET DEVIP".

9.3.3 wget Utility

WGET is an industry standard utility that allows you to download files over TCP/IP protocols FTP, HTTP and HTTPS. If you are using macOS or Linux, WGET is usually already installed (or can using your package manager). Windows users will need to install it, please refer to <https://www.gnu.org/software/wget/>.

The WGET utility can be used for a number of things:

- Updating the device application image
- Retrieving device configuration information in JASON
- Updating device configuration information in JASON

In the examples below we use an example device IP address of 10.1.1.60, and an application name of myApplication.bin.

9.3.3.1 Program an Application

To program a new application into the device:

```
wget --post-file=myApplication.bin 10.1.1.60:20034/appupdate.html
```

All updates are processed by the Configuration Server running on the device. The `--post-file` specifies a POST operation is to be performed. The IP address and configuration port number are next, along with the server post destination that will always be appupdate.html.

If using authentication with a username of "user", and password of "pass":

```
wget --auth-no-challenge --user=user --password=pass --post-file=myApplication.↵  
bin 10.1.1.60:20034/appupdate.html
```

9.3.3.2 Read The Configuration

Read the current configuration into a file named config.txt: `wget 10.1.1.60:20034/Config`.

In this case the destination is Config, rather than appupdate.html.

If you would like to specify a directory to store the file, use the `-P` option: `wget 10.1.1.60:20034/Config -P \myDir`

9.3.3.3 Program New Configuration Settings

The easiest way to do this is to first read the configuration and save to a file so you have a template to work with, then edit the settings you need. Then post the configuration file to each new device:

```
wget --post-file=newconfig 10.1.1.60:20034/Config
```

9.4 Customer Configuration

Once deployed, your customers can modify the configuration by:

- Using the interactive web interface at 10.1.1.60:20034. Note that you can create your own web interface to override the default NetBurner interface, and use your custom brand.
- If connected to the Internet, a web browser at: discover.netburner.com, which provides a link to the device configuration page and also the device's main web page on port 80.
- The NetBurner localdiscover utility, which provides a link to the device configuration page, and also the device's main web page on port 80.
- Using WGET
- Your application can provide the means to change configuration

Chapter 10

Programmers Guide

The documents in this section are provide Programmers with background information and examples on the various aspects of the NetBurner development system.

Topic Links:

10.1 Introduction

The NetBurner Programming Guide is intended to provide an overview of the features and capabilities of the NetBurner Network Development Kit. The primary goal of this guide is to provide a brief explanation of common network applications and illustrate how you can implement these applications using NetBurner hardware, software and development tools. Prerequisites for this guide:

- You have installed the NetBurner Network Development kit
- You have a running NetBurner device that is configured for your network, and you are familiar with the NBEclipse development (ref: NBEclipse Getting Started Guide), or you are using your own environment and the command line tools.
- You are familiar with the network configuration of your target device
- You have successfully created a project and can run applications on your target device

The approach of this guide is to learn by example. The first program example, called Template, can be used as a starting point for most applications, and each application in this guide uses it as a base.

10.1.1 Source Code for Example Programs

Source code for the examples in this document are located in the `\nburn\examples` directory of your NetBurner tools installation.

10.1.2 Tools and Library Version Information

This documentation applies to the following version of the NNDK, which utilizes the listed external tools and libraries.

NetBurner Network Development Kit Tools 3.3.2

wolfSSL 4.3 Utilized by the SSL/TLS library.

GNU GCC 8.1 The documentation for this compiler can be found [here](#).

10.1.3 Application Wizard Project

We will start with a basic application created with the NBEclipse Application Wizard. If you are not familiar with creating an application or NBEclipse please refer to the NBEclipse Getting Started Guide before continuing. When running the Application Wizard select the Standard Initialization and Web server options. Once the project is complete, you should have a `main.cpp` file as shown below:

```
#include <predef.h>           // System level options and definitions
#include <stdio.h>           // Standard I/O functions
#include <nbrtos.h>          // NetBurner Real Time Operating System (RTOS)
#include <http.h>           // HTTP functions
#include <init.h>           // Initialization functions

const char * AppName = "AppWizard"; // Name of application. Will be displayed by discovery programs

void UserMain(void * pd)
{
    init(); // Initialize system
    WaitForActiveNetwork(TICKS_PER_SECOND * 5); // Wait up to 5 seconds for active network activity
    StartHttp(); // Start HTTP web server. Note StartHttps() starts
               // secure web server

    iprintf("Application %s started\n", AppName ); // Print message to stdout, which is the debug serial
           // port by default

    while (1) // Infinite loop
    {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

The system will automatically start the RTOS and `UserMain()` as its own task. This simple application is a fully functional network application with a web server.

The `init()` function will do the following:

- Initialize stdio to be the debug/console port.
- Read and process the system configuration information. This includes things such as network interface settings, serial port settings and boot options.
- Initialize the network stack.
- Set the RTOS task priority of `UserMain()` to `MAIN_Prio`.
- Enable the Task Monitor utility support.

- Whenever the project is built in debug mode, enable the GDB debugger.

The `WaitForActiveNetwork()` function will wait for an active network link before proceeding, up until the specified timeout.

`StartHttp()` starts the web server. The default port is 80. If you wish to start on a different port you can specify the port number as a parameter to the function.

The system supports `printf()` and `iprintf()`. The `iprintf()` function (*i* = integer only) will consume less system resources if you do not need floating point support.

Your application should never return from `UserMain()`; the `while()` loop will run forever. The

```
#define TICKS_PER_SECOND
```

should be used with the delay function in case the system ticks per second value is ever modified.

10.2 Config Server Programming Guide

10.2.1 Introduction

The NetBurner configuration system is used to configure and store system and application defined values and data in flash memory. These values can be accessed and modified through:

- The System Configuration Web Server (port 20034)
- Your application
- Your web page interface
- Serially through the Serial Config Server

The web interface also provides a convenient way of uploading a new application onto the module. While the web interface provided is fully functional, it is possible to override this with a custom web interface in your application for purposes such as branding or adding/removing features.

The configuration data itself is stored and presented as JSON blobs. It's possible to access, modify, and send the entire JSON blob, or any subsection of the data, down to individual components.

10.2.2 Configuration Parameters

The configuration server holds the module's boot settings, network interface settings, and any custom application information you wish to save, display or modify. Your application can view and/or modify these parameters a variety of ways:

- The system configuration server web page
- Your own custom configuration server web page
- Any type of web interface in your application
- In your application code directly

The configuration system has a tree structure with "leaves". There are a number of built-in leaves described below, such as "Config", "AppData", and "Boot".

10.2.2.1 Config

`Config` is the top level object that contains everything else. Underneath are the `AppData` and `Sys` settings. There is also a `Version` field that is updated automatically when new settings are saved. The `Reboot` option, when checked, will force the module to reboot when the configuration record is updated.

10.2.2.2 Config.AppData

The AppData leaf is set aside at the top leaf for user application data. The application can select from the many configuration objects to store strings, integers, list boxes, etc. More information on how to use these can be found in the BasicConfigVariable NetBurner Basic Config Demo.

10.2.2.3 Config.Sys

The Sys leaf contains the device system settings such as boot parameters, application name, and network interface settings.

10.2.2.3.1 Config.Sys.Boot

Boot settings include:

- **Abort:** This specifies the keys that needs to be pressed in order to break out of the normal boot sequence. This prevents anything after the `init()` function from running in `UserMain()`. This will load the serial configuration server, enable the config web interface and effectively stops the user's application from running. The default value for this is "A".
- **BootBaud:** The baud rate that the `BootUart` will use.
- **BootDelay:** How long the application will delay to wait for the `Abort` characters before continuing.
- **BootQuiet:** Whether or not to display the boot output data on the `BootUart`.
- **BootUart:** The UART used by the system to display output related to the device booting.
- **Password:** When this is set along with `User`, both will be required when making changes to the config settings, or when updating the user application.
- **Serial Config:** There are four different options for this, which are outlined below.
 - **DuringBoot:** This will make the serial configuration server available during the boot process by using the `Abort` characters set above.
 - **AlwaysEnabled:** This will set the serial configuration server to always be available through the `BootUart`. Note that if this is selected, attempting to receive other serial input through the `BootUart` (such as debug commands, etc.) has the potential to break the configuration record.
 - **PauseAfterBoot:** This option will cause the boot process to pause indefinitely before the user's application is launched (specifically after `init()` is called), and will cause the serial configuration server to be enabled over the `BootUart`. The user's application can be resumed by typing `boot`.
 - **Disabled:** This prevents the serial config server from being enabled, and does not pause during the boot process, which stops the user from being able to enter the `Abort` character sequence.
- **User:** When this is set along with `Password`, it must be entered when trying to make changes to the configuration record's values or uploading a new application to the module.

10.2.2.3.2 Config.Sys.NetIf

The settings underneath NetIf deal with the different network interfaces available on the module. This will include all of the Ethernet ports, as well as any Wifi ports available. What is actually listed underneath these interfaces will depend on the interface itself. Common settings are listed below:

Config.Sys.NetIf.Ethernet0

Ethernet settings include:

- **DeviceName:** A name given to the interface, which is used to register for DDNS and NetBIOS.
- **DhcpDiscoverSec:** How long to wait after boot before sending a DHCP Discover message.
- **DiscoveryReportInterval:** How often a device should report itself to the discovery server.

- `DiscoveryReportUrl`: The location of the discovery server. By default, this points to NetBurner's discovery server. However, if desired, this field can be changed to be blank so that the device does not report itself. It can also be set to another URL if the user wishes to run their own discovery server.
- `MAC`: The MAC address of the interface.

Config.Sys.NetIf.Ethernet0.IPv4

IPv4 Settings include:

- `ActiveAddr`: The current IPv4 IP address in use.
- `ActiveDNS1`: The current IPv4 DNS server (1) in use.
- `ActiveDNS2`: The current IPv4 DNS server (2) in use.
- `ActiveGate`: The current IPv4 gateway in use.
- `ActiveMask`: The current IPv4 mask in use.
- `AutoIPAddr`: The current IPv4 auto address in use.
- `AutoIPEn`:
- `Mode`: Specifies which method to use to acquire IPv4 active values. The options are as follows:
 - `DHCP`: Use the values provided by the `DHCP` server.
 - `DHCP w Fallback`: Try to get values from the `DHCP` server, and use the static values as a backup.
 - `Static`: Use the static values defined in the interface's config record.
 - `Disabled`: Disable the interface.
- `StaticAddr`: The manually configured IPv4 IP address.
- `StaticDNS1`: The manually configured IPv4 DNS(1).
- `StaticDNS2`: The manually configured IPv4 DNS(2).
- `StaticGate`: The manually configured IPv4 gateway.
- `StaticMask`: The manually configured IPv4 mask.

Config.Sys.NetIf.Ethernet0.IPv6

IPv6 settings include:

- `ActiveAddr`: Lists the current IPv6 addresses in use.
- `ActiveDNS`: Lists the current IPv6 DNS servers in use.
- `ActiveRoutes`: Lists the current IPv6 routes in use.
- `Mode`: Specifies which method to use to acquire IPv4 active values. The options are as follows:
 - `DHCP`: Use the values provided by the `DHCP` server.
 - `DHCP w Fallback`: Try to get values from the `DHCP` server, and use the static values as a backup.
 - `Static`: Use the static values defined in the interface's config record.
 - `Disabled`: Disable the interface.
- `StaticAddr`: The manually configured IPv6 IP address.
- `StaticDNS1`: The manually configured IPv6 DNS(1).
- `StaticDNS2`: The manually configured IPv6 DNS(2).

10.2.3 The Configuration Web Interface

The device's configuration web server is available on port number 20034. To view in a web browser, type the device's IP address followed by the port number. For example, "10.1.1.100:20034". The default system configuration server web page is shown below. Note that you can easily create your own custom web page for things as simple as branding with your own logo, to formatting and adding fields in any way you wish. Clicking on the tree structure leafs will navigate through the settings.

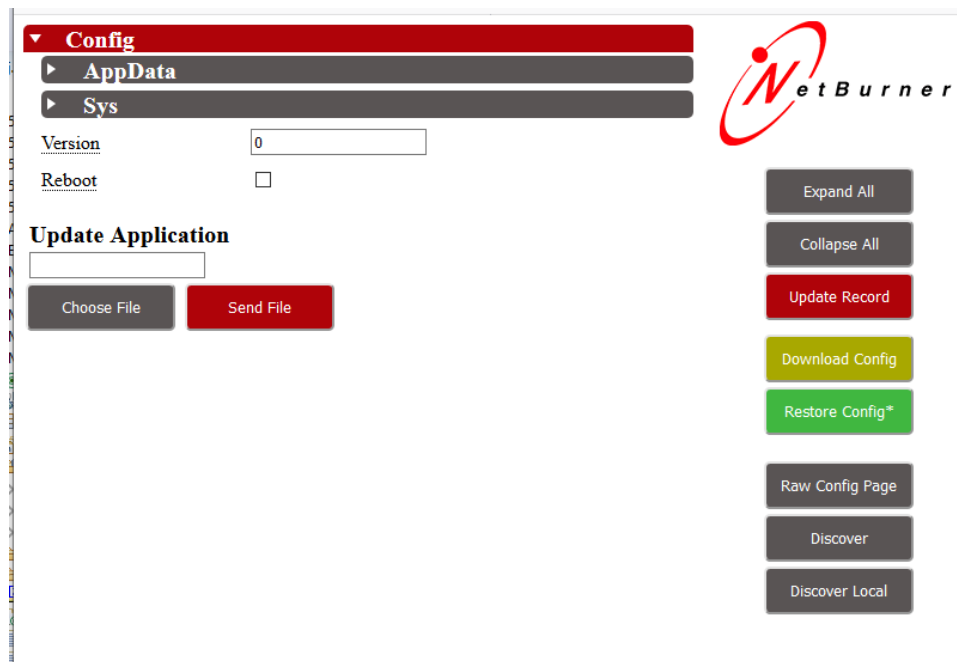

Figure 10.1 Config Web Interface

Located on the right side of the interface, you will also notice that there are several buttons. These provide the following functionality:

- `Expand All`: This expands the entire config tree structure.
- `Collapse All`: This collapses the entire config tree structure.
- `Update Record`: This updates the config record with the values that are currently entered in config structure on the web page.
- `Download Config`: Download the configuration object in JSON.
- `Restore Config`: Upload a JSON configuration object.
- `Raw Config Page`: Display a non-stylized version of the web interface, which can be edited.
- `NB Discover`: This takes you to [NetBurner's Discover](#) page.
- `Discover Local`: Discover device on the local network, Internet access is not required.

The Update Application section provides for an application update by selecting a .bin file. Use the Choose File button to select the image, followed by selecting Send File.

10.2.4 Serial Configuration Interface

In addition to the web interface, it's possible to navigate and modify the config record through a serial terminal. To do this, you will need to enter the serial config server through the `BootUart` using a method defined by the `SerialConfig` option in the Boot settings outlined above.

The most common method will be to type in the string specified by the `Abort` setting listed in the Boot configuration section. Reset the module and send the abort string before the boot timeout expires. The boot delay text is:

Type \`<Abort Value>` to Abort boot...

The default Abort Value is a capital 'A'. Upon successfully entering the serial configuration monitor, the `>` prompt will be displayed:

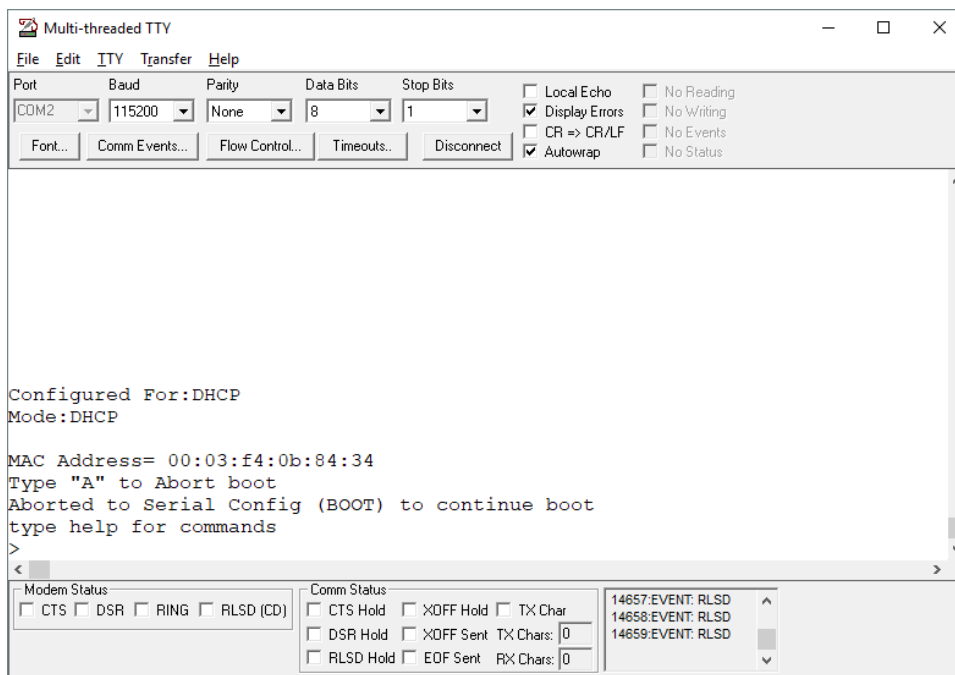

Figure 10.2 Serial Config Prompt

Navigating through the config data via the serial menu has been designed to operate much like a standard file system. Typing the name of a config object will move you into that section of the config data, much like navigating into a directory through a command prompt. Where you are in the config structure will be displayed at the prompt. For example, from the initial prompt, `>`, if you were to type `Config.Sys` and hit enter, the prompt would then read `Config.Sys.>`, illustrating that you are currently at the system settings for the config object.

In addition, several commands have been added to aid in navigating and modifying the config data, as well updating the device. Typing "help" at the prompt will display a list of these commands. Each of these is explained below:

- `help`: Displays the commands that can be used in the serial config system.
- `boot`: This will exit the serial config server, and continue to boot the user's application.
- `reboot`: This will reboot the module.
- `flash`: This will allow to you upload a new application serially. To do this in MTTY, after typing this command hit "F5" to open a file dialog box and select a new `.bin` file to upload.
- `<configvar>?`: Type the name of a config variable followed by a "?" to list the config structure underneath the config variable specified. For example, typing `Config?` will show the entire contents of the config structure, while `Config.Sys` will show all of the system settings.
- `<configvar>=<value>`: This will assign a value to a specific config variable.
- `..`: This will take you up one level in the config object structure from the current position.

- `ls`: This will show the current level of the config object.
- `save`: This will save any changes made to the values stored in the config object.

10.2.5 Creating a Custom Web Interface

The config web interface was designed so that it could be easily replaced by customers with their own web interfaces and logos. To do this, simply replace `<NNDK Install Directory>\nbrtos\source\ROOT.html` with your own file, and rebuild the system libraries as outlined in the [Rebuilding Projects & Libraries](#) NBEclipse Guide. If you simply want to replace the logo shown in the config web interface, replace `LOGO.gif` with your own image, and rebuild the system libraries as mentioned above.

An example has been setup that shows how the current config web interface has been structured and built. It can be found in the examples folder of your NNDK install at `<NNDK Install Directory>\examples\Configuration\BasicWebConfig`.

10.2.6 Configuration API Examples

There are several examples that outline how to properly use NetBurner's config objects. These can all be found in the examples folder of your NNDK install at `<NNDK Install Directory>\examples\Configuration`. They are listed here with brief descriptions for your convenience.

- `BasicConfigVariable` `Basic Config Variable`: This program shows the basics of using NetBurner's config system objects.
- `BasicWebConfig` `Basic Web Config`: This program shows the basics of using NetBurner's config system and presenting the information through a dynamically generated web interface.
- `CustomWebConfig` `Custom Web Config`: This program shows how to use NetBurner's config system combined with a more complicated web interface featuring Bootstrap and jQuery.

10.3 Custom Branding

NetBurner is an OEM manufacturer and our products can be customized to present your custom brand to your customers. Some customizations are very simple such as changing the logo on the configuration screens, to more complex such as having your own cloud server instead of using `discover.netburner.com`. Some suggestions for customization and branding are:

- Replace the company logo on the configuration server page. Please refer to the `CustomWebConfigSystem` example.
- Create your own configuration interface as part of your application. Examples are located in the `\nburn\examples\web` folder. The configuration server is not required to change system settings. An application has full access to display, change and save any configuration setting through a web interface, or within the application code itself.
- Order your NetBurner device without a NetBurner label. We also provide label templates so that you can change just the logo and part number.
- Customize the NetBurner utilities, such as `localdiscover` or `find`. Source code for these utilities are located in `\nburn\pctools`.

- Create your own cloud server in place of `discover.netburner.com`. This is very advanced.

10.4 IPv4/IPv6 Dual Stack Guide

Releases prior to 2.8.0 use a type of IPADDR that was a 32-bit number. The most significant change for 2.8.0 and beyond is that the IPADDR type is now an object that can hold IPv4 or IPv6 address information. This document will provide more information on this issue in the IPADDR class section.

10.4.1 Obtaining IPv6 addresses

IPv6 addressing is quite a bit different than IPv4, in which there is typically one IP address per network interface which is assigned by [DHCP](#) or set to a static address. In order for an interface to have more than one IP address it can use the Multihome feature. For example, a host's IPv4 AutoIP address.

10.4.1.1 Link-Local

When using IPv6, all interfaces have multiple IP addresses. For starters there is the 'link-local' address (`fe80::/64`). This is an address that is valid only for the local link that the device is connected to, and is used to negotiate the other addresses for the interface. While it can be used for any communication on the link, it is not a routable address. The link-local address is derived from the MAC address of the interface. As a result it is fixed for a given interface and determined without having to be explicitly set. For example, a device with the mac `00:03:f4:01:23:47` would have the link-local address `fe80::203:f4ff:fe01:2347`.

10.4.1.2 Router Auto-Configuration

In addition to the link-local address, IPv6 routers can tell the device to auto-configure based on the router's assigned prefix. To configure the end address, the device takes a number of bits of the router's prefix (usually 64), and combines this with its auto-configure address (the calculated portion of link-local) to obtain the prefix address. In our previous case, let's assume a router advertised a prefix of `2001:db8:1:2::`. In this case, the full prefix address would be `2001:db8:1:2:203:f4ff:fe01:2347`. This applies for all routers on the link that advertise auto-configuration. It's entirely possible (and reasonable in large corporate networks!) for an interface to have multiple prefix addresses from multiple routers.

10.4.1.3 DHCPv6

IPv6 addresses can also be assigned by a DHCPv6 server. Like [DHCP](#) for IPv4, this is used for assigning addresses to devices, along with passing other information like DNS and NTP servers. It is also possible for routers to notify devices that there is a [DHCP](#) server present on the network. In the case where such notification occurs, the NetBurner will automatically configure to obtain the relevant information. There are two types of [DHCP](#) servers in IPv6 networks: Information-only and full Stateful Configuration. Information-only servers exist solely to provide additional information about the network, but do not assign IP addresses. These will allow for the auto-configuration of DNS, NTP servers, or other desired information. Full Stateful configuration additionally assigns addresses for use on the device's link. It is possible to manually start the [DHCP](#) client as well, for use on networks without a router.

10.4.1.4 Static IP Addresses

Finally, if all of these methods are insufficient, it is possible to manually assign an address to the device's interface as well.

10.4.2 IPADDR Class

The IPADDR type in NetBurner tool releases prior to 2.8.0 was a 32-bit unsigned integer. In order to be able to handle IPv6 addresses with the least impact to existing applications, it is now a C++ object. You will not need to

know C++ in order to use these objects. Most function calls will not have to change, and the system will do the appropriate action for both IPv4 and IPv6 addresses. One major change for users that have created custom storage structures that store IPADDRs in UserParams or a file on a file system is that when compiled for IPv6, the IPADDR is now 128 bits instead of 32. This means that unless plans are made for this, reading back stored IPADDRs will cause a problem for the application configuration in previously deployed devices that are updated. One way to address this issue is to use something like a 32-bit storage "key". Whenever reading the configuration structure check that the key in the application matches the key stored in memory. If different, then you must initialize the values. Any time you make a change to the stored information, such as adding a variable, increment the key.

The most significant difference is that while an unsigned 32-bit integer can be checked for a value of 0, an object cannot. For example, many applications check for a static IP address setting with `if (EthernetIP == 0)`. If EthernetIP is now an IPADDR object, the test should now be: `if (EthernetIP.IsNull())`.

For function parameters that were previously set to 0 to represent a null value, you can use `IPADDR::NullIP()`. For example, in previous releases a 0 was used for parameter 3, the DNS Server IP address, to tell the system to use the current runtime system DNS IP address value. This will generate an error in the new tools release since the 3rd parameter must be a typed object rather than an integer value. You may also use the `INADDR_ANY`, which is defined as `IPADDR::NullIP()` in the system files.

```
DNSResult = GetHostByName( serverName, &serverIp, 0, TICKS_PER_SECOND * 20
);
```

Becomes

```
DNSResult = GetHostByName( serverName, &serverIp, IPADDR::NullIP(), TICKS_↵
PER_SECOND * 20 );
```

10.4.3 IPADDR Member Functions

C programmers are used to creating structures that contain variables. A very simplistic way to look at a C++ object is that it is a structure that contains both variables and function declarations. These functions are called member functions. They are called using a dot notation instead of calling the function by itself. For example, in prior releases to print an IP address to the debug serial port (stdout) you might use the function: `ShowIP(EthernetIP)`. In the new release this becomes: `EthernetIP.printf()`. To print to a file descriptor such as a TCP socket, you can use: `EthernetIP.fprintf(fd)`.

Some common functions are described below in their simplest form. Many of the functions have optional parameters, and experienced C++ programmers may want to know more detailed information, such as which are static and default parameters. Please refer to the NetBurner API documents for more information: [IPADDR6](#)

10.4.3.1 Setting IP Address Values with Member Functions

Member functions are called using a "." after the object instance name. For example:

```
IPADDR myIpObject;
myIpObject.SetNull(); // set the IP address to null
```

10.4.3.2 Member functions to set an IP address:

- `void SetNull()` Set the IP address of an existing IPADDR object to null
- `void SetFromAscii(const char *pStr)`, Set the IP address to the value of the ASCII representation in the string pointed to by pStr
- `void SetFromIP4(IPADDR4 ip)`, Set the IP address of an [IPADDR4](#) object from an existing [IPADDR4](#) object

10.4.3.3 Setting IP Address Values with Static Functions

A "static" function is one that is not attached to any particular instance of an object. They are invoked with a double colon "::". For example, `IPADDR::NullIP()` is used to represent an object instance with an IP address of null.

- `static IPADDR6 NullIP()`, Return an [IPADDR6](#) object whose IP address is NULL. For example, `IPADDR::NullIP()`;
- `IPADDR AsciiToIp(const char * pStr)`, Sets the IP address to the value represented by the ASCII string pointed to by pStr. For example, `IPADDR myIpAddr = IPADDR::AsciiTo↵
Ip("192.168.1.1");`

10.4.3.4 Reading and Checking IP Address Values

- `bool IsNull()`, Returns true if the IP address is null
- `bool IsLoopBack()` Returns true if the IP address is the loopback address
- `bool IsMultiCast()` Returns true if the IP address is a multicast address
- `bool IsLinkLocal()` Returns true if the IP address is the IPv6 link local address. A link local address is of the format
`FE80::/10`
 - `bool IsEmbeddedIPV4()` The same storage space is used to represent an IPv4 or IPv6 address. The function returns true if the address is
`::FFFF:xx.xx.xx.xx`
, where the x's represent the IPv4 address.
- `MACADDR McastMac()` Returns the MAC address for multicasts at this IP address, or null if not a multicast address.

10.4.3.5 Output an IP Address

- `void printf()` Print the IP address value to stdout. The default stdout is the debug serial port
- `void fdprintf(int fd)` Print the IP address value to the specified file descriptor
- `int sprintf(char *pStr, int maxL)` Sends output to the string pointed to by pStr. maxL = Maximum number of characters to write. Returns the number of characters written.

10.4.4 Domain Name Service (DNS)

The function signature for DNS changes slightly between IPv4 and IPv6. However, if you use the default parameters, your code can be identical in both cases.

- `GetHostByName4()` IPv4 only and always available
- `GetHostByName6()` Available when IPV6 is enabled
- `GetHostByName()` Defined to `GetHostByName4()` in IPv4 mode and `GetHostByName6()` in IPv6 mode

The following code example will work in both cases:

```
GetHostByName("thename.com", &resultIP, IPADDR::NullIP(), 10 * TICKS_PER_↵
SECOND);
```

This will put the IP address of "thename.com" in the resultIP. If you need DNS records other than just the name you can add additional type parameters. The types are:

- `DNS_A`, IPv4 address record
- `DNS_CNAME`, Canonical name record
- `DNS_MB`, Mailbox resource record
- `DNS_MG`, Mail group resource record
- `DNS_MX`, Mail exchange record
- `DNS_AAAA` IPv6 address record

When using DNS in IPv6 you need to decide which address to choose if the server has both an IPv6 and IPv4 address. The function `GetHostByName6()` has two default value types:

```
int GetHostByName6( const char *name, // Name to resolve
IPADDR *pResultIP, // Stores resultant IP
const IPADDR &dnsServerIP, // DNS server IP address to use, or IPADDR::NullIP() for
system
WORD timeout, // Timeout in system time ticks
WORD TYPE1 = DNS_A, // Defaults to IPv4 address
WORD TYPE2 =DNS_AAAA ); // Defaults to IPv6 address
```

The function will first try to get the TYPE1 value. If that fails, it will try to get the TYPE2 value. In the default case as defined in the header file it tries to get an IPv4 address, and if that fails it gets an IPv6. If you want to reverse this priority and try to get the IPV6 first then add the additional types in the function call:

```
`GetHostByName("thename.com", &resultIP, IPADDR::NullIP(), 10 * TICKS_PER_SECOND, DNS_AAAA, DNS_A);`
```

10.4.5 Note for OSX Users

At the time of this writing, BSD derived network stacks (including Apple's OS X) are not able to navigate to link-local addresses in a browser. You must use something refer to as a scope ID.

10.5 EFFS Programming Guide

This guide covers the NetBurner implementation of the HCC Embedded Flash File System (EFFS) and NetBurner flash card hardware interface. The EFFS is just one part of the NetBurner suite of tools and software. You may need to reference other documents for configuration and hardware specifics for your particular NetBurner platform. Topics Covered:

- An overview of examples, supported platforms and debugging information
- Overview of the flash card EFFS-FAT File System Operation
- Overview of the on-chip EFFS-STD File System Operation
- Hardware interface design for external flash cards

10.5.1 Example Programs

A list of examples is provided in the Example Applications section of this document.

10.5.2 Reference Manuals for the EFFS API

The function call reference manuals for the EFFS-FAT and EFFS-STD file systems are located in the `\nburn\docs\NetBurner\EFFS` folder.

10.5.3 Supported Hardware Platforms

All platforms support the on-board flash chip EFFS-STD file system. The implementation of the flash card EFFS-FAT file system is as described below. All devices can implement an external flash card design, while some platforms also have a flash card socket located on the device itself. There are two types of external flash card implementations:

- SPI: operates in native SPI mode with a single data channel
- SDIO: operated with four data channels

Platform	External	On-board
MODM7AE70	SPI	N/A
MOD54415	SPI	SPI
MOD54417	SPI	SPI
SB800EX	SDIO	
NANO54415	SPI	SDIO

The flash card sockets on the MOD-DEV-70CR and NANO development boards support SPI mode.

Topic Links:

- [Flash Card Hardware Interface Design](#)
- [EDFS-FAT File System Operation](#)
- [EDFS-STD File System with On-chip Flash](#)

10.5.4 Debug Port

Throughout this guide, we will refer to the "debug port". The debug port is one of the RS-232 ports that can be used to interact with your NetBurner device in the example programs. By default `stdout`, `stdin` and `stderr` are mapped to the debug port, so when you use functions like `printf()`, `scanf()`, `gets()`, etc. they read and write to the debug port. All of this is configurable. You can also disable the debug port and use the port as a general purpose UART, or you can reassign the `stdio` file descriptors to use other serial or network interfaces.

10.5.5 Flash Card Hardware Interface Design

10.5.5.1 Flash Card Hardware Interface Design

10.5.5.1.1 MMC/SD Hardware Interface

10.5.5.1.1.1 Schematic Representation

The SD/MMC flash card interface is installed on NetBurner Network Development Kit (NNDK) development board. The schematic representation is shown below:

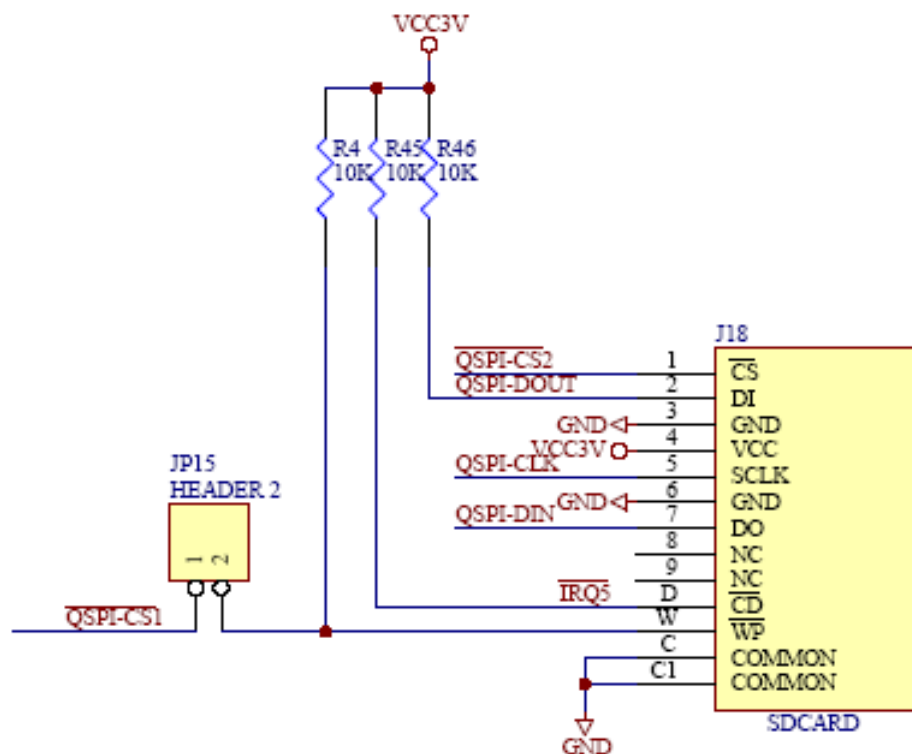

Figure 10.3 Development Board Schematic

10.5.5.1.1.2 Signal Description

SD/MMC Pin	SD/MMC Signal Name	Modxxxx Signal Connection
1	/CS, Chip Select	J2-35 - with 10k pull-up*
2	DI, Data In	J2-28 - QSPI DOUT
3	GND	Ground
4	VCC	VCC 3.3V
5	CLK	J2-J5 - QSPI CLK
6	GND	Ground
7	DO, Data Out	J2-J7 - QSPI DIN
8	NC, No Connection	No Connection
9	NC, No Connection	No Connection
D	CD, Card Detect	J2-47 - with 10k pull-up*
W	WP, Write Protect	J2-40 - with 10k pull-up*
Com	Common	Ground
Com	Common	Ground

These signals can be any available GPIO pins on the NetBurner module, with a corresponding software change in `mmc_m7.cpp` for the MODM7AE70 or `mmc_mcf.cpp` for the other platforms to specify the signal name.

10.5.5.1.1.3 SD/MMC Connector Part Number

The SD/MMC flash card connector used on the NetBurner development board is available from Mouser Electronics, part number 688-SCDA1A0901.

10.5.5.1.1.4 SD/MMC Card Compatibility

The SD/MMC must support native SPI mode transfers, which is common for most SD/MMC cards. Up to 2GB is supported for standard SD/MMC and up to 32GB is supported for SDHC.

10.5.5.1.1.5 Exclusive Use of the SPI

The EDFS normally requires exclusive use of the SPI interface. The standard software and drivers operate in this mode. There are also performance reasons for exclusive use. While it may be possible to share the SPI with other peripherals, it is not supported in the development tool suite.

10.5.5.1.1.6 SD/MMC Interface Control Pins

You can modify the default pin selections for the interface control signals in `\nburn\platform\<platform>\mmc_m7.cpp` for the MODM7AE70, or `\nburn\platform\<platform>\mmc_mcf.cpp` for the other platforms. The relevant functions in this file are listed below. Note that the values in these functions must be used on the NetBurner development board since the board is wired in this configuration.

```
void MMC_BaseInit(int CurrentDrive) // Configure pins to be used for SD/MMC interface control
int get_cd(int currentDrive) // Get the Card Detect state
int get_wp( void ) // Get the Write Protect state
void spi_cs_lo( void ) // Set SPI chip select low
void spi_cs_hi( void ) // Set SPI chip select high
```

10.5.5.1.1.7 Interrupt Driven SPI

For the ColdFire based platforms (MOD5441X, SB800EX, and NANO54415), you can enable the SD/MMC SPI interface to work with the NetBurner interrupt driven SPI driver instead of the default polling mode driver. This will result in slightly lower SD/MMC performance but overall higher system performance. This is useful if you find that your network performance or user tasks run poorly during file system accesses. A modification must be made in `nburn\platform\<platform>\mmc_mcf.cpp`, followed by a rebuild of the platform system directory. Near to top of this file, the following line should be uncommented:

```
define SD_IRQ_SPI
```

10.5.6 EFFS-FAT File System Operation

10.5.6.1 EFFS-FAT File System Operation

Typical file system operation will involve mounting a drive, opening and closing files, and reading and writing files. The following is a list of the most common function calls used to perform these operations. For a complete list of functions refer to the EFFS Programming Guide.

10.5.6.1.1 Common EFFS FAT Function Calls

Create/delete working directory for current task priority:

```
int f_enterFS(void)
void f_releaseFS(void)
```

Mount/dismount a flash card:

```
int f_mountfat(MMC_DRV_NUM, mmc_initfunc, F_MMC_DRIVE0)
int f_delvolume(int drivenum)
```

Open/Close a file

```
F_FILE *f_open(const char *filename, const char *mode)
int f_close(F_FILE *filehandle)
```

Read, write, and related functions:

```
int f_getfreespace(int drivenum, F_SPACE *pspace)
long f_write(const void *buf, long size, long size_st, F_FILE *filehandle)
long f_read( void *buf, long size, long size_st, F_FILE *filehandle)
long f_seek(F_FILE *filehandle, long offset, long whence)
int f_eof(F_FILE *filehandle)
int f_rewind(F_FILE *filehandle)
int f_delete(const char *filename)
```

Directory functions:

```
int f_findfirst(const char *filename, F_FIND *find)
int f_findnext(F_FIND *find)
```

```
int f_chdir(const char *dirname)
int f_mkdir(const char *dirname)
```

File time functions

```
int f_settimedate(const char *filename, unsigned short ctime, unsigned short cdate)
int f_gettimedate(const char *filename, unsigned short *ptime, unsigned short *pdate)
```

10.5.6.1.2 File Time and Date Stamps

The EFFS supports file time and date stamps. There are a number of ways to obtain the current world time for an embedded system, including a Network Time Server (NTP), Real-time clock (RTC), and setting it manually. For simplicity the first two examples concentrate on file system calls. The third example includes methods to set the time and date through all the aforementioned methods. If no time or date is set, the file time stamp will be January 1, 1980.

10.5.6.1.3 File System Utils

All of the NetBurner EFFS examples include a helpful utility file called `FileSystemUtils.cpp`. This file provides an easy use interface for initializing, getting status, testing, reading and writing to a CF or SD/MMC card. To select between the types of cards, edit the header file `cardtype.h`. This file also demonstrates many of the commonly used EFFS function calls. These utility files are located in `<nburn_install>\examples\↵_common\EFFS\FAT` or `<nburn_install>\examples_common\EFFS\STD`, depending on if you want to use an SD card (FAT), or the on chip file system (STD). The examples for EFFS that take advantage of these utility files can be found in `<nburn_install>\examples\EFFS\FAT` or `<nburn_↵install>\examples\EFFS\STD`, again, depending on which file system you wish to use.

10.5.6.1.4 EFFS FAT Example Programs

10.5.6.1.4.1 EFFS FAT

Example applications for using the file system as simple storage, with FTP, HTTP, HTTP with Variable tags, multiple tasks, RAM drive, and application updates are located at: `\nburn\examples\EFFS\Fat`

10.5.6.1.4.2 EFFS FAT Used In Security Applications

Example applications using the file system in security applications are:

- `HttpsDualCert` to demonstrate how to have both a permanent compiled-in certificate and key, as well as one that can be loaded from an SD/MMD flash card using the EFFS FAT file system for a web server.
- `SSL_pop3` to demonstrate how to implement retrieving email from a server that requires SSL, and then saves it to an SD/MMD flash card using the EFFS FAT file system.
- `SendMailAttach` demonstrates how to attach files from the EFFS FAT file system to an email and send it securely using SSL/TLS encryption.

10.5.6.1.5 Project Settings

To create a project that uses the EFFS-FAT file system, you will need to complete a few extra steps in addition to your normal project setup.

For NBEclipse users:

- Add the EFFS-FAT library, `libFatFile.a`, to the linker path. This is done by right clicking the NBEclipse project in the "Project Explorer" -> C/C++ Build -> Settings -> GNU C/C++ Linker -> Libraries -> Add "FatFile" to the list of "Libraries (-l)".
- Import the source files found here into your project: `<nburn_install>examples_common\EFFS\FAT`

For projects that use the command line tools, add the following lines to your makefile:

```
XTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libFatFFile.a
include $(NNDK_ROOT)/examples/_common/EFFS/FAT/common.mak
```

10.5.7 EFFS-STD File System with On-chip Flash

10.5.7.1 Using the EFFS-STD File System with On-chip Flash

10.5.7.1.1 EFFS-FAT vs. EFFS-STD

The previous sections of this guide have focused on the EFFS-FAT file system, which is a FAT32 file system used for external flash cards. The EFFS-STD file system uses the on-chip flash memory of your NetBurner device. It has a different set of libraries and functions than the EFFS-FAT file system. In most cases the differences between the EFFS-STD and EFFS-FAT are simply a change in functioncall prefix from `f_` to `fs_`. For example, the EFFS-FAT function call `f_open()` is `fs_open()` for EFFS-STD. A list of the documented functions can be found at [EFFS-STD Flash File System](#).

10.5.7.1.2 Overview

When using the on-chip flash you need to be aware that the flash will be shared between your application and the file system. You will need to specify the amount of space to be used by the file system, while making sure you leave enough room for your application. The amount of flash used by your application is displayed each time you compile. You want to use the compressed number, not the uncompressed. You certainly want to leave enough additional space so your application can grow.

The flash memory chip will be divided into sectors, typically 4k or 64k bytes in size. The EFFS-STD file system requires that you allocate a number of these sectors to be used by the file system. Please review the data sheet for the flash memory used on your NetBurner device so you are familiar with the architecture. The configuration settings are dependent on the specific flash chip you are using.

10.5.7.1.3 Examples

10.5.7.1.3.1 EFFS STD Examples

The HTTP example located at `\nburn\examples\EFFS\Std` demonstrates HTTP access to the STD file system. Web pages can be served from the application itself, or overridden if the same file name exists in the file system.

10.5.7.1.3.2 EFFS STD With NetBurner's Security Library

Example are located at `\nburn\examples\SSL` `HttpsUploadCert` - This program will demonstrate how to upload certificates and keys to support SSL/TLS web page access and store them in the EFFS-STD file system. `SslVerifyPeerEfs` - This program will demonstrate how to upload CA Lists to use in support of verify peer, and store them in the EFFS-STD file system.

10.5.7.1.4 Adding EFFS-STD Functionality to an Existing NBEclipse Project

To add EFFS-STD file system to your project, you will need to complete a few extra steps in addition to your normal project setup.

For NBEclipse users, there are three steps:

1) Import the source files found here into your project `<nburn_install>\examples_common\EFFS\STD`

2) Add the EFFS-STD library `StdFFile.a` to the linker path:

- Right click on your project.
- Navigate to `C/C++ Build > Settings > GNC C/C++ Linker > Libraries`.
- In the Libraries section, add "StdFFile". Note there is no `.a` extension.

3) The third step is platform specific:

10.5.7.1.4.1 MODM7AE70, SBE70LC Platforms

The "Locate Application at Fixed Address in Flash" feature must be enabled. This will disable the background Flash erase feature, would will erase the flash file system sectors.

- Right-click on the project and select "Properties"
- Navigate to `C/C++ Build > Settings > NB Flashpack > General`
- Check the checkbox for "Locate Application at Fixed Address in Flash"

10.5.7.1.4.2 NANO54415, SB800EX Platforms

Modify the `CompCode` Flag settings that are used to reserve space in the memory map for the file system.

- Right click on your project.
- Navigate to `C/C++ Build > Settings > NBCompCode > General`
- Modify the memory address range field from:
`COMPCODEFLAGS = 0x04000 0x800000 // Original`
to
`COMPCODEFLAGS = 0x04000 0x700000 // Reserve space for file system`
- Note: The first address parameter is the start of application space, and the second is the start of file system space

10.5.7.1.4.3 MOD54415, MOD54417 Platforms

Modify the CompCode Flag settings that are used to reserve space in the memory map for the file system.

- Right click on your project.
- Navigate to C/C++ Build > Settings > NBCompCode > General
- Modify the memory address range field from:
`COMPCODEFLAGS = 0xC0040000 0xC2000000 // Original`
to
`COMPCODEFLAGS = 0xC0040000 0xC1F00000 // Reserve space for file system`
- Note: The first address parameter is the start of application space, and the second is the start of file system space

10.5.7.1.5 Adding EFFS-STD Functionality to a Makefile for Use With Command Line Tools:

There are two modifications to the makefile needed:

1. Add the EFFS-STD Library with the following additions to the makefile:
`XTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libStdFFile.a`
`DBXTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libStdFFile.a`
2. Add the compcode flags (SB800EX, NANO54415, MOD5441x) or enable application fixed address (MODM7AE70, SBE70LC). The platform specific modifications are as follows:

10.5.7.1.5.1 MODM7AE70, SBE70LC Platforms

- Enable "Locate Application at Fixed Address in Flash" with:
`EXTRAPACKARGS += -cflag C:3`

10.5.7.1.5.2 NANO54415, SB800EX Platforms

- Modify the memory address range field from:

```
COMPCODEFLAGS = 0x04000 0x800000 // Original
to
COMPCODEFLAGS = 0x04000 0x700000 // Reserve space for file system
```

10.5.7.1.5.3 MOD54415, MOD54417 Platforms

- Modify the memory address range field from:

```
COMPCODEFLAGS = 0xC0040000 0xC2000000 // Original
to
COMPCODEFLAGS = 0xC0040000 0xC1F00000 // Reserve space for file system
```

10.5.7.1.6 Flash Memory Addresses

The flash memory on your NetBurner device is used for the Boot Monitor, System Parameter Storage, User Parameter Storage, Application, and now the EFFS-STD file system. A table of memory sizes for NetBurner platforms at the time of this writing is shown below. The example column illustrates one possible configuration. You can modify the parameters to suit your requirements. The COMPCODE flag starting address specifies the starting memory location of your application. The end address specifies the end location of the application. You should not modify

the starting address! The Boot Monitor, Configuration Record and User Parameters occupy the space between the start of flash memory address and the start of the application memory address. You will only need to modify the end address to represent the amount of memory allocated for the flash file system.

Platform	Total Size in Bytes	Start Address	End Address	Configuration Definition Example
MODM7AE70	2MB	0x00400000	0x005FFFFFFF	<p>Example for 512K flash file system</p> <p>Application must begin at 0x0040600</p> <p>COMPCODEFLAGS = 0x00406004 0x005A0000</p> <pre>#define FLASH_SIZE (2*1024*1024) // Total flash size
#define FS_SIZE (256*512) // Size of filesystem</pre>

10.5.7.1.6.1 Configuration File for SAME70Q21

Please refer to the SAME70Q21.h file located at `\nburn\examples_common\EFFS\STD\src\flash← Chip`

10.6 File Descriptors

The NetBurner environment integrates the RTOS, TCP/IP stack, and other peripherals with a file I/O system based on file descriptors. A file descriptor can be described as a handle to a network socket, serial port, system peripheral, or any other object that can be read or written to. Most of the API functions pass a file descriptor as a parameter to such an object

By default there are a maximum of 255 file descriptors:

- 0 – 2 for stdin, stdout and stderr
- 3 – 4 for the first two UART serial ports, 0 and 1.
- 5 – 128 for TCP (32 in total)
- 129 – 250 for expansion (additional UARTs, TCP sockets, or custom)

The expansion file descriptor positions can be used for many things, including additional serial ports, such as an external UART, TCP ports, or even buffers.

10.6.1 Creating Custom I/O Drivers Using File Descriptors

The header file in `\nburn\include\iointernal.h` defines the programming interface functions to create a custom file descriptor.

- `SetDataAvail()`
- `ClrDataAvail()`
- `SetWriteAvail()`
- `ClrWriteAvail()`

- `SetHaveError()`
- `ClrHaveError()`

```

struct IoExpandStruct
{
    int ( * read ) ( int fd, char *buf, int nbytes );
    int ( * write ) ( int fd, const char *buf, int nbytes );
    int ( * close ) ( int fd );
    void *extra;
}

int GetExtraFD( void *extra_data, struct IoExpandStruct *pFuncs );
void *GetExtraData( int fd );
void FreeExtraFd( int fd );

```

The TCP state call back, `fd = socket has new data`, `fd < 0` means error `typedef void (tcp_read_notify_handler) (int tcp_fd);`

When data comes in or the TCP connection enters an error state, register a callback to handle the event `void RegisterTCPReadNotify(int tcp_fd, tcp_read_notify_handler *newhandler);`

The `Set` and `Clr` functions are used to update the state of your `fd` device for file I/O functions such as `select()`, `read()` and `write()`. The `IoExpandStruct` is used to declare function pointers for the `read()`, `write()` and `close()` functions that will be implemented in your application, as well as an "extra" void pointer that you can use for whatever you wish.

`GetExtraFD()` is the function that will return a `fd` for the object passed as the `IoExpandStruct`. The `extra_data` void pointer is optional, and can be used to pass data into your `fd`. You can read the `extra_data` value at any time with the `GetExtraData()` function. `FreeExtraFd()` will release the `fd` back to the pool of available `fds`. The `tcp_read_notify_handler` and `RegisterTCPReadNotify()` are callback functions. These functions will get called by the system if you define them for the corresponding TCP event.

10.6.2 Using File Descriptors to Pend on Multiple Events

Once you have created a file descriptor you can use the `select()` function call just as you would for network or serial file descriptors. In fact, you can pend on a mixture of them all at the same time.

10.7 HTML Processing

10.7.1 Introduction

The Web Server will process all content in a project's "html" folder. If you are using any of the html examples or the application wizard, the html folder will have been created for you. If adding html and web server functionality to a project without a html folder, simply create one, and add the corresponding `StartHttp()` or `StartHttps()` function call to your application to start web server services.

You can add whatever content you wish to the html folder: HTML, CSS, java script, java, images, etc. The NetBurner tools will automatically compile and link them into the application image that you download into your NetBurner device. You can use whatever web development tools you wish to create content, or write content with a text editor. The content in the html folder can be static pages or take advantage of dynamic content using function callback and variable tags. Static content can also be delivered from the onboard EFFS-STD file system and the external EFFS-FAT file system used by flash cards.

Note

When using NBEclipse, you can view web content source by right-clicking on the file and selecting Open With -> Text Editor

The function `StartHttp()` with no parameters will default to port 80. To use a different port number add a parameter, such as `StartHttp(2000)`. Similarly, `StartHttps()` will default to port 443. The function can have up to 2 parameters, one for HTTPS and one for HTTP. `StartHttps(527)` changes the HTTPS port number. `StartHttps(442, 80)` enables both HTTPS and HTTP on the standard ports.

10.7.2 Dynamic Content

Dynamic content is generated at run-time on your NetBurner device. For example, you can a web page for an instrument in which the content changes to match the current state of the instrument, such as gauges, light indicators, and switches. Or you can provide a graph showing data by creating an image or using any of the advanced tool such as Bootstrap. There are many examples of this in the `\nburn\examples\web` folder.

Dynamic content can be created in a number of ways:

- Function callback tags in HTML code to call a C/C++ function in real time as the web page is being rendered, such as `CPPCALL`
- Variable tags in HTML code to insert application variable values in real time as the web page is being rendered, such as `VARIABLE`
- Languages such as Javascript that runs in the browser
- A HTTP GET request handler that will be called when a web page is requested from the web browser
- A HTTP POST handler that will be called when a web page FORM post data to the web browser
- Web Sockets for two-way communication
- Web content can be delivered from multiple sources: content compiled into the application, generated by application code, internal file system (EFFS-STD in on-chip memory), or an external file system (EFFS-FAT) such as microSD flash cards.

10.7.3 HTML Tags

You can think of web server operation as receiving a request from a web browser for a file, and responding by sending that file as a data stream back to the browser. One method to create dynamic content is to embed a "tag" in the HTML source code file so that when the web server encounters it while streaming the content to the web browser, it takes some type of action in real-time. The NetBurner web server uses a number of tags to accomplish real-time dynamic content.

Tag	Description
<code>CPPCALL</code>	Call a C++ function in the application without parameters
<code>VARIABLE()</code>	Call a C++ function with parameters
<code>VARIABLE</code>	Insert the value of an application variable

The tags are used inside a HTML comment so they do not interfere with standard HTML processing. For example, a function callback could be used to format and display client information from the web browser:

```
Client Info: <!--CPPCALL webShowClientInfo -->
```

Warning

The space characters in the HTML comment block are important. there should be no space between `!--` and `CPPCALL`, and there must be a space between the end of the function name and `-->`: `<!--CPPCALL YourFunctionName -->`

10.7.3.1 Configuration System Tags

While the previously mentioned tags can be used to display and/or modify any type of system configuration or application variables, the `CONFIG` tags are another option and can greatly simplify the interface. The `CONFIG` tags are designed to operate on the variables in the Configuration Record, which holds system configuration variables as well as any application variables in the `AppData` leaf of the configuration tree structure.

Tag	Description
CONFIGVALUE	Display a configuration or application variable value.
CONFIGINPUT	Display a configuration or application variable value and create a HTML "<input>" field. The current variable value will be displayed.
CONFIGTABLE	Create a table of the object and all sub-objects

-

10.7.3.2 The CPPCALL Tag

When the web server encounters a CPPCALL tag, it executes the corresponding C++ function in the application code. The function is passed the file descriptor to the open TCP socket and a pointer to the URL of the web page. The function then has control and can do whatever is desired by the application: create web content, perform operations such as controlling hardware, change software options, etc.

Note

The FUNCTIONCALL tag is a 2.x tools tag and deprecated. The difference is the CPPCALL does not require extern "C" declarations in application source code to prevent C++ name mangling.

The screen shot below shows the usage for CPPCALL, VARIABLE and VARIABLE(x, y) tags:

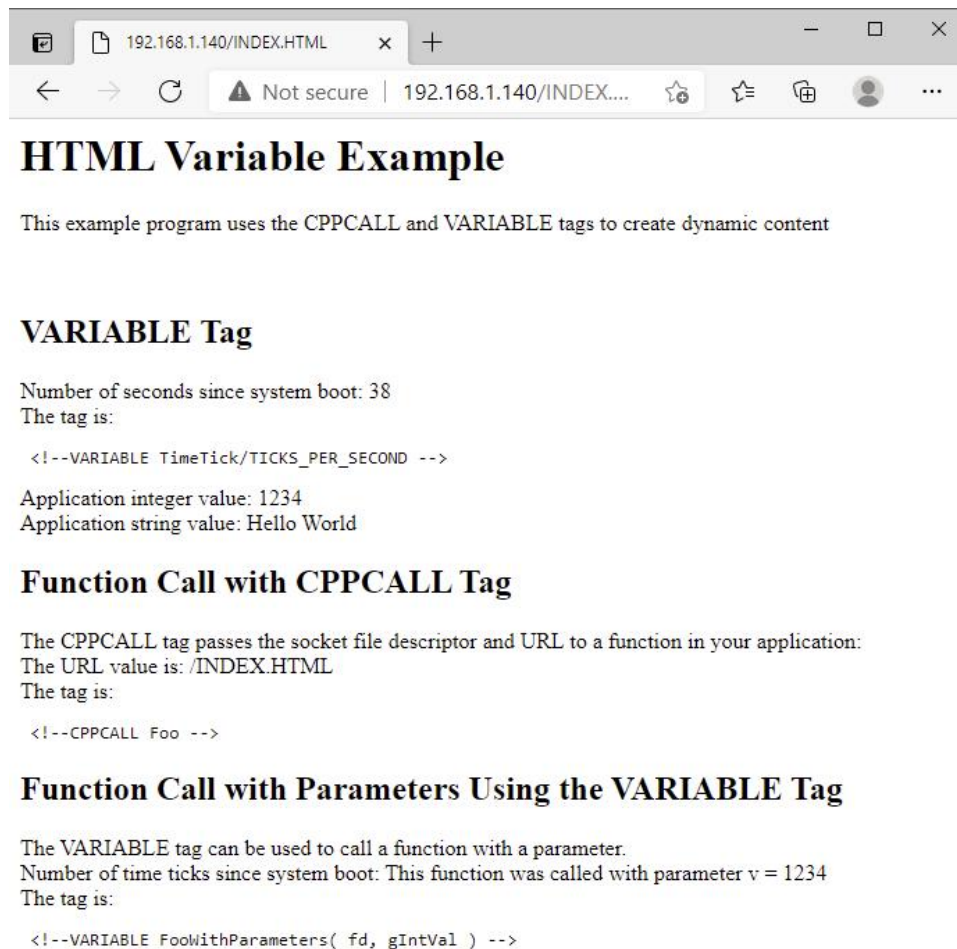

Figure 10.4 HTML Page with CPPCALL and VARIABLE Tags

The CPPCALL function signature is:

```
void YourFunctionName( int sock, PCSTR url )
{
    // add code here
}
```

For example, to display the IP address and port number of the client that made the web page request:
HTML Code:

```
<html>
<body>
    Client Address: <!--CPPCALL webShowClientInfo -->
</body>
</html>
```

The corresponding C++ function in the application:

```
void webShowClientInfo( int sock, PCSTR url )
{
    IPADDR localIP = GetSocketLocalAddr( socket );
    uint32_t remotePort = GetSocketRemotePort( socket );

    localIP.fdisplay( socket ); // Write IP address
    fprintf( sock, " : %d<br>\r\n", remotePort ); // Write port number
}
```

10.7.3.3 The VARIABLE Tag

The VARIABLE tag has two uses:

1. Simply inserting a variable or expression
2. Calling an application function with variable parameters (essentially a CPPCALL with function parameters)

To display a variable the format is: `<!--VARIABLE <name> -->`

Where `<name>` is the name of the application variable or an expression. For example, the system time tick variable, `TimeTick` can be displayed with `<!--VARIABLE TimeTick -->`

Or you can display the time in seconds with the equation: `<!--VARIABLE TimeTick/TICKS_PER_SECOND -->`

The VARIABLE tag is processed during the compilation of the application by parsing the text between "`<!--VARIABLE`" and the trailing "`-->`", then the NetBurner tools automatically convert it into a function call with a signature that contains a file descriptor and variable. For example, `WriteHtmlVariable(fd, TimeTick/TICKS_PER_SECOND);`

The following parameter types are available and defined in `\nburn\include\htmlfiles.h`:

```
void WriteHtmlVariable(int fd, char c);
void WriteHtmlVariable(int fd, int i);
void WriteHtmlVariable(int fd, short i);
void WriteHtmlVariable(int fd, long i);
void WriteHtmlVariable(int fd, uint8_t b);
void WriteHtmlVariable(int fd, uint16_t w);
void WriteHtmlVariable(int fd, unsigned long dw);
void WriteHtmlVariable(int fd, const char *);
void WriteHtmlVariable(int fd, MACADDR ip);
```

10.7.3.4 The INCLUDE Tag and htmlvar.h Header File

The functions that are created from the VARIABLE tags are located in an auto-generated file named `htmldata.cpp`. Since these functions reference the variable names, there must be a way for the linker to resolve them. For example, to display `TimeTick` the application would need to include `<nbrtos.h>`, otherwise a linker error will occur.

Include files for the HTML code/files to enable linking can be handled two ways:

1. An include HTML tag, `<INCLUDE headername.h>` in the HTML code
2. Create a header file in the project with the name "htmlvar.h". The tools will automatically look for a file of this name if `<INCLUDE>` tags are not detected in the HTML source files.

Example of a HTML file using the INCLUDE tag with a user defined header file name:

```
<html>
<body>
<!--INCLUDE myIncludeFile.h -->
Value = <!--VARIABLE MyVar --><br>
</body>
</html>
```

Example of `htmlvar.h` header file that exposes two variables, the `<nbrtos.h>` header file, and a function that takes an integer parameter:

```
#ifndef HTMLVARS_H_
#define HTMLVARS_H_

#include <nbrtos.h> // For access to TimeTick

extern int gIntVal;
extern char gStrVal[];

const char *FooWithParameters(int fd, int v);

#endif /*HTMLVARS_H_*/
```

10.7.3.5 The VARIABLE() Tag With Parameters

If you need to specify a function callback but need to pass a parameter, the CPPCALL tag will not work because the function signature parameters are fixed as the socket file descriptor and URL. In this case we can use the VARIABLE tag to achieve the functionality of calling a function with a variable.

The include file (e.g. htmlvar.h) must specify the function definition in the format below. In this case we are passing an integer value 'v'. The first parameter must always be the socket file descriptor: `const char * myIntFunction(int fd, int v);`

The HTML source code then uses the VARIABLE tag with the function definition. In this example we are passing the integer value of TimeTick. `<!--VARIABLE MyIntFunction(fd, TimeTick) -->`

When the application is compiled, the function definition will be created as: `WriteHtmlVariable(fd, MyIntFunction(fd, TimeTick));`

This function returns an empty string, which will have no effect on the web page. An example of what a function might do is shown below:

```
const char *FooWithParameters(int fd, int v)
{
    fdprintf(fd, "This function was called with parameter v = %d\r\n", v);
    return "\0"; // Return a const char * here of zero length so it will
                // not print anything
}
```

10.7.3.6 Extending the VARIABLE Tag

The VARIABLE functionality can be extended to support user defined types, such as displaying a user defined structure or class. Let's say you have a structure you want to display on a web page called myStruct:

```
struct my_struct {
    int i;
    char buf[80];
    uint32_t dVal;
} MY_STRUCT;

MY_STRUCT myStruct;
```

In your include file add the function definition: `void WriteHtmlVariable(int fd, MY_STRUCT myStruct);`

Now you can display it on the web page with the VARIABLE tag: `<!--VARIABLE myStruct -->`

Which will compile to: `WriteHtmlVariable(fd, myStruct);`

Note that you still have to write the implementation of the above function. The function below is the source code for the MAC address type already defined by the system:

```
void WriteHtmlVariable(int fd, MACADR ma)
{
    PBYTE lpb = ( PBYTE ) &ma;
    for (int I = 0; I < 5; i++)
    {
        fd_writehex( fd, lpb[i] );
        write(fd, ":", 1);
    }
    fd_writehex( fd, lpb[6] );
}
```

10.7.3.7 The CONFIGVALUE Tag

10.7.4 HTTP GET Request Handler

When you click on a link or enter an address in the URL field of a web browser, it sends a GET request to the web server. At its most basic level a GET request is the word "GET" and the requested file name. A GET handler is a mechanism by which an application can take control of the GET request instead of it being handled by the

normal web server processing. For example, if an application implemented a GET handler for a HTML page named "showstatus.html", the GET handler could create whatever type of status output it wanted instead of the web server delivering a file named "showstatus.html".

A GET handler is also useful for URL encoding. Two common methods for delivering data from a client (eg. web browser) to a web server are URL encoding and HTML forms using a POST submission. URL encoding involves sending data to the web server by adding it to the end of the URL. For example, an e-commerce application might store product information such as: `http://www.store.com/orderform?type=order123`. The data sent to the web server to be processed "type=order123" in the URL. Everything following the "?" character is ignored by the browser, so your application can store information there. Another advantage of this method is that the application can be stateful, meaning multiple users can access the same application and each user's session is maintained by the data encoding in the URL.

When a web browser requests something from a web server, such as an HTML page or image, it makes a GET request. The web server normally handles static web pages and dynamic web pages with the CPPCALL and VARIABLE tags, but your application can intercept the request and take control of the processing using a callback function object called `CallbackFunctionPageHandler`. When you declare the instance of the object you specify the name of the request to intercept and a pointer to the function in your application to process the request. For example, to take control of processing for a HTML page named setcookie.html:

To create a HTTP GET handler:

1. Create an application callback function to process the GET request
2. Create a `CallbackFunctionPageHandler` declaration to specify the URL mask, application callback function, and additional configuration parameters

A GET handler consists of a callback function to handle the actual processing, and a page handler declaration specify the conditions in which the callback function should be executed. The callback function sends an HTML header to identify the content, in this case it is HTML, determines if the system seconds timer is odd or even, then sends the appropriate HTML file as a response. Note that OddEven.html does not exist as a file. The GET request for OddEven.html is intercepted by the callback.

The callback has the function signature: `'int callbackGetOddEven(int sock, HTTP_Request &pHttpRequest)'`

The page handler declaration has the signature:

```
CallbackFunctionPageHandler(const char *pUrl,
                            http_gethandlerfunc *pFunction,
                            HTTP_RequestTypes reqType = tGet,
                            int accessGroup = 0,
                            bool beforeFiles = false)

/*-----
 * Callback to intercept a GET request for URL OddEven.html. The purpose of this callback
 * example is to demonstrate how to add custom processing and send an existing HTML file.
 * The URL OddEven.html does not exist as a file. If the page is requested by a browser,
 * this callback function is executed, which does some processing and decides which web
 * page file to send to the browser based on the current system seconds timer value.
 *
 * - Sends a HTML header to the browser to specify the content that follows is HTML
 * - Reads the system seconds timer, and sends the file odd.html or even.html
 * - A return value of 1 tells the system the HTML request was handled by the callback
 *
 * Notes:
 * - HTTP_Request is a structure containing detailed information of the request
 *-----*/
int callbackGetOddEven(int sock, HTTP_Request &pHttpRequest)
{
    // Send the web page header telling the browser we are sending HTML content
    SendHTMLHeader(sock);

    //----- Add custom processing here -----
    // Display message to serial terminal showing requested URL
    iprintf("Executing GET request callback function: callbackGetOddEven\r\n");
    iprintf("Request URL: %s, from: %I\r\n", pHttpRequest.pURL, pHttpRequest.client_IPAddr);

    if ( (Secs % 2) == 0)
        SendFileFragment("even.html", sock);
    else
        SendFileFragment("odd.html", sock);

    // Notify system we handled the GET request
    return 1;
}
```

```

}

/*
 * Declare the callback function. Parameters:
 *   OddEven.html      URL to intercept
 *   callbackGetOddEven Pointer to the callback function
 *   tGet              HTTP Request Type (ref HTTP_RequestTypes)
 *   0                 User Access Group, 0 = no password
 *   true              When to call (beforeFiles parameter):
 *                     true: Always called for the specified URL
 *                     false: Only called if the if the requested URL cannot be satisfied elsewhere
 */
CallbackFunctionPageHandler getHandlerOddEven("OddEven.html", callbackGetOddEven, tGet, 0, true);

```

A key component is the `CallbackFunctionPageHandler` declaration. Lets look at each parameter:

pURL: is the URL name to match. In this case it is fully defined as "OddEven.html", but wildcards can also be used. Although not very useful in this case, it could have been "Odd*", which would result in the callback being executed for anything beginning with "Odd".

pFunction: is a pointer to the function callback.

tGet: is the request type, in this case it is a GET, which has a request type of tGet.

accessGroup: is used for security/password access. Not the subject of this example, so a 0 for no access restriction is used.

beforeFiles: refers to the html content in the html folder of the project. If true, the callback will be executed without the web server first checking to see if a file by that name exists. If false, if a file by the pURL name is found, it will be sent to the client first.

10.7.5 HTTP Form POST Handler

You have probably encountered forms many times on the web, such as e-commerce and feedback forms. The format is typically some number of text fields, check boxes, radio buttons, combo boxes and a submit button. When you click on the submit button, the data from the form is sent to the web server as a HTTP POST. The web server then parses the data and takes appropriate action.

A form is declared in HTML by the `<form>` tag. User input is controlled by various `<input>` tags. For example, the web page below creates a form with a text field. NetBurner tags such as CPPCALL, VARIABLE and CONFIG tags can be used to populate input fields with their current value.

To create a HTTP POST form handler:

1. Create a HTML web page with a form
2. Create a corresponding application callback function to process the posted data
3. Create a `HtmlPostVariableListCallback` declaration to specify the matching callback mask and attach the application callback function

The example below creates a HTML page with four input fields, and a POST handler callback function to process them.

Figure 10.5 HTML form with four variables

HTML Code:

```
<html>
<title>HTML Post Example</title>
<body>
  
  <h1><font face=arial>HTML Form Post Example, Second Form</font></h1>
  <br>

  <form action="form2" method=post>
    Enter data to post var0: <input type="text" name="Var0" value="Var0"><br><br>
    Enter data to post var1: <input type="text" name="Var1" value="Var1"><br><br>
    Enter data to post var2: <input type="text" name="Var2" value="Var2"><br><br>
    Enter data to post var3: <input type="text" name="Var3" value="Var3"><br><br>

    <br><input type="submit" value="Submit"><br>
  </form>
</body>
</html>
```

Corresponding Application Source Code:

```
/*
 * Callback function for Form2. This function will be called once for each variable
 * in the form.
 */
void form2PostCallBack(int sock, PostEvents event, const char * pName, const char * pValue)
{
  // Received a call back with an event, check for event type
  switch (event)
  {
    // Called at the beginning of the post before any data is sent
    case eStartingPost:
      for (int i = 0; i < numVars; i++)
        strVar[i][0] = '\0';
      form2ParseError = false;
      break;

    // Called once for each variable in the form
    case eVariable:
      if (strcmp("Var0", pName) == 0)
      {
        strncpy(strVar[0], pValue, varLen - 1);
        fprintf("strVar0 set to: \"%s\"\r\n", strVar[0]);
      }
      else if (strcmp("Var1", pName) == 0)
```

```

    {
        strncpy(strVar[1], pValue, varLen - 1);
        fprintf("strVar1 set to: \"%s\"\r\n", strVar[1]);
    }
    else if (strcmp("Var2", pName) == 0)
    {
        strncpy(strVar[2], pValue, varLen - 1);
        fprintf("strVar2 set to: \"%s\"\r\n", strVar[2]);
    }
    else if (strcmp("Var3", pName) == 0)
    {
        strncpy(strVar[3], pValue, varLen - 1);
        fprintf("strVar3 set to: \"%s\"\r\n", strVar[3]);
    }
    else
    {
        fprintf("*** Error: Form variable name not found\r\n");
        form2ParseError = true;
    }

    break;

//Called back with a file handle if the post had a file
case eFile:
    break; //No file type here so we do nothing

// Called back when the post is complete. You should send your response here.
case eEndOfPost:
    {
        fprintf("Variable Summary:\r\n");
        for (int i = 0; i < numVars; i++)
            fprintf(" Var%d = \"%s\" \r\n", i, strVar[i]);

        if (form2ParseError)
            fprintf("*** Error: Form variable name not found\r\n");

        RedirectResponse(sock, "complete.html");
    }
    break;
} //switch
}

// Create a global static post handling object that responds to the specified html page.
// A separate post handler can be created for each form in your application.
HtmlPostVariableListCallback postForm2("form2*", form2PostCallBack);

```

When a post is submitted the callback post handler will be executed a number times for the following events:

Event	Description
eStartingPost	Occurs once at the first event of a post
eVariable	Occurs once for each variable in the form
eFile	Occurs if a file is being posted
eEndOfPost	Occurs once at the end of post processing

In this example the following events will occur:

- eStartingPost is called first and enables the application to initialize the array.
- eVariable is called once for each variable (input field). In this example it will be called 4 times. The callback function must parse for the input field name on each call.
- eFile is called. Since we are not posting a file no action is taken.
- eEndOfPost is called last. In this example it is used to print a summary of the input field values

The [HtmlPostVariableListCallback](#) declaration is used to specify the URL name and mask, as well as a pointer to the post handler callback. Full URL names can be specified with and multiple callback functions, or a wildcard can be used and the post handler callback must parse the URL information to determine the correct action.

10.8 Interrupt Handling

10.8.1 Overview

An interrupt is a hardware or software request to interrupt the currently executing code and jump to a routine/code to process the event. After the interrupt processing is complete, the execution of non-interrupt code will resume. The code that processes an interrupt is commonly called an Interrupt Service Routine (ISR) or Interrupt Handler. Although it varies by platform, NetBurner devices commonly handle interrupts from sources such as timers, serial port, Ethernet ports, external hardware inputs, and software traps.

As mentioned, interrupt handling varies by processor hardware. In some cases, such as ColdFire, NetBurner provides macros to make the more involved ISR entry and exit much easier. ARM platforms tend to be much simpler, requiring only the Interrupt Service Routine function.

10.8.2 Recommended Interrupt Functions

The three recommended interrupt functions that work on all NetBurner platforms are listed below. There are also lower level functions for situations that require fine tuning. The [PinIO](#) object was created to make the configuration of a processor pin easier than having to configure all the required processor registers.

Configure a pin to handle an external interrupt by specifying the pin number as a [PinIO](#) object, the polarity (high/low), and the Interrupt Service Routine that will be called to process the interrupt:

```
bool SetPinIrq( PinIO pin, int polarity, PinIrq_t func);
```

Enable the interrupt:

```
void EnableIrq( PinIO pin );
```

Disable the interrupt:

```
void DisableIrq( PinIO pin );
```

10.8.3 Functions That Cannot Be Called in an ISR

Warning

The code within an ISR can be called at any time, therefore certain RTOS and I/O functions cannot be called from within the ISR.

10.8.3.1 All nbrtos init and pend functions (all OsxxPendNoWait functions are okay):

- OSxxPend
- OSCritEnter
- OSChangePrio
- OSTaskDelete
- OSLock
- OSUnlock
- OSTaskCreate
- OSTimeDly

10.8.3.2 I/O functions:

- write
- writeall
- read
- printf
- fprintf
- fdprintf
- iprintf
- scanf
- gets
- puts

10.8.3.3 Memory management functions:

- malloc
- free
- new
- delete

10.8.4 MODM7AE70 and SBE70LC Platforms (SAME70)

Any GPIO pin on the SAME70 processor can be used as an interrupt source. Pin IRQs are inputs on General Purpose I/O (GPIO) ports. The Cortex M7 architecture is structured in a way that all pins on the same port share the same GPIO priority. In other words, there is one IRQ per port.

10.8.4.1 Configure the interrupt request (IRQ) priority for a PIO pin

Configure a port priority by specifying a [PinIO](#) object.

10.8.4.1.1 Synopsis

```
bool SetPortIrqPriority( PinIO pin, int priority);
```

10.8.4.1.2 Description

The PIO controller on the SAME70 configures the IRQ priority by PIO ports. **Therefore, configuring the priority of an IRQ for a specific pin will change the IRQ priority for the entire PIO port.** SetPinIrq() will set the pin IRQ with the priority that is configured with SetPortIrqPriority(). Therefore, SetPortIrqPriority() should be called before SetPinIrq().

Name	Description
pin	A PinIO object that is to be configured as an IRQ Pin.
priority	Priority of the interrupt. A priority value of 1 being the highest priority IRQ, and 7 being the lowest.

Returns true if successfully if the PIO port's IRQ priority was successfully configured, otherwise false.

10.8.4.2 Configure the interrupt request (IRQ) priority for a PIO port

Configure a port priority by specifying a port number.

10.8.4.2.1 Synopsis

```
bool SetPortIrqPriority( int portNum, int priority);
```

10.8.4.2.2 Description

The PIO controller on the SAME70 configures the IRQ priority by PIO ports. Therefore, configuring the priority of an IRQ for a specific pin will change the IRQ priority for the entire PIO port. SetPinIrq() will set the pin IRQ with the priority that is configured with SetPortIrqPriority(). Therefore, SetPortIrqPriority() should be called before SetPinIrq().

Name	Description
portNum	PIO port number. Where PIOA = 0, and PIOE = 4.
priority	Priority of the interrupt. A priority value of 1 being the highest priority IRQ, and 7 being the lowest.

Returns true if successfully if the PIO port's IRQ priority was successfully configured, otherwise false.

10.8.4.3 Set up an interrupt request (IRQ) pin

10.8.4.3.1 Synopsis

```
bool SetPinIrq( PinIO pin, int polarity, PinIrq_t func);
```

10.8.4.3.2 Description

Set up a [PinIO](#) object pin with polarity and pointer to an ISR function.

Name	Description
pin	A PinIO object that is to be configured as an IRQ Pin.
polarity	Polarity and edge vs. level sensitivity configuration. 2: high level sensitive 1: positive edge sensitive 0: (either) edge sensitive -1: negative edge sensitive -2: low level sensitive
func	A function pointer of type PinIrq_t to register as the service handler (ISR) for the given PinIO .

Returns true if [PinIO](#) was successfully registered for IRQs, otherwise false.

10.8.4.4 Enable the interrupt for the given PinIO

10.8.4.4.1 Synopsis

```
void EnableIrq( PinIO pin );
```

10.8.4.4.2 Description

Enable the interrupt for the given [PinIO](#)

Name	Description
pin	The PinIO object to enable interrupts for.

10.8.4.5 Disable the interrupt for the given PinIO

10.8.4.5.1 Synopsis

```
void DisableIrq( PinIO pin );
```

10.8.4.5.2 Description

Disable the interrupt for the given [PinIO](#)

Name	Description
pin	The PinIO object to disable interrupts for.

10.8.5 MOD54415, MOD54417, NANO54415 and SB800EX Platforms (MCF5441x)

The MCF5441x processor requires more setup and configuration than ARM platforms. To simplify implementation, the NetBurner platform implements the following functions:

- An INTERRUPT() Macro to provide the Interrupt Service Routine entry and exit.
- The SetIntC() function to configure the Interrupt Controller hardware.

Each are described in the following sections.

10.8.5.1 INTERRUPT() Macro

MCF5441x platforms use the INTERRUPT() macro as described below, which handles the ISR entry and exit coding. The header file to include is [cfinter.h](#), located in: "\nburn\arch\coldfire\include\cfinter.h". ColdFire interrupts have values from 1 to 7, with 7 being the highest priority.

Note

Once you use the INTERRUPT macro to define the interrupt function, you will need to use the SetIntc(), set interrupt controller function, to set up your interrupt controller variables to point the processor's interrupt vector at that function. Please refer to the appropriate NXP hardware reference manual, located in "\nburn\docs\nxp" for your specific interrupt source number and controller number (some ColdFire's have more than one interrupt controller).

10.8.5.1.1 Header Files

```
#include <nbrtos.h>
#include <cfinter.h>
```

10.8.5.1.2 Synopsis

```
INTERRUPT( FunctionName, sr_value )
```

10.8.5.1.3 Description

The INTERRUPT macro sets up an interrupt function and the code block to save and restore the CPU registers. In addition, this macro tells the RTOS that an interrupt is occurring.

Note

Level 7 interrupts are unmaskable, which means they will interrupt any other processing, including the level 7 ISR itself. Therefore, any level 7 ISR used in an application must ensure it can complete its processing before another level 7 interrupt occurs.

10.8.5.1.4 Parameters

Name	Description
FunctionName	The name of the Interrupt Service Routine, to be used with the SetIntC() function. This is the name of a C/C++ function in an application created to process the interrupt.
SR_Value	The ColdFire Status Register (SR) value that the processor will have during the interrupt. This is used as a mask to specify which, if any higher priority interrupts can interrupt the ISR. The mask bits define the current interrupt level. Interrupt requests are inhibited for all priority levels less than or equal to current level, except edge-sensitive level 7 requests, which cannot be masked. For example, if a level 5 interrupt is currently executing, specifying a value of 0x2500 will allow a IRQ level 6 or higher to interrupt.

10.8.5.1.5 Status Register Values

The status register is 32-bits. The mask bits are 24-26 and range from 000 to 111. The eight permitted SR register values are shown below. Bit 29 is the supervisor bit, which should always be set.

- 0x2000 - Allows all interrupts
- 0x2100 - Blocks all interrupts below level 2
- 0x2200 - Blocks all interrupts below level 3
- 0x2300 - Blocks all interrupts below level 4
- 0x2400 - Blocks all interrupts below level 5
- 0x2500 - Blocks all interrupts below level 6
- 0x2600 - Blocks all interrupts below level 7
- 0x2700 - Blocks all interrupts below level 7

10.8.5.2 SetIntC() function (Set Interrupt Controller)

MOD54415, MOD54417, NANO54415 and SB800EX SetIntC() functions are located in Hardware Abstraction Layer (HAL) cpp file for the particular platform. For example, for the MOD5441x it is located in "\nburn\platform\MOD5441x\hal.cpp". The SetIntC() function must be declared as an extern in your application .cpp file, it is not available in a header file. For example:

```
void SetIntC(int intcnum, long func, int vector, int level)
```

Parameters:

Name	Description
intcnum	Interrupt Controller Number. For MCF5441x processors there are two: 0 and 1.
func	Pointer to ISR function name.
vector	Interrupt Vector Number. There are 256 exception vectors; the first 64 are defined for the core and the remaining 192 are device-specific peripheral interrupt vectors. See Chapter 17, "Interrupt Controller Modules (INTC)" for details on the device-specific interrupt sources, and table 17.2.9.1 Interrupt Sources. For example, the UART 0 vector number is 26, and the PIT2 timer is 15.

Name	Description
level	Interrupt level. Range is from 0 (disabled) to 7, with 7 being the highest level/priority. For example, a level 6 interrupt request can interrupt a level 1 Interrupt Service Routine.

10.8.5.3 Example, OneWire Interrupt Configuration

```
extern void SetIntc(int intc, long func, int vector, int level);

// Interrupt Service Routine
void OWMasterIsr()
{
    // ISR code...
}

// INTERRUPT macro to set vector ISR function and mask to level 6
INTERRUPT( ow_master_int_routine, 0x2600 )
{
    OWMasterIsr();
}

// Initialization call to use in UserMain() of application. The purpose of this example is only
// to demonstrate the use of SetIntC().
void OWInit()
{
    // Initialize 1-Wire module registers (MCF5441x Reference Manual Chapter 36.3: 1-Wire Memory
    // Map/Register Definitions)
    siml.ow.cr = 0;
    siml.ow.div = 0x7C; // Divides the peripheral bus clock to run at 1 MHz
    siml.ow.cmd = 0;
    siml.ow.ier = OW_IER_ERBF;

    // 63 is the interrupt source number for the 1-Wire module, and we're using IRQ level 3
    SetIntc(0, ( long ) &ow_master_int_routine, 63, 3 /* IRQ 3 */);

    ow_struct.state = OK;
}
```

10.8.6 SOMRT1061 Platform

10.9 JSON Lexer

10.9.1 Using the JSON Lexer Interface

Note

This application note applies to NNDK tools version 3.3.9 and later. The many additional features added will not build in earlier tools versions.

The Json Lexer interface is in [json_lexer.h](#). The two object types that are of interest are:

1. [ParsedJsonDataSet](#): represents a complete JSON object parsed and stored internally.
2. [JsonRef](#): represents a positional reference of location inside a [ParsedJsonDataSet](#). It can be used as a pointer to a variable or sub object inside a [ParsedJsonDataSet](#) object to make decoding the hierarchy much simpler and easier to understand. A [JsonRef](#) is not limited to just pointing at internal objects; it can point to any JSON parsed token/type.

The [ParsedJsonDataSet](#) has two decoding interfaces. The previous interface prior to 3.3.9 should be considered deprecated. If you have used this class in the past this code will still work, but we have added a new much clearer

easier to understand interface based on the [JsonRef](#) object and the associated overloaded operators. This interface should be used for all decoding going forward.

Before we can practice decoding JSON, we need to get the JSON content into a [ParsedJsonDataSet](#) object. There are multiple methods to accomplish this:

1. Load from a text blob as demonstrated in the example: `\nburn\examples\JsonLexer\ParseTest`. Calling the function `ParsedJsonDataSet pjd((const char *)jdata, jlen, true);` will construct an object from plain text.
2. Load from an external web page as demonstrated in the examples:
 - `\nburn\examples\JSON\GetJsonFromServer`
 - `\nburn\examples\JSON\PostAndGetJsonExternalServer`
 - `\nburn\examples\WebClient\EarthQuake`
1. Load from some type of external interface, web socket, serial port, etc.
 - `ParsedJsonDataSet pjds; // declare the object`
 - `pjds.ReadFrom(int fd); // read the content from a file descriptor`

Once you have a complete [ParsedJsonDataSet](#), you can operate on it and decode the JSON content.

For example, we have a simple JSON structure:

```
{ "Anumber": 1234,
  "AString": "ImaString",
  "AnObject": {"Item1": 1,
               "Item2": "TheItem2"
             },
  "AnArray" : [1,2,3,4]
}
```

Using one of the three methods listed above will convert the JSON content into a [ParsedJsonDataSet](#) object named `pjds`. Internally, the [ParsedJsonDataSet](#) tokenizes the JSON it is loaded with and stores the results in minimized form in NetBurner poolBuffers. None of these internals really matter to the user.

To extract values from the parsed data set:

```
int i = pjds("Anumber"); // Read an integer

// Strings can be accessed as a NBString object or const char *.
// The const char * is only valid until the dataset is destroyed or cleaned up.
NBString s = pjds("AString");
const char * pStr = pjs("AString");

// JsonRef can be used as a pointer to reference interior variables and objects
// in the data set and access them in the same manor.
JsonRef jr = pjds("AnObject");
int i1 = jr("Item1");
NBString s2 = jr("Item2");

// Arrays can be indexed using the array operator
for(int i = 0; i < 4; i++)
    printf("Item[%d] = %d\n", i, pjds("AnArray")[i]);
```

In general, you can use ("name") to find an element and [i] to index in an array. You can then assign the result to the desired object or variable.

[ParsedJsonDataSet](#) types:

```
operator bool () const {return PermissiveCurrentBool(); };
operator float () const {return (float)CurrentNumber(); };
operator double () const {return CurrentNumber(); };
operator uint8_t () const {return (uint8_t)CurrentNumber(); };
operator int () const {return (int)CurrentNumber(); };
operator uint16_t () const {return (uint16_t)CurrentNumber(); };
operator uint32_t () const {return (uint32_t)CurrentNumber(); };
operator int8_t () const {return (int8_t)CurrentNumber(); };
operator int16_t () const {return (int16_t)CurrentNumber(); };
operator int32_t () const {return (uint32_t)CurrentNumber(); };
operator time_t () const {return (time_t)CurrentNumber(); };
operator const char * () const {return CurrentString(); };
operator NBString () const {return (NBString)CurrentString(); };
```

There are corresponding check functions as well in the form of: `bool IsValid();` to determine if the dereferenced [ParsedJsonDataSet](#) element or [JsonRef](#) point to something valid.

Continuing from the example above:

```
pjds("AnArray")[3].IsValid(); // returns true, a valid decode
pjs("AnArray")[4].IsValid(); // returns false as there are only array elements 0 - 3
```

Additional Check Functions:

```

IsNumber ()
IsObject ()
IsString ()
IsBool ()
IsNull ()
IsArray ()

```

These functions are demonstrated very well in: `\nburn\examples\JsonLexer\ParseTest`. The example `\nburn\examples\webclient\Earthquake` uses these functions to extract various fields from inside a very large complicated JSON blob and is an interesting example to see the simplification these methods provide.

10.9.2 Earthquake Example

Note

If you wish to use any of this code, do not copy from this document. Get the latest code from the example source: `\nburn\examples\webclient\Earthquake`

10.9.2.1 Source Code

```

/*NB_REVISION*/

/*NB_COPYRIGHT*/
#include <init.h>
#include <stdio.h>
#include <ctype.h>
#include <buffers.h>
#include <json_lexer.h>
#include <webclient/http_funcs.h>
#include <nptime.h> // Include for NTP functions

const char *url = "https://earthquake.usgs.gov/earthquakes/feed/v1.0/summary/4.5_day.geojson";

const char *AppName = "EarthQuake";

void UserMain(void *pd)
{
    init(); // Initialize network stack
    // Enable system diagnostics. Probably should remove for production code.
    EnableSystemDiagnostics();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5); // Wait for DHCP address

    iprintf("Application started\n");

    bool bTimeSet = SetTimeNTPFromPool();

    if(bTimeSet)
    {
        printf("Time Set\r\n");
    }

    ParsedJsonDataSet JsonResult;
    bool result = DoGet(url, JsonResult);

    if (result)
    {
        // JsonResult.PrintObject(true);
        int32_t nQuakes = JsonResult("metadata")("count");
        printf("In the last Day we have had %ld Earthquakes > 4.5\r\n", nQuakes);

        for (int i = 0; i < nQuakes; i++)
        {
            // A JsonRef is a pointer into a ParsedJsonDataSet object variable or object to simplify access.
            // The following code creates a pointer into the event array to capture the properties object.
            JsonRef OneQuakeProperties = JsonResult("features")[i]("properties");
            if (OneQuakeProperties.Valid())
            {
                double magnitude = OneQuakeProperties("mag");
                NBString place_name = OneQuakeProperties("place");
                printf("Magnitude :%2.1f at %s", magnitude, place_name.c_str());

                if (bTimeSet)
                {
                    time_t when = OneQuakeProperties("time");
                    when /= 1000;
                    time_t now = time(NULL);
                    time_t delta = (now - when);
                    int sec = delta % 60;
                    int mins = (delta / 60) % 60;
                    int hour = (delta / 3600);
                    printf(" %02d:%02d:%02d ago", hour, mins, sec);
                }
            }
        }
    }
}

```

```

        printf("\r\n");
    } //Array object look up is valid
    else
    {
        printf("Parse error failed to find array element %d\r\n", i);
    }

    } // for
} // valid result
else
{
    iprintf("Failed to contact server\r\n");
}

while (1)
{
    OSTimeDly(TICKS_PER_SECOND * 1);
}
}

```

10.9.2.2 Earthquake Summary Serial Output

This is the summary output from the example:

In the last Day we have had 17 Earthquakes > 4.5 Magnitude :4.5 at Fiji region 01:44:12 ago Magnitude :4.6 at 128 km W of San Juan, Peru 10:06:35 ago Magnitude :4.5 at 7 km NW of Papayal, Peru 10:32:50 ago Magnitude :4.9 at 56 km SSE of Sand Point, Alaska 10:47:22 ago Magnitude :4.9 at 22 km SSE of Padong, Philippines 11:05:28 ago Magnitude :5.1 at 70 km WNW of San Antonio de los Cobres, Argentina 12:25:58 ago Magnitude :5.3 at 116 km SSE of Kushiro, Japan 13:12:09 ago Magnitude :4.6 at 112 km SSE of Kushiro, Japan 13:13:00 ago Magnitude :4.8 at 129 km WNW of Pangai, Tonga 13:49:43 ago Magnitude :4.9 at 256 km ESE of Ust'-Kamchatsk Staryy, Russia 20:15:25 ago Magnitude :4.6 at 120 km NNE of Tobelo, Indonesia 20:23:53 ago Magnitude :4.9 at 57 km ESE of Koseda, Japan 21:28:56 ago Magnitude :4.8 at 24 km NE of La Paz, Philippines 22:38:44 ago Magnitude :4.5 at northern Qinghai, China 23:10:02 ago Magnitude :4.6 at 8 km S of Padong, Philippines 23:13:24 ago Magnitude :4.5 at Fiji region 23:19:04 ago Magnitude :5.1 at 108 km SSE of Hihifo, Tonga 23:39:10 ago

10.9.2.3 JSON Data Parsed From Web Site

The raw JSON content is shown below. This is a good example of how a very complex JSON blob can be easily parsed with the [ParsedJsonDataSet](#) object. To view this data when running the example, uncomment the line: `// JsonResult.PrintObject(true);` in the source code.

10.10 NetBurner RTOS

The NetBurner Real-Time Operating System (NBRTOS) a full featured preemptive multitasking real-time operating system, supporting multiple tasks, semaphores, mail boxes, FIFOs, queues, and critical sections just to name a few. As part of the NetBurner development package, the RTOS is pre-configured and running. The task you will normally start with is named `UserMain()`.

There are 255 priority levels (1 through 255). The lower the number, the higher the priority. Some of these tasks are reserved by the system, such as the idle task. You can specify a priority when the task is created, and change the priority later if you wish. A priority level can only be used by one task at a time. Be sure to check the return values when creating a task or changing a task priority to verify that the operation was successful.

10.10.1 What is a Preemptive RTOS?

10.10.2 Preemptive Operation, Priorities and Blocking

In a preemptive operating system the highest priority task ready to run will always run. This is an extremely important point, so we will mention it again: the highest priority task ready to run will always run. This is different than a Windows or Unix system that employs a round-robin in which each task will run based on its time slice. If you create a high priority task that can always run and never blocks, then no lower priority tasks will ever run. Lower priority tasks can only run when a higher priority task blocks on a resource or blocking function call.

For example, there are two tasks A and B. Task A has priority 50 and Task B has priority 51. Since Task A is of higher priority, it will always run (and Task B will never run) unless it calls a blocking function. Task B will then run for as long as Task A blocks; this could be 1 second due to a call to `OSTimeDly(TICKS_PER_SECOND)`, until a shared resource is available due to a call to `OSSemPend()`, or until data is available from a network connection due to a `select()` or `read()`. If both tasks are in a blocking state, then the RTOS idle task will run.

10.10.2.1 RTOS Blocking Functions

Generally any function that pends on a resource or creates a time delay:

- `OSTimeDly()`
- `OSSemPend()`
- `OSMboxPend()`
- `OSQPend()`
- `OSFlagPendAny()`
- `OSFlagPendAll()`

10.10.2.2 I/O Functions That Can Block

Generally any function that does a read operation or pends on a file descriptor

- `select()`
- `read()`, including variants with timeouts
- `write()`, blocks until at least one char can be written
- `gets()`
- `getchar()`
- `fgets()`

10.10.2.3 Network Functions That Can Block

Generally calls that will pend on an incoming connection or received data

- `accept()`
- Creation of a `UDPPacket` packet object when initialized to receive data

10.10.2.4 Functions That Can Enable a Task To Be "Ready To Run"

Generally functions that post to pending objects

- `OSMboxPost()`
- `OSQPost()`
- `OSSemPost()`

10.10.2.5 System Task Priorities

The number and type of system tasks and priorities used by the system will depend on your platform and the system features used by your application. For example, if your application calls `StartHTTP()` to enable web services, then a system task will be created that handles web server requests. The system task priority levels are defined in `\nburn\nbrtos\include\constants.h`.

10.10.3 Task Creation

Whether you use the Application Wizard in NBEclipse to create a new application, or start with one of the example programs, you will notice that the point at which your application takes control is a function named `UserMain()`. `UserMain()` is a task created by the system. The first few lines will consist of system initialization functions such as `init()` and `StartHttp()`.

Additional tasks are created with the `OSTaskCreatewName()` or `OSSimpleTaskCreatewName()` functions. The following is an example program that demonstrates the use of each function. When using `OSTaskCreatewName()` you specify all parameters:

- Task function name
- Optional parameter to pass to the task, NULL if not used
- Top of the task stack
- Bottom of the task stack
- Task priority
- Task name

A significant benefit of the full function call is that it returns the status of the task creation process. For example, one possible error is that you cannot create a second task at the same priority as any other task.

The `OSSimpleTaskCreatewName()` implementation lets you specify just the task function, priority, and name.

```

/*
 * This example demonstrates how to use two of the task creation
 * functions:
 * - OSSimpleTaskCreatewName()
 * - OSTaskCreatewName()
 */
#include <init.h>
#include <stdlib.h>
#include <nbrtos.h>
#include <system.h>
#include <utils.h>

const char *AppName = "OSTaskCreate Example";

// Allocate stack space
uint32_t TaskAllParamsStack[USER_TASK_STK_SIZE];

/*-----
 * Task created with OSTaskCreatewName() using all function parameters.
 * The void *pd parameter can be cast to any type of data you wish to send to
 * the task, or NULL if not used.
 *-----*/
void TaskAllParams(void *pd)
{
    uint32_t loopCount = 0;
    uint32_t delayTime = (uint32_t)pd;

    iprintf("TaskAllParams delay time set to: %ld seconds\r\n", delayTime);

    while (1)
    {
        iprintf("TaskAllParams, %ld\r\n", loopCount);
        loopCount++;
        OSTimeDly(TICKS_PER_SECOND * delayTime);
    }
}

/*-----
 * Task created with OSSimpleTaskCreatewName(). The primary difference from the

```

```

* full version is that it allocates the task stack for you.
*-----*/
void TaskSimple(void *pd)
{
    uint32_t loopCount = 0;
    uint32_t delayTime = 6;

    iprintf("TaskSimple delay time set to: %ld seconds\r\n", delayTime);

    while (1)
    {
        iprintf("TaskSimple, %ld\r\n", loopCount);
        loopCount++;
        OSTimeDly(TICKS_PER_SECOND * delayTime);
    }
}

/*-----*/
* UserMain
*-----*/
void UserMain(void *pd)
{
    uint32_t delayTime = 3;
    int returnCode;

    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5); // Initialize network stack
                                                // Wait for DHCP address

    iprintf("Creating TaskAllParams...\n");
    returnCode = OSTaskCreateName( TaskAllParams, // Task function name
                                   (void *)delayTime, // Optional parameter to
                                   pass to the task function
                                   &TaskAllParamsStack[USER_TASK_STK_SIZE], // Top of stack
                                   TaskAllParamsStack, // Bottom of stack
                                   MAIN_PRIO - 1, // Task priority
                                   "TaskAllParams" ); // Task name

    if (returnCode == OS_NO_ERR)
        iprintf("Task creation successful\r\n");
    else
        iprintf("*** Error: status = %d\r\n", returnCode);

    iprintf("Creating TaskSimple\r\n");
    OSSimpleTaskCreateName(TaskSimple, MAIN_PRIO - 2, "TaskSimple");

    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND * 1);
    }
}

```

10.10.4 Protecting Shared Data

The following RTOS mechanisms can be used to protect shared data resources. They are listed in a decreasing order of severity as regarding system latency (all pend and post functions are at the same level).

<code>OSSemPend()</code> <code>OSSemPost()</code>	Protects an area of memory or resource. A task calls <code>OSSemPend</code> , which will block until the resource is available. <code>OSSemPost</code> releases the resource.
<code>OSMboxPend()</code> <code>OSMboxPost()</code>	Same as semaphore, except a pointer variable is passed as the "message". A task or ISR can post a message, but only a task can pend on a message. Both the posting task and pending task must agree on what the pointer points to.
<code>OSQPend()</code> <code>OSQPost()</code>	A Queue is basically an array of mailboxes. It is used to post one or more messages. When you initialize a Queue, you must specify the maximum number of messages. The first message posted to the queue will be the first message extracted from the queue (FIFO).

<pre>OSFifoPend() OSFifoPost() OSFifoPostFirst() OSFifoPendNoWait()</pre>	<p>A FIFO is similar to a queue, but is specifically designed to pass pointers to <code>OS_FIFO</code> structures. The first parameter of the structure must be a <code>(void *)</code> element, which is used by the operating system to create a linked list of FIFOs. When initializing a FIFO, you do not specify the maximum number of entries as with a queue. Instead, your application has the ability (and responsibility) to allocate memory (static or dynamic) in which to store the structures. This can be done statically by declaring global variables, or dynamically by allocating memory from the heap. As with a queue, the first message posted to the FIFO will be the first message extracted from the queue.</p>
<pre>OSCritEnter OSCritExit OSCritObj</pre>	<p>This is a counted critical section that restricts access to resources to one task at a time, sometimes called a “mutex”. For example, you have a linked list that is maintained by 3 separate tasks. If one task is manipulating the list, you could first call <code>OSCritEnter</code> for that object (the list). If any other task tries to manipulate the list, it will block at the <code>OSCritEnter</code> until the task that previously called <code>OSCritEnter</code>, calls <code>OSCritExit</code>. Note that the number of enter calls must match number of exit calls. <code>OSCritObj</code> is a C++ implementation that uses scoping to automatically call the enter and exit functions. See example below.</p>
<pre>OSLock() OSUnlock() OSLockObj</pre>	<p>Disables other tasks, but not interrupts. Increments for each <code>OSLock</code>, decrements for each <code>OSUnlock</code>. The C++ object <code>OSLockObj</code> was created to assist in making sure that an unlock is called for each lock. When an <code>OSLockObj</code> is created, the constructor calls <code>OSLock()</code>. When the object goes out of scope, <code>OSUnlock()</code> is automatically called by the destructor.</p>
<pre>USER_ENTER_CRITICAL() USER_EXIT_↔ CRITICAL()</pre>	<p>Macro that disables other tasks and interrupts. Increments count on enter, decrements on exit.</p>

How do you decide which type of mechanism to use? Some guidelines are:

- If you need some type of signal, but do not need to pass any data, use a Semaphore. A semaphore is a single 32-bit integer that increments and decrements for each pend or post.
- If you want to pass a single 32-bit number, you can use a Mailbox or Queue. Most applications use the 32-bit number as the data, but it could also be a pointer to a structure or object. A queue is like an array of mailboxes. You declare the number of queue entries a compile time.
- If you want to pass a structure or object, then use a FIFO. You may be wondering how a FIFO differs from a Queue. The difference is that a Queue has a predefined number of entries. The FIFO implementation uses a linked list, so the only limit to the number of entries is available memory. Using a FIFO is not as simple as any of the other mechanisms, because your application must implement some type of memory management to allocate and deallocate the FIFO objects. This is usually done by managing a predeclared array of objects, or through dynamic memory allocation. We encourage all embedded designers to avoid dynamic memory allocation if at all possible, since in any embedded system memory fragmentation could eventually occur and the call to allocate a new object could fail. If you create an array of objects at compile time you will always be guaranteed the maximum number can exist.

10.10.5 Semaphore

A semaphore is a protected variable that is used to control access to shared system resources (such as memory or serial ports), to signal the occurrence of events and task synchronization. A task can request a semaphore and wait until the resource or event takes place (called pending). A task can also post to a semaphore to indicate it no longer needs a resource, or to signal an event has taken place. To create a semaphore you declare one of type `OS_SEM` and initialize with `OSSemInit()`: `OS_SEM MySemaphore; OSSemInit(&MySemaphore, 0); // set initial value to 0`

Your application tasks can now use the post and pend functions on the semaphore: `OSSemPost(&MySemaphore); // post to a semaphore OSSemPend(&MySemaphore, 0); // pend on a semaphore`

The second parameter in the `OSSemPend()` function specifies the number of time ticks to wait. A value of 0 waits forever. A good way to express a wait value is to use the `TICKS_PER_SECOND` definition provided by the RTOS: `OSSemPend(&MySemaphore, TICKS_PER_SECOND * 5)` to wait 5 seconds.

10.10.6 Queues

A message queue is an object that enables tasks and interrupt service routines to pend and post pointer sized messages. The pointer values typically point to some type of object or structure that contains the actual message or data.

10.10.7 FIFO

A FIFO is similar to a queue, but is specifically designed to pass pointers to `OS_FIFO` structures. The first parameter of the structure must be a `(void *)` element, which is used by the operating system to create a linked list of FIFOs. When initializing a FIFO, you do not specify the maximum number of entries as with a queue. Instead, your application has the ability (and responsibility) to allocate memory (static or dynamic) in which to store the structures. This can be done statically by declaring global variables, or dynamically by allocating memory from the heap. As with a queue, the first message posted to the FIFO will be the first message extracted from the queue.

10.10.8 Critical Section

`OSCritEnter()`, `OSCritExit()` and an `OSCritObj` enable an application to use counted critical sections that restrict resource access to one task at a time (also called a “mutex”). For example, you have a linked list that is maintained by 3 separate tasks. If one task is manipulating the list, you call `OSCritEnter()` before modifying the list. If any other task tries to access the list, the task will block at the `OSCritEnter()` call until the task that previously called `OSCritEnter()`, calls `OSCritExit()`. Since this is a counting critical section implementation, the number of enter calls must match number of exit calls for each task.

`OSCritObj` is a C++ implementation that uses scoping to automatically call the enter and exit functions so you do not need to manually match each enter with an ext. In comparison with `OsLock()`, `OSCritEnter()` does not restrict task swapping unless two tasks want to access the same resource. `OsLock()` prevents all task swapping.

10.10.9 OS Flags

`OSFlags` enables a function or task to pend on multiple flags or events, in contrast to a `OSSemaphore` which can pend on only a single event. The `OSFlag` implementation is essentially a 32-bit bitmap in which each bit position represents a “flag”. You create a `OSFlag` object with `OSFlagCreate()`, then set, clean and read the flags with

the appropriate function. There are a number of functions used to monitor or pend on the flags, and provide the ability to pend on any one or more of the flags being set, or pending on all of flags being set at one time.

Flag Functions

- [OSFlagSet \(\)](#) Set the bits asserted with bits_to_set
- [OSFlagState \(\)](#) Return the current value of the flags
- [OSFlagClear \(\)](#) Clear the bits asserted in bits_to_clr
- [OSFlagPendAll \(\)](#) Wait until all of the flags indicated by mask are set
- [OSFlagPendNoWait \(\)](#) Check (but do not wait) if all of the flags indicated by the mask are set
- [OSFlagPendAny \(\)](#) Wait until any of the flags indicated by the bit mask are set
- [OSFlagPendAnyNoWait \(\)](#) Check (but do not wait) if any of the flags indicated by the mask are set

10.11 Network Protocols

This section describes the NetBurner TCP and UDP protocols.

Topic Links:

- [TCP vs UDP](#)
- [TCP Server](#)
- [TCP Client](#)
- [UDP Class](#)
- [UDP Sockets](#)

10.11.1 TCP vs UDP

A very common question that arises when designing a network application is whether to use TCP (Transmission Control Protocol) or UDP (User Datagram Protocol). There are a few guidelines and features that can determine which would be the preferred protocol.

TCP is a point to point stream based protocol. It is used in applications where reliability and data sequencing is needed: acknowledgments, error detection, re-transmission of data, and will guarantee the data received will be sequenced in the same order as it was sent.

UDP is a connectionless protocol that does not guarantee delivery or data packet sequence (although each segment is numbered). It is a send and forget protocol that does not use acknowledgments. A common comparison is that TCP is similar to a phone call and UDP is similar to a post card. With TCP, you connect to a specific destination phone number. When that person answers, they say "hello", you say "Hi, my name is Bob", and then the conversation continues with each side speaking and responding (in a well-behaved conversation!). With UDP you essentially transmit a datagram, like writing on a post card, and send it without verifying it was received.

When choosing between TCP and UDP, some major concerns are the overhead it takes to establish a TCP connection, speed and the reliability of data transmission. For example, SNMP uses UDP. SNMP is used to monitor networks, and many messages are sent and received for status updates and alerts. If TCP were used, the overhead of establishing, maintaining and closing a connection for each message and each host would create a lot of unnecessary traffic. A second example of when UDP is a better choice is when an application handles its own reliability at the application layer. Using TCP in this instance would be redundant.

As mentioned previously, TCP is a stream based protocol and UDP is a datagram based protocol. Let's take an example of an application in which a NetBurner device takes A/D readings and sends them to another network device or host PC. Using UDP, each output operation (i.e. creating and sending a UDP packet) results in exactly one IP packet being created and sent. The result of taking and sending 10 A/D readings is that the host will receive 10 individual packets, each containing one reading.

The host PC can then easily identify each reading, although each reading will have to be sent with a sequence number so that the reading order can be recreated. If TCP is used with a single continuous network connection (i.e. the connection is not closed and reestablished for each reading), you do not have control over how many readings are sent with each IP packet. You would need to add start message and stop message identifiers to separate the data from each reading.

Some applications that use TCP are: HTTP, FTP, Telnet and SMTP. Some applications that use UDP are: DHCP, BOOTP, SNMP and DNS.

10.11.1.1 TCP

TCP is used to create a reliable byte stream connection between two network hosts. The host that listens for incoming connections is referred to as the server, and the host that initiates a connection the client. Although TCP and UDP both use IP, TCP sends information as a stream of data. There are no record markers to delimit the data. For example, if a server is sending analog-to-digital (A/D) readings to a client, the client will see a stream of digits; TCP will not automatically insert delimiters to allow the client to determine where one measurement ends and the next begins. To the client, the stream may look like: 98273129323424. Even if the client knew each reading was 4 digits, it would not know where one ended and the next began. Four parameters are required for a TCP connection: source IP address, source port number, destination IP address, and destination port number.

In contrast to TCP, UDP (covered in the next chapter) is an unreliable, datagram-oriented connectionless protocol. Delivery is not guaranteed, but each output operation creates and sends one UDP datagram. In the above A/D example, each reading (or some number of multiple readings) could be sent as a single datagram and the client could then process one datagram at a time.

10.11.2 TCP Server

A TCP server is basically an application that creates a listening socket, and then listens on the socket for incoming connections. When an incoming connection request is received, it must be accepted before communication can begin. A web server is an example of a TCP server. A web server listens on port number 80 for incoming connections. Once a connection is established, the web browser sends a GET request to the web server, which then sends the requested information and terminates the connection.

To connect to a TCP server you must specify a port number. A port number is a 16-bit value. Since you must know the port number before connecting, many port numbers have been defined for common protocols, and are called well-known port numbers. Some of these values are shown below:

FTP	21
Telnet	23
SMTP	25
DNS	53
TFTP	69
HTTP	80
POP3	110
NTP	123

10.11.2.1 NetBurner TCP Server Basics

When creating a TCP server with the NetBurner you will use the following functions:

- `listen()`: Open a listening socket on a specific port number

- `accept()`: Accept a connection request on a listening port
- I/O functions to send and receive data such as `read()`, `write()`, `fdprintf()`, `writestring()`, etc.
- `close()`: Close a network socket

10.11.2.2 Simple TCP Server Example

This example is located in `\nburn\examples\TCP`. It will listen on port 23 for incoming connections, send a sign on message to the client when a connection is made, and display all received data to the debug serial port. A telnet program on a host PC can be used to connect to the server.

```
#include <predef.h>
#include <stdio.h>
#include <tcp.h>
#include <nbrtos.h>
#include <iosys.h>
#include <init.h>
#include <fdprintf.h>

const char *AppName = "Simple TCP Server Example";

#define TCP_LISTEN_PORT 23 // Telnet port number
#define RX_BUFSIZE (4096)

char RXBuffer[RX_BUFSIZE];

// Allocate task stack for TCP listen task
uint32_t TcpServerTaskStack[USER_TASK_STK_SIZE];

/*-----
 * TCP Server Task
 *-----*/
void TcpServerTask(void * pd)
{
    int listenPort = (int) pd;

    // Set up the listening TCP socket
    int fdListen = listen(INADDR_ANY, listenPort, 5);

    if (fdListen > 0)
    {
        IPADDR    clientAddress;
        uint16_t  clientPort;

        while(1)
        {
            /* The accept() function will block until a TCP client requests a connection. Once a client
             * connection is accepting, the file descriptor fdAccept is used to read/write to it.
             */
            iprintf("Waiting for connection on port %d...\n", listenPort );
            int32_t fdAccept = accept(fdListen, &clientAddress, &clientPort, 0);
            iprintf("Connected to: %I\r\n", GetSocketRemoteAddr(fdAccept));

            writestring(fdAccept, "Welcome to the NetBurner TCP Server\r\n");
            fdprintf(fdAccept, "You are connected to IP Address %I:%d\r\n", GetSocketRemoteAddr(fdAccept),
                GetSocketRemotePort(fdAccept) );

            while (fdAccept > 0)
            {
                /* Loop while connection is valid. The read() function will return 0 or a negative number if
                 the
                 * client closes the connection, so we test the return value in the loop. Note: you can also
                 use
                 * ReadWithTimeout() in place of read to enable the connection to terminate after a period of
                 inactivity.
                 */
                int n = 0;
                do
                {
                    n = read( fdAccept, RXBuffer, RX_BUFSIZE );
                    RXBuffer[n] = '\0';
                    iprintf("Read %d bytes: %s\n", n, RXBuffer );
                } while ( n > 0 );

                iprintf("Closing client connection: %I\r\n", GetSocketRemoteAddr(fdAccept) );
                close(fdAccept);
            }
        }
    }
}
```

```

        fdAccept = 0;
    }
} // while(1)
} // while listen
}

/*-----
User Main
-----*/
void UserMain(void * pd)
{
    init();

    // Create TCP Server task
    OSTaskCreateName( TcpServerTask,
                    (void *)TCP_LISTEN_PORT,
                    &TcpServerTaskStack[USER_TASK_STK_SIZE] ,
                    TcpServerTaskStack,
                    MAIN_PRIO - 1, // higher priority than UserMain
                    "TCP Server" );

    while (1)
    {
        OSTimeDly( TICKS_PER_SECOND * 5 );
    }
}

```

This is an extremely simple example designed to illustrate how the `accept()` and `listen()` calls can be used. It only listens to a single port number, and processes a single connection at a time. Any information sent from the Client will be displayed in the MTTY window. The application does not have the capability to terminate the incoming connection.

There are `#define` options for the TCP listen port number and the incoming TCP buffer storage array size. `RXBuffer[]` is then declared and will hold the received data. The `listen()` function call sets a socket to listen for an incoming connection from any IP address on port number 23, the telnet port number.

If the `listen()` succeeds in creating a listening socket, we then enter a second while loop. The application will block at the `accept()` function call until an incoming connection request is received, such as when the telnet program on a PC attempts to connect. When the connection is established, the `accept()` function returns and the sign-on message is sent to the telnet application.

We now enter the do loop: `while(n > 0)`. The `read()` function will block until data is received or an error occurs such as the client terminating the connection. When data is sent from the telnet application, the `read()` function will return with the data in the `RXBuffer[]` array. The application will stay in this while loop until the connection is terminated by the telnet client (or you reset the NetBurner device). If the connection is broken by the telnet client, the application will then loop back to the `accept()` function call and wait for another incoming connection.

10.11.2.3 Advanced TCP Server for Multiple Connections

In the previous example the TCP server processed only a single incoming connection. The `select()` function has the ability to pend on multiple file descriptors, which can be used for TCP or serial connections. The example below demonstrates how the TCP Server can be written using `select()`.

```

/*-----
This example creates a TCP server that listens on the specified TCP port
number and can handle multiple TCP connections simultaneously (10 in this
example). The select() function is a great way method to pend and process
multiple connections.

An easy way to test the example is to use multiple Telnet sessions to create
simultaneous connections to the NetBurner device. Status messages are sent
out stdio to the debug serial port, and to the client TCP connections.
-----*/
#include <predef.h>
#include <constants.h>

```

```

#include <utils.h>
#include <system.h>

            close( fdArray[i] );
            fdArray[i] = 0;
        }
    } // if fd is valid
} // process each connection in the array
} // while (1)
} // UserMain

```

10.11.3 TCP Client

The previous section demonstrated how a TCP Server waits for incoming connections from a TCP client. This section will demonstrate how a TCP client initiates a connection using the `connect ()` function. Features of this example:

- A web page interface is created with input fields for the destination IP address, destination port number, and the message to send to the server
- Demonstrates how to use HTML forms to submit user data
- The web page interface will use the `connect ()` function to create an outgoing connection to a TCP Server, send the message, and close the socket

A screen shot of the running application is shown below:

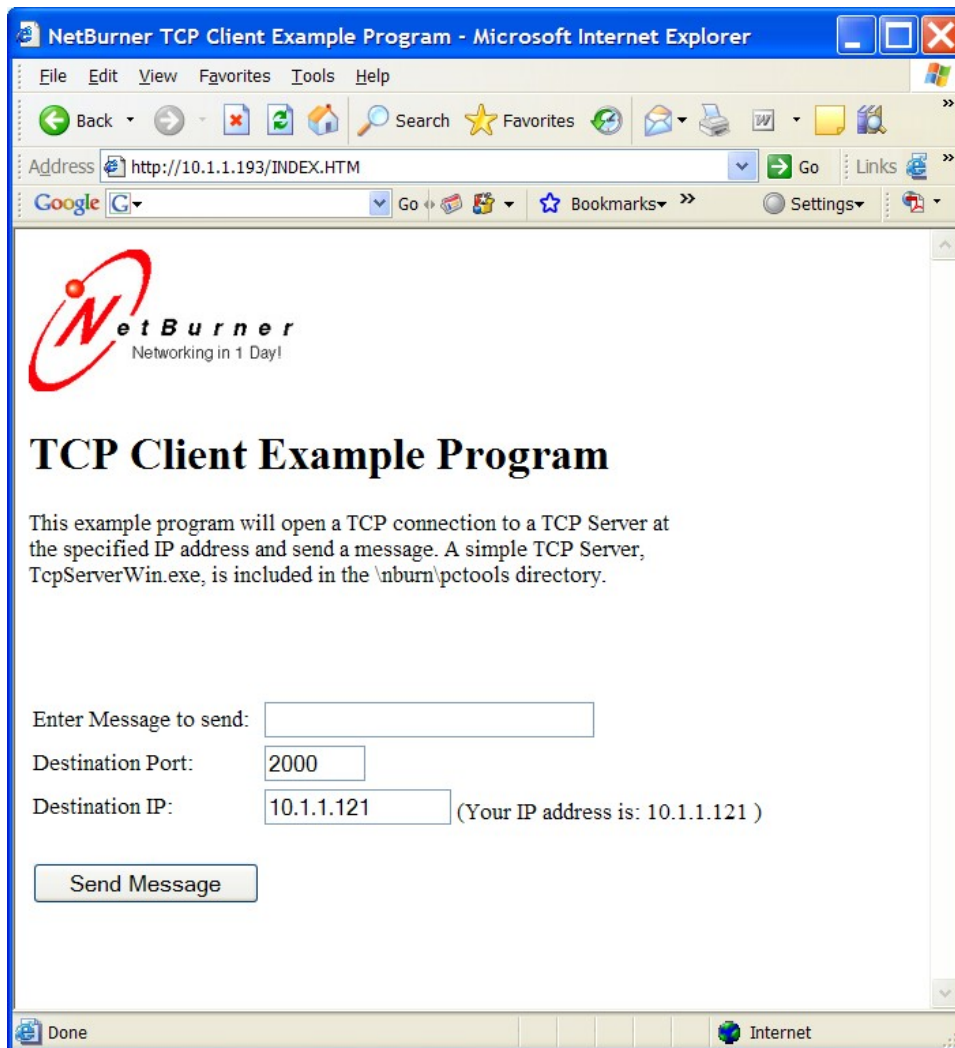

Figure 10.6 TCP Client Web Interface

10.11.3.1 Application Source Code

The application consists of the following source files:

File Name	Description
main.cpp	Application initialization, starts the web server
clientweb.h	Header file for clientweb.cpp
clientweb.cpp	Handles the user interface interaction, makes the outgoing connection
index.html	HTML code for the user interface

10.11.3.1.1 main.cpp

This is a very simple source file that initializes the system. All the action occurs in clientweb.cpp when a user posts web form data. The purpose of the RegisterPost () function is to use our own POST handler instead of just calling the system POST handler.

```

/*-----*
   This program demonstrates how to create a TCP Client. All interaction is
   through the web page interface, which enables you to type a message as
   well as the IP address and port number of the destination TCP server.
   You should be able to use any TCP server. If you do not have one,
   we have a windows example TCP server in the \nburn\pctools\TCP\TcpServerWin
   directory (as well as source code).
   -----*/
#include <predef.h>
#include <stdio.h>
#include <startnet.h>
#include <init.h>
#include <ipshow.h>
#include "clientweb.h"

void UserMain(void * pd)
{
    init(); // Initialize system
    StartHttp(); // Start web server
    WaitForActiveNetwork(TICKS_PER_SECOND * 10);
    showIpAddresses(); // Display IP information to serial port
    RegisterPost(); // Register custom HTML Post function

    while (1)
    {
        OSTimeDly( TICKS_PER_SECOND );
    }
}

```

10.11.3.1.2 clientweb.h

The only function we need to call outside of clientweb.cpp is RegisterPost ()

```

#ifndef _NB_CLIENTWEB_H
#define _NB_CLIENTWEB_H

void RegisterPost();

#endif

```

10.11.3.1.3 index.html

Web page implements a form to send data to the TCP server using a web POST. Inside the HTML <form> tags there is a table for formatting, with three HTML <input> fields. The message input field is straight HTML and any data entered in the text box will be sent to the server as data in the POST. The second and third input fields make use of the NetBurner CPPCALL function callback tag to execute functions that provide default values in the input fields when the page is displayed.

```

<html>
<head>
<title>NetBurner TCP Client Example Program</title>
</head>

<br>
<h1>TCP Client Example Program</h1>
This example program will open a TCP connection to a TCP Server at
the specified IP address and send a message. A simple TCP Server,
TcpServerWin.exe, is included in the \nburn\pctools directory.

<form ACTION="nothing.html" METHOD=POST><br>

<table>
<tr>
<td>Enter Message to send: </td>
<td><input NAME="tfMessage" TYPE="text" SIZE="30"></td>
</tr>

<tr>
<td>Destination Port: </td>
<td><input NAME="tfDestPortNum" <!--CPPCALL WebDestPort --> TYPE="text" SIZE="6"></td>
</tr>

<tr>

```

```

        <td>Destination IP: </td>
        <td><input NAME="tfDestIpAddr" <!--CPPCALL WebDestIp --> TYPE="text" SIZE="15">
        (Your IP address is: <!--CPPCALL WebShowClientIp --> )
        </td>
    </tr>

    <tr>
        <td> <br></td>
    </tr>

    <tr>
        <td><input NAME="SendMessage" TYPE="submit" VALUE="Send Message"></td>
    </tr>
    <br><br>
</table>

</form>
</body>
</html>

```

10.11.3.1.4 clientweb.cpp

This code module handles the dynamic content and web server interface. When the web page is displayed, current values for the port numbers and IP addresses are filled in as default values.

```

/*-----
 * This code implements the web page entries for the message,
 * destination IP address and destination port number. When the
 * web page first loads it will automatically fill in the IP
 * address from the source requesting the web page, because in
 * most cases it will also be the address of the TCP Server.
 * The web page is a form, and when a user presses the submit
 * button the SendMsg() function will open a TCP connection to
 * the server, send the message, and close the connection.
 * Any error messages will be sent to stdout and can be viewed
 * with MTTY.
 *
 * A TCP server program must already be listening at the specified
 * IP address and port number for the message to be sent. A simple
 * TCP Server called TcpServerWin.exe is located in the
 * \nburn\pctools directory of your NetBurner installation.

```

10.11.3.1.5 TCP Client Program Operation

The application boots and executes the initialization functions in main.cpp. From that point forward all interaction occurs through the web interface. When a client web browser connects to the device's web server, the CPPCALL functions `WebDestPort()` and `WebDestIp()` fill in the current values in the input text fields. A port number of 2000 is specified as the default port. The `WebDestIp()` function will default to the last value entered by the user,

or if no value has been entered yet, it will enter the IP address of the host running the web browser. It extracts the IP address from the TCP connection request.

The message to send it is just a temporary string displayed in the web browser. To send a message, the user clicks on the Send Message submit button. This is a HTML command that sends a web POST to the web server containing all the information contained in the form. This is where the `MyDoPost()` function in `clientweb.cpp` comes into play. It parses the POST data, assigns data to the runtime variables, extracts the message data, and calls `SendMsg()`. `SendMsg()` in `clientweb.cpp` makes a `connect()` call using the passed message and the values of the destination port number and IP address. Once the connection is made, `SendMsg()` calls `write()` to send the message followed by `close()` to terminate the connection.

Note

The "%I" parameter in the `ipprintf()` functions will display an IP addresses for an `IPADDR` object in dotted notation (eg. 192.168.1.1). An `IPADDR` object can hold an IPv4 or IPv6 address. For `IPADDR4` objects, use "%hI".

10.11.4 UDP Class

The NetBurner API provides two mechanisms to implement UDP: sockets and a C++ class. The choice of which to use is Dependent of which method you find most comfortable using. There is not a performance difference.

10.11.4.1 Receiving UDP Packets Using the UDP Class

To receive UDP Packets:

- Create an `OS_FIFO` to hold incoming UDP packets
- Register a UDP FIFO with `RegisterUDPFifo()` to listen for and store incoming packets. If listening on more than one port number, a separate `OS_FIFO` can be used for each port, or one `OS_FIFO` can be used to listen on multiple ports by calling `RegisterUDPFifo()` for each port number and specifying the same `OS_FIFO`.
- Call a UDP constructor such as: `UDPPacket upkt(&fifo, timeout)`, which will block until a packet is received, then accept and store the packet.
- Call the `Validate()` member function to verify the packet
- Call the `GetDataBuffer()` member function to obtain the data in the packet

10.11.4.2 Sending a UDP Packet Using the UDP Class

To send a UDP packet:

- Declare an instance of a UDP object
- Specify the source and destination port numbers
- Add data to the packet using the class member functions
- Call the `Send()` member function to send the packet

Note

Unlike TCP, there is no connection between the client and sever, so I/O functions such as `read()` and `write()` cannot be used. When sending, a UDP packet must be created for each transmission.

10.11.4.3 UDP Send/Receive Example with UDP Class**Note**

You can use the NetBurner UDPTerminal utility on Windows platforms to send/receive UDP packets on your PC.

```

/*
 * This example program will receive a UDP packet from another device or
 * host computer, and then send a response. To run the example, connect a serial
 * port from your PC to the debug serial port on your NetBurner device and run a
 * terminal program such as MTTY. On the PC, run the NetBurner UDP Terminal
 * (be sure to set the IP address and port numbers to match). You will then
 * be able to type characters in the UDP Terminal and see them in MTTY,
 * and vice versa.
 *
 * You will be prompted for the port number to send/receive data and the
 * destination IP address of the other device or host. Note that the application
 * uses the same port number to send and receive data, but you can use any other
 * port number you wish.
 *
 * The application will create a thread to receive packets and display them
 * on the debug port, while the main task will take any data you type in
 * to the MTTY terminal and send it as a UDP packet to the destination IP
 * address.
 */

#include <init.h>
#include <stdlib.h>
#include <system.h>
#include <udp.h>
#include <utils.h>

const char *AppName = "UDP Send/Receive Example";

// Allocate stack space for the listen task
uint32_t UdpReceiveTaskStack[USER_TASK_STK_SIZE];

/*
 * This UDP task will wait for incoming packets on the specified port number,
 * which is passed as a OSTaskCreate() void * parameter.
 */
void UdpReceiveTask(void *pd)
{
    static OS_FIFO fifo; // Create a FIFO for the UDP packet and initialize it
    int listenPort = (int)pd;

    iprintf("Listening on UDP port: %d\r\n", listenPort);

    // Register the OS_FIFO. Received packets will be stored in the OS_FIFO.
    RegisterUDPFifo(listenPort, &fifo);

    while (1)
    {
        // Construct a UDP packet object using the previously declared FIFO.
        // The UDP constructor will block until a packet has been received.
        // The second parameter is a timeout value (time in ticks). A value of 0 will
        // wait forever.
        UDPPacket upkt(&fifo, 0 * TICKS_PER_SECOND);

        // Did we get a valid packet, or just time out?
        if (upkt.Validate())
        {
            uint16_t len = upkt.GetDataSize();
            iprintf("Received UDP packet with %d bytes from: %I\r\n", (int)len, upkt.GetSourceAddress());
            ShowData(upkt.GetDataBuffer(), len); // hex dump function
            iprintf("\r\n");
        }
    }
}

/*

```

```

* UserMain
*/
void UserMain(void *pd)
{
    int     portNumber;
    IPADDR  destIpAddress;
    char    buffer[80];

    init(); // Initialize network stack
    WaitForActiveNetwork(TICKS_PER_SECOND * 5); // Wait for DHCP address

    iprintf("Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());
    iprintf("Enter the UDP port number (will be used for send & receive): ");
    gets(buffer);
    portNumber = atoi(buffer);

    iprintf("\r\nEnter the destination IP Address: ");
    gets(buffer);
    destIpAddress = AsciiToIp(buffer);

    iprintf("Listening/Sending on UDP Port %d, Sending to IP address: %I\r\n", portNumber, destIpAddress);

    // Create UDP listen task
    OSTaskCreateName( UdpReceiveTask,
                    (void *)portNumber,
                    &UdpReceiveTaskStack[USER_TASK_STK_SIZE] ,
                    UdpReceiveTaskStack,
                    MAIN_PRIO - 1, // higher priority than UserMain
                    "UDP Receive" );

    // while loop to process user input and send as a UDP packet
    iprintf("Enter data and hit return to send.\r\n");
    while (1)
    {
        gets(buffer);

        UDPPacket pkt;
        pkt.SetSourcePort(portNumber);
        pkt.SetDestinationPort(portNumber);
        pkt.AddData(buffer);
        pkt.AddDataByte(0);
        pkt.Send(destIpAddress);
        iprintf("\r\n");

        iprintf("Sent \"%s\" to %I:%d\r\n", buffer, destIpAddress, portNumber);
    }
}

```

10.11.4.3.1 Sending Packets

In the while loop of `UserMain()` you can see that a `UDPPacket` object named "pkt" is created. Member functions are then called to specify the source port number, destination port number, add the message data, add a null string terminator, and finally to send the packet. In practice it is a good idea to choose random source port numbers.

10.11.4.3.2 Receiving Packets

`UserMain()` creates a task named `UdpReceiveTask()`. The task declares an `OS_FIFO` to use to store incoming packets. Note that it is static so the FIFO is located in global variable space. A `UDPPacket` object constructor is then called for `upkt`. It will block until a packet is received. When one does arrive it is verified with the `Validate()` member function. If it is a valid packet the `ShowData()` utility function is used to display the data in hex format to the debug serial port.

10.11.5 UDP Sockets

The NetBurner API provides two mechanisms to implement UDP: sockets and a C++ class. The choice of which to use is Dependant of which method you find most comfortable using. There is not a performance difference.

10.11.5.1 Receiving UDP Packets using UDP Sockets

To receive UDP Packets:

- Use the `CreateRxUdpSocket ()` function to open a listening socket. It will return a file descriptor.
- Use the `recvfrom ()` function to receive packets. The industry standard behavior of this function is to block forever until a packet is received. If you want to allow your application to have better control, you can wrap the `recvfrom ()` function inside a `select ()` function using the UDP file descriptor and a timeout.

10.11.5.2 Sending UDP Packets using UDP Sockets

To send UDP Packets:

- Use the `CreateTxUdpSocket ()` function to open a socket. It will return a file descriptor.
- Use the `sendto ()` function to send packets.

10.11.5.3 UDP Send/Receive Example Using Sockets

```

/*
 * This application will send/receive UDP packets with another host on a network,
 * such as a PC. Use the MTTY serial port program to access the menu and
 * prompts to specify the destination IP address and port number.
 *
 * NetBurner also supplies an API for handling UDP as a C++ Class using UDPPacket.
 *
 * For an external UDP host you can use the NetBurner Java example, or the
 * NetBurner UDP terminal program.
 */

#include <init.h>
#include <stdlib.h>
#include <string.h>
#include <system.h>
#include <udp.h>
#include <utils.h>

const char *AppName = "UDP Sockets Example";

// Allocate stack space for the listen task
uint32_t  UdpReceiveTaskStack[USER_TASK_STK_SIZE];

/*
 * This task will wait for incoming UDP packets and process them.
 */
void UdpReceiveTask(void *pd)
{
    int listenPort = (int)pd;

    iprintf("UdpReceiveTask monitoring port %d\r\n", listenPort);

    // Create a UDP socket for receiving
    int udpFd = CreateRxUdpSocket(listenPort);
    if (udpFd <= 0)
    {
        iprintf("Error Creating UDP Listen Socket: %d\r\n", udpFd);
        while (1)
        {
            OSTimeDly(TICKS_PER_SECOND);
        }
    }
    else
    {
        iprintf("Listening for UDP packets on port %d\r\n", listenPort);
    }

    while (1)
    {
        IPADDR sourceIpAddress;    // UDP packet source IP address
        uint16_t localPort;        // Port number UDP packet was sent to
        uint16_t sourcePort;      // UDP packet source port number
        char buffer[80];

        int len = recvfrom(udpFd, (uint8_t *)buffer, 80, &sourceIpAddress, &localPort, &sourcePort);
    }
}

```

```

        buffer[len] = '\0';

        iprintf("\r\nReceived a UDP packet with %d bytes from : %I\r\n%s\r\n", len, sourceIpAddress,
        buffer);
    }
}

/*
 * UserMain
 */
void UserMain(void *pd)
{
    int    portNumber;
    IPADDR destIpAddress;
    char   buffer[80];

    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);    // Initialize network stack
                                                // Wait for DHCP address

    iprintf("Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());

    // Get destination IP address
    iprintf("Enter the UDP Server destination IP address: ");
    gets(buffer);
    destIpAddress = AsciiToIp(buffer);
    iprintf("\r\n");

    // Get the port number. This application uses the same port number for send and receive
    iprintf("Enter the source/destination port number: ");
    gets(buffer);
    portNumber = atoi(buffer);
    iprintf("\r\n");

    // Create a UDP socket for sending
    int udpFd = CreateTxUdpSocket(destIpAddress, portNumber, portNumber);
    if (udpFd <= 0)
    {
        iprintf("Error Creating UDP Socket: %d\r\n", udpFd);
        while (1)
        {
            OSTimeDly(TICKS_PER_SECOND);
        }
    }
    else
    {
        iprintf("Sending/Receiving with host %I: %d\r\n", destIpAddress, portNumber);
    }

    // Create UDP receive task. The priority is higher than UserMain() so packets get processed as they are
    // received
    OSTaskCreateName( UdpReceiveTask,
                     (void *)portNumber,
                     &UdpReceiveTaskStack[USER_TASK_STK_SIZE] ,
                     UdpReceiveTaskStack,
                     MAIN_PRIO - 1,    // higher priority than UserMain
                     "UDP Receive" );

    iprintf("Enter data and hit enter to send.\r\n");

    while (1)    // Loop forever displaying UDP data
    {
        gets(buffer);
        iprintf("\r\n");
        iprintf("Sending \"%s\" using UDP to %I : %d\r\n", buffer, destIpAddress, portNumber);

        sendto(udpFd, (uint8_t *)buffer, strlen(buffer), destIpAddress, portNumber);
        iprintf("\r\n");
    }
}

```

10.12 SSL/TLS Programming Guide

10.12.0.1 Table of Contents

- [SSL/TLS Fundamentals](#)
- [Certificate Issuer Decision Matrix](#)
- [SSL/TLS Instructions](#)

- [SSL/TLS Troubleshooting](#)

10.12.1 Quick Start

Familiar with SSL and just want to get going with zero fuss?

- **Server:** See the [Automatic Onboard ACME](#) section.
- **Client:** See the [Creating Certificate Authority Lists](#) section.

Both sections have examples to help you get going. The rest of this document is provided for advanced, custom, introductory and historical purposes.

See also [SSL/TLS API documentation](#).

10.12.2 SSL/TLS Fundamentals

Note

For brevity, this document will say "SSL" when we mean SSL/TLS.

The NetBurner SSL/TLS library makes SSL as easy as possible. However, if this is your first experience with SSL, some outside reading on how public key cryptography works is extremely helpful.

When you use SSL to connect to <http://www.amazon.com> (for example) with a normal web browser, you will not need to know anything about certificates. This is because Amazon purchased a certificate from Verisign, and your browser vendor preinstalled the Verisign Certificate Authority as a trusted entity that can issue certificates for organizations like Amazon, which are then trusted by association in what's called a "chain of trust" or "certificate chain."

Figure 10.7 A Normal SSL Connection

Above is a picture of a perfectly normal TCP or SSL connection; the client (most often a browser) has connected through the network to a server. If we do not have any entities doing bad things on our network then there is no need for SSL. However, if the data we are sending is worth stealing, we might have a very different network picture:

Figure 10.8 An Unsecure Connection

If our connection is routed through a third party (a normal TCP connection), we have no guarantee that this third party is not an attacker trying to steal or modify our data. The SSL protocol was designed to eliminate this man in the middle attack. SSL is designed not only to make sure that the data we send over the network is hidden from

snooping eyes, but it is also designed to make sure we are connected to the proper server without any "attackers" in the middle. This verification is done with Public Key (PK) Cryptography and a hierarchy of trust.

Why do we trust a doctor when we go to the emergency room? We trust the doctor we have never met because we trust the hospital to employ qualified doctors. The hospital vouches for their skills and we trust the hospital. Their medical school also vouches for them by giving them a diploma with their name and the school's seal or signature. We trust the school, we trust the hospital, and thus we trust the doctor. We also don't generally ask for private details like the doctor's birthday or fingerprints or government ID, because if your hospital is letting unauthorized people walk in and put fake credentials on the wall you have much bigger problems.

SSL works in a very similar way. When a client connects to the server sends the client a certificate. This certificate has three major elements:

- A name (i.e. who is this server)
- A public key (e.g. think of an open padlock)
- A signature (by a trusted third party that vouches for the name and the public key)

A doctor's diploma is very similar; it also has three major elements: The doctor's name, the type of degree and the medical school (that vouches for the doctor). For example, Bob and George both graduate from Harvard Medical School. They both have Harvard diplomas. However, the diplomas are unique to each doctor. The diplomas are not interchangeable. Bob's diploma would be of no use to George and vice versa.

Note

Each unique SSL server must have a certificate issued for it. You cannot usually reuse an SSL server certificate between servers of a different domain name, because the certificates are distinguished by the "common name" or "CN" on the certificate which in the case of web servers is usually "example.com".

It is possible to buy multi-subdomain, wildcard-subdomain, or multiple-domain certificates to allow the same certificate to work for "www.example.com", "mail.example.com", "*.example.com" or even "example.org" by using the Subject Alternative Name, SAN, or "alt name" certificate field, however this needs to be set up in advance, you can't simply copy-paste a certificate issued for one domain name and use it on some other domain.

If you went into a new doctor's office and saw a diploma from Harvard medical school, you would feel comfortable with the doctor's skills. You trust Harvard and Harvard will vouch for this doctor. If instead, the diploma were from the Medical School of Antarctica, you might be more skeptical. We do not have the same inherent trust of this unrecognized school as we did with Harvard.

So in setting up our SSL client, we have to decide who we will trust to sign our certificates. This list of trusted certificate authorities needs to be explicitly configured into the client, otherwise the client will be forced to choose between failing to connect or operating in an insecure mode (like choosing "Proceed (unsafe)" or "Accept the Risk and Continue" on a browser security warning page). When the web browser or OS was installed on your PC, it probably installed a list of trusted certificate authorities. With the NetBurner SSL/TLS library, we should explicitly decide whom we are going to trust to sign server certificates.

Note

An SSL client should be pre-configured with a list of Certificate Authorities (CAs) that it will trust to sign server certificates. This list can be common across all the clients and does not have to be unique. Failing to install a list of trusted CAs will cause the client to either fail or operate insecurely.

Finally, SSL can be used to validate not just the server ("doctor") but client ("patient") also. This is like presenting your health plan ID card or government ID to the hospital when you walk in. The client will need some kind of name or identifier (hopefully something more stable than an IP Address) and they will also need a private key and certificate (which of course includes a public key and signature.)

10.12.2.0.1 What do I need to do to make SSL work?

- You should configure SSL clients with a list of certificate authorities it should trust.
- If creating new SSL certificates, you must create or choose a certificate authority to issue them.

Note

Creating a certificate authority involves creating a CA certificate and key, usually separate from any other certificates and keys.

- You must create a private key for each SSL server and have it signed by the certificate authority you have chosen. The signing process creates a certificate from the key via a Certificate Signing Request (CSR).
- If using client-side validation (using SSL to validate clients, not just servers) then you must create a key and certificate for the client to use.

10.12.2.0.2 How do I find or create a certificate authority?

Using the medical school example, you can go to Harvard pay lots of \$\$\$ and get a diploma that is trusted by everyone. You can also choose to start your own medical school and issue diplomas. Almost everyone in the world would trust a Harvard diploma. Almost no one will trust a "Bob's Medical School" diploma, unless you spend the time convincing them that it is a quality medical school. In the end, you will likely only be able to convince your family, and then only for non-life threatening needs.

SSL certificates are a lot like medical schools; you can go and purchase server certificates. To see what a certificate looks like, open your web browser (e.g. Internet Explorer), and connect to <https://www.NetBurner.com> (notice the s on the end of https). On Internet Explorer's menu, choose File then Properties. Now, click the Certificates button, and look at all the tabs shown in this section.

10.12.2.0.3 How do I know whom my browser trusts?

On your (Internet Explorer) browser's menu - choose Tools then Internet Options. Open the Content tab, click the Certificates button, and open the Trusted Root Certificate Authorities tab. Add Verisign or Thawte and every browser in the world will trust your certificate and your server.

If you want to save some money and create your own certificate authority then you can do so. However, none of the clients will accept your certificate until you convince them to add "Bob's Certificate Authority" to their list of trusted certificate authorities. If, the users using the embedded SSL system you are deploying are all in one business entity, then it is relatively simple to add your own certificate authority to the list of trusted authorities. If you are responsible for both the client and server end of the connection, it is even easier; you can configure the clients to accept a single server authority - yours.

SSL is based on Public Key Cryptography (PK) and a little bit of background on PK is necessary in order to deploy a secure SSL solution. Public Key Cryptography is different from Symmetric Key Cryptography. In PK, the keys used for encryption are broken into two parts, much like a padlock (the public part) and a key (the private part). If you give someone an open padlock and a steel box, they can put things into the box, close the lid, and lock the lock. Unless they have the key to the lock, they cannot open the box. They can be confident that if they mail you the box, none of the mailmen along the way can look inside. Only the person who holds the (private) key to the padlock can open the box. For additional information on Public Key Cryptography, please read the Cryptography FAQ (<http://isc.faq.org/faqs/cryptography-faq>).

When the SSL client connects to a server, the server sends back a certificate with a public key (open padlock). This certificate also includes the name of the server and a signature vouching for both the public key and the name. If any part of the certificate is changed, the signature will compute to be invalid.

So, if we have an attacker in the middle, they can watch the padlock going from the server to the client. But, when the client puts their secret information into the box and locks it, the attacker cannot see inside. They only know that the client sent something in the box to the server. The secrets in the box are safe from the prying eyes of the attacker. This safety only exists if the server has done a good job of protecting the private key. If the attacker sneaks into the server room, logs on the server console, and makes a copy of the private key, they can intercept all of the traffic. They can also change the content at will.

Note

When using Public Key Cryptography (as SSL does), the system is only as secure as the security of the private key. Since a server needs access to the private key to unlock the data from the client, the private key must exist on the server.

Also: If the private key exists on the server, then the system is only as secure as the physical security of the server. If the server is not physically secure, then someone (i.e. the attacker) can attach an emulator or other

hardware to the server and read out the private key. This applies to Certificate Authority private keys also: an insecure CA could issue certificates for anyone, even attackers.

Conversely: The CA certificate and any client or server certificates can and should be publicized freely. The more widely known and trusted a certificate is, the easier it is for everyone to verify its trustworthiness.

For example, suppose the attacker wants to intercept your credit card number when you send it to Amazon to order a book. We have already shown that they cannot read the data unless they have Amazon's private key. However, they have one other option - they can pretend to be Amazon and offer their own certificate to you, the client. If this certificate is properly signed by a Certificate Authority the client trusts, then client will accept the connection. If any "Certificate Authority" in the list of trusted authorities is compromised, then the system is insecure. If the attacker has the ability to add a new "Certificate Authority" to the client, then they can completely compromise the system.

Note

If the ability to add a "Certificate Authority" to the client's list of trusted authorities is not secure, then system is not secure.

Also: If the list of trusted "Certificate Authorities" exists on the client, then the system is only as secure as the physical security of the client. If the client is not physically secure, then someone (i.e. the attacker) can attach an emulator or other hardware to the client and add a "trusted" authority.

So, this implies that it is not possible to build a system that is more secure than the physical security of the device being secured.

Attention

All the cryptography in the world will not help if someone can gain access to your computer and hide a bug inside the keyboard; or even easier, add or modify a system file to record your keystrokes and periodically send them over the internet to some nefarious foe.

10.12.2.0.4 Self-signed vs CA-signed, trusted vs untrusted

For development, testing, or internal-only purposes it may be faster or cheaper to install self-signed certificates on your device. This is the default behavior in many NetBurner examples since it requires nearly zero configuration, third parties, or cost. In this arrangement the device acts as its own CA, creating a new certificate that is its own CA.

The downside of this is that by default no browser or client will trust that certificate, so browsers will pop up scary SSL warning messages meant to discourage most users from accessing the server. These warnings can usually be ignored by the user or bypassed by choosing insecure or no-validation client configuration options, but obviously that makes it hard to trust the resulting connection's security.

The NNDK also ships with CreateCerts scripts which can create a private CA and certificates for your devices with just a few SSL commands, but that CA still won't be trusted by browsers by default. You would need to install the self-signed certificate or private CA certificate into every browser that accesses your NetBurner devices in order to properly resolve the browser warnings.

So, for public-facing, deployment and production purposes it's preferable to obtain certificates that are issued by a trusted Certificate Authority like Verisign, Comodo, GoDaddy, etc. You can do this easily by using our new ACME feature introduced in NNDK 3.5.0, which uses the Let's Encrypt CA by default but also supports the BuyPass CA out of the box, both of which are generally trusted. The downside of ACME is that the CA (Let's Encrypt) needs to verify that the device's domain name is actually controlled by that device, so devices that aren't accessible via a public DNS name can't use this method.

You can also manually generate and send a Certificate Signing Request to a CA of your choice and install the resulting certificate and key onto your device. The downside of this is that the keypair is compiled into the program, so the same manual steps will need to be repeated prior to the certificate's expiration (usually just over 1 year.)

Enterprise customers may also choose to configure and host their own ACME server for automatically issuing and renewing certificates: this is also supported via our ACME feature, contact Support if more information is required.

10.12.3 Certificate Issuer Decision Matrix

10.12.3.0.0.1 Definitions

- NB: NetBurner Device
- CA: Certificate Authority
- CN: Common Name and/or Subject Alternative Name

10.12.3.0.0.2 Naming Options

- mDNS (.local)
- IPv4 or IPv6
- DNS name

10.12.3.0.1 Types of Certificate Issuers

10.12.3.0.1.1 Self Signed Certificate

The certificate is auto-generated by a NetBurner device and is its own CA.

Pros

- Simple solution for a single NetBurner device accessed by one or two computers.
- To avoid a browser warning message the certificate must be downloaded from the NetBurner device and installed in all computers and/or browsers that accesses the device.
- When a certificate expires, a new certificate will be automatically generated.

Cons

- Multiple NetBurner devices and/or Computers: Each have their own unique certificate, and each device's certificate must be downloaded and installed into each computer that needs access.

Note

When a certificate expires or the IP address/name changes, the new certificate must be downloaded from the NetBurner device and installed in the computer and/or browser.

If the name.local feature can be used (eg MyDevice.local), the certificate loaded in the computer/browser will still be value (no need to upload a new one). In order to use local names, the auto-generation must be configured to use local names.

10.12.3.0.1.2 Private Certificate Authority Signed Certificate

A Certificate Authority (CA) certificate is generated on an external computer, which in turn is used to sign a device certificate that is later uploaded to a NetBurner device.

Pros

- The same CA certificate can be loaded on all computers and used to access all the NetBurner devices without a browser warning.

Cons

- The application must have the ability to receive and store a device certificate. There are examples of this, just not as simple as an auto-generated certificate.

Note

When a device certificate expires, a new device certificate must be generated and uploaded to the device. However, the CA certificate does not need to be reloaded into the computer and/or browser.

10.12.3.0.1.3 Outside Certificate Authority Signed Certificate

Similar to the Private Certificate method. In this case the CA certificate is from a known company and pre-loaded into the computer and/or web browser. The procedure is more complicated. A certificate request must be generated, sent to the CA, and the CA will in turn send back a device certificate signed by their CA certificate. The device certificate must then be uploaded to the NetBurner device.

Pros

- Computers and/or browsers will already have the CA certificate installed.

Cons

- Each time a device certificate expires, a new certificate must be requested from the outside CA and uploaded to the NetBurner device.
- There may be fees involved to purchase a device certificate.

10.12.3.0.1.4 ACME Client

Automated Certificate Management Environment (ACME) is a protocol that makes it possible to automate the issuance and renewal of certificates by a third party CA. It is essentially an automated version of method number 3. A key is generated on the NetBurner device, which is used to obtain a device certificate from an ACME compliant server CA. NetBurner devices currently support Let's Encrypt, which is a free service.

Note

Device must be accessible from the outside Internet. Requires a DNS entry to be established for the device name.

Pros

- Automatically renews.
- Easiest solution.

Cons

- Reliant on the ACME CA used to obtain the certificate.
- Requires device have a name, not an IP address.

10.12.3.0.2 Use Cases**10.12.3.0.2.1 Isolated LAN, no Internet access, no DNS or mDNS (.local) capability.**

The methods that support an IP address CN are:

- Self Signed Certificate.
- Private Certificate Authority Signed Certificate.

10.12.3.0.2.2 Isolated LAN, no Internet access, accessed via DNS name.

The device certificate CN will be a name, not an IP address.

- Self Signed Certificate.
- Private Certificate Authority Signed Certificate.
- Outside Certificate Authority Signed Certificate.

10.12.3.0.2.3 Isolated LAN, no Internet access, accessed via DNS name, with private ACME server.

The device certificate CN will be a name, not an IP address.

- Self Signed Certificate.
- Private Certificate Authority Signed Certificate.
- Outside Certificate Authority Signed Certificate.

10.12.3.0.2.4 Device can be accessed from the Internet via DNS name

The ACME CA must be able to access the device from the Internet.

- Any of the described methods, including ACME.

10.12.3.0.2.5 Advanced

There are other ways to use ACME, like DNS verification, routable IPv6 addresses, or router port forwarding.

10.12.4 SSL/TLS Instructions**10.12.4.1 Automatic Onboard Trusted Certificate Creation with an ACME CA**

To help developers tackle the growing burden of implementing and managing security on embedded and IoT devices, NetBurner now offers the ability for automatic onboard trusted certificate issuance via the ACME protocol. This means that modules running NNDK 3.5+ can in just a few lines of code (assuming a valid public IP and DNS name) request, install, and renew valid certificates that are trusted in all major browsers.

See the ACME example in `<nndk_install>\examples\SSL\acmeservlet` or blog post at <https://www.netburner.com/learn/new-feature-easy-ssl-certificates-with-acme-and-lets-encrypt/> for more information.

If a valid public IP and DNS name isn't an option, consider one of these other options:

10.12.4.2 Automatic Onboard Self-Signed Certificate Creation

With very little effort (a single line of code, in fact), NetBurner modules acting as a server and running NNDK 3.x can automatically generate a self-signed certificate that can be used in secure SSL communications.

This feature is designed to allow engineers to have maximum control over the certificates that are used by their devices and can be modified in several different ways. Currently, the default behavior is as follows:

- 1) If a certificate is manually loaded on the module prior to the initialization of the SSL server, that certificate will be used, and the device will generate nothing.
- 2) If a TLS connection is attempted, either through `SSL_connect()`, `SSL_accept()`, or `StartHttps()`, and the device does not have a certificate loaded already, one will be generated automatically.
- 3) If a certificate has been generated previously and a new certificate is manually loaded on the device, the newly loaded certificate will be used in place of the automatically generated one. This will take place once the device has gone through a power cycle. The automatically-generated certificate will still be available on the module.
- 4) If `ENABLE_AUTOCERT_REGEN` is defined (found in `predef.h`), then the module will periodically check to see if the automatically-generated cert has expired, and if it has, it will automatically generate a new one. How often it is checked is defined by `AUTO_CERT_GEN_CHECK` (also in `predef.h`), and defaults to once per minute.

Certificates generated with this functionality are good for one year. These certificates live in non-volatile memory and will survive if the device is powered off. The auto-generated certificate creation system has been extended substantially since it was first introduced. The following examples are available to demonstrate the capabilities of the system, including several examples for advanced users who need more control over how the certificates are generated. The are located in `<nndk_install>\examples\SSL\SslOnboardCertGeneration`:

- `Simple`: Shows how to initialize the system to enable onboard certificate generation.
- `Advanced`: Shows how to manually call `SSL_CreateNewSelfSignedCert()` with properly formatted alt names.
- `CompiledCa`: Shows how to create a custom self signed cert function that uses a compiled in Certificate Authority to sign the generated certificate.

When generating the certificate, the random number generator will need to be properly seeded. This is done by analyzing serial and network traffic. Pinging the device or visiting the device's config page from a browser will speed this process up.

By default, the certificate is generated using ECC with SECP384R1. This can be changed to an RSA key by undefining `ENABLE_ECCKEY_CREATE` in `nburn\libraries\crypto\platform\<platform name>\user_settings.h`, and then rebuilding your application. To specify what curve or RSA key length is used in certificate generation, define `DEFAULT_KEY_TYPE` as one of the values defined by `SslKeyType_t`.

10.12.4.3 Manual Private CA Certificate Creation

The NNDK ships with some open source tools for the generation and maintenance of SSL privately-issued keys and certificates. In the `\nburn\CreateCerts` directory there is a `ReadMe.txt` file which provides information on the `.bat` and `.sh` scripts used to make the creation process easier. Please refer to these files if you want more information.

These scripts are thin shell script wrappers around OpenSSL. OpenSSL is usually included in the NNDK at `\Nburn\gcc\msys\1.0\bin\openssl.exe`. OpenSSL is subject to the OpenSSL License, which is not part of the NetBurner License.

10.12.4.4 Obtaining Certificates via a third-party Certificate Authority

If you are going to have your certificates signed by an external entity, they will need a CSR file.

Note

The common name you enter in this step must match the deployed DNS name or IP Address of the Server it will be used on.

- Open a command prompt/DOS window
- Navigate to the directory that you want to house your device files
- To make a Device Certificate Request file, execute the command (and press the Enter key when finished)↵

```
: openssl genrsa -out Server.key 1024 openssl req -new -key Server.key
-out Server.csr
```

- Send this `Server.csr` to the CA that will create your certificate.
- Make sure you request your certificate in PEM format (which is typical for open source software like Apache: it's just plain text.)

When you get the certificate (usually something like `example_com.crt`) it will usually come with CA certificates and/or Chain certificates. These are important for helping other SSL clients or servers validate your certificate since every single CA isn't installed on every single device: instead, your certificate will often be issued by some Intermediate, and there is a chain of trust that eventually goes back to some Root CA which is installed on most devices. So, we want to help that chain be unbroken by providing others with the full chain:

- Open your new certificate and the CA and/or Chain certificates in a text editor.
- Review all the open certificates (you may need to scroll significantly in the Chain file) and see if the Chain file includes your new certificate at the top (unlikely) or the separate CA certificate at the bottom (also unlikely) – we don't want to duplicate anything in the next steps.
- Create a new file called something like `device_chain.crt`
- Copy-paste in order from top to bottom:
 - Your new certificate (if not duplicated below)
 - The chain certificates (in order from most intermediate to most root, though you won't be able to see this without using some certificate parsing tool)
 - The root certificate (if separate and not duplicated above)
- Use this `device_chain.crt` instead of `device.crt` in the [Manual Certificate Installation instructions](#) below in order to install it on your device. This will provide the full chain of trust to wolfSSL, which will allow other devices to securely talk with yours with much fewer issues.

Warning: If you lose the `Server.key` file associated with this particular device, then you will not be able to use the certificate file they send back. Once you have a signed certificate and private key, you may discard the `Server.csr` file: it's only used for that request.

10.12.4.5 Manual Certificate Installation

The `compfile` utility converts `.crt` and `.key` files to C++ source code files that can be built into your application (note this implies that each device needs its own application image). It is already part of in the batch and shell files mentioned previously. This section is included in the event you wish to run it separately against your `.crt` and `.key` files.

- Open a command prompt in `\nburn\CreateCerts\ECDSA` or `\nburn\CreateCerts\RSA`, depending on the type of certificate you are converting.
- Execute the commands:

```
compfile device.key comp_key comp_key_len key.cpp
compfile device.crt comp_cert comp_cert_len cert.cpp
```

Note

`comp_key`, `comp_key_len`, `comp_cert`, and `comp_cert_len` all refer to global variables available in the application that represent the key data, the length of the key data, the cert data, and the length of the cert data respectively.

10.12.4.5.1 Adding the Module to your Code Set

Take the `key.cpp` and `cert.cpp` files previously created and import it into your project directory. If you are using command line tools, copy it to your project directory and add it to your makefile.

10.12.4.6 Testing Your Certificates

The batch and shell files `checkcert` and `checkkey` can be found in `\nburn\CreateCerts\ECDSA` or `\nburn\CreateCerts\RSA`. For example: `checkcert device.crt checkkey device.key`

10.12.4.7 Creating a Certificate Authority List

To create a CA List that will hold all of the CA certificates you are willing to accept, you can either compile the certificate data into your project, or you can load it dynamically from a flash drive.

To use the compiled in data, create a header file in your project directory that will hold the certificate data. In this file, create a const char array for each certificate that is initialized as a string literal with each corresponding CA certificates' data. Make sure to take note of the length of the array, as it will be passed into `SSL_connect()` as function parameters. The example `nburn\examples\SSL\SslClientVerifyPeerBasic` demonstrates this method.

To use an SD card or onchip flash to store the certificate data, please see the example `nburn\examples\SSL\SslClientVerifyPeerEffs` for further guidance. In that example, we initialize the SSL system with a call to `SslInit()` before we start the HTTPS server so that we might add the certificates with calls to `SSL_AddCertToClientCaList()` for each certificate that we want to load. In this example we do this before the calls to `SSL_connect()` so that we can add multiple certificates stored on the SD card or onchip flash.

10.12.5 SSL/TLS Troubleshooting

10.12.5.1 Troubleshooting Browser Warnings

There are multiple reasons why an SSL client like a web browser, command-line client like curl, or built-in library like OpenSSL or wolfSSL, might fail to connect and display a secure connection warning. There are many requirements for a secure, trusted connection with SSL:

- Certificate must be issued by CA trusted by the client
 - If the certificate is self-signed, it must be manually installed on every client that connects otherwise a warning will be displayed saying that the certificate is not trusted.
 - This doesn't mean that the connection won't be encrypted, but rather that your client can't validate who you're talking to: if an attacker has redirected your connection to go through them, the client wouldn't be able to warn you any other way. An encrypted connection to an untrusted "Man in the Middle" wouldn't be ultimately considered very secure.
- Enough of the CA certificate chain must be installed on both the client and server to form an adequate chain of trust
 - When installing trusted SSL server certificates or SSL client certificates, a CA certificate or certificate chain is usually provided alongside. This should also be installed using the server or client's documented process. For NetBurner, see [Third-Party Certificate Authority](#).
- Certificate name (CN or SAN) must match the hostname of the server
 - If a certificate is only issued for example.com or 10.1.1.77 but the client is accessing it via example.net or 10.1.1.66, a warning will be displayed that there is a mismatch.
- Certificate expiration (Not After) time and issue (Not Before) time can't be after/before the client's clock.
 - This error is most often encountered when the client's clock isn't set properly; configuring and waiting for NTP before initiating SSL connections is the most common fix.
- Certificate algorithm must be supported by the client and server (RSA, ECDSA, etc)
 - Some older clients or servers don't yet support ECDSA, but many CAs switched to ECDSA around 2022 so this should be a declining concern outside of legacy support.
- Certificate can't be revoked. If the client's revocation list says the certificate is bad, you either need a new certificate or to troubleshoot the client's revocation list.

There are also a few SSL issues not directly relevant to the certificate which can cause warnings:

- An SSL version can't be agreed upon by both client and server

- Ex: if the server requires TLS 1.2+ but the client only supports 1.1 or lower. Note that "SSL" version numbers are all older than any TLS version number: the order is SSL2, SSL3, TLS1.0, TLS1.1, TLS1.2, TLS1.3, etc.)
- An SSL cipher suite couldn't be agreed upon by both client and server
 - Each NetBurner NNDK release ships with and supports the default ciphers provided by wolfSSL, however over time old ciphers stop being trusted and new ciphers are released that may not be fully supported by all clients and servers. When there is no overlap between these supported ciphers, secure communication can no longer be established.
- SSL negotiation process failed for an unknown reason
 - Maybe a bad connection, software failure, invalid cert/key format, or cert/key file permissions
- Mixed content warnings or failures
 - If an HTML page is loaded via HTTPS but includes resources via HTTP, browsers may warn or fail to load that content for security reasons.
- If a client previously accessed an IP or hostname via HTTPS, and HTTP Strict Transport Security was set on the server, the client will fail to connect to that host via HTTP.

An easy way to avoid most of these problems is to use our automated [ACME certificate process](#) if your device has a public IP and is accessible via a public DNS name.

10.13 SSH Programming Guide

10.13.1 SSH Overview

The Secure Shell Protocol (SSH) is a secure network protocol that has been around since 1995. It was designed to facilitate operating network services over an encrypted connection, and is still widely used today.

SSH has been a part of NetBurner's offerings for quite awhile now, starting with NNDK version 2.0. Up until recently, we utilized Dropbear to provide the SSH capability to our library. As of NNDK 3.3.6, however, we have migrated to wolfSSH. This change provides our library with several benefits. First, it provides better security with an updated list of ciphers compared to the version of Dropbear we were utilizing previously. It also allowed us to provide additional features, such as the capability to support running an SSH client on our devices, where we had been unable to do so before. Finally, because it shares the same underlying library with our SSL/TLS library, wolfCrypt, we were able to reduce the amount of code required to run both libraries simultaneously.

10.13.1.1 Supported Key Types, Sizes, and Formats

The SSH library currently supports both ECC and RSA keys, though we recommend ECC. The default key size for RSA is 2024, but support for a 4096 key can be enabled by defining `ENABLE_RSA_4K` in `<nndk_install>\nbrtos\include\predef.h`. ECC key sizes can range from 160 to 512.

Both ECC and RSA keys can be presented in either PEM or ASN1 formats.

10.13.1.2 Migrating from NNDK 3.3.5 and earlier to 3.3.6 or later

We've made every effort to make sure that the updates to the SSH library would be backward compatible. However, in some cases change was unavoidable, and in others, developers would be better served to update their applications to use newer versions of existing functions.

When building applications that use the SSH libraries in NBEclipse, the following include paths need to be added to projects:

```
{NNDK_ROOT}/libraries/include/ssh
{NNDK_ROOT}/libraries/include/crypto
```

To do this, first right click on your project in NBEclipse, and select the properties option at the bottom of the menu. The following window will be displayed.

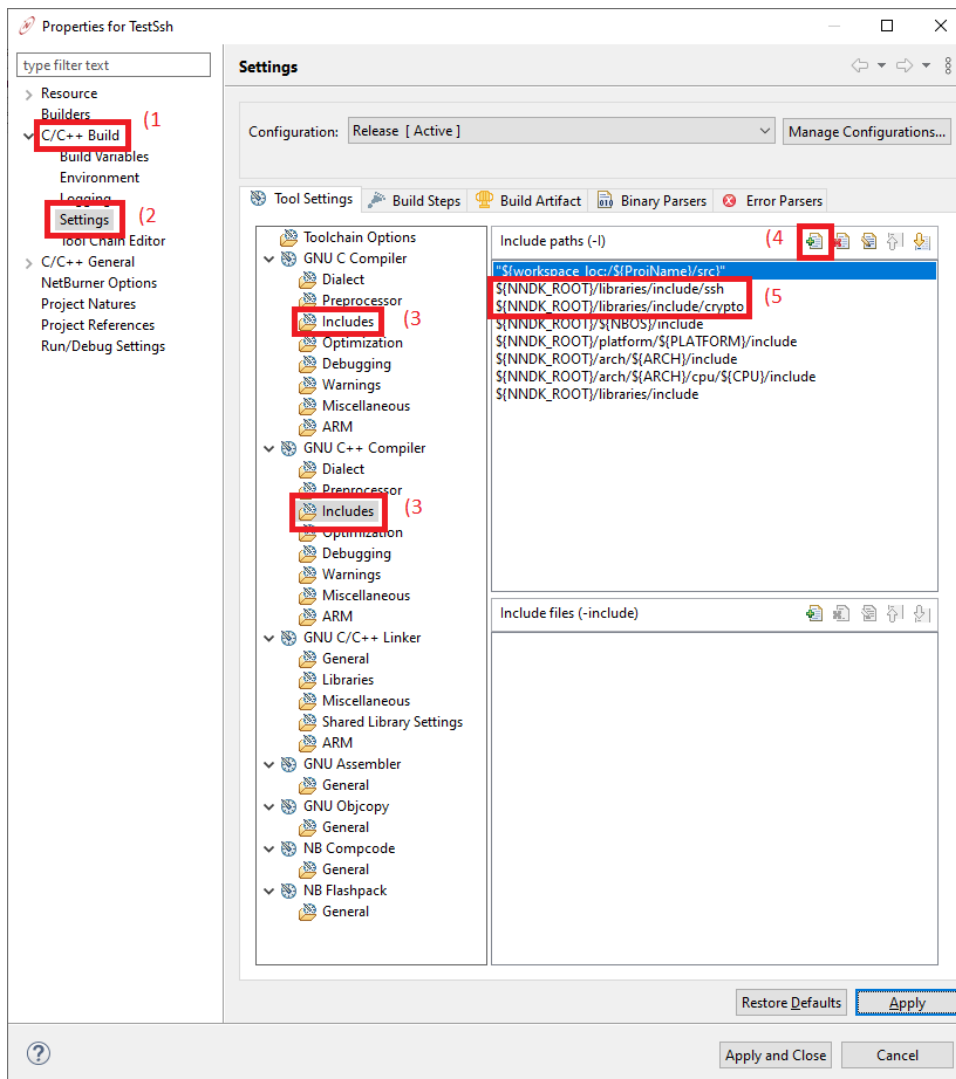

Figure 10.9 Adding the SSH Include Paths

From the left side menu, select "C/C++ Build" (1) followed by "Settings" (2). In the main window, you'll want to select the "Includes" (3) folder under both the "GNU C Compiler" and "GNU C++ Compiler". Once here, hit the icon with the green plus on it (4), and then add the paths so that they are listed above (5). Finally, hit "Apply", and then clean the project. It should find the required files during the build and complete successfully.

10.13.1.2.1 Removed and Updated Functions

The following functions have been removed from our API. They were specific to the Dropbear library and no longer make sense to have in our current API.

- `SshConvertDecodedOpenSSLKey` This function converted a PEM formatted SSL key to the Dropbear format. The new API supports both PEM and ASN1 formatted keys, and we no longer support the Dropbear format.
- `SshSetchansessionrequest` This function set a user callback routine for handling server side channel requests. These requests are handled internally by wolfSSH.
- `SshSetTaskPriority` This function set the task priority for the SSH session. Where each SSH session had its own task previously, both SSH and SSL/TLS sessions are now managed by the CryptoServer object. This object runs a task of priority SECURITY_TASK_PRIO, which is defined in `<nndk_install>\nbrtos\include\constants.h`.

The following functions and function pointers have updated versions that we encourage developers to take advantage of.

- `sshUserAuthenticateFn` An updated version of this function pointer, `sshUserAuthenticateWithTypeFn`, has been added to the API. Instead of just taking a pointer to the username and password as its parameters, it now additionally takes a parameter of `AuthType` that specifies if the authentication value passed in is a password or a key.
- `SshSetUserAuthenticate` This function should be replaced with `SshSetUserAuthenticateWithType()`, and takes as its parameter a function pointer of type `sshUserAuthenticateWithTypeFn`.
- `SshGetUserAuthenticate` This function should be replaced with `SshGetUserAuthenticateWithType()`, and returns a function pointer of type `sshUserAuthenticateWithTypeFn`, if it has been set with a call to `SshSetUserAuthenticateWithType()`.

10.13.1.3 Onboard Generated Keys

As is the case with our updated SSL/TLS library, SSH can now take advantage of onboard generated keys. This means that SSH keys can be automatically generated on the device if required. The mechanism for this is exactly the same, and in fact, the SSH key is the same key that is generated as part of generating an SSL/TLS certificate. To understand how to use the functionality, we encourage developers to look at the appropriate examples, found in `<nndk_install>\examples\SSL\SslOnboardCertGeneration`.

Auto-regeneration of this key can be enabled by defining `ENABLE_AUTOCERT_REGEN`, found in `<nndk_install>\nbrtos\include\predef.h`.

10.13.1.4 Order of Key Use

There are several methods in which a key could be installed on the device. In order of consideration during runtime, these are:

- Set a function callback with `SshSetUserGetKey()` that will return the server key via the passed in parameters.
- Using a compiled in key, and overriding the weak function `GetPrivateKeyPEM()`.
- Using an onboard generated key.

10.13.1.5 User Authorization

To assist with storing and managing user authentication data, we've provided a simple class, `UserAuthManager`. This class provided the methods required to store, retrieve, and compare user credentials for authentication and authorization purposes. Two callback signatures are provided, `LoadAuthRecordsFn` and `SaveAuthRecordsFn`, that can be used to load and save user authorization into the `UserAuthManager` object. This allows the developer to use any type of storage device or location to save the data.

Passwords and keys are hashed when added to the manager, so there is no possibility for leaking plain text data that could potentially compromise the security of the system. Our provided example, `sshServerUserAuth`, demonstrates this using the devices User Param space to save the data as a JSON blob.

10.14 Web Server

Topic Links:

- [Basic Web Server](#)
- [Dynamic Web Content](#)

10.14.1 Basic Web Server

The Application Wizard creates a `main.cpp` file, and also a directory in your project named "html" with a file named `index.html`:

```
<html>
<body>
The main page for the AppWizard project.
</body>
```

```
</html>
```

In NBEclipse you can open a HTML file in text edit mode by right-clicking on the file and selecting the text editor option:

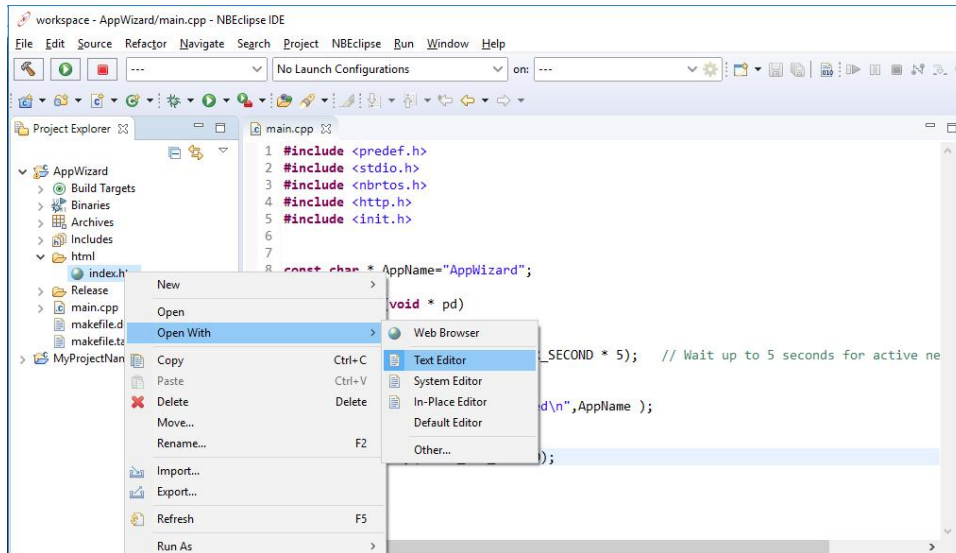

Figure 10.10 Open with text editor

The project html folder is where you can all the files you need for your application, including images, javascript, html files, etc. You can also add folders. For example adding a folder for images is very common. For example, if you created a folder in the html directory named images and added the file logo.jpg, you could add it to your index page by adding the img tag:

```
<html>
<body>
The main page for the AppWizard project.
<img src = images/logo.jpg>
</body>
</html>
```

10.14.2 Dynamic Web Content

Dynamic web content (web content created at run-time) can be created using the following NetBurner HTML tags:

- A C++ callback function CPPCALL:

```
<!--CPPCALL YourCppFunction -->
```

When the web server delivers the web page it will call your C++ function.
- The VARIABLE tag:

```
<!--VARIABLE YourVariable -->
```

. When the web server delivery the web page it will insert the specified variable.
- A C callback function FUNCTIONCALL. This tag is included for those porting from older tool sets. FUNCTIONCALL is a C only tag, and is deprecated.

10.14.2.1 Dynamic Content Using the CPPCALL Tag

To add a C++ callback we can add a function to main.cpp such as:

```
void webHelloWorld( int sock, PCSTR url )
{
    writestring( sock, "Hello World" );
}
```

And modify index.html to add the tag:

```
<html>
<body>
The main page for the AppWizard project.
<!--CPPCALL webHelloWorld -->
</body>
</html>
```

When a web client requests the index.html page, the web server will begin streaming the static content. When it gets to the CPPCALL, it will call the webHelloWorld() function, which will send "Hello World" to the client using the open TCP socket. When the function returns, the web server will continue sending the index.html web page. A web page can have any number of CPPCALL and VARIABLE tags. The parameters passed to the CPPCALL function are the open TCP socket handle, and a pointer to a constant string containing the entire URL of the client web browser. In this way your function can parse the URL if that is important to your application. For example, anything after a '?' character is application specific.

10.14.2.2 Displaying Variables Using the VARIABLE Tag

Variables in an application can be displayed on a web page using the VARIABLE tag. This can be useful for displaying information such as time, an IP address, temperature, etc. The format of the tag is:

```
<!--VARIABLE <name> -->
```

Where "name" is the name of the application variable or an expression. For example, the system time tick variable TimeTick can be displayed with

```
<!--VARIABLE TimeTick -->
```

Or you can display the time in seconds with the equation:

```
<!--VARIABLE TimeTick/TICKS_PER_SECOND -->
```

The VARIABLE tag is processed during the compilation of the application by parsing the text between <!--< VARIABLE and the trailing --> and converting it into a function call such as: WriteHtmlVariable(fd, TimeTick/TICKS_PER_SECOND); In this function fd is a file descriptor to the current TCP connection to the web client.

Variable types are handled with C++, but you do not need to know anything about C++ to use this feature.

The parameter types are defined by the function definitions located in \nburn\include\htmlfiles.h:

```
void WriteHtmlVariable(int fd, char c);
void WriteHtmlVariable(int fd, int i);
void WriteHtmlVariable(int fd, short i);
void WriteHtmlVariable(int fd, long i);
void WriteHtmlVariable(int fd, BYTE b);
void WriteHtmlVariable(int fd, WORD w);
void WriteHtmlVariable(int fd, unsigned long dw);
void WriteHtmlVariable(int fd, const char *);
void WriteHtmlVariable(int fd, MACADR ip);
```

In addition, we have included a class named IPCAST () that takes a 32-bit value and converts it into an IP address format (e.g. 192.168.1.2). This example will display the IP address in dotted notation, rather than a 32-bit integer:

```
IP address: <!--VARIABLE IPCAST(IpAddress) !-->
```

10.14.2.3 Linking to Variables Using the INCLUDE Tag and htmlvar.h Header File

When an application with web content is built by the NetBurner tools, a file named `htmldata.cpp` is created. When using the VARIABLE tag for dynamic data, the application must be able to link to the variable. This can be achieved in either of two ways:

- Create a header file in your project named `htmlvar.h`.
- Use the INCLUDE HTML tag in the .html folder.

An example of a `htmlvar.h` file to display a variable named `Temperature`, and a VARIABLE function call-back named `webMyVarFunction()` to display an integer:

```
#ifndef HTMLVARS_H_
#define HTMLVARS_H_

#include <startnet.h>

extern int Temperature;

const char *webMyVarFunction(int fd, int v);

#endif // HTMLVARS_H_
```

10.14.2.4 Function Callbacks With Variables Using the VARIABLE Tag

If you need to use a function that can take a parameter, the CPPCALL tag will not work because the parameters are fixed as the socket `fd` and URL. However, the VARIABLE tag can be used for both the function call and variable parameter. The `htmlvar.h` include file must specify the function definition in one of the formats described in the previous section. The format below. For example, to pass an integer variable `webMyInteger` in a callback function named `webMyFunction`:

```
const char * webMyVarFunction(int fd, int webMyInteger);
```

The HTML file calls the function with:

```
<!--VARIABLE MyFunction(fd, webMyInteger) -->
```

When the application is compiled the resultant function call will be:

```
WriteHtmlVariable( fd, MyFunction(fd, webMyInteger) );
```

In your .cpp source code the function could look something like this:

```
const char * webMyVarFunction(int fd, int v)
{
    char buffer[255];
    sprintf( buffer, "MyFunction() was called with v = %d\r\n", v );
    writestring( fd, buffer );

    return "\0"; // Return a const char * of zero length so it will not print to the HTML page
}
```

10.14.2.5 Extending the VARIABLE tag for User Defined Types

The VARIABLE functionality can be extended to support user defined types, such as a user defined structure or class. Lets say you have a structure you want to display on a web page called `MyStruct`:

```
struct my_struct {
    int i;
    char buf[80];
    uint32_t dVal;
} MY_STRUCT;
```

```
MY_STRUCT MyStruct;
```

In your include file add the function definition: `void WriteHtmlVariable(int fd, MY_STRUCT MyStruct) ;` You then need to implement the function to display the data. For example:

```
void WriteHtmlVariable(int fd, MY_STRUCT MyStruct)
{
    fprintf(fd, "int: %d<br>", i);
    fprintf(fd, "buf: %s<br>", buf);
    fprintf(fd, "uint32_t: %ld<br>", dVal);
}
```

You can then display it on the web page with the VARIABLE tag:

```
<!--VARIABLE MyStruct -->
```

Chapter 11

System Diagnostics

11.1 Introduction

System Diagnostics can be viewed from a device's Configuration Server web page (port 20034) by calling the [EnableSystemDiagnostics\(\)](#) function in your application. Diagnostic information includes items such as system definitions, variables, TCP stack status, and RTOS state information.

11.2 Configuration Server Page with Diagnostics Enabled

When system diagnostics are enabled, an additional button will appear on the configuration server web page in the lower right corner:

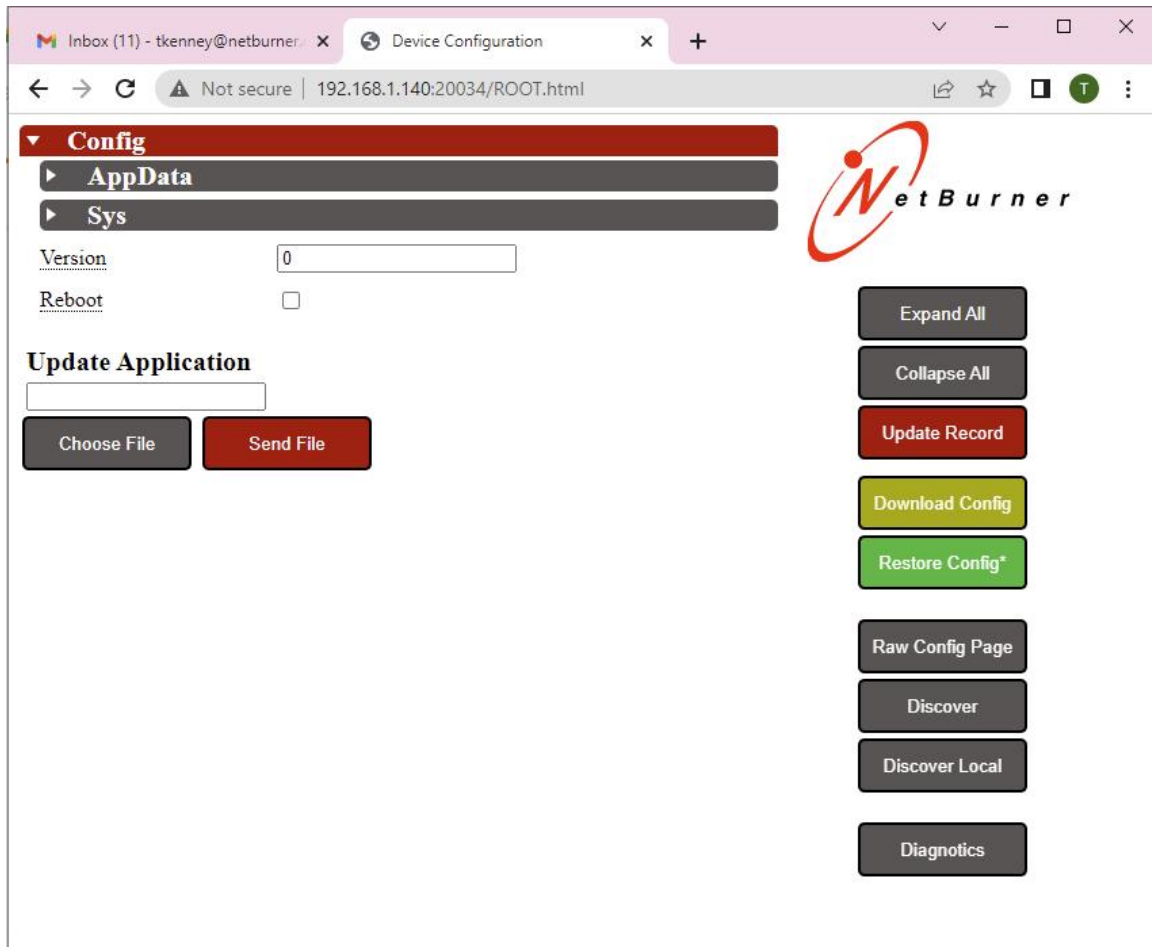

Figure 11.1 Configuration Server With Diagnostics Button

11.3 System Configuration Web Page Display

Clicking on the Diagnostics button will display system information. An example of the raw data is shown below:

```

```

If you are using Firefox or have the Pretty Print extension in Chrome, the JSON data will be formatted and much easier to read. If the output you see looks identical to the previous raw information, it means the browser you are using does not support JSON data formatting. The image below shows a snippet of a formatted file displayed in Firefox:

11.4 Adding Your Own Diagnostic Information

You can add your own diagnostic information using the `MyVarMon()` functions. Please refer to the System Diagnostics example for more details. In the example output in the previous section, the variables below were added to the standard system output:

```
"My Int":4677,  
"My String":"My String",
```

The application code to implement the display from the example is:

```
// Variables to monitor  
int myInt;  
char myString[80];  
  
// Declarations to add variables to Diagnostic Web page  
static DiagVarMon MyIntMon("My Int", myInt);  
static DiagVarMon MyStrMon("My String", myString);
```

Chapter 12

Example Applications

12.1 Example Applications Main Page

Included in your NNDK software installation folder are over 200 examples to aid you in your product development and learning the NetBurner platform, demonstrating functionality such as:

- Web pages, Web servers and Web clients
- TCP client and server
- TLS client and server, certificate, auto cert generation and management
- UDP client and server
- Device configuration
- Real-Time operating system such as semaphore, tasks, queues and critical sections
- JSON
- File system
- VLAN
- Web sockets
- Hardware board locking to secure application code
- Hardware peripherals such as [I2C](#), SPI, UART, USART, 1-Wire, GPIO, ADC, DAC, PWM, Timers
- PPP
- FTP
- SSH
- MQTT
- ACME certificate support

These are just some of the extensive topics covered. There are a few ways to browse the examples:

1. The HTML and PDF documents
2. Browsing the folder structure in `nburn\examples`
3. When using NBEclipse, you can browse and import examples

There are two main categories of examples:

1. The `\nburn\examples` folder contains examples that can be run on all platforms.

2. The `\nburn\examples\PlatformSpecific` folder contains examples that are specific to a NetBurner product, such as hardware peripherals: I2C, SPI, 1-Wire, ADC, DAC, etc.

Links to the example sections are below, or you can use the tree control structure in the online docs.

12.2 AES

A basic description of AES can be obtained from Wikipedia, and if you are new to AES, you should definitely do some research to understand the implementation. The description below is from Wikipedia:

In cryptography, a block cipher is a symmetric key cipher which operates on fixed-length groups of bits, termed blocks, with an unvarying transformation. When encrypting, a block cipher might take a (for example) 16-bit block of plaintext as input, and output a corresponding 16-bit block of ciphertext. The exact transformation is controlled using a second input - the secret key. Decryption is similar: the decryption algorithm takes, in this example, a 16-bit block of ciphertext together with the secret key, and yields the original 16-bit block of plaintext.

To encrypt messages longer than the block size, a mode of operation is used. Block ciphers can be contrasted with stream ciphers; a stream cipher operates on individual digits one at a time, and the transformation varies during the encryption. The distinction between the two types is not always clear-cut: a block cipher, when used in certain modes of operation, acts effectively as a stream cipher.

This example demonstrates how to use the AES key, encryption, and decryption function calls on a 16 byte block of data. Since AES is a block cipher, all data must be encrypted in 16 byte blocks. If you have more than 16 bytes to transfer, you must break the data into 16 byte blocks, encrypt them (you can use the same key for all blocks), send them, then decrypt them in 16 byte blocks on the other end.

12.4 Clear Configuration Flash

Simple program used to clear the NetBurner 3.0 configuration flash area. Once the flash area is erased, resetting the NetBurner device will re-initialize the configuration parameters. Note: on 5441x based devices this program will not clear the configuration parameters used by the Alternate Boot Monitor.

12.5 Clear User Parameter Flash

Small program to clear the User Parameter area in flash memory. In practice, your application should have the ability to reset any non-volatile settings, rather than a full erase. This utility is useful if switching between examples/applications that use User Parameter storage in different ways, without having to create code to do a default reset.

12.6 Configuration

Examples to demonstrate how to:

- Customize the configuration server
- Set configuration parameters via web page and through the application code

Examples:

- [Application Data](#)
- [Config and System Params](#)
- [Config Web Interfaces](#)
- [Detached Config Object](#)

12.6.1 Application Data

The examples in this directory show how to use the configuration system to create, modify, and store persistent data values that can be used in user applications.

- [BasicConfigVariables](#) - Shows how to create, modify and store basic config variable types with the config system
- [ConfigClass](#) - Expands on [BasicConfigVariables](#), and shows how to create new class types that inherit from base config objects, and how they can be combined together to create complex objects
- [NestingConfigObjects](#) - Expands on [ConfigClass](#), and shows how config objects can be grouped together to create a nested hierarchy of data

Examples:

- [Basic Config Variables](#)
- [Config Class](#)
- [Nesting Config Objects](#)

12.6.1.1 Basic Config Variables

The config system stores system-defined boot and interface information, such as default BaudRate and current IP settings, and also provides a system for the user to define and store their own persistent variables.

In this example, we've created some very basic config objects to represent the basic data types that are created when the device first boots, and whose values persist after the device has been power cycled. The currently available config objects that can be used are as follows:

- `config_obj` // base object, used as a container for other objects

- `config_bool` // bool
- `config_int` // int
- `config_double` // double
- `config_string` // string
- `config_chooser` // multiple choice option
- `config_pass` // password
- `config_IPADDR4` // IP4 Address
- `config_IPADDR6` // IP6 Address
- `config_MACADR` // MAC Address

12.6.1.2 Config Class

This program shows the basics of using NetBurner's config system. The config system stores system-defined boot and interface information, such as default BaudRate and current IP settings, and also provides a system for the user to define and store their own persistent variables.

In this example, which expands on the BasicConfigVariable example, we create some custom classes that inherit from an empty config object type. We then use these classes to group additional config data together. The objects of these types are created when the device first boots, and their values persist after the device has been power cycled. The currently available config objects that can be used are as follows:

- `config_obj` // base object, used as a container for other objects
- `config_bool` // bool
- `config_int` // int
- `config_double` // double
- `config_string` // string
- `config_chooser` // multiple choice option
- `config_pass` // password
- `config_IPADDR4` // IP4 Address
- `config_IPADDR6` // IP6 Address
- `config_MACADR` // MAC Address

12.6.1.3 Nesting Config Objects

This program shows the basics of using NetBurner's config system, specifically, how config objects can be nested inside each other. The config system stores boot and interface information, such as default BaudRate and current IP settings, and also provides a system for the user to define and store their own persistent variables.

In this example, we have expanded on the ConfigClass example, and created an additional config class that is used to nest several instances of our previously defined class. This nesting allows for control over the structure and hierarchy of the data when it is saved in the flash as a JSON blob. The currently available config objects that can be used are as follows:

- `config_obj` // base object, used as a container for other objects
- `config_bool` // bool
- `config_int` // int
- `config_double` // double
- `config_string` // string

- [config_chooser](#) // multiple choice option
- [config_pass](#) // password
- [config_IPADDR4](#) // IP4 Address
- [config_IPADDR6](#) // IP6 Address
- [config_MACADR](#) // MAC Address

12.6.2 Config and System Params

The examples in this directory show how to access and modify system values through the configuration system.

- [ShowConfig](#) - Shows how to view the entire JSON config blob
- [ModifyBoot](#) - Shows how to view and modify the Boot system values through the global config variable `monitor_config`
- [ModifyEthernet](#) - Shows how to view and modify the interface system values (default is typically Ethernet0) through the config system

Examples

- [Modify Boot](#)
- [Modify Ethernet Interface](#)
- [Show Configuration](#)

12.6.2.1 Modify Boot

The config system stores system-defined boot and interface information, such as default BaudRate and current IP settings, and also provides a system for the user to define and store their own persistent variables. This program shows how to view and modify the values of the "Boot" config record.

12.6.2.2 Modify Ethernet Interface

The config system stores boot and interface information, such as default BaudRate and current IP settings, and also provides a system for the user to define and store their own persistent variables. This program shows how to view and modify the values of the Ethernet interface in the config record.

12.6.2.3 Show Configuration

The configuration system stores settings controlling how the device boots, as well as network and serial interface settings, in a JSON format. This example demonstrates how to:

- Read the system configuration and display on the serial port
- Display the amount of memory used by the configuration settings and total available space

12.6.3 Config Web Interfaces

The system configuration web page interface is located on network port number 20034. These example demonstrate how to provide the same configuration interface as part of the application web server (default port numbers are 80 or 443 for SSL/TLS), so that the configuration web pages are consistent with the rest of the application web interface.

Examples:

- [Basic Web Config](#)
- [Basic Web Config with SSL/TLS](#)
- [Config Tags](#)
- [Custom Web Config](#)
- [Custom Web System Config](#)

12.6.3.1 Basic Web Config

The system configuration web page interface is located on network port number 20034. This example demonstrates how to provide the same configuration interface as part of the application web server on port 80 (or 443 for SSL/TLS), so that the configuration web pages are consistent with the rest of the application web interface.

The web page is dynamically generated, and provides access to view and/or modify boot and interface settings, such as default serial port baud rates and IP addresses, as well as application specific data.

The code used to generate and process the web form is in `html/index.html`. This example does not use any external JavaScript libraries, and all of the form generation code is located at the bottom of `index.html`. For a more advanced example that utilized Bootstrap and jQuery, please see the CustomWebConfig example.

Currently available config objects that can be used are as follows:

- `config_obj` // base object, used as a container for other objects
- `config_bool` // boolean
- `config_int` // integer
- `config_double` // double float
- `config_string` // string
- `config_chooser` // multiple choice option
- `config_pass` // password
- `config_IPADDR4` // IP4 Address
- `config_IPADDR6` // IP6 Address
- `config_MACADR` // MAC Address

Note that because we are only processing the config object, we are able to avoid writing a custom POST handler that is used in the other examples. If you include more to your web interface than is provided here, that will need to be incorporated as well.

12.6.3.2 Basic Web Config with SSL/TLS

This example is identical to the BasicWebConfig example with the addition of SSL/TLS. Please refer to that documentation for a description of how the configuration server operates.

Certificates can be handled a number of ways: auto-generated, self-signed, compiled into the application, or uploaded to a file system. To simplify things, this example provides files for a compiled certificate and key, named `ServerCert.cpp` and `ServerKey.cpp`.

To generate your own self-signed certificates, use the script files in the `\nburn\CreateCerts` folder:

- `makeca.bat` to generate a Certificate Authority certificate and key
- `makeserver.bat` to generate the HTTPS server certificate and key

For the common name (CN), use the IP address of your device, then copy the generated `.cpp` files to your project's `src` folder.

Please refer to the `\nburn\examples\ssl` folder for more advanced SSL/TLS certificate handling.

12.6.3.3 Config Tags

This program demonstrates the use of the following dynamic web content tags that can be used to display and modify configuration variables:

- `CONFIGVALUE`
- `CONFIGINPUT`
- `CONFIGTABLE`

The example shows how to just get the raw data from the board, as well as how it can be styled using Bootstrap and CSS. While `VARIABLE` and `CPPCALL` HTML tags can be used to present the same information, the `CONFIG` tags simplify things by combining the data with HTML code to create input fields, tables and value displays.

12.6.3.4 Custom Web Config

This example is an advanced version BasicWebConfig example that implements the content with JavaScript and jQuery. It also demonstrates how to store and display custom application data in the AppData section.

Configuration objects are created when the device first boots, then they are stored so they are persist after the device has been power cycled. The web interface adds custom styling beyond the basic server presentation to view and set the values. The currently available configuration objects are:

- `config_obj` // base object, used as a container for other objects
- `config_bool` // bool
- `config_int` // int
- `config_double` // double
- `config_string` // string
- `config_chooser` // multiple choice option
- `config_pass` // password
- `config_IPADDR4` // IP4 Address
- `config_IPADDR6` // IP6 Address
- `config_MACADR` // MAC Address

Note that because we are only processing the config object, we are able to avoid writing a custom POST handler that is used in the other examples .If you include more to your web interface than is provided here, that will need to be incorporated as well.

12.6.3.5 Custom Web System Config

The majority of examples for creating a custom configuration interface create a configuration page in the application code so that it will be part of the application's web interface. This enables the configuration interface to be consistent with the rest of the web pages. In contrast, this example will demonstrate how to change the device's system configuration server that appears on network port number 20034. The change can be as simple as branding with your logo, or modification to the web page content.

You can combine both the custom application and custom system configuration to brand your product

The logo and html files are converted to .cpp files and compiled into the application. The files involved are located in `\nburn\nbrtos\source`:

- LOGO.gif, the logo displayed on the configuraiton page.
- ROOT.html, the javascript root configuration page.
- RAW.html, Low level HTML only page with links to configuration and the `UI.html` page that displays the entire JSON object.
- UI.html, displays the entire JSON object.

To customize, follow the overload procedure in which you copy and modify the desired files into your project's overload directory. For example, to change just the logo, create a folder in the overload directory where the file is located: `\nbrotos\source`, and copy your LOGO.gif file there. The majority of customizations will only need to change the logo, but the html overrides are there to suppor any type of customizatn an appli-cation requires. A sample LOGO.gif file is provided for you in this application's src folder. Copy this gif to the `override\nbrtos\source` folder to see the modification.

Running the Example: The example is based on SimpleHtml and provides a basic web page on port 80. Viewing the system configuration page on port 20034 will show the custom modifications. A LOGO.gif file is already provided to demonstrate the use of a custom logo, so you can build and run the example as-is before adding your own customizations.

12.6.4 Detached Config Object

This example demonstrates how to create JSON configuration objects (data or structures) in a "detached" mode, meaning they do not appear in the web page configuration screen, nor are they saved, but are exposed via individual web pages. In Detached mode they are created at boot time and can be modified and used by the application.

The example will:

- Create a number of configuration object classes
- Use the classes to create Detached configuration objects
- For reference, shows how they would be exposed in the normal configuration tree
- Expose those objects as web pages containing the JSON information

For example, if your device IP address is 10.1.1.10, opening a web browser and typing "10.1.1.10/set.json" will display that object and it's data:

```
ctrl_set
Hset
  D 0
  I 0.0001
  P 1
Vset
  D 0
  I 0.0001
  P 1
rev 0
```

12.7 DNS Device Name

The device name is stored in the device's flash configuration. There are two ways to give your device a name:

1. Use the configuration web interface, which is your device's <device ip address>:20034.
2. You can change the configuration flash setting in your application. You will then need to reboot the device for the name to take effect.

This example demonstrates how to change the device name in an application.

Additional information on DNS naming

When a network device (such as the NetBurner module) requests an IP address from a [DHCP Server](#), the device sends it MAC address and an optional device name (this is supported by your NetBurner device). The [DHCP Server](#) supplies the dynamic IP address and maintains a table containing the MAC address, IP address and device name for each device that has accepted a [DHCP lease](#).

The purpose of a DNS server is to convert a name into an IP address. To do this it must get the information from your [DHCP Server](#). On windows server platforms that run both a [DHCP server](#) and DNS server, this can be configured in a dialog box. On Linux/Unix it may be more complicated. Basically, every time the [DHCP server](#) gives out a new dynamic IP address it updates the DNS server. If you are not using [DHCP](#), and are assigning static IP addresses, then you must update the DNS server with the entries manually (i.e. name and IP address).

If you do not have a DNS server, you can modify the `lmhosts` file on your PC to add the IP address and name of each network device you want to address by name. You would need to do this on every PC that wants to use the name.

Windows has a proprietary protocol called WINS (only Microsoft products can use it). Windows machines can have a name, and the protocol enables windows machines to talk to one another. This is achieved by having one windows PC maintain the table of MAC address, IP address and names.

12.8 DHCP

[DHCP](#) Examples:

- [DHCP Client - Change IP Address](#)
- [DHCP Client - Test DHCP](#)
- [DHCP Server \(DHCPD\)](#)
- [DHCP Client - Change IP Address Via Webpage](#)

12.8.1 DHCP Client - Change IP Address

Demonstrate how to view IP address and change between [DHCP](#) and static IPv4 IP settings.

To change from [DHCP](#) to Static:

- Read the Static settings from the configuration record
- Set address mode to "Static"
- save to the configuration flash
- Option to reboot or change runtime settings

To change from Static to [DHCP](#):

- You can leave the static settings intact if you wish, it will not affect [DHCP](#)
- Set address mode to "DHCP" or "DHCP w Fallback"
- Save to the configuration flash
- Option to reboot or change runtime settings

12.8.2 DHCP Client - Test DHCP

12.8.2.1 Example of advanced DHCP functionality

Most applications can simply use the `GetDhcpAddress()` function call to automatically handle obtaining a [DHCP](#) address and configuration. If you need finer control, you can create a [DHCP](#) Object and manage the [DHCP](#) functions from within your application. This example shows how you can create a [DHCP](#) object and use a pointer to the object to monitor and control [DHCP](#) services.

It also will show you the internal workings of [DHCP](#) by displaying UDP packet information and [DHCP](#) variables on `stdio`, which is `UART0` by default (view with `MTTTY`). It is not the intent of the example to be a tutorial on [DHCP](#). For detailed [DHCP](#) information please refer to RFC 2131.

For the purposes of education/demonstration, this application will access the C++ private class variables of a [DHCP](#) object. This is NOT required for end applications, it is just used here for education.

To obtain access to private class variables in the [DHCP](#) object, you will need to enable debugging in the `\nburn\system\dhcpc.cpp` file by removing the comments from the following line:

```
#define DHCP_DEBUG 1
```

Warning

COMMENT OUT THE `#define DHCP_DEBUG 1` when you are done with this example, it should not be enabled in normal applications.

This example will:

- Create a [DHCP](#) object global variable
- Start [DHCP](#) and monitor a semaphore for completion
- Provide an interactive menu to start and stop dhcp services, modify the system timer, and display dhcp status.

12.8.3 DHCP Server (DHCPD)

Demonstrates how to create a [DHCP](#) Server on your NetBurner device

12.8.4 DHCP Client - Change IP Address Via Webpage

Demonstrate how to view IP address and change between [DHCP](#) and static IPv4 IP settings using a webpage interface. After submitting IP setting changes through the webpage form, the webserver will redirect the webpage to the new address of the device if necessary. The webpage also handles multiple interfaces, in case the module supports multiple interfaces (such as dual-ethernet and/or WiFi).

To change from [DHCP](#) to Static:

- Read the Static settings from the configuration record
- Set address mode to "Static"
- save to the configuration flash
- Option to reboot or change runtime settings

To change from Static to [DHCP](#):

- You can leave the static settings intact if you wish, it will not affect [DHCP](#)
- Set address mode to "DHCP" or "DHCP w Fallback"
- Save to the configuration flash
- Option to reboot or change runtime settings

12.9 DNS Client

DNS Client Example

DNS example using [GetHostByName\(\)](#), [GetHostByName4\(\)](#) and [GetHostByName6\(\)](#) to resolve a name to an IP address for both IPv4 and IPv6.

To run this program:

- Start MTTY and connect to the debug serial port
- You will be prompted to enter a name, such as [www.netburner.com](#)
- The DNS IP address resolution will be displayed

For this example to function, your NetBurner device must have access to the Internet, with a working configuration for the IP address, mask and gateway.

12.10 Embedded Flash File System (EFS)

Embedded Flash File System (EFS) examples. There are two types of file systems:

- EFS FAT: A FAT 32 file system used for flash memory cards
- EFS STD: A power fail-safe file system that resides in the flash memory of the module itself

Example Categories:

- [FAT File System \(EFS-FAT\)](#)
- [Standard File System \(EFS-STD\)](#)

12.10.1 FAT File System (EFS-FAT)

EFS FAT32 Examples:

- [Application Update](#)
- [Basic](#)
- [FTP FTP](#)
- [HTTP](#)
- [HTML Variables](#)
- [Multiple Tasks](#)
- [Performance Tests](#)
- [RAM Drive](#)

12.10.1.1 Application Update

This application demonstrates how to update a NetBurner application in onboard flash memory from an external SD flash card. The application will look for a file on the flash card with the name specified by APPFILENAME. Use MTTTY to monitor the serial output of your NetBurner device. If this file is found, an application update can be performed by typing a character in response to the MTTTY prompt.

Note

All EFFECTS FAT examples require that you add the Embedded Flash File System File Allocation Table (EFFECTS FAT) library to your project: [Add a Library to a Project](#)

12.10.1.2 Basic

This program illustrates basic file system operations for SD/MMC and Compact Flash cards:

- Mounting a drive
- Determining amount of used and free file space
- Creating files
- Writing data
- Reading data
- Unmounting a drive

When the program executes it will display program status information through the debug serial port. This application has web server support for onboard flash/ram only, web pages cannot be run from external flash cards. This capability is demonstrated in the EFFECTS-HTTP example to illustrate the difference between the two operations.

Note

All EFFECTS FAT examples require that you add the Embedded Flash File System File Allocation Table (EFFECTS FAT) library to your project: [Add a Library to a Project](#)

12.10.1.3 FTP

This program illustrates file system and FTP operations for SD Flash cards:

- Mounting a flash drive
- Determining amount of used and free file space
- FTP access. We recommend Filezilla or WinScp

Status messages will be sent out the debug serial port.

Modules with an onboard microSD flash socket should use the multi MMC header files and functions because the modules are capable of supporting both onboard and external flash cards (even if you application only uses one).

Note

All EFFECTS FAT examples require that you add the Embedded Flash File System File Allocation Table (EFFECTS FAT) library to your project: [Add a Library to a Project](#)

12.10.1.4 HTTP

12.10.1.4.1 Overview

This example demonstrates how to use the EFFECTS-FAT file system with SD cards. This file system is different than the EFFECTS-STD file system which uses onboard flash chip memory.

Note

All EFFECTS FAT examples require that you add the Embedded Flash File System File Allocation Table (EFFECTS FAT) library to your project: [Add a Library to a Project](#)

12.10.1.4.1.1 Application Functionality

- Creation of a text file from within the application named "TestFile.txt"
- Display of the text file
- Read/Write test of the text file
- Display of file space and amount used
- Format of the file system
- Test for file access functions: fgets(), fputs(), fprintf()

12.10.1.4.1.2 Network Functionality

- NTP is used to set the system time and time zone so that file time stamps are correct.
- HTTP web page interface and file display. If you use FTP to put in your own index.html page, it will be used in place of the example default page.
- FTP Server for file access. You can use client programs such as FileZilla to upload/download files

Note

Running the example in an environment where the device has Internet access will enable the Network Time Protocol (NTP) to automatically set the time. Otherwise, you can set the time manually through the serial port menu.

The EDFS-FAT manual, "EDFS-FAT-R3p31.pdf", is located in the "\nburn\docs" folder.

12.10.1.4.2 Building The Example

12.10.1.4.2.1 NBEclipse With Example Import Feature or Command Line

If you build a new project and use the NBEclipse Example Import feature, all settings will be take care of automatically. If you are building using the example makefile on the command line, the makefile contains all necessary settings.

12.10.1.4.2.2 Copy index.html and MIME.txt files

Copy index.html and and MIME.txt from the example's root directory to your flashcard, or put your own there. This can be done once the example is running with FTP as well.

12.10.1.4.2.3 Changing the Flash Card Type

The Flash card type can be modified in cardtype.h. The default is a SD card.

12.10.1.4.2.4 Adding EDFS-FAT Functionality to an Existing NBEclipse Project

Add the FatFile.a library to the GCC Linker settings

- Right click on your project.
- Navigate to C/C++ Build > Settings > GNC C/C++ Linker > Libraries.
- In the Libraries section, add "FatFile". Note there is no .a extension.

12.10.1.4.2.5 Adding EDFS-FAT Functionality to a Makefile

In the makefile, add:

```
XTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libFatFile.a
DBXTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libFatFile.a
```

12.10.1.4.3 Running the Example

The application provides access through an interactive serial port menu, web page, and FTP.

12.10.1.4.3.1 Serial Interface

- Run MTTY or some other serial terminal program and connect to the device
- Status messages will be displayed as well as an interactive menu. If this is the first time the application has been run, the file system will be formatted.
- You can experiment with the various menu options.

12.10.1.4.3.2 Web Server (HTTP)

- The default web page will provide various interactive options and information display.
- Entering the IP address followed by "/DIR" (eg. `http://10.1.1.57/DIR`) will display the file directory
- The web server will display the default page based on what is in the file system in the following order: – The `index.html` (will superced `index.html` file compiled into the application) – The first available `*.html` file
- Use FTP (see below) to upload your own `index.html` file and it will replace the application default.

12.10.1.4.3.3 FTP Operation

Connection to the device with a FTP client such as FileZilla will enable you to upload, download and view files.

12.10.1.4.3.4 File Priority

When viewing the web page, the page displayed depends on the following order and their availability on the flash card:

- `index.html` file
- The first available `.html` file
- A web page list of all directories and files that exist on the flash card

Note

If `*.html` files exist on the flash card, then the program will always access the first available web page file by default.

12.10.1.5 HTML Variables

This example program sets up HTTP access to the FAT file system on SD Flash cards.

To run this example:

1. Compile the example for your chosen flash card in `cardtype.h`. The NetBurner development board supports SD Flash cards.
2. Copy `index.html` and `MIME.txt` from the example's root directory onto your flashcard, or put your own there.
3. When the program runs, status messages will be displayed on the module debug serial port.
4. You can view the files on the flash card with any web browser by typing in the IP address of the module at the "/DIR" folder Example: "`http://10.1.1.57/DIR`".

5. When accessing the module via browser, what web pages will be displayed depends on the following order and their availability on the flash card:
- index.html files
 - The first available .html file
 - A web page list of all directories and files that exist on the flash card

Note

If .html files exist on the flash card, then the program will always access the first available web page file by default. If you want to access the web page list of all existing directories and files on the flash card, then you type in the URL of the module, followed by "/dir" (Example: "http://10.1.1.57/dir").

12.10.1.6 Multiple Tasks

This program illustrates basic file system operations for SD Flash cards for multiple tasks:

- Mounting a drive
- Determining amount of used and free file space
- Creating files
- Writing data
- Reading data
- Unmounting a drive

When the program executes it will display program status information through the debug serial port.

Note

All EDFS FAT examples require that you add the Embedded Flash File System File Allocation Table (EDFS FAT) library to your project: [Add a Library to a Project](#)

12.10.1.7 Performance Tests

This example is used to test the speed of the EDFS FAT file system for operations such as file creation and data storage speed. All testing was done on a MOD54415.

Hardware:

- MOD54415-100IR on MOD-DEV-70 development board
- Kingston microSDHC 32GB Class 4, with MidroSC Adapter

Software: NetBurner tools revision 2.8.6 Date: February 7, 2018

Test results for file creation:

- 1 file: 15ms
- 100 files:32ms
- 1,000 files:93ms

Test results for data transfer, using 1MB of data:

- Write speed: 0.61 MBytes per second
- Read speed: 2.18 MBytes per second

12.10.1.8 RAM Drive

This program illustrates basic file system operations for RAM drives:

- Mounting a drive
- Determining amount of used and free file space
- Creating files
- Writing data
- Reading data
- Un-mounting a drive

When the program executes it will display program status information through the debug serial port.

This example is similar to the EFFECTS-BASIC example, but uses a RAM drive for the file system. The RAM drive configuration is located in the 'ramdrvMcf.cpp' source file.

To build any of the EFFECTS- examples to use the RAM drive, add the 'ramdrvMcf.cpp' file to the build list and modify 'cardType.h' to define USE_RAM instead of USE_MMC and set the EXT_FLASH_DRV_NUM to the correct RAM drive number.

The RAM drive supports 12, 16 and 32 bit file systems. The most commonly used size is 12-bit, which supports drive sizes from 50k up to 2.8MB. If you change the FAT size, you must make the corresponding change in the function: `int fstat = f_format(RAM_DRV_NUM, F_FAT12_MEDIA);`

To change the RAM drive file size, edit `ramdrv_mcf.cpp`.

Minimum RAM drive file system sizes: FAT12: 50KB (most commonly used) FAT16: 2.8MB FAT32: 32MB

Note

All EFFECTS FAT examples require that you add the Embedded Flash File System File Allocation Table (EFFECTS FAT) library to your project: [Add a Library to a Project](#)

12.10.2 Standard File System (EFFECTS-STD)

Examples for on-chip flash file system:

- [EFFECTS-STD HTTP](#)

12.10.2.1 EFFECTS-STD HTTP

12.10.2.1.1 Overview

This example demonstrates how to use the EFFECTS-STD on-chip flash file system. This file system is different than the EFFECTS-FAT file system which is a FAT32 file system that works with SD Flash cards.

12.10.2.1.1.1 Application Functionality

- Creation of a text file from within the application named "TestFile.txt"
- Display of the text file
- Read/Write test of the text file
- Display of file space and amount used
- Format of the file system
- Read/Write of a diagnostics text file. This will be the data displayed on the System Diagnostics web page if that feature is enabled.

12.10.2.1.1.2 Network Functionality

- NTP is used to set the system time and time zone so that file time stamps are correct.
- HTTP web page interface and file display. If you use FTP to put in your own index.html page, it will be used in place of the example default page.
- FTP Server for file access. You can use client programs such as FileZilla to upload/download files

Note

Running the example in an environment where the device has Internet access will enable the Network Time Protocol (NTP) to automatically set the time. Otherwise, you can set the time manually through the serial port menu.

12.10.2.1.1.3 File System Size

The example provides suggested file system sizes based on the total amount of available flash memory in each product. For example, the MODM7AE70 has a total of 2MB and 128k is allocated in the example. The MOD5441x products has 32MB total flash, and 1MB is used for the file system.

The flash chip configuration header files are located in the "flashChip" folder of the EFFS-STD example:

Platform	Header File	Total Flash	Example EFFS Size
MODM7AE70, SBE70LC	SAME70↔ Q21.h	2MB	128K
MOD54415, MOD54417	MX29GL256↔ F.h	32MB	1MB
NANO54415, SB800EX	MX25L6406↔ E.h	8MB	1MB

Please refer to the header files if you wish to change the size of the file system.

Note

The EFFS-STD manual, "EFFS-STD-R1p91.pdf", is located in the "\nburn\docs" folder.

12.10.2.1.2 Building The Example

12.10.2.1.2.1 NBEclipse With Example Import Feature or Command Line

If you build a new project and use the NBEclipse Example Import feature, all settings will be take care of automatically. If you are building using the example makefile on the command line, the makefile contains all necessary settings.

12.10.2.1.2.2 Adding EFFS-STD Functionality to an Existing NBEclipse Project

There are two steps to add EFFS-STD to your project.

1. Add the StdFFile.a library to the GCC Linker
2. Reserve space in the Flash memory for the file system

The first step is the same for all platforms:

- Right click on your project.
- Navigate to C/C++ Build > Settings > GNC C/C++ Linker > Libraries.
- In the Libraries section, add "StdFFile". Note there is no .a extension.

The second step is described in the following sections.

MODM7AE70, SBE70LC Platforms

The "Locate Application at Fixed Address in Flash" feature must be enabled. This will disable the background Flash erase feature, would will erase the flash file system sectors.

- Right-click on the project and select "Properties"
- Navigate to C/C++ Build > Settings > NB Flashpack > General
- Check the checkbox for "Locate Application at Fixed Address in Flash"

NANO54415, SB800EX Platforms

The CompCode Flag settings are used to reserve space in the memory map for the file system.

- Right click on your project.
- Navigate to C/C++ Build > Settings > NBCompCode > General
- Modify the memory address range field from:
COMPCODEFLAGS = 0x04000 0x800000 // Original
to
COMPCODEFLAGS = 0x04000 0x700000 // Reserve space for file system

The first address parameter is the start of application space, and the second is the start of file system space

MOD54415, MOD54417 Platforms

The CompCode Flag settings are used to reserve space in the memory map for the file system.

- Right click on your project.
- Navigate to C/C++ Build > Settings > NBCompCode > General
- Modify the memory address range field from:
COMPCODEFLAGS = 0xC0040000 0xC2000000 // Original
to
COMPCODEFLAGS = 0xC0040000 0xC1F00000 // Reserve space for file system

The first address parameter is the start of application space, and the second is the start of file system space

12.10.2.1.2.3 Adding EFFS-STD Functionality to a Makefile

There are two steps:

1. Add the EFFS-STD Library
2. Add the compcode flags (SB800EX, NANO54415, MOD5441x) or enable application fixed address (MODM7AE70, SBE70LC)

Add the EFFS-STD Library

```
XTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libStdFFile.a
DBXTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libStdFFile.a
```

MODM7AE70, SBE70LC Platforms

Enable "Locate Application at Fixed Address in Flash" with: EXTRAPACKARGS += -cflag C:3

NANO54415, SB800EX Platforms

Modify the memory address range field from:

```
COMPCODEFLAGS = 0x04000 0x800000 // Original
```

to

```
COMPCODEFLAGS = 0x04000 0x700000 // Reserve space for file system
```

MOD54415, MOD54417 Platforms

Modify the memory address range field from:

```
COMPCODEFLAGS = 0xC0040000 0xC2000000 // Original
```

to

```
COMPCODEFLAGS = 0xC0040000 0xC1F00000 // Reserve space for file system
```

12.10.2.1.3 Running the Example

The application provides access through an interactive serial port menu, web page, and FTP.

12.10.2.1.3.1 Serial Interface

- Run MTTY or some other serial terminal program and connect to the device
- Status messages will be displayed as well as an interactive menu. If this is the first time the application has been run, the file system will be formatted.
- You can experiment with the various menu options.

12.10.2.1.3.2 Web Server (HTTP)

- The default web page will provide various interactive options and information display.
- Entering the IP address followed by "/DIR" (eg. <http://10.1.1.57/DIR>) will display the file directory
- The web server will display the default page based on what is in the file system in the following order: – The `index.html` (will superced `index.html` file compiled into the application) – The first available `*.html` file
- Use FTP (see below) to upload your own `index.html` file and it will replace the application default.

12.10.2.1.3.3 FTP Operation

Connection to the device with a FTP client such as FileZilla will enable you to upload, download and view files.

12.11 Ethernet

Ethernet examples:

- [Manual Configuration](#)

12.11.1 Manual Configuration

Demonstrates how to set Ethernet speed and duplex manually instead of the default of autonegotiate.

12.12 Exception Try/Catch

This example program illustrates how to use C++ exceptions. It will throw an exception and verify it can be caught. The output is displayed to stdout, which can be viewed with MTTY on the debug serial port.

COMPILATION INSTRUCTIONS To keep the application size small for users who do not need C++ exceptions, this feature is disabled by default. To enable exceptions you need to add the "-fexceptions" and flag to the C++ build options. In addition, "-frtti" also needs to be added. If these options are not enabled, the compiler output console window will notify you.

In this example, exceptions have already been enabled. To enable in your own application:

- Right-click on your project and select Properties
- Select "GNU C++ Compiler"
- Select "Miscellaneous"
- In the Other Flags field, add "-fexceptions -frtti"

12.13 External IRQ

Supported Platforms: MOD5441x, NANO54415, MODM7AE70, SBE70LC

This example program uses a GPIO pin to trigger an external interrupt pin. A jumper must be placed from the GPIO pin to the desired interrupt input. To run the example use MTTY or some other serial terminal to interact with the menu to trigger the interrupt and view the interrupt counter.

12.14 Extra FD Circular Buffer

The NetBurner system software has support for implementing your own custom I/O device using a File Descriptor. It is Extra File Descriptors are defines in the 'iointernal.h' header file.

This is a simple example that creates a circular buffer and treats it as an I/O device by using a file descriptor. The I/O device is a 256 byte circular buffer that you can than [write\(\)](#) to and [read\(\)](#) from. The 256 byte buffer size makes the circular buffer wrap around simple for a byte array.

The 6 fd status functions are interrupt safe:

```
void SetDataAvail( int fd ); void ClrDataAvail( int fd ); void SetWriteAvail( int fd ); void ClrWriteAvail( int fd ); void SetHaveError( int fd ); void ClrHaveError( int fd );
```

Side note: If you have an I/O device and wish to use interrupts, after adding the appropriate interrupt code that is specific to your device, you would use USER_ENTER_CRITICAL and USER_EXIT_CRITICAL to protect the internal data structures.

12.15 FileDescriptor

These series of examples provide code utilizing file descriptors.

JSON Examples:

- [Extra FD Circular Buffer](#)
- [FDBuffer](#)
- [fdprintf - printf to file descriptor](#)
- [FdToNBString](#)

12.16 Extra FD Circular Buffer

The NetBurner system software has support for implementing your own custom I/O device using a File Descriptor. It is Extra File Descriptors are defines in the 'iointernal.h' header file.

This is a simple example that creates a circular buffer and treats it as an I/O device by using a file descriptor. The I/O device is a 256 byte circular buffer that you can than [write\(\)](#) to and [read\(\)](#) from. The 256 byte buffer size makes the circular buffer wrap around simple for a byte array.

The 6 fd status functions are interrupt safe:

```
void SetDataAvail( int fd ); void ClrDataAvail( int fd ); void SetWriteAvail( int fd ); void ClrWriteAvail( int fd ); void SetHaveError( int fd ); void ClrHaveError( int fd );
```

Side note: If you have an I/O device and wish to use interrupts, after adding the appropriate interrupt code that is specific to your device, you would use `USER_ENTER_CRITICAL` and `USER_EXIT_CRITICAL` to protect the internal data structures.

12.16.1 FDBuffer

Many of NetBurner's libraries utilize file descriptors(fd) for data input/output(I/O) transmission. To name a few, some libraries that utilize fd's include TCP, WebSockets, HTTP, FTP, email, serial, and the config system.

The user may find themselves wanting to capture I/O data from an fd to a buffer instead of using the fd as originally intended by a library. This may helpful for debugging, printing to serial, or logging. The intent of this example is to demonstrate exactly that.

This example utilizes the FDBuffer class which associates a buffer with an fd which can then be used with API's that utilize fd's. The FDBuffer class is defined in [fd_adapter.h](#). The FBuffer class supports the use of file descriptor functions defined in [iosys.h](#), such as [read\(\)](#), [write\(\)](#), and [close\(\)](#).

This example will demonstrate the use of an FDBuffer object to read the config system's JSON object. The config system maintains config variables and their values as a JSON object. The config system API exposes functions to write the JSON object to an fd, which can be used to write the JSON to a TCP socket or to serial. Instead, we will use the FDBuffer to write the config JSON to a local buffer. The local buffer can be adapted to be stored to persistent storage (flash, SD card, etc), or transmitted remotely (email, syslog, FTP, etc).

An FDBuffer object, by default, can dynamically allocate as many as 20 pool_buffers to store data. Each pool_buffer is capable of storing `ETHER_BUFFER_SIZE` (1548) bytes. This translates to a total of 30,960 bytes of storage in an FDBuffer object. This value can be increased by modifying the `MAX_FDBUFFER_FIFO_BUFFERS` macro defined in `/nburn/nbrtos/include/fd_adapter.h`.

12.16.2 fdprintf - printf to file descriptor

Application that demonstrates the ability to close, open, and print to file descriptors

12.16.3 FdToNBString

Many of NetBurner's libraries utilize file descriptors(fd) for data input/output(I/O) transmission. To name a few, some libraries that utilize fd's include TCP, WebSockets, HTTP, FTP, serial, and the config system.

The user may find themselves wanting to capture I/O data from an fd to a local variable instead of using the fd as originally intended by a library. This may helpful for logging, debugging, or printing to serial. The intent of this example is to demonstrate capturing file descriptor I/O data to an [NBString](#).

This example utilizes the NBStringBuilder class which associates a buffer with a file descriptor which can then be used with API's that utilize fd's. The NBStringBuilder class is defined in [nbstring.h](#). The NBStringBuilder class supports the use of file descriptor functions defined in [iosys.h](#), such as [read\(\)](#), [write\(\)](#), and [close\(\)](#).

This example will demonstrate the use of an NBStringBuilder object to read the system diagnostics data set. With the use of [EnableSystemDiagnostics\(\)](#), the system maintains a diagnostics data set as a JSON object. The diagnostics API exposes functions to write the JSON object to an fd, which can be used to write the JSON to a TCP socket or to serial. Instead, we will use the NBStringBuilder to write the diagnostics data to an [NBString](#). The [NBString](#) can be utilized to store the diagnostics to persistent storage (flash, SD card, etc), or transmitted remotely (email, syslog, FTP, etc). For the simplicity of an example, this application will print the [NBString](#) to serial.

12.17 FTP

FTP can be run with or without a file system. The examples in this section do not use a file system. These are useful for applications such as:

- Simple download of data as a file by a FTP client, such as measurement readings.
- Updating an application image.
- Viewing web or interface data in a file format.

Since there is no file system, these examples use callback functions to handle the various FTP transactions, such as reading, writing and listing a file. If you do not wish to use the callback scheme, please refer to the file system examples described below.

Examples of FTP using a file system take advantage of the Embedded Flash File System (EFFS). These examples are located in the "\nburn\examples\EFFS" folder. There are two types of file systems:

- EFFS FAT (File Allocation Table), which is a FAT32 file system used by external flash cards.
- EFFS STD (Standard File System), which is a custom file system that runs in the onboard flash memory of the NetBurner device.

FTP in this section:

- [FTP Client](#)
- [Display HTML Files \(FTPD\)](#)
- [Simple FTP Server \(FTPD\)](#)

12.17.1 FTP Client

This program will run a FTP Client program on the NetBurner board to do the following:

- Connect to a FTP Server
- Change to a remote directory called "test1"
- Obtain a directory listing and print the listing to stdout
- Create a file on the FTP Server called WriteTest.txt
- Read back contents of WriteTest.txt and send to stdout

Setup Requirements:

1. Access to a FTP Server
2. User name and password for the FTP Server
3. A directory called "test1" must exist on the FTP Server
4. Write permissions to the test1 directory
5. You must modify the `#define` values in this file to match your FTP server.

12.17.2 Display HTML Files (FTPD)

Example to display the files in a project's HTML directory as a read-only file system.

- Serial port output displays status information
- Device web page provides example information and a link to display files, using the CPPCALL HTML tag
- Files can also be accessed with FTP clients such as Filezilla

This is an advanced application and requires knowledge of FTP and FTP applications. A significant part of the complexity involved concerns navigating and displaying file names and directories.

Starting in 2020 some browsers have begun to block FTP access. In such a case FTP client programs can be used instead.

12.17.3 Simple FTP Server (FTPD)

Simple example of a FTP server implementation without a file system. It can be very useful for a lightweight method to download system information and data, and upload configuration information. Interaction with the FTP server in an application is accomplished using callback functions to handle events, such as listing the files, sending a file, and receiving a file. Please refer to the additional FTP examples for use with a file system.

- Status messages and data are sent out the debug serial port and can be viewed with a terminal such as mttty.
- Enables the FTP client to download a file named ReadFile.txt. While this is fixed content, it can contain whatever dynamic content you wish.
- Enables the FTP Client to upload an ASCII text file named WriteFile.txt. The file is not stored in memory, but is sent out the debug serial port.

12.18 GDB Debugger

This is a very simple application to run with the debugger on a NetBurner network-enabled hardware platform. The application will boot and stay in a while() loop that displays how long the program has been running to the default serial port.

12.19 General Purpose I/O

These general GPIO examples apply to multiple NetBurner platforms. Please refer to the "Example Applications > Platform Specific" section of this document for additional GPIO examples specific to your particular NetBurner platform.

Examples in this section:

- [GPIO Blink](#)
- [General Purpose I/O Service](#)

12.19.1 GPIO Blink

This example demonstrates the basic operation of GPIO pins using the [PinIO](#) class. It blinks one of the indicator LED on the device carrier board.

This example is purposely simple and does not demonstrate all the [PinIO](#) capabilities. For further information on what the [PinIO](#) class can be used for or how to use it, see the [GpioServer](#) example or refer to the [PinIO](#) documentation. Additionally, most platforms have additional GPIO examples in the Platform Specific example directory which focus on GPIO specifics.

Please refer to the "Example Applications > Platform Specific" section of the NetBurner Documentation for additional GPIO examples specific to your particular NetBurner platform.

12.19.2 General Purpose I/O Service

Example to control GPIO pins through command interface.

This is a general purpose GPIO example and a large portion of the code is dedicated to a parser and command structure. Most platforms have additional GPIO examples in the Platform Specific example directory which focus on GPIO specifics.

This example sets up a command parser on the default serial port to configure and control GPIO signals on the NetBurner module. For devices with multiple connectors the example uses the peripheral connector, such as P2 or J2, or the main connector for devices with a single connector. Depending on your specific device, not all signals can be GPIO. Please consult the device data sheet for additional information.

To run the example build and load the project into your device. Then run the MTTTY serial terminal and connect to your device's debug/status port.

The menu options are:

- HI Set a pin high
- LO Set a pin low

- TGL Toggle a pin
- OUT Configure a pin to be an output
- IN Configure a pin to be an input
- RD Tristate and read a pin

For example, to set pin 5 high use the command: "HI 5".

Please refer to the "Example Applications > Platform Specific" section of the NetBurner Documentation for additional GPIO examples specific to your particular NetBurner platform.

12.20 IP Address Object (IPADDR)

IPADDR IP Address Object Example

An IPADDR object is a C++ object that can contain either an IPv4 or IPv6 IP address. An object is used to enable application support both IPv4 and IPv6 without having to change source code. Once you assign an address to the object, its member functions will automatically call the appropriate member function for the task to be performed.

For example, if you have an IPADDR object named myIPAddr and assign it a value of 192.168.1.10, then calling `myIPAddr.print()` will print the address in IPv4 notation. If you assign it an IPv6 address, calling `myIPAddr.print()` will print the address in IPv6 notation.

The NetBurner system has added a printf formatting option of "%I", enabling you to easily display IP addresses with formatting. For example, `iprintf("My IP address is %I\r\n", myIPAddr);` This formatting option works for all printf variants, such as printf, iprintf, sprintf, etc.

In rare cases in which you want to create an object of a specific type, you can create objects as [IPADDR4](#) or [IPADDR6](#). However, we highly recommend using IPADDR for all your IP addresses. Note that if you are using a printf style format specifier, you must use "%HI" instead of "%I" and pass in a [IPADDR4](#) object, otherwise the value displayed will be 0.0.0.0.

12.21 IPv6

IPv6 Examples:

- [DHCPv6](#)

12.21.1 DHCPv6

This example demonstrates the various callback functions of the DHCPv6 Client for requesting, adding, and processing DHCPv6 options.

The [DHCP](#) offer name is set by the DEVICE_NAME parameter in the configuration settings for each network interface.

12.22 JSON

These series of examples provide code for a JSON server running on a NetBurner device, "demo.netburner.com", and JSON client examples for GET, POST, loading applications and HTML. If you type "demo.netburner.com" in your web browser and can see a JSON server, you can run the client examples against it.

- [JSON Lexer](#)

JSON Examples:

- [NetBurner Demo Server for JSON Client Examples](#)
- [Get JSON Object From Server](#)
- [Get Non-JSON Object From Server](#)
- [Get JSON Object From Server](#)

- [Post JSON to Server and Display Result](#)
- [Post JSON to Server](#)
- [Get Application Image and Load it From a Web Server](#)
- [Simple JSON HTML Example](#)
- [Simple JSON Post Receiver Example](#)

12.22.1 JSON Lexer

The examples here show how to use the [JSON Lexer](#) classes, [ParsedJsonDataSet](#) and [JsonRef](#), to build and interact with JSON data sets.

JSON Lexer Examples:

- [JSON Array](#)
- [JSON Array with Objects](#)
- [Parse Test](#)

12.22.1.1 JSON Array

This program shows how to use the [JSON Lexer](#) classes [ParsedJsonDataSet](#) and [JsonRef](#) to create and access array information.

12.22.1.2 JSON Array with Objects

This program shows how to use the [JSON Lexer](#) classes [ParsedJsonDataSet](#) and [JsonRef](#) to create and access arrays containing sub-objects.

12.22.1.3 Parse Test

This program shows how to use the [JSON Lexer](#) classes [ParsedJsonDataSet](#) and [JsonRef](#) to create and access JSON information.

12.22.2 NetBurner Demo Server for JSON Client Examples

This is the source code for the application running on the [demo.netburner.com](#) web site. The JSON Client examples in this section interface to this server to demonstrate each of the features. The source code for this server is here for reference and completeness rather than something you need to implement on your own. All of the techniques used here and more clearly illustrated with the other JSON examples.

Warning

This project requires a certificate and private key to build

12.22.3 Get JSON Object From Server

Simple program that demonstrates retrieving a JSON object from a site and using it to present the user with dynamic output

12.22.4 Get Non-JSON Object From Server

Simple program that demonstrates retrieving non-JSON object from a site and using it to present the user with dynamic output

12.22.5 Post JSON to Server and Display Result

Simple program that demonstrates POSTing a JSON object to a server and then displaying the returned JSON result.

12.22.6 Post JSON to Server

Simple program that demonstrates POSTing a JSON object to a server and then displaying the returned result as text.

12.22.7 Get Application Image and Load it From a Web Server

Simple program that demonstrates retrieving a new code image from the web.

12.22.8 Simple JSON HTML Example

Shows several methods to have a NetBurner respond to web requests with JSON objects. Shows how to:

- Respond and generate the text directly
- Respond and generate the response with a JSON lever object.
- Respond and generate the response using configuration variables.
- Respond and generate the response using a pre-built page stored in with web pages and using the dynamic web page capabilities.

12.22.9 Simple JSON Post Receiver Example

Simple JSON Post Receiver Example shows how to receive a JSON object as a post from an external Restful API or from Javascript within a web page.

12.23 malloc

This example demonstrates the usage of malloc and free. It identifies way's to track heap space usage by calling [spaceleft\(\)](#) and [mallinfo\(\)](#), which can help prevent an applications from running out of dynamic memory.

It is important to use both [spaceleft\(\)](#) and [mallinfo\(\)](#) to determine the size of the heap. As this application demonstrates, [spaceleft\(\)](#) alone will not always give the total space available to malloc.

Dynamic memory and fragmentation is beyond the scope of this example, but in short, the largest amount of contiguous dynamic memory an application can malloc depends on how the application handles malloc and free. For example:

- A heap has a total of 1MB of memory available.
- The application allocates 100KB 3 times, lets call them A, B and C.
- There is now 700KB left. Functions [spaceleft\(\)](#) and [mallinfo\(\)](#) will report this number.
- The [spaceleft\(\)](#) function always reports the amount of "untouched" memory. This is memory that has never been allocated, and does not include the amount available to the application that has been allocated and freed. It is useful in that it provides the application with the amount of contiguous dynamic memory that can be allocated. It is commonly referred to as a "watermark".
- The [mallinfo\(\)](#) function returns the total amount of heap space available, including both untouched and freed memory. So at this point in this 1MB example, it would report 700KB a well.
- Now the application frees A and B. The [spaceleft\(\)](#) function will report the watermark value of 700KB. The [mallinfo\(\)](#) function will include the freed memory and report 900KB.

In this code example the application will allocate 3 chunks of space. The first is 1MB, then a 3MB, then a 512KB chunk. It will then free the data in a different order.

After every malloc and free, the amount of heap space will be displayed by both reporting functions showing heap space used, free, and untouched.

12.24 Multicast

This example program enables you to add a NetBurner device to a multicast group by specifying the multicast ip address and port number in MTTTY when prompted. You can then send data by typing it in MTTTY, or view received data.

This example only supports IPv4

12.25 Multihome

Multihome application example (IPv4 only)

This program will demonstrate how to implement both a [DHCP](#) address and static IP address using the Multihome functionality of the NetBurner TCP/IP Stack. The NetBurner device will try to obtain a dynamic IP address from a [DHCP](#) Server for the first Network Interface, and set a static IP address for the second Network Interface. The end result is that the NetBurner device will respond to either IP address. The example will print debug information out the debug serial port, and display the IP address information on a web page that can be accessed from either IP address.

To enable multihome capability, you must uncomment the MULTIHOME definition in the include file `\nburn\nbrtos\include\predef.h` and rebuild the system files.

12.26 NB Approve Shutdown

The `NBApproveShutdown` callback function can be used by an application to put the system in a safe state before an application update, configuration update, or reboot event occurs. For example, closing active TCP sockets, ensuring Flash and/or file system write operations are complete, and putting critical peripherals in a safe state. The `NBApproveShutdown()` function as a weak reference to a system function that always returns true by default. If an application creates its own function using the same signature, that function will be used instead.

A reason for the reboot request is passed to the function. The system will automatically call `NBApproveShutdown()` for the following reasons:

```
#define SHUTDOWN_CODEUPDATE      (1) // A code update is requested
#define SHUTDOWN_CONFIGURE_REBOOT (2) // Configuration values have been modified with a requested reboot
```

An application can choose to ignore the parameters or add its own. For custom reasons, the application should call `NBApproveShutdown()` with the appropriate reason:

```
// Custom reboot reason. System reasons start at 1, so pick something much larger
#define SHUTDOWN_CUSTOM_REBOOT 100
```

```
if ( NBApproveShutdown (SHUTDOWN_CUSTOM_REBOOT) )
{
    OSTimeDly (TICKS_PER_SECOND * 5);
    ForceReboot ();
}
```

This example provides a serial port menu with options enable or disable a reboot for application or settings updates. For testing purposes you can select reboot from the serial menu, or attempt an application code update.

12.27 NBString Class

This example program demonstrates the functionality `NBString` class.

12.28 NetBios Name

The example demonstrates how to use NetBIOS naming, so you can access your NetBurner device by name as well as IP address on a local area network. The name can be changed on the web page.

The NetBios Name can contain any alphanumeric character except spaces and `\ : / * ? ; |`. It must be 15 characters or less.

12.29 Network Time Server (NTP) Client

A simple example that will get the time from a NTP server and display the UTC and PDT time through the debug serial port. Use MTTTY to monitor the output.

For this example to function, your NetBurner device must have access to the Internet, with a working configuration for the IP address, mask and gateway.

12.30 NTP & Real-Time Clock

NTP-SYSTEM-RTC DEMO APPLICATION

HARDWARE SETUP: Tested with MOD54415 on a MOD-DEV-70 hardware rev 1.93.

This example demonstrates the following features:

- Updates the system time with the current UTC time pulled from an available NTP server (pool.ntp.org). If your module is set to static IP address settings, then you will need to manually assign a DNS server address for this feature to work.
- Take the current system time and save it to the real-time clock (RTC). The RTC will then be running in sync with the system time.
- Take the current time in the RTC and set the system time information. The system time will then be running in sync with the RTC.
- When the device or module is reset or powered on again after a recent power loss, the system time will be reset, but the RTC can continue running until the super-capacitor is discharged. The software-reset option is available to demonstrate the RTC's ability to retain saved time information once it is properly set.
- Set the local time zone information with a call to `tzsetchar()`. For more more information on this function, refer to "Chapter 14 - NBTime Library" of the NetBurner Runtime Libraries PDF document. In this example, Pacific time zone information is used as a demonstration.
- Display the current system and RTC times, and local time zone information if applicable. It is preferred that the RTC store the UTC time, not local time.
- In order to take advantage of setting and getting time information from the real-time clock (RTC), a device that contains an RTC component or a module that is mounted on a development board with an RTC component must be used. Current RTC components supported in this example at the time of this writing are the Intersil X1226 and NXP PCF8563.

12.31 Overload Directory & System Files

The Overload Directory Example is a basic demonstration of the overload directory in a project. The overload directory is used to override any system file by including local copies of system source files or headers. This allows the user to make changes to system files exclusively for a project. The overload directory provides an alternative to modifying the original system files, which would affect all projects.

To use this feature, the file to be overloaded should be placed in the overload directory under a directory structure that matches the file's location relative to the NNDK install directory.

This example application utilizes the overload directory to override [predef.h](#) (a NetBurner configuration header file). The overloaded [predef.h](#) defines the macro `NBRTOS_TIME`, which is not defined by default.

To overload the [predef.h](#) header, the directory structure is replicated inside the overload directory. For example, [predef.h](#) is located in the following directory in the NNDK install:

```
/nburn/nbrtos/include/predef.h
```

Therefore, the directory structure is replicated inside the overload directory with the following structure:

```
<project root>/overload/nbrtos/include/predef.h
```

Additional instructions if the overload directory is used in an NBEclipse project:

After adding the file to be overloaded, clean and rebuild the NetBurner Archive by selecting "Clean NetBurner Archive" under the Build Targets pull-down in the project. From that point on, modifying [predef.h](#) (or any overloaded source/header) will automatically rebuild the necessary files in the NetBurner Archive when then project builds.

If a system include folder is overloaded, this folder should be added to your project include paths. Right click on the project and select project properties. Under C/C++ Build->Settings, select GNU C++ Compiler->Includes and add the overload include folder. If utilizing C code, then GNU C Compiler->Includes should also be added.

12.32 PLATFORM SPECIFIC

With the exception of the Platform Specific examples, all examples in the `\nburn\examples` directory can be run on any of the NetBurner 3.x platforms: MODM7AE70, MOD5441x, NANO54415 and SB800EX. The Platform Specific examples in this section have specific hardware requirements.

The example categories are:

- Examples designed for only one platform: MODM7AE70, MOD5441x, NANO54415 or SB800EX
- Multi-Platform: Some examples for platforms that use the same microprocessor take advantage of that fact and share the same application source code. In these instances the section will be labeled with the supported platforms, such as the section labeled: "MOD5441x, NANO54415, SB800EX".

Platform specific examples

- [MOD5441x, NANO54415, SB800EX](#)
- [MODM7AE70](#)
- [MODM7AE70, SBE70LC](#)
- [SOMRT1061](#)
- [External IRQ](#)
- [SPI](#)

12.32.1 MOD5441x, NANO54415, SB800EX

Platform Platform specific examples for ColdFire MCF5441x based products:

- MOD54415
- MOD54417
- NANO54415
- SB800EX

- [1-Wire](#)
- [Analog to Digital](#)
- [CAN to Serial](#)
- [Digital to Analog \(DAC\)](#)
- [DSPI to Serial](#)
- [Load Application From Flash Card](#)
- [SDHC Flash Card](#)
- [EMI Emissions Reduction](#)
- [External NMI IRQ 7](#)
- [RTC - External](#)
- [I2C](#)
- [RTC - On Chip](#)
- [Periodic Interrupt Timer](#)

- [Pulse Generator and Counter](#)
- [PWM](#)
- [Core Watchdog Timer \(CWT\)](#)
- [WAV File Audio Player](#)

- [MOD5441x Only](#)
- [NANO54415 Only](#)
- [SB800EX Only](#)

12.32.1.1 1-Wire

Supported Platforms: MOD5441x, NANO54415

This program used the 1-wire peripheral to read a registration number from the DS2401 Silicon Serial Number chip.

12.32.1.2 Analog to Digital

MOD5441x and NANO54415 Analog to Digital Platform Examples

- [Simple ADC](#)
- [Periodic ADC](#)

12.32.1.2.1 Simple ADC

Simple Analog to Digital converter example

Supported Platforms: MOD5441x, NANO54415

This example demonstrates how to read all 8 ADC inputs. The ADC register values will be displayed on the serial port interface, as well as the floating point conversion values.

Please refer to the data sheet for your specific platform to determine which of the 8 ADC channels are routes to interface connectors.

12.32.1.2.2 Periodic ADC

PeriodicAD - DMA Driven, periodic sampling Analog to Digital example

Supported Platforms: MOD5441x, NANO54415

This example shows how to setup a periodic sampling Analog to Digital conversion with buffering. It uses the onboard Analog to Digital Converter in loop mode to continuously sample. It then utilizes the DMA Timer to trigger a dma transfer from the selected ADC channel, to the next location in the sample buffer. The example includes interrupt triggers at a half-full and completely full buffer. Finally, the specific result of the application is to sample for some period of time, record the data to an output .wav file, and repeat.

This example requires an external SD Flash card, such as the one on the NetBurner development board.

To build and run this example:

- Create a new project.
- Import the example source files to the src directory
- Import the following EDFS support files from `\nburn\examples_common\EDFS\FAT: cardtype.h, FileSystemUtils.cpp, FileSystemUtils.h`.

- If you are using NBEclipse, then you will also need to tell the linker to include the FatFile library:
 - In NBEclipse, right-click on your project, and select "Properties"
 - Select "C/C++ Builds -> Settings" on the left-hand side
 - Select "GNU C/C++ Linker -> Libraries" under the "Tool Settings" tab
 - In the "Libraries" list box, add "FatFile" by using the action icons provided in top-right corner of the list

12.32.1.3 CAN to Serial

CAN TO SERIAL EXAMPLE PROGRAM

The Controller Area Network (CAN) bus is a twisted pair multidrop cable is specified with a length ranging from 1,000m at 40Kbps to 40m at 1Mbps. The maximum payload of a message is 8 bytes, and all messages carry a cyclic redundancy code (CRC). Each message has an identifier, which can be interpreted differently depending on the application or higher-level protocols used. All nodes on the network receive each message and then decide whether that identifier value is of interest.

The NetBurner CAN to Serial example program uses the NetBurner CAN API to send and receive CAN messages though a serial port interface. It will listen for frames using the RegisterCanRxFifo() function. Frames are received using the CanRxMessage class, and are sent out the RS-232 debug port of your NetBurner CB34EX module. Note that you must have at least two CAN devices run any CAN programs.

SETUP This application has been tested on the SB800EX, MOD54415, MOD54417 and NANO54415. The CAN signals were connected to a CAN analyzer. MTTTY was run on a PC to enter the data to the RS-232 serial port that is then transmitted out the CAN interface. If you have 2 NetBurner devices you can connect them together (in place of the CAN analyzer) and send data in both directions.

PLATFORM NOTES

- This example was written to run on multiple platforms.
- The MCF5441x processor has 2 CAN modules, 0 and 1. Some platforms bring out both, but others with limited pin count only bring out only one.
- Please refer to the data sheet to determine which CAN signals correspond to which module or development board pin.
- The MOD5441x devices were tested in a MOD-DEV-100 development board which has a CAN transceiver
- The SB800EX comes in 2 versions: CAN 0 on the 5-pin terminal strip, or CAN 1 on the DB9 connector.

RUNNING THE EXAMPLE

- A minimum of TWO CAN devices are required for CAN to operate
- This example application sets the CanInit() mask to 0, which will listen for all packets and display the info on MTTTY.
- This example application will send data you type in MTTTY with an id of 101 (0x65).
- If you receive a message indicating the CAN message could not be sent, it usually means the other device did not acknowledge the CAN packet.

12.32.1.4 Digital to Analog (DAC)

This example demonstrates how to use the DAC0 signal in two modes:

1. Step up the output from 0 to 0xFFFF by writing to the DAC data register.
2. Use the auto waveform generator feature synced to DMA timer 0 to step up the output.

You must have a voltage reference as described below

12.32.1.4.0.1 MOD5441x Platforms

The DAC0 signal is on pin on pin J2.9. You must also have the analog reference voltage pin connected to something between 0 and 3.3VDC. The easiest way is to connect 3.3VDC by jumpering J2.2 (Vcc) to J2.5 (Analog ref. input)

12.32.1.4.0.2 NANO54415 Platforms

The DAC0 signal in on pin on pin J2.9. You must have the analog reference voltage pin connected to something between 0 and 3.3VDC. On the NANO Development board you can jumper P3.2 (Vcc) to P2.8 (Analog ref. input)

12.32.1.5 DSPI to Serial

DSPI TO SERIAL EXAMPLE

Supported Platforms: MOD5441x, NANO54415

This program will illustrate how to use the NetBurner DSPI driver. The driver provides most of the standard DSPI options while providing some extra features, including:

- 4-32 bit transfers instead of the standard 4-16 bit
- Automation of the queuing system
- Interrupt driven transfers

In this example we demonstrate how to take advantage of the interrupt feature by using a Semaphore. This will allow any other lower priority tasks to run during the transfer. There is also an option to not use a semaphore and poll the transfer using the bool `DSPIDone()`; function provided in [qspi.h](#).

This example can be used with no external SPI device by placing a jumper across J2[27]-J2[28] on the DEV-70/100 carrier board or Pins[33]-Pins[35] for the Nano54415 dev board. This will loop-back the DSPI data and echo the sent character back to the serial terminal.

The DSPI2Serial example can easily be expanded to DSPI2TCP by creating a TCP socket file descriptor similar to the TCP2Serial example. This TCP file descriptor would then used in place of the serial file descriptor.

12.32.1.6 Load Application From Flash Card

Example of how to update an application from a binary image file on a flash card.

Supported Platforms: MOD5441x

This application uses the Extra File Descriptor (ExtraFD) mechanism to read a binary application image as an input stream from a flash card to the FD. This image is then programmed into flash memory as an application. As with any application update, a reboot is required to run the new application.

As with any Extra FD object, you must create and assign callback functions for read, write, close and peek. There is another example of using the Extra FD with a circular buffer in the `\nburn\examples` directory.

This application was created and tested on a MOD5441x platform using the onboard microSD Flash card. There are also comments on how to use the external Flash card interface as well.

12.32.1.7 SDHC Flash Card

Supported Platforms: MOD5441x, NANO54415, SB800EX

This program demonstrates the EDFS FAT file system and FTP operations for SD/MMC/SDHC Flash cards on 5441x platforms:

- Mounting a flash drive
- Determining amount of used and free file space
- Using FTP to upload and download files

NetBurner 5441x based platforms have two types of flash card interfaces:

1. Native SPI
2. SDHC

These types are mutually exclusive and the flash card connector on the device must be wired one way or the other. As of the writing of this example: MOD54415, MOD54417:

- Onboard microSD connector is SPI.
- MOD-DEV-70 development board is wired for SPI.
- Signals are available on the module headers to wire for SDHC or SPI

NANO54415:

- Onboard microSD wired for SDHC
- NANO development board wired for SPI

SB800EX

- Onboard microSD connector is wired for SDHC

Any SPI connected card is able to run any of the EFFS FAT examples located in the EFFS directory of `\nburn\examples`.

To run the speed test you will need to place a file named TEST.BIN on the flash card. You can do this with FTP to the device directly, or copy it onto the flash drive from another device. Test results will be displayed through the debug serial port.

Modules with an onboard microSD flash socket should use the multi mmc header files and functions because the modules are capable of supporting both onboard and external flash cards (even if your application only uses one).

12.32.1.8 EMI Emissions Reduction

Supported Platforms: MOD5441x, NANO54415, SB800EX

This example demonstrates how to implement the EMI reduction options described in the associated document EMI Noise Reduction Suggestions. Each design will have its own unique behaviors and some or all of these suggestions can help reduce EMI. In addition to the code described below, the app note also covers design considerations for Ethernet cabling, cables in general, enclosure design, input power filtering (very important), and PCB routing. The example code includes:

- Enable/disable unused clocks
- Enable/disable unused peripherals
- Modify signal slew rates
- Putting the processor in wait mode while idle
- The MOD54415 also has the ability to enable spread spectrum clock mode for the processor (available on h/w revisions 2.3 and later).

12.32.1.9 External NMI IRQ 7

MCF441X NON-MASKABLE IRQ 7 EXAMPLE

Supported Platforms: MOD5441x, NANO54415

This example program uses a GPIO pin to trigger a level 7 interrupt. A jumper must be placed from the GPIO pin to the interrupt input pin. To run the example, use MTTTY or some other serial terminal to interact with the menu to trigger the interrupt and view the interrupt counter.

The MCF54415 processor is used on both the MOD54415 and NANO54415 modules. The table below lists the GPIO jumper configuration:

MOD54415:

- GPIO signal pin: J2.33
- IRQ 7: pin 48

NANO54415, and dev board revision 1.3:

- GPIO signal: Nano pin 12 = Dev board pin P2.12
- IRQ 7: Nano pin 9 = Dev board pin P1.9

Examples of assembly language and C/C++ ISR processing functions are provided.

12.32.1.10 RTC - External

External I2C RTC example

Supported Platforms: MOD5441x, NANO54415

HARDWARE SETUP: Tested with MOD54415 on a MOD-DEV-70 hardware rev 1.93.

This example demonstrates the following features:

- Updates the system time with the current UTC time pulled from an available NTP server (pool.ntp.org). If your module is set to static IP address settings, then you will need to manually assign a DNS server address for this feature to work.
- Take the current system time and save it to the real-time clock (RTC). The RTC will then be running in sync with the system time.
- Take the current time in the RTC and set the system time information. The system time will then be running in sync with the RTC.
- When the device or module is reset or powered on again after a recent power loss, the system time will be reset, but the RTC can continue running until the super-capacitor is discharged. The software-reset option is available to demonstrate the RTC's ability to retain saved time information once it is properly set.
- Set the local time zone information with a call to `tzsetchar()`. For more more information on this function, refer to "Chapter 14 - NBTime Library" of the NetBurner Runtime Libraries PDF document. In this example, Pacific time zone information is used as a demonstration.
- Display the current system and RTC times, and local time zone information if applicable. It is preferred that the RTC store the UTC time, not local time.
- In order to take advantage of setting and getting time information from the real-time clock (RTC), a device that contains an RTC component or a module that is mounted on a development board with an RTC component must be used. Current RTC components supported in this example at the time of this writing are the Intersil X1226 and NXP PCF8563.

12.32.1.11 I2C

MCF5441x I2C Platform Examples

- [I2C Address Scan](#)
- [I2C PicKit Demo Board](#)

12.32.1.11.1 I2C Address Scan

Scan the I2C bus for devices and display their addresses.

Supported Platforms: MOD5441x, NANO54415

ScanI2CBus sends out a request on the I2C bus and waits for an ack, scanning each address in the address space.

If a device responds, the device address is reported.

This utility is very helpful to:

- Verify the hardware is connected correctly.
- Understanding the addressing in I2C device data sheets. Some data sheets include the read/write bit as part of the address, and some do not.

Notes when using a MOD5441x and the MOD-DEV-70 development board:

- The MOD5441x has up to 5 I2C ports that can be used: 0, 1, 2, 4 and 5.
- I2C0, J2-39 and J2-42: This is the default I2C peripheral. It has 4.7k pull up resistors on SDA and SCL, and is connected to a real time clock chip.
- I2C1, J2-41 and J2-44: Signals are not connected to anything, but you will need to add pull up resistors.

- I2C2, J2-17 and J2-18, are used for USB, but can be converted to I2C2 by moving 2 resistors on the MOD5441x. The ordering model number is MOD54415-100IR-I2C2. Refer to PCN 001 on the MOD5441x product page.
- I2C4, J2-3 and J2-4: Signals are used for UART0 serial port
- I2C5, J2-21 and J2-22: Signals are used for UART1 serial port

12.32.1.11.2 I2C PicKit Demo Board

Microchip Pickit Serial I2C Demo Board Driver

Supported Platforms: MOD5441x, NANO54415

Demonstrates the use of 5 Microchip I2C Peripherals:

- 24LC0B EEPROM, 2Kbit (256 x 8)
- MCP9800 Temperature sensor
- MCP23008 GPIO port expander, connected to LEDs
- TC1321 10-bit DAC
- MCP3221 12-bit ADC

12.32.1.12 RTC - On Chip

Supported Platforms: MOD5441x, NANO54415

A simple Real Time Clock (RTC) example using the RTC on the MCF5441x microprocessor. Demonstrates how to get and set time through NTP, RTC and manually. An interactive menu is accessed through MTTTY.

For this example to function, your NetBurner device must have access to the Internet, with a working configuration for the IP address, mask, gateway and DNS server.

12.32.1.13 Periodic Interrupt Timer

Periodic Interrupt Timer (PIT) Example

Supported Platforms: MOD5441x, NANO54415 SB800EX

There are a total of 4 PIT timers on the MCF54415 processor, numbered 0 - 3:

- 0 is reserved for the RTOS system clock
- 3 is reserved for the network debugger
- 1 and 2 are available for customer use

The PIT functions below are part of the 54415 system libraries, and defined in `pitr_sem.cpp` and `pitr_sem.h`, located in the include and system folders of your MOD54415 or NANO54415 platform directories.

In this example a semaphore will be set in the PIT interrupt routine, and the semaphore count will be displayed through the serial port.

12.32.1.14 Pulse Generator and Counter

Supported Platforms: MOD5441x, NANO54415

Demonstrates how to use the DMA Timers to generate a waveform output on one timer, and use the timer capture feature to count the waveform pulses on a second timer. Features include:

- Programmable frequency output
- Measurement of frequency input
- Timer count display
- Values also displayed on the web page interface

The application will work on the MOD54415, MOD54417 and NANO5441. The selected timer channels must be jumpered together on the development board so that the waveform output is connected to the capture input.

MOD5441x: Timer J2 Pin

0 36 1 34 2 33 3 32

NANO54415: Timer Pin

0 19 1 21 2 23 3 25

12.32.1.15 PWM

Example program for ColdFire MCF5441x PWM capability on the MOD5441x core module.

Supported Platforms: MOD5441x, NANO54415

Description: Toggles a PWM signal on pin 35 on the NetBurner NANO or MOD54415 module using two different settings. While each PWM module on the 5441x core is capable of producing multiple output signals for use in controlling motors as well as other applications, this example sets the output for one pin only.

There are 2 functions illustrating different methods to create the pulses:

1. Center-Aligned pulses
2. Edge-Aligned pulses

12.32.1.16 Core Watchdog Timer (CWT)

Supported Platforms: MOD5441x, NANO54415, SB800EX

This example demonstrates how to enable the watchdog, set the timeout value, and service the watchdog. An interactive menu and status messages are displayed through the debug serial port. If the watchdog is not serviced before the timeout expires, events such as a system reset or interrupt service request (IRQ) can occur. The following watchdog timeout modes are supported by the 5441x processor:

- System reset
- IRQ only
- IRQ on first timeout, then system reset on the second timeout
- Windowed mode, this is an advanced mode of operation that processes a timeout in 25% increments. Please refer to the MCF5441X Users Manual for more information. This mode is not covered in the example.

Servicing the watchdog can be accomplished in a number of ways:

1. A higher priority task that uses a timer, such as the Periodic Interrupt Timer (PIT). This is the most common method.
2. In an Interrupt Service Routine (ISR). A drawback here is that interrupts can still occur, even if a specific task is not functioning correctly.
3. Servicing throughout an application with specific function calls. This is very difficult to cover all of the edge cases.

A good system implementation would be to use the task and timer method, along with flags, counters or some other indication in each critical task that is evaluated in the watchdog service task to ensure the system is functioning properly.

The example includes code for both the task with timer method and interrupt method; you will only need one of these in your application.

Example Features:

- Demonstrates 3 service methods: task with timer, interrupt and manual
- Interactive menu on serial port provides options for enabling, disabling and servicing modes

This example does not enable the watchdog in the Flash memory system configuration so that a power cycle will reset the system with the watchdog disabled. This is done to make it easier to experiment with the various watchdog modes of operation. If you wish to have the watchdog persistently enabled through power cycles without explicitly enabling it in your application, the watchdog must be enabled in the configuration system.

12.32.1.17 WAV File Audio Player

Supported Platforms: MOD5441x, NANO54415

This example demonstrates how to play audio files (uncompressed WAV) using the onboard Digital to Analog Converters (DAC) on the MCF5441X processor. It is fully capable of playing 8 bit and down converted 16 and 32 bit stereo audio at 44100 samples per second. It has minimal support for 24 bit samples, treating it as 8 bit data with sample padding.

Before attempting to build the application, you will first need to extract the "wav_data_srcs.zip" archive, containing the sample audio files converted to data arrays. The originals used to create these source files are found in the archive 'SD_card.zip'. This contents directory are also intended to be placed directly onto an (micro)SD card and files be played from it.

IMPORTANT: Since these files are external references in main.cpp, they must be aligned on an even boundary. One way to do this is the aligned attribute. For example: `uint8_t sinewav_440[] attribute((aligned(16))) = { }` You can see the full declaration in the nbwav_44k .cpp file

12.32.1.18 MOD5441x Only

MOD5441x Platform Examples

- [MOD5441x Multiple EFFS Flash Card Test](#)
- [MOD5441x Factory application](#)
- [MOD5441x Rapid GPIO](#)
- [MOD5441x USB Mass Storage Device](#)

12.32.1.18.1 MOD5441x Multiple EFFS Flash Card Test

Supported Platforms: MOD5441x

Application to demonstrate how to access both the microSD flash card on the module as and the external flash card on the NetBurner MOD-DEV-70 development board.

12.32.1.18.2 MOD5441x Factory application

Supported Platforms: MOD5441x

Application that is pre-loaded on MOD5441x modules at the factory. Features include:

- Web server
- FTP server
- EFFS flash file system access to the development board flash card socket

This example requires that you edit the project properties to add the FatFile library.

12.32.1.18.3 MOD5441x Rapid GPIO

Supported Platforms: MOD5441x

Example program for ColdFire MCF5441x Rapid GPIO capability on the MOD5441x core module.

The RGPIO module provides 16-bits of high-speed GPIO functionality, mapped to the processor's bus. The key features of this module include:

- 16 bits of high-speed GPIO functionality connected to the processor's local 32-bit bus
- Memory-mapped device connected to the ColdFire core's local bus
- Support for all access sizes: byte, word, and longword
- All reads and writes complete in a single data phase cycle for zero wait-state response
- Data bits can be accessed directly or via alternate addresses to provide set, clear, and toggle functions
- Alternate addresses allow set, clear, toggle functions using simple store operations without the need for read-modify-write references
- Unique data direction and pin enable control registers
- Pin toggle rates typically 1.5–3.5x faster than comparable pin mapped onto peripheral bus

This example:

- Toggles RGPIO signal 0 (module pin 37) 50 times as fast as possible at 1 second intervals.
- The time from rising edge to rising edge of a pulse measures 16ns (62.5MHz).
- The processor slew rate must be set to maximum to achieve a speed this fast and you will
- need a fast scope and probe with a very short (1 inch) ground connection to measure it.

There are 3 functions illustrating the various methods to create the pulses in order of fastest to slowest:

- Assembly code
- Hybrid of assembly and C
- C/C++ code

12.32.1.18.4 MOD5441x USB Mass Storage Device

Supported Platforms: MOD5441x

Required Hardware: -MOD54415 or MOD54417 -NBUSB-ADPT-100R: USB development adapter -MOD-DEV-70↔
CR: development board

Very simple example program that demonstrates USB Mass Storage Device functionality.

This example demonstrates:

- Using USB Mass Storage Device Host Mode to connect to external USB flash drives
- Reading files and directories from a USB flash drive
- Writing files to USB flash drives
- Deleting files on USB flash drives

12.32.1.19 NANO54415 Only

NANO54415 Platform Examples

- [NANO54415 Factory App](#)

12.32.1.19.1 NANO54415 Factory App

Supported Platforms: NANO54415

Application that is pre-loaded at the factory. Features include:

- Web server
- FTP server
- EDFS flash file system access to the development board flash card socket

This example requires that you edit the project properties linker settings to add the `FatFile` library.

12.32.1.20 SB800EX Only

SB800EX Platform Examples

- [Serial Transceiver Test](#)
- [SB800EX Diagnostic Monitor](#)

12.32.1.20.1 Serial Transceiver Test

Supported Platforms: SB800EX

Application to demonstrate how to configure the SB800EX software programmable transceivers.

The SB800EX has the ability to switch between RS-232, RS-422 and RS-485 in software. This means customers do not need to remove the cover and manually configure jumpers. This is a very simple program demonstrating how you can modify these settings in your application.

12.32.1.20.2 SB800EX Diagnostic Monitor

Supported Platforms: SB800EX

Adds a web page diagnostic monitor and log file

12.32.1.21 MODM7AE70

- [Watchdog Timer](#)

12.32.1.21.1 Open All Serial Ports

Supported Platforms: MODM7AE70

Demonstrates how to open all available serial ports on the MODM7AE70. There are a total of 7 named SerialPort 0 - 6, which correspond to USARTs 0 and 1, and UARTs 0 - 4. Note that the difference between a USART and a UART is that the UARTs can only be used for regular serial with TX and RX signals. The USARTs also include hardware handshaking, can be used for RS-422/485, and support other serial modes such as SPI.

12.32.1.21.1.1 Serial-to-SPI QuadSPI

Supported Platforms: MODM7AE70

The Serial-to-SPI example demonstrates the basic configuration of the SPI driver and sending/receiving data over an SPI interface. This example demonstrates how to use the driver for the QuadSPI peripheral in single-bit, master mode SPI.

Supported Platforms: MODM7AE70

The Serial-to-SPI example demonstrates the basic configuration of the SPI driver and sending/receiving data over an SPI interface. This example demonstrates how to use the driver for the QuadSPI peripheral in single-bit, master mode SPI.

12.32.1.21.2 Analog to Digital (ADC)

Supported Platforms: MODM7AE70

The Simple ADC example implements basic analog input functions of the MODM7AE70.

The MODM7AE70 offers two Analog Front-End Controllers (AFEC) that are based on an Analog Front-End (AFE) cell. The MODM7AE70 provides seven 12-bit Analog-to-Digital (ADC) lines available through the P2 header. The SBE70LC provides 8 12-bit ADC lines available between the JP1 and JP3 headers. Both platform's have one additional ADC line that is connected to the CPU's internal temperature sensor – it cannot be reconfigured for other applications.

An ADC voltage reference is required for accurate ADC readings. The MODM7AE70 ADC voltage reference is accessible through pin P2[5]. If using the MODM7AE70 with a MOD-DEV-70 development board, a jumper can be applied to the JP5 header on the MOD-DEV-70 to apply a 3.3V reference. The SBE70LC ADC voltage reference is accessible through the JP3[1] pin.

The following table maps the available ADC lines on the MODM7AE70 to the corresponding pins on the P2 header:

Pin	AFE Module	ADC Channel	P2[3]	P2[7]	P2[8]	P2[21]	P2[29]	P2[38]	*Temp
0	10								
1	3								
0	6								
0	2								
0	11								

Temperature sensor internal to the CPU, not available through the pin header

Note that AFE module 0, channel 1 (P2[3]) collides with serial port 0 receive. If using this ADC channel (like this example does), the application will not be able to receive data on serial port 0. It can still print to serial port 0, though.

The following table maps the available ADC lines on the SBE70LC to the corresponding pins on the JP1 and JP3 headers:

Pin	AFE Module	ADC Channel	JP1[5]	JP1[10]	JP1[11]	JP1[13]	JP1[14]	JP3[3]	JP3[5]	*Temp	Temperature sensor
0	2										
1	0										
0	1										
0	5										
0	6										
0	11										

Temperature sensor internal to the CPU, not available through the pin header

12.32.1.21.3 CAN Send and Receive

Supported Platforms: MODM7AE70

A very simple CAN example to send and receive packets:

- Creates a CAN receive task
- Serial port menu with options to send, receive, manipulate RTR filters
- CAN communication requires 2 CAN devices. As a test you can send/receive by jumpering the CAN pins together

12.32.1.21.4 EBI Page Control

Supported Platforms: MODM7AE70

The EBI Page Control example implements a transparent Page Fault based page manager for the SAME70's External Bus Interface. It is primarily intended for use with systems requiring a full 24-bit address bus or for multiplexing a specific chip select against multiple identical devices.

12.32.1.21.5 EBI Page Control - Simple

Supported Platforms: MODM7AE70

This example demonstrates basic use of the SAME70's External Bus Interface (EBI). To implement a bus interface requires an understanding of the EBI signals, which are provided in the Microchip SAME70 Reference Manual and Data Sheet location in the "\nburn\docs" folder of your installation. Section 33 "External Bus Interface" provides an overview of EBI operation. The most common interface is described in section 35 "Static Memory Controller (SMC)". The example demonstrates configuration of the EBI via the NetBurner EBI driver, performing a single read or write operation on the bus.

12.32.1.21.6 GPIO - Simple

Supported Platforms: MODM7AE70

Very simple GPIO example that blinks a LED on P2[15] of the MOD-DEV-70 development board. There is a more advanced multi-platform example in the `\nburn\examples` folder.

12.32.1.22 I2C

MODM7AE70, SBE70LC [I2C](#) Examples

- [I2C Address Scan](#)
- [I2C PicKit Demo Board](#)

12.32.1.22.1 I2C Address Scan

Supported Platforms: MODM7AE70 SBE70LC

Scans the [I2C](#) bus for devices and display their addresses.

ScanI2CBus sends out a request on the [I2C](#) bus and waits for an ack, scanning each address in the address space.

If a device responds, the device address is reported.

This utility is very helpful to:

- Verify the hardware is connected correctly.
- Understanding the addressing in [I2C](#) device data sheets. Some data sheets include the read/write bit as part of the address, and some do not.

12.32.1.22.2 I2C PicKit Demo Board

Supported Platforms: MODM7AE70 SBE70LC

Microchip PicKit Serial [I2C](#) Demo Board Driver

Demonstrates the use of 5 Microchip [I2C](#) Peripherals:

- 24LC0B EEPROM, 2Kbit (256 x 8)
- MCP9800 Temperature sensor
- MCP23008 GPIO port expander, connected to LEDs
- TC1321 10-bit DAC
- MCP3221 12-bit ADC

12.32.1.22.3 Factory Application

Supported Platforms: MODM7AE70

Application that is pre-loaded on MODM7AE70 modules at the factory. Features include:

- Web server
- FTP server
- EDFS flash file system access to the development board flash card socket

This example requires that you edit the project properties to add the FatFile library.

12.32.1.22.4 Interrupts

MODM7AE70 Interrupt Platform Examples

- [External Pin IRQ](#)
- [Pin Interrupt Request](#)

12.32.1.22.4.1 External Pin IRQ

Supported Platforms: MODM7AE70

This example is based on the PinIrq example, which shows how to use the interrupt capabilities of the PIO controller and the PinIrq functions for the MODM7AE70.

This example is much simpler. It uses a single pin as a IRQ input, and a second pin to generate IRQ requests once every second. These 2 pins will need to be jumpered on the development board in order for the example to run.

When configuring the IRQ priority for a pin, the configuration affects the entire port that the GPIO pin belongs to. For example, this application configures pin P2[8] for an IRQ input. As can be seen in the table below, P2[8] belongs to PIO_PORT_A. Therefore, the IRQ priority configuration will also affect pins P2[9], P2[12] and so on. The other ports are unaffected by the IRQ priority configuration of PIO_PORT_A in this example.

The table below maps the pins on the P1 and P2 headers of the MODM7AE70 to the port that they belong to.

=====+ PIO_PORT_A PIO_↔											
PORT_B	PIO_PORT_C	PIO_PORT_D	PIO_PORT_E							PIO_PORT_A	PIO_↔
P2[8]	P2[3]	P2[6]	P2[7]	P1[20]					P2[9]	P2[4]	P1[4]
P2[10]	P1[22]				P2[12]	P2[11]	P1[6]	P2[15]	P1[23]		
				P2[13]	P2[12]	P1[11]	P2[23]	P1[24]			
				P2[16]	P2[22]	P1[12]	P2[24]	P1[25]			
				P2[17]	P2[29]	P1[13]	P2[25]	P1[27]

				P1[46]							
								P1[47]			
=====+											

12.32.1.22.4.2 Pin Interrupt Request

Supported Platforms: MODM7AE70

The PinIrq example shows how to use the interrupt capabilities of the PIO controller and the PinIrq functions for the MODM7AE70.

12.32.1.22.5 Open All UARTs

Supported Platforms: MODM7AE70

Open all serial ports on MODM7AE70 SOM Platform

There can be a maximum of 7 serial port configured on the device. Note that each signal pin on the microprocessor can be configured for up to 5 different functions, so to achieve the maximum number of serial ports some functions/peripherals will be unavailable.

The SAME70 processor has two peripherals that can be used as a UART function: Three USARTs, representing Serial Port numbers 0 and 1 (USART numbers 0 - 1) Four UARTs, representing Serial Port numbers 3, 4, 5 and 6 (UART numbers 0 - 4) This mapping is described in the MODM7AE70 data sheet.

Serial Port	P1 Pin	P2 Pin	Periph	Mode	USART/UART
0	RX	3	C	USART	0
0	RX	0	TX	4	C
0	TX	0	CTS	29	C
0	CTS	0	RTS	38	C
0	RTS	0	RTS	38	C
1	RX	21	A	USART	1
1	RX	1	TX	22	D
1	TX	1	RTS	32	A
1	RTS	1	CTS	33	A

1	DSR	1	DCD	17	A
1	DCD	1	DTR	18	A
1	DTR	1	RI	20	A
1	RI	20	A	USART	1
2	RX	34	A	UART	0
0	RX	NOTE: tied to LED on mod-dev-70	2	TX	35
0	TX	35	A	UART	0

3 RX 12 C UART 1 RX, PA5* 3 TX 31 C UART 1 TX 3 TX 42 C UART 1 TX (Alternate) 3 TX 44 D UART 1 TX (Alternate)

4 RX 41 C UART 2 RX 4 TX 44 C UART 2 TX

5 RX 23 A UART 3 RX 5 TX 7 A UART 3 TX 5 TX 24 B UART 3 TX (Alternate)

6 RX 10 C UART 4 RX 6 TX 7 C UART 4 TX CAUTION: P1.7 Cannot be used if the external address/data bus interface (EBI) is enabled.

12.32.1.22.6 PWM

Supported Platforms: MODM7AE70

Demonstrates the use of the PWM peripheral.

12.32.1.22.7 NTP & Real-Time Clock

Supported Platforms: MODM7AE70

NTP-SYSTEM-RTC DEMO APPLICATION

HARDWARE SETUP: Tested with MODM7AE70 on a MOD-DEV-70 hardware rev 1.93.

This example demonstrates the following features:

- Updates the system time with the current UTC time pulled from an available NTP server (pool.ntp.org). If your module is set to static IP address settings, then you will need to manually assign a DNS server address for this feature to work.
- Take the current system time and save it to the real-time clock (RTC). The RTC will then be running in sync with the system time.
- Take the current time in the RTC and set the system time information. The system time will then be running in sync with the RTC.
- When the device or module is reset or powered on again after a recent power loss, the system time will be reset, but the RTC can continue running until the super-capacitor is discharged. The software-reset option is available to demonstrate the RTC's ability to retain saved time information once it is properly set.
- Set the local time zone information with a call to `tzsetchar()`. For more more information on this function, refer to "Chapter 14 - NBTTime Library" of the NetBurner Runtime Libraries PDF document. In this example, Pacific time zone information is used as a demonstration.
- Display the current system and RTC times, and local time zone information if applicable. It is preferred that the RTC store the UTC time, not local time.
- In order to take advantage of setting and getting time information from the real-time clock (RTC), a device that contains an RTC component or a module that is mounted on a development board with an RTC component must be used. Current RTC components supported in this example at the time of this writing are the Intersil X1226 and NXP PCF8563.

12.32.1.22.8 Serial Callback Function

Supported Platforms: MODM7AE70

The Serial Empty Callback example demonstrates a robust process for triggering a specified action upon complete transmission of all data written to a specified serial port. The expected use case for this would be disabling a transmitter connected to a shared physical layer such as with RS485 or a wireless link (when using one of the device's UART serial ports).

As an aside, it should be noted that when enabling the `Serial485HalfDupMode` for one of the MODM7AE70s `USART` serial ports, the underlying hardware module will automatically toggle the RTS line for enabling and disabling the transmitter.

12.32.1.22.9 SPI

MODM7AE70 SPI Platform Examples

- [Serial-to-SPI QuadSPI](#)
- [Serial-to-SPI USART](#)

12.32.1.22.9.1 Serial-to-SPI QuadSPI

Supported Platforms: MODM7AE70

The Serial-to-SPI example demonstrates the basic configuration of the SPI driver and sending/receiving data over an SPI interface. This example demonstrates how to use the driver for the QuadSPI peripheral in single-bit, master mode SPI.

Supported Platforms: MODM7AE70

The Serial-to-SPI example demonstrates the basic configuration of the SPI driver and sending/receiving data over an SPI interface. This example demonstrates how to use the driver for the QuadSPI peripheral in single-bit, master mode SPI.

12.32.1.22.9.2 Serial-to-SPI USART

Supported Platforms: MODM7AE70

The Serial-to-SPI example demonstrates the basic configuration of the SPI driver and sending/receiving data over an SPI interface. This example demonstrates how to use the driver for the USART peripheral in single-bit, master mode SPI.

12.32.1.22.10 SSC I2S Interface

Supported Platforms: MODM7AE70

SSC_I2S implements an I2S interface using the Synchronous Serial Controller and uses it to communicate with a [WM8904](#) Audio Codec.

12.32.1.22.11 Timers

MODM7AE70 Timer Platform Examples

- [Timer Capture](#)
- [Timer Waveform Output](#)
- [Chaining Timers](#)

12.32.1.22.12 Timer Capture

Supported Platforms: MODM7AE70 SBE70LC

Timer Counter Capture Example

This example will generate a pulse waveform on Timer 11, and capture the waveform on Timer 7.

For the MODM7AE70: The timer 11 output is on P2.28, and the timer 7 capture is on P1.4. You will need to add a jumper between these two pins. After the capture is complete, the frequency and duty cycle of the captured waveform will be displayed.

For the SBE70LC The timer 11 output is on J1.4, and the timer 2 capture is on J4.6. You will need to add a jumper between these two pins. After the capture is complete, the frequency and duty cycle of the captured waveform will be displayed.

This is a good example to demonstrate how to:

- Learn the structure of the SAME70 Timer Counter peripheral
- Produce a pulse output waveform of various frequencies and duty cycles
- Capture and count waveform pulses
- Implement a peripheral interrupt service routine

SAME70 Timer Architecture

- There are a total of 12 16-bit timers, numbered 0 - 11.
- They are divided up into 4 blocks. Each block is called a Timer Counter: TC0, TC1, TC2, TC3.
- Each timer within a Timer Counter block is called a Timer Counter Channel. While the timers number from 0 to 11, each Timer Counter Channel within a Timer Counter block is numbered from 0 to 2. For example, Timer Counter Channel 11 is in Timer Counter group TC3, with Timer Counter Channel number 2.

- While all Timer Counter Channels can be used, not all signal pins are brought out to the headers on the MODM7AE70/SBE70LC.
- The diagrams in the Timer Counter (TC) section of the SAME70 Reference Manual describe the structure of the Timer Counters.

12.32.1.22.13 Timer Waveform Output

Supported Platforms: MODM7AE70 SBE70LC

Timer Counter Waveform Output Example

This example will generate a pulse waveform on Timer 11. The timer 11 output is on P2[28] on the MODM7AE70, and J1[4] on the SBE70LC

See also: Timer Waveform Capture example.

This is a good example to demonstrate how to:

- Learn the structure of the SAME70 Timer Counter peripheral
- Produce a pulse output waveform of various frequencies and duty cycles

SAME70 Timer Architecture

- There are a total of 12 16-bit timers, numbered 0 - 11.
- They are divided up into 4 blocks. Each block is called a Timer Counter: TC0, TC1, TC2, TC3.
- Each timer within a Timer Counter block is called a Timer Counter Channel. While the timers number from 0 to 11, each Timer Counter Channel within a Timer Counter block is numbered from 0 to 2. For example, Timer Counter Channel 11 is in Timer Counter group TC3, with Timer Counter Channel number 2.
- While all Timer Counter Channels can be used, not all signal pins are brought out to the headers on the MODM7AE70. The table below describes the header pinout.
- The diagrams in the Timer Counter (TC) section of the SAME70 Reference Manual describe the structure of the Timer Counters.

12.32.1.22.14 Chaining Timers

Supported Platforms: MODM7AE70 SBE70LC

Timer Chaining Example

This example will chain timers 9, 10 and 11 to create a 48-bit timer. The output pulse waveform will appear on timer 11 as indicated in the pin tables below.

Timer channels 9, 10 and 11 are chained together to create a 48-bit timer. The default settings for the chained timers LineA are P2.28 for the MODM7AE70, and J1.4 for the SBE70LC. A GPIO output is used to output a pulse signal on each timer interrupt. P2.30 for the MODM7AE70, and J1.3 for the SBE70LC.

Warning

P2.28 on the NetBurner MOD-DEV-70 development board also connects to the SD Flash socket. The socket must be empty for this example to run properly, or you should select alternate pins for the timer functions.

See also: Timer Waveform Capture example.

This is a good example to demonstrate how to:

- Learn the structure of the SAME70 Timer Counter peripheral
- Produce a pulse output waveform of various frequencies and duty cycles

SAME70 Timer Architecture

- There are a total of 12 16-bit timers, numbered 0 - 11.
- They are divided up into 4 blocks. Each block is called a Timer Counter: TC0, TC1, TC2, TC3.

- Each timer within a Timer Counter block is called a Timer Counter Channel. While the timers number from 0 to 11, each Timer Counter Channel within a Timer Counter block is numbered from 0 to 2. For example, Timer Counter Channel 11 is in Timer Counter group TC3, with Timer Counter Channel number 2.
- While all Timer Counter Channels can be used, not all signal pins are brought out to the headers on the MODM7AE70. The table below describes the header pinout.
- The diagrams in the Timer Counter (TC) section of the SAME70 Reference Manual describe the structure of the Timer Counters.

Timer signals on MODM7AE70 header pins:

Timer 0		
P2.19	LineB	TIOB0
P2.42	Clock	TCLK0
Timer 1		
P2.16	Clock	TCLK1
Timer 2		
P2.17	LineA	TIOA2
P2.18	LineB	TIOB2
P2.20	Clock	TCLK2
Timer 5		
P1.7	LineB	TIOB5
Timer 7		
P1.4	LineA	TIOA7
Timer 8		
P1.6	Clock	TCLK8
P1.8	LineA	TIOA8
P2.6	LineB	TIOB8
		Note: cannot be used if EBI is enabled
		Note: cannot be used if EBI is enabled
Timer 11		
P2.15	Clock	TCLK11
P2.28	LineA	TIOA11
P2.25	LineB	TIOB11

Timer signals on SBE70LC header pins:

Timer 11		
J1.4	LineA	TIOA11
J1.7	LineB	TIOB11

Note

Timer 11 signals are alternate functions to SPI0 MOSI and Clock

12.32.1.22.15 DACC Tone Generator

Supported Platforms: MODM7AE70

Digital to Analog converter (referred to as "DACC" in the SAME70 manuals) example implementing basic DACC interface and timer triggered conversions.

12.32.1.23 Watchdog Timer

Supported Platforms: MODM7AE70 SBE70LC

The Watchdog example shows how to use the watchdog on the SAME70.

12.32.2 MODM7AE70, SBE70LC

Platform specific examples for Microchip ARM SAME70 based products: MODM7AE70 and SBE70LC.

- [GPIO Command Server](#)
- [I2C](#)

- [SPI](#)
- [Timers](#)
- [Watchdog Timer](#)
- [MODM7AE70](#)
- [SBE70LC](#)

12.32.2.1 GPIO Command Server

SUPPORTED_PLATFORMS = MODM7AE70 SBE70LC

This example uses the Command Processor Library to establish a GPIO server that provides external control and readback functionality for general purpose input/outputs.

The example establishes the GPIO server using a telnet server by default, but it can also be configured to operate through the serial port or a TCP connection.

A detailed description of the applications features and command set can be found on the application's webpage. That can be accessed by running the application and accessing the device with a web browser.

12.32.2.2 I2C

MODM7AE70, SBE70LC [I2C](#) Examples

- [I2C Address Scan](#)
- [I2C PicKit Demo Board](#)

12.32.2.2.1 I2C Address Scan

Supported Platforms: MODM7AE70 SBE70LC

Scans the [I2C](#) bus for devices and display their addresses.

ScanI2Cbus sends out a request on the [I2C](#) bus and waits for an ack, scanning each address in the address space. If a device responds, the device address is reported.

This utility is very helpful to:

- Verify the hardware is connected correctly.
- Understanding the addressing in [I2C](#) device data sheets. Some data sheets include the read/write bit as part of the address, and some do not.

12.32.2.2.2 I2C PicKit Demo Board

Supported Platforms: MODM7AE70 SBE70LC

Microchip PicKit Serial [I2C](#) Demo Board Driver

Demonstrates the use of 5 Microchip [I2C](#) Peripherals:

- 24LC0B EEPROM, 2Kbit (256 x 8)
- MCP9800 Temperature sensor
- MCP23008 GPIO port expander, connected to LEDs
- TC1321 10-bit DAC
- MCP3221 12-bit ADC

12.32.2.3 SPI

These SPI examples are common to the MODM7AE70 and SBE70LC However, there are additional SPI examples in the MODM7AE70 and SBE70 folders, such as the MODM7AE70 QuadSPI and USART SPI peripherals.

- [SPI PicKit Demo Board](#)

12.32.2.3.1 SPI PicKit Demo Board

Microchip Pickit Serial SPI Demo Board Driver

Supported Platforms: MODM7AE70, SBE70LC

Demonstrates the use of 7 Microchip SPI Peripherals:

- 25LC020A 2K SPI Bus Serial EEPROM
- TC77-5.0 Thermal Sensor with SPI Interface
- MCP3201 2.7V 12-Bit A/D Converter with SPI Serial Interface
- MCP4822 12-Bit DAC with Internal VREF and SPI Interface
- MCP41010 Single/Dual Digital Potentiometer with SPI Interface
- MCP6S92 Single-Ended, Rail-to-Rail I/O, Low-Gain PGA
- MCP23S08 8-Bit I/O Expander with Serial Interface

12.32.2.4 Timers

SAME70 Timer Platform Examples

- [Timer Capture](#)
- [Chaining Timers](#)
- [Timer Waveform Output](#)

12.32.2.4.1 Timer Capture

Supported Platforms: MODM7AE70 SBE70LC

Timer Counter Capture Example

This example will generate a pulse waveform on Timer 11, and capture the waveform on Timer 7.

For the MODM7AE70: The timer 11 output is on P2.28, and the timer 7 capture is on P1.4. You will need to add a jumper between these two pins. After the capture is complete, the frequency and duty cycle of the captured waveform will be displayed.

For the SBE70LC The timer 11 output is on J1.4, and the timer 2 capture is on J4.6. You will need to add a jumper between these two pins. After the capture is complete, the frequency and duty cycle of the captured waveform will be displayed.

This is a good example to demonstrate how to:

- Learn the structure of the SAME70 Timer Counter peripheral
- Produce a pulse output waveform of various frequencies and duty cycles
- Capture and count waveform pulses
- Implement a peripheral interrupt service routine

SAME70 Timer Architecture

- There are a total of 12 16-bit timers, numbered 0 - 11.
- They are divided up into 4 blocks. Each block is called a Timer Counter: TC0, TC1, TC2, TC3.
- Each timer within a Timer Counter block is called a Timer Counter Channel. While the timers number from 0 to 11, each Timer Counter Channel within a Timer Counter block is numbered from 0 to 2. For example, Timer Counter Channel 11 is in Timer Counter group TC3, with Timer Counter Channel number 2.
- While all Timer Counter Channels can be used, not all signal pins are brought out to the headers on the MODM7AE70/SBE70LC.
- The diagrams in the Timer Counter (TC) section of the SAME70 Reference Manual describe the structure of the Timer Counters.

12.32.2.4.2 Chaining Timers

Supported Platforms: MODM7AE70 SBE70LC

Timer Chaining Example

This example will chain timers 9, 10 and 11 to create a 48-bit timer. The output pulse waveform will appear on timer 11 as indicated in the pin tables below.

Timer channels 9, 10 and 11 are chained together to create a 48-bit timer. The default settings for the chained timers LineA are P2.28 for the MODM7AE70, and J1.4 for the SBE70LC. A GPIO output is used to output a pulse signal on each timer interrupt. P2.30 for the MODM7AE70, and J1.3 for the SBE70LC.

Warning

P2.28 on the NetBurner MOD-DEV-70 development board also connects to the SD Flash socket. The socket must be empty for this example to run properly, or you should select alternate pins for the timer functions.

See also: Timer Waveform Capture example.

This is a good example to demonstrate how to:

- Learn the structure of the SAME70 Timer Counter peripheral
- Produce a pulse output waveform of various frequencies and duty cycles

SAME70 Timer Architecture

- There are a total of 12 16-bit timers, numbered 0 - 11.
- They are divided up into 4 blocks. Each block is called a Timer Counter: TC0, TC1, TC2, TC3.
- Each timer within a Timer Counter block is called a Timer Counter Channel. While the timers number from 0 to 11, each Timer Counter Channel within a Timer Counter block is numbered from 0 to 2. For example, Timer Counter Channel 11 is in Timer Counter group TC3, with Timer Counter Channel number 2.
- While all Timer Counter Channels can be used, not all signal pins are brought out to the headers on the MODM7AE70. The table below describes the header pinout.
- The diagrams in the Timer Counter (TC) section of the SAME70 Reference Manual describe the structure of the Timer Counters.

Timer signals on MODM7AE70 header pins:

Timer 0		
P2.19	LineB	TIOB0
P2.42	Clock	TCLK0
Timer 1		
P2.16	Clock	TCLK1
Timer 2		
P2.17	LineA	TIOA2
P2.18	LineB	TIOB2
P2.20	Clock	TCLK2
Timer 5		
P1.7	LineB	TIOB5
Timer 7		
P1.4	LineA	TIOA7
Timer 8		
P1.6	Clock	TCLK8
P1.8	LineA	TIOA8
P2.6	LineB	TIOB8
		Note: cannot be used if EBI is enabled
		Note: cannot be used if EBI is enabled
Timer 11		
P2.15	Clock	TCLK11
P2.28	LineA	TIOA11
P2.25	LineB	TIOB11

Timer signals on SBE70LC header pins:

```
Timer 11
  J1.4   LineA TIOA11
  J1.7   LineB TIOB11
```

Note

Timer 11 signals are alternate functions to SPI0 MOSI and Clock

12.32.2.4.3 Timer Waveform Output

Supported Platforms: MODM7AE70 SBE70LC

Timer Counter Waveform Output Example

This example will generate a pulse waveform on Timer 11. The timer 11 output is on P2[28] on the MODM7AE70, and J1[4] on the SBE70LC

See also: Timer Waveform Capture example.

This is a good example to demonstrate how to:

- Learn the structure of the SAME70 Timer Counter peripheral
- Produce a pulse output waveform of various frequencies and duty cycles

SAME70 Timer Architecture

- There are a total of 12 16-bit timers, numbered 0 - 11.
- They are divided up into 4 blocks. Each block is called a Timer Counter: TC0, TC1, TC2, TC3.
- Each timer within a Timer Counter block is called a Timer Counter Channel. While the timers number from 0 to 11, each Timer Counter Channel within a Timer Counter block is numbered from 0 to 2. For example, Timer Counter Channel 11 is in Timer Counter group TC3, with Timer Counter Channel number 2.
- While all Timer Counter Channels can be used, not all signal pins are brought out to the headers on the MODM7AE70. The table below describes the header pinout.
- The diagrams in the Timer Counter (TC) section of the SAME70 Reference Manual describe the structure of the Timer Counters.

12.32.2.5 Watchdog Timer

Supported Platforms: MODM7AE70 SBE70LC

The Watchdog example shows how to use the watchdog on the SAME70.

12.32.2.6.1 Open All Serial Ports

Supported Platforms: MODM7AE70

Demonstrates how to open all available serial ports on the MODM7AE70. There are a total of 7 named SerialPort 0 - 6, which correspond to USARTs 0 and 1, and UARTs 0 - 4. Note that the difference between a USART and a UART is that the UARTs can only be used for regular serial with TX and RX signals. The USARTs also include hardware handshaking, can be used for RS-422/485, and support other serial modes such as SPI.

12.32.2.6.1.1 Serial-to-SPI QuadSPI

Supported Platforms: MODM7AE70

The Serial-to-SPI example demonstrates the basic configuration of the SPI driver and sending/receiving data over an SPI interface. This example demonstrates how to use the driver for the QuadSPI peripheral in single-bit, master mode SPI.

Supported Platforms: MODM7AE70

The Serial-to-SPI example demonstrates the basic configuration of the SPI driver and sending/receiving data over an SPI interface. This example demonstrates how to use the driver for the QuadSPI peripheral in single-bit, master mode SPI.

12.32.2.6.2 Analog to Digital (ADC)

Supported Platforms: MODM7AE70

The Simple ADC example implements basic analog input functions of the MODM7AE70.

The MODM7AE70 offers two Analog Front-End Controllers (AFEC) that are based on an Analog Front-End (AFE) cell. The MODM7AE70 provides seven 12-bit Analog-to-Digital (ADC) lines available through the P2 header. The SBE70LC provides 8 12-bit ADC lines available between the JP1 and JP3 headers. Both platform's have one additional ADC line that is connected to the CPU's internal temperature sensor – it cannot be reconfigured for other applications.

An ADC voltage reference is required for accurate ADC readings. The MODM7AE70 ADC voltage reference is accessible through pin P2[5]. If using the MODM7AE70 with a MOD-DEV-70 development board, a jumper can be applied to the JP5 header on the MOD-DEV-70 to apply a 3.3V reference. The SBE70LC ADC voltage reference is accessible through the JP3[1] pin.

The following table maps the available ADC lines on the MODM7AE70 to the corresponding pins on the P2 header:

Pin	AFE Module	ADC Channel	Pin	AFE Module	ADC Channel
P2[3]	0	10	P2[7]	0	0
P2[6]	1	3	P2[21]	0	1
P2[8]	0	6	P2[29]	0	5
P2[38]	0	2	*Temp	0	11

Temperature sensor internal to the CPU, not available through the pin header

Note that AFE module 0, channel 1 (P2[3]) collides with serial port 0 receive. If using this ADC channel (like this example does), the application will not be able to receive data on serial port 0. It can still print to serial port 0, though.

The following table maps the available ADC lines on the SBE70LC to the corresponding pins on the JP1 and JP3 headers:

Pin	AFE Module	ADC Channel
JP1[5] 0 2	JP1[10] 1 0	JP1[11] 0 10
JP1[13] 0 1	JP1[14] 0 5	
JP3[3] 1 3	JP3[5] 0 0	
JP3[7] 0 6	*Temp 0 11	Temperature sensor internal to the CPU, not available through the pin header

12.32.2.6.3 CAN Send and Receive

Supported Platforms: MODM7AE70

A very simple CAN example to send and receive packets:

- Creates a CAN receive task
- Serial port menu with options to send, receive, manipulate RTR filters
- CAN communication requires 2 CAN devices. As a test you can send/receive by jumpering the CAN pins together

12.32.2.6.4 EBI Page Control

Supported Platforms: MODM7AE70

The EBI Page Control example implements a transparent Page Fault based page manager for the SAME70's External Bus Interface. It is primarily intended for use with systems requiring a full 24-bit address bus or for multiplexing a specific chip select against multiple identical devices.

12.32.2.6.5 EBI Page Control - Simple

Supported Platforms: MODM7AE70

This example demonstrates basic use of the SAME70's External Bus Interface (EBI). To implement a bus interface requires an understanding of the EBI signals, which are provided in the Microchip SAME70 Reference Manual and Data Sheet location in the "\nburn\docs" folder of your installation. Section 33 "External Bus Interface" provides an overview of EBI operation. The most common interface is described in section 35 "Static Memory Controller (SMC)". The example demonstrates configuration of the EBI via the NetBurner EBI driver, performing a single read or write operation on the bus.

12.32.2.6.6 GPIO - Simple

Supported Platforms: MODM7AE70

Very simple GPIO example that blinks a LED on P2[15] of the MOD-DEV-70 development board. There is a more advanced multi-platform example in the \nburn\examples folder.

12.32.2.7 I2C

MODM7AE70, SBE70LC [I2C](#) Examples

- [I2C Address Scan](#)
- [I2C PicKit Demo Board](#)

12.32.2.7.1 I2C Address Scan

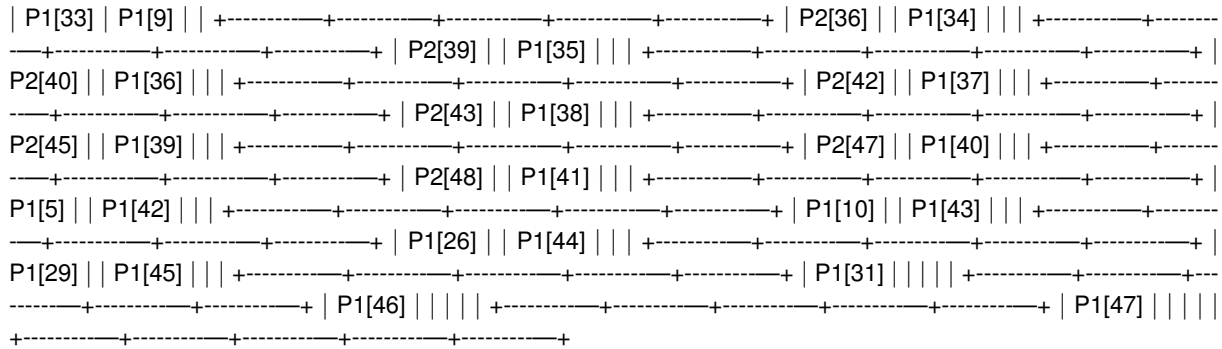

Supported Platforms: MODM7AE70 SBE70LC

Scans the [I2C](#) bus for devices and display their addresses.

ScanI2Cbus sends out a request on the [I2C](#) bus and waits for an ack, scanning each address in the address space. If a device responds, the device address is reported.

This utility is very helpful to:

- Verify the hardware is connected correctly.
- Understanding the addressing in [I2C](#) device data sheets. Some data sheets include the read/write bit as part of the address, and some do not.

12.32.2.7.4.2 Pin Interrupt Request

Supported Platforms: MODM7AE70

The PinIrq example shows how to use the interrupt capabilities of the PIO controller and the PinIrq functions for the MODM7AE70.

12.32.2.7.5 Open All UARTs

Supported Platforms: MODM7AE70

Open all serial ports on MODM7AE70 SOM Platform

There can be a maximum of 7 serial port configured on the device. Note that each signal pin on the microprocessor can be configured for up to 5 different functions, so to achieve the maximum number of serial ports some functions/peripherals will be unavailable.

The SAME70 processor has two peripherals that can be used as a UART function: Three USARTs, representing Serial Port numbers 0 and 1 (USART numbers 0 - 1) Four UARTs, representing Serial Port numbers 3, 4, 5 and 6 (UART numbers 0 - 4) This mapping is described in the MODM7AE70 data sheet.

Serial Port P1 Pin P2 Pin Periph Mode USART/UART

0 RX 3 C USART 0 RX 0 TX 4 C USART 0 TX 0 CTS 29 C USART 0 CTS 0 RTS 38 C USART 0 RTS Note: Serial port 0 is stdio by default

1 RX 21 A USART 1 RX 1 TX 22 D USART 1 TX 1 RTS 32 A USART 1 RTS 1 CTS 33 A USART 1 CTS 1 DSR 16 A USART 1 DSR 1 DCD 17 A USART 1 DCD 1 DTR 18 A USART 1 DTR 1 RI 20 A USART 1 RI

5 RX 23 A UART 3 RX 5 TX 7 A UART 3 TX 5 TX 24 B UART 3 TX (Alternate)

6 RX 10 C UART 4 RX 6 TX 7 C UART 4 TX CAUTION: P1.7 Cannot be used if the external address/data bus interface (EBI) is enabled.

12.32.2.7.6 PWM

Supported Platforms: MODM7AE70

Demonstrates the use of the PWM peripheral.

12.32.2.7.7 NTP & Real-Time Clock

Supported Platforms: MODM7AE70

NTP-SYSTEM-RTC DEMO APPLICATION

HARDWARE SETUP: Tested with MODM7AE70 on a MOD-DEV-70 hardware rev 1.93.

This example demonstrates the following features:

- Updates the system time with the current UTC time pulled from an available NTP server (pool.ntp.org). If your module is set to static IP address settings, then you will need to manually assign a DNS server address for this feature to work.
- Take the current system time and save it to the real-time clock (RTC). The RTC will then be running in sync with the system time.

- Take the current time in the RTC and set the system time information. The system time will then be running in sync with the RTC.
- When the device or module is reset or powered on again after a recent power loss, the system time will be reset, but the RTC can continue running until the super-capacitor is discharged. The software-reset option is available to demonstrate the RTC's ability to retain saved time information once it is properly set.
- Set the local time zone information with a call to `tzsetchar()`. For more more information on this function, refer to "Chapter 14 - NBTime Library" of the NetBurner Runtime Libraries PDF document. In this example, Pacific time zone information is used as a demonstration.
- Display the current system and RTC times, and local time zone information if applicable. It is preferred that the RTC store the UTC time, not local time.
- In order to take advantage of setting and getting time information from the real-time clock (RTC), a device that contains an RTC component or a module that is mounted on a development board with an RTC component must be used. Current RTC components supported in this example at the time of this writing are the Intersil X1226 and NXP PCF8563.

12.32.2.7.8 Serial Callback Function

Supported Platforms: MODM7AE70

The Serial Empty Callback example demonstrates a robust process for triggering a specified action upon complete transmission of all data written to a specified serial port. The expected use case for this would be disabling a transmitter connected to a shared physical layer such as with RS485 or a wireless link (when using one of the device's UART serial ports).

As an aside, it should be noted that when enabling the `Serial485HalfDupMode` for one of the MODM7AE70s *USART* serial ports, the underlying hardware module will automatically toggle the RTS line for enabling and disabling the transmitter.

12.32.2.7.9 SPI

MODM7AE70 SPI Platform Examples

- [Serial-to-SPI QuadSPI](#)
- [Serial-to-SPI USART](#)

12.32.2.7.9.1 Serial-to-SPI QuadSPI

Supported Platforms: MODM7AE70

The Serial-to-SPI example demonstrates the basic configuration of the SPI driver and sending/receiving data over an SPI interface. This example demonstrates how to use the driver for the QuadSPI peripheral in single-bit, master mode SPI.

Supported Platforms: MODM7AE70

The Serial-to-SPI example demonstrates the basic configuration of the SPI driver and sending/receiving data over an SPI interface. This example demonstrates how to use the driver for the QuadSPI peripheral in single-bit, master mode SPI.

12.32.2.7.9.2 Serial-to-SPI USART

Supported Platforms: MODM7AE70

The Serial-to-SPI example demonstrates the basic configuration of the SPI driver and sending/receiving data over an SPI interface. This example demonstrates how to use the driver for the USART peripheral in single-bit, master mode SPI.

12.32.2.7.10 SSC I2S Interface

Supported Platforms: MODM7AE70

SSC_I2S implements an I2S interface using the Synchronous Serial Controller and uses it to communicate with a [WM8904](#) Audio Codec.

12.32.2.7.11 Timers

MODM7AE70 Timer Platform Examples

- [Timer Capture](#)
- [Timer Waveform Output](#)
- [Chaining Timers](#)

12.32.2.7.12 Timer Capture

Supported Platforms: MODM7AE70 SBE70LC

Timer Counter Capture Example

This example will generate a pulse waveform on Timer 11, and capture the waveform on Timer 7.

For the MODM7AE70: The timer 11 output is on P2.28, and the timer 7 capture is on P1.4. You will need to add a jumper between these two pins. After the capture is complete, the frequency and duty cycle of the captured waveform will be displayed.

For the SBE70LC The timer 11 output is on J1.4, and the timer 2 capture is on J4.6. You will need to add a jumper between these two pins. After the capture is complete, the frequency and duty cycle of the captured waveform will be displayed.

This is a good example to demonstrate how to:

- Learn the structure of the SAME70 Timer Counter peripheral
- Produce a pulse output waveform of various frequencies and duty cycles
- Capture and count waveform pulses
- Implement a peripheral interrupt service routine

SAME70 Timer Architecture

- There are a total of 12 16-bit timers, numbered 0 - 11.
- They are divided up into 4 blocks. Each block is called a Timer Counter: TC0, TC1, TC2, TC3.
- Each timer within a Timer Counter block is called a Timer Counter Channel. While the timers number from 0 to 11, each Timer Counter Channel within a Timer Counter block is numbered from 0 to 2. For example, Timer Counter Channel 11 is in Timer Counter group TC3, with Timer Counter Channel number 2.
- While all Timer Counter Channels can be used, not all signal pins are brought out to the headers on the MODM7AE70/SBE70LC.
- The diagrams in the Timer Counter (TC) section of the SAME70 Reference Manual describe the structure of the Timer Counters.

12.32.2.7.13 Timer Waveform Output

Supported Platforms: MODM7AE70 SBE70LC

Timer Counter Waveform Output Example

This example will generate a pulse waveform on Timer 11. The timer 11 output is on P2[28] on the MODM7AE70, and J1[4] on the SBE70LC

See also: Timer Waveform Capture example.

This is a good example to demonstrate how to:

- Learn the structure of the SAME70 Timer Counter peripheral
- Produce a pulse output waveform of various frequencies and duty cycles

SAME70 Timer Architecture

- There are a total of 12 16-bit timers, numbered 0 - 11.
- They are divided up into 4 blocks. Each block is called a Timer Counter: TC0, TC1, TC2, TC3.

- Each timer within a Timer Counter block is called a Timer Counter Channel. While the timers number from 0 to 11, each Timer Counter Channel within a Timer Counter block is numbered from 0 to 2. For example, Timer Counter Channel 11 is in Timer Counter group TC3, with Timer Counter Channel number 2.
- While all Timer Counter Channels can be used, not all signal pins are brought out to the headers on the MODM7AE70. The table below describes the header pinout.
- The diagrams in the Timer Counter (TC) section of the SAME70 Reference Manual describe the structure of the Timer Counters.

12.32.2.7.14 Chaining Timers

Supported Platforms: MODM7AE70 SBE70LC

Timer Chaining Example

This example will chain timers 9, 10 and 11 to create a 48-bit timer. The output pulse waveform will appear on timer 11 as indicated in the pin tables below.

Timer channels 9, 10 and 11 are chained together to create a 48-bit timer. The default settings for the chained timers LineA are P2.28 for the MODM7AE70, and J1.4 for the SBE70LC. A GPIO output is used to output a pulse signal on each timer interrupt. P2.30 for the MODM7AE70, and J1.3 for the SBE70LC.

Warning

P2.28 on the NetBurner MOD-DEV-70 development board also connects to the SD Flash socket. The socket must be empty for this example to run properly, or you should select alternate pins for the timer functions.

See also: Timer Waveform Capture example.

This is a good example to demonstrate how to:

- Learn the structure of the SAME70 Timer Counter peripheral
- Produce a pulse output waveform of various frequencies and duty cycles

SAME70 Timer Architecture

- There are a total of 12 16-bit timers, numbered 0 - 11.
- They are divided up into 4 blocks. Each block is called a Timer Counter: TC0, TC1, TC2, TC3.
- Each timer within a Timer Counter block is called a Timer Counter Channel. While the timers number from 0 to 11, each Timer Counter Channel within a Timer Counter block is numbered from 0 to 2. 12.32.2.7.15 DACC Tone Generator

Supported Platforms: MODM7AE70

Digital to Analog converter (referred to as "DACC" in the SAME70 manuals) example implementing basic DACC interface and timer triggered conversions.

12.32.2.8 Watchdog Timer

Supported Platforms: MODM7AE70 SBE70LC

The Watchdog example shows how to use the watchdog on the SAME70.

12.32.2.9 SBE70LC

SBE70LC Platform Examples

- [GPIO - Simple](#)
- [PWM](#)

12.32.2.9.1 GPIO - Simple

Supported Platforms: SBE70LC

Very simple GPIO example that toggles the GPIO on J1[3] of the SBE70LC development board. There is a more advanced multi-platform example in the `\nburn\examples` folder.

12.32.2.9.2 PWM

Supported Platforms: SBE70LC

Demonstrates the use of the PWM peripheral. The PWM module is used to generating a 5kHz square wave with a 50% duty cycle on pin J1[7] and a 10 Hz square wave with a 60% duty cycle on pin J1[15].

12.32.3 SOMRT1061

SOMRT1061 Platform Examples

- [Analog to Digital \(ADC\)](#)
- [Open All UARTs](#)
- [I2C](#)
- [SEMC, Smart External Memory Controller](#)
- [EFS Multiple Partitions](#)

12.32.3.1 Analog to Digital (ADC)

Supported Platforms: SOMRT1061

Simple ADC example implementing basic analog input functions of the SOMRT1061

12.32.3.2 Open All UARTs

Supported Platforms: SOMRT1061

Open all serial ports on SOMRT1061 Platform

There can be a maximum of 7 serial port configured on the device. Note that each signal pin on the microprocessor can be configured for up to 5 different functions, so to achieve the maximum number of serial ports some functions/peripherals will be unavailable.

Serial Port Pin Number Peripheral Mode LPUART Comments for use with DEV-S61-100CR

0 TX 8 2 LPUART 3 TX 0 RX 7 2 LPUART 3 RX 0 CTS 6 2 LPUART 3 CTS 0 RTS 4 2 LPUART 3 RTS Note: Serial port 0 is stdio by default

Cannot be used with SD card is mounted. WARNING: LPUART 8 cannot be used if an SD card is mounted in the SD card socket.

12.32.3.3 I2C

SOMRT1061 [I2C](#) Examples

- [I2C Address Scan](#) subpage exampleI2CPicKitSerialDemoBd-SOMRT1061

12.32.3.3.1 I2C Address Scan

Supported Platforms: SOMRT1061

Scans the [I2C](#) bus for devices and display their addresses.

ScanI2Cbus sends out a request on the [I2C](#) bus and waits for an ack, scanning each address in the address space. If a device responds, the device address is reported.

This utility is very helpful to:

- Verify the hardware is connected correctly.
- Understanding the addressing in [I2C](#) device data sheets. Some data sheets include the read/write bit as part of the address, and some do not.

12.32.3.4 SEMC, Smart External Memory Controller

Supported Platforms: SOMRT1061

Example demonstrating the basic usage of the SOMRT1061 External Memory interface.

12.32.3.5 EFFS Multiple Partitions

This example program demonstrates how to create a second partition in the Application Flash, so that a guaranteed amount can be reserved for NNDK System usage, while still allowing general Application usage as well.

12.33 External IRQ

Supported Platforms: MOD5441x, NANO54415, MODM7AE70, SBE70LC

This example program uses a GPIO pin to trigger an external interrupt pin. A jumper must be placed from the GPIO pin to the desired interrupt input. To run the example use MTTY or some other serial terminal to interact with the menu to trigger the interrupt and view the interrupt counter.

12.33.1 SPI

These SPI examples are common to all 3.x platforms.

Note

These SPI examples work on multiple processor/product architectures. There are additional SPI examples in the processor/product specific folders that may be of interest. For example, the MODM7AE70 has a quad SPI peripheral, but the MOD5441x does not.

- [DSPI Multiplex](#)
- [Serial to SPI](#)

12.33.1.1 DSPI Multiplex

Supported Platforms: MOD5441X NANO54415 MODM7AE70 SBE70LC SB800EX

This example demonstrates how to use the [DSPIModule](#), object based DSPI driver, to use multiple bus configurations on the same DSPI hardware module without having to re-initialize the driver every time when switching configurations.

12.33.1.2 Serial to SPI

Supported Platforms: MOD5441X NANO54415 MODM7AE70 SBE70LC

The Serial to SPI example demonstrates the basic configuration of the SPI driver and sending and receiving data over an SPI interface.

12.34 PPP

This PPP example shows how to create two PPP server instances.

There are two types of high level connections that can be made with PPP is either direct or modem. A direct connection is usually performed with only a serial cable connection and will jump right into the PPP negotiations with the host or client. A modem connection is one where there is a modem between the PC and NetBurner. The modem PPP functions will send AT commands before any PPP negotiation to initialize the modem.

A good way to test PPP is to create a PPP interface on a computer and make a direct PPP connection to the server.

12.35 Profiler

This is a very simple profiler program. The way the NBR_TOS_TIME functions operate is that there is an additional routine that runs during task switching to record the tick and tickfraction since the task swapped in (runtime since last change).

This feature has overhead and you normally only use it for development. By default, this example enabled profiling through the overload folder functionality. To enable profiling in your own application, you can copy the overload folder in to your application, or following these steps:

1. Edit `\nburn\nbrtos\include\prefef.h` and uncomment: `#define NBR_TOS_TIME(1)`

2. Rebuild the system libraries

The following functions are now available:

`uint32_t GetCurrentTaskTime(uint32_tconst TotalTicks);` Returns the number of time ticks the current task has run. TotalTicks = the total number of ticks recorded.

```
void ShowTaskTimes( void );
```

Print a list of tasks, times and percentages to stdout (normally uart0)

```
void ClearTaskTimes( void );
```

Resets all task times to 0

12.36 RTOS

NetBurner RTOS (NBRTOS) Examples:

- [OSCrit - Critical Section](#)
- [OSFifo - FIFO](#)
- [OSFlags](#)
- [OSMailbox](#)
- [Multiple Task User Input](#)
- [OSQueue](#)
- [OSSemaphore](#)
- [OSTaskCreate](#)

12.36.1 OSCrit - Critical Section

This example will show how to create critical sections with the standard C type function calls `OSCritEnter()` and `OSCritLeave()`, and compare them to the C++ object type which eliminates the problem of matching each `OSCritEnter()` to a corresponding `OSCritLeave()`.

While this example is trivial with only a simple global variable, critical sections need to be used for objects, such as linked lists, that could be changed by multiple tasks. In such cases, each task would use a critical section to ensure the modifications could be completed before a task switch occurred.

12.36.2 OSFifo - FIFO

This program creates two tasks and a FIFO. Messages are sent from one task to another using the FIFO. A timeout value for the pend function is used to illustrate the timeout feature of the FIFO.

12.36.3 OSFlags

This illustrates how OSFlags can be used to pend on multiple events. `UserMain()` creates 3 tasks, each of which will set a OSFlag after a time delay of some number of seconds. `UserMain` will then pend and block until ANY of the 3 flags are set. You can also modify the example to pend until ALL of the 3 flags are set.

12.36.4 OSMailbox

This program will create 2 tasks and a mailbox. The `UserMain` task will block for a mailbox message posted from `MyTask`. The output for this example is displayed through the serial debug port, which can be viewed with the `MTTTY` program.

12.36.5 Multiple Task User Input

This program illustrates how to create a task and use a mailbox to accept user input from a serial port. This example also illustrates how to terminate a task

1. UserMain task will wait pend on a mailbox for user input
2. UserInput task will block waiting for a user to type in data from the serial port

12.36.6 OSQueue

Queue Example Program

This program creates two tasks and a Queue. Messages are sent from one task to another using the Queue. A timeout value for the pend function is used to illustrate the timeout feature of the FIFO.

12.36.7 OSSemaphore

This program will create 2 tasks and a semaphore. The UserMain task will block for a semaphore posted from My↔ Task. The output for this example is displayed through the serial debug port, which can be viewed with the MTTY program.

12.36.8 OSTaskCreate

This example demonstrates how to use two of the task creation functions:

- [OSSimpleTaskCreatewName\(\)](#)
- [OSTaskCreatewName\(\)](#)

12.37 Save to User Parameter Flash

The User Parameter Flash functionality was introduced in the NetBurner 2.x tools. The preferred method for non-volatile storage and settings in the 3.x tool set is the Configuration Server, which provides for multi-platform web access, application access and JSON capabilities. All of these methods are configurable. Please see the configuration users guide and the configuration examples for more information.

In contrast, the User Parameter Flash is a sector of flash memory set aside to be used as raw bulk storage. In situations such as bulk binary storage, or porting a 2.x application to 3.x with minimal changes, this method of storage can be useful.

This example demonstrates how to read and write data to the on-board flash memory User Parameter Area. The amount of flash space is equal to one flash sector, which will vary from 8k bytes to 64k bytes depending on your platform.

Warning: Data corruption can occur under the following circumstances:

1. If power is interrupted during the flash programming process. We strongly recommend that UserParameters are not written immediately upon power-up, since it is not uncommon for a user to cycle a power switch on/off quickly every once in a while.
2. Your application writes beyond the UserParameter size allocated for your platform (8k or 64k). In this situation the application may be corrupted.

Important notes on packed versus integer alignment when using structures and classes: This example uses a structure named `NV_SettingsStruct`, which consists of types that are 8, 16 and 32 bits long. If you do not add an attribute tag at the end of the structure, the default will be integer-aligned (32-bits in this case). This means that padding will be added to ensure each member will be on an integer boundary.

While this can increase execution speed, it also means that the stored data will be a bit larger, and doing something like an overlay or indexing into the structure with a pointer will not work correctly. To tell the compiler not to use any padding, add `__attribute__((packed))`; to the end of the structure definition as demonstrated in this example. Be aware that when using a packed structure elsewhere in your application, access is packed as well.

12.38 Serial

Serial Port Examples:

- [Dual TCP To Serial](#)
- [Serial To Ethernet](#)
- [Serial HTTP Get Request](#)
- [Serial Receive Callback](#)
- [Serial to Serial](#)
- [TCP to Serial](#)

12.38.1 Dual TCP To Serial

This sample application connects two serial ports to two different TCP ports, and continuously transfers data between them. In other words, you have a dual serial-to-Ethernet device. An easy way to test this operation is to open two telnet sessions and two MTTY sessions as shown below. To start a telnet session on a windows pc, open a command prompt and type `telnet 10.1.1.2 2000`, where you would replace 10.1.1.2 with the IP address of your NetBurner device.

Telnet on port 2000 >-----< MTTY on serial port 0

Telnet on port 2001 >-----< MTTY on serial port 1

Now anything you type in the first telnet session will be sent to serial port 0, and vice versa. Anything you type in the second telnet session will be sent to serial port 1 and vice versa.

12.38.2 Serial To Ethernet

This program is designed to connect a RS-232 device to a network. It opens a serial port and an Ethernet port, then connect them. This allows any data sent to the Ethernet port to be forwarded to the serial port, and vice versa.

A connection timeout is used to check for link activity, and the connection will be closed if the timeout expires. The timeout value is set with `TIMEOUT_LIMIT`. A value of 0 will disable the timeout feature.

Only one connection is allowed at a time. Additional client connections will be queued, and serviced as the active connection completes.

Override Timeout: When a new TCP connection is attempted while there is already an active connection, one of 3 actions can be taken:

1. Don't ever disconnect the active connection. Set `OVERRIDE_TIMEOUT` to `0xFFFFFFFF`.
2. Only disconnect the existing connection if it has been idle for x seconds. Set `OVERRIDE_TIMEOUT` to the number of seconds.
3. Always disconnect the existing connection. Set `OVERRIDE_TIMEOUT` to 0.

12.38.3 Serial HTTP Get Request

Example of sending a HTTP GET request through serial port when running a serial to Ethernet application.

Hardware Configuration:

Serial Device <-serial--> NetBurner Serial to Ethernet Device <-ethernet--> Internet

In this example we will be using a SB800EX as the "Serial Device", but this would typically be a microprocessor or FPGA with a UART that needs to communicate over a network. The source code in this file is an example of what you would need to implement in your own microprocessor to send a GET request through a NetBurner device to some other device on the network/Internet running a web server.

The code in the main.cpp source file was tested with the SB800EX, but should work with any of the NetBurner standard devices. A serial cable was connected from port 1 of the SB800EX to port 1 of the SBL2e development board. Since the SBL2e development board DB9 connector is cross-wired for RX and TX, all you need is a straight through serial cable.

SB800EX <-serial--> SBL2e <-ethernet--> Internet

The web page contacted is `myip.dnsdynamic.com`, which return the IP address of the HTTP GET request.

Software Configuration for SBL2e, serial port 1:

Running the SBL2e factory serial to Ethernet application. This was done through the web page, but you can also do it through serial AT commands.

1. Incoming TCP Settings: Uncheck Listen for Incoming Network Connections
2. Outgoing TCP Settings: Make outgoing connections: If serial data received
3. Outgoing TCP Settings: Connect on network port: 80
4. Outgoing TCP Settings: Connect to this address: myip.dnsdynamic.com

12.38.4 Serial Receive Callback

Demonstrates how to register a callback function to intercept system serial port receive processing.

12.38.5 Serial to Serial

This simple program opens both serial ports and sends data from one to another using the `select()` function, which can pend on multiple file descriptors at one time.

The serial ports are initialized by the monitor in polled mode. To enable buffered interrupt driven mode, the serial ports are closed and then reopened with `OpenSerial()`.

12.38.6 TCP to Serial

This is a very simple TCP to Serial example. It listens on a TCP port for a single incoming connection. Once a TCP connection is accepted, all data received will be sent out the serial port, and all data received by the serial port will be sent out the TCP connection.

A simple way to test this program is to use the Telnet program on a PC and connect to the NetBurner device. Telnet is available to run from a command prompt, or with a program such as PUTTY.

If you would like to extend this example and create a robust Serial To Ethernet application, the next step would be to add error detection and timeouts to handle a situation such as the TCP client crashing or going away without a proper TCP close connection sequence. That would result in a half open socket condition and the NetBurner device would have no way of knowing what happened.

To help combat situations such as these this application takes a simple approach of closing the connection is no activity has taken place for a period of time.

12.38.7 Serial Webserver

The Serial Webserver is a simple example demonstrating receiving and replying to HTTP requests over a serial port, using the NetBurner web server implementation. The example will display a "Hello World" type message on the device's index page: `index.html`.

An valid HTTP GET request that is compatible with this application is the following:

Note

The webserver expects a double carriage return line feed

```
`GET /INDEX.HTML HTTP/1.1\r\n\r\n`
```

The expected response should look similar to the following:

```
HTTP/1.0 200 OK
Pragma: no-cache
MIME-version: 1.0
Content-Type: text/html
Content-length: 231

<html>
<head><link rel="stylesheet" type="text/css" href="style.css"></head>
<body>
<a href="http://www.netburner.com"></a>
<h1>Thank you for NetBurning!</h1>
</body>
</html>
```

12.39 SHA1 Digest

Calculate the SHA1 128-bit digest on an application. To display the digest when building the application in NBE-clipse, go to the project properties and add -D to the comcode flags.

12.40 Show Network Interfaces

Example program to display IPv4 and IPv6 address information on both the serial port and on a web page. The web page will also display the addresses as links that can be clicked on to view the web page using the respective IP addresses, such as IPv4, IPv6 and AutoIP.

Note

IPv6 routable addresses can take from a few seconds up to 30 seconds to appear. The amount of time is dependent on the particular IPv6 router response times.

12.41 SOCKS5 Client

This program demonstrates how to create a client connection using the SOCKS5 protocol. This protocol is detailed in RFC 1928. The NetBurner libraries support no authorization and plain text username/password options, and provide a callback for the user to implement their own version of GSSAPI, [AuthWithGssApi\(\)](#). This function can be overridden to implement GSSAPI according to specific requirements.

To test this, you can use a Docker image that will run a SOCKS5 server, found here: [https://hub.↵
docker.com/r/serjs/go-socks5-proxy/](https://hub.docker.com/r/serjs/go-socks5-proxy/)

12.41.1 SPI

These SPI examples are common to all 3.x platforms.

Note

These SPI examples work on multiple processor/product architectures. There are additional SPI examples in the processor/product specific folders that may be of interest. For example, the MODM7AE70 has a quad SPI peripheral, but the MOD5441x does not.

- [DSPI Multiplex](#)
- [Serial to SPI](#)

12.41.1.1 DSPI Multiplex

Supported Platforms: MOD5441X NANO54415 MODM7AE70 SBE70LC SB800EX

This example demonstrates how to use the [DSPIModule](#), object based DSPI driver, to use multiple bus configurations on the same DSPI hardware module without having to re-initialize the driver every time when switching configurations.

12.41.1.2 Serial to SPI

Supported Platforms: MOD5441X NANO54415 MODM7AE70 SBE70LC

The Serial to SPI example demonstrates the basic configuration of the SPI driver and sending and receiving data over an SPI interface.

12.42 SSH

Secure Shell (SSH) Examples:

- [SSH Server](#)
- [SSH Server with User Key](#)

- [SSH Client](#)
- [SSH Server with User Authorization](#)
- [SecureSerToEthFactoryApp](#)

12.42.1 SSH Server

SSH Minimal Server Example

A SSH Server task is created that will listen for incoming SSH connections on TCP port 22. This simple example uses the SSH key stored in the NetBurner library.

To use the example:

- Compile and load the application into your NetBurner device.
- Run MTTTY and connect to USB or Serial port to view status messages and send data to the SSH Client.
- Run a SSH Client like Putty, and connect to the NetBurner device.

12.42.2 SSH Server with User Key

This example demonstrates how to use the NetBurner SSH library to create a SSH server that can utilize the SSH library key, user application compiled-in key and upload a user supplied key.

Please refer to the pdf documentation in the example directory for detailed information.

12.42.3 SSH Client

This example shows how to run a minimal SSH client application. This application will try to create an SSH connection to the server with the IP address defined by SSH_SERVER_NAME. Upon connection, it will read data from the server until the connection is closed.

To use the example:

- Find an SSH server that you'd like to connect to, and set the IP address as SSH_SERVER_NAME.
- Compile and load the application into your NetBurner device.
- Run MTTTY and connect to USB or Serial port to view status messages and send data to the SSH Client.

12.42.4 SSH Server with User Authorization

SSH Server with User Authorization Example

A SSH Server task is created that will listen for incoming SSH connections on TCP port 22. This simple example uses a key that is generated onboard the device the first time it is powered on. This key will be valid for one year. To allow the certificate to automatically renew when it's expired, enable `ENABLE_AUTOCERT_REGEN`, found in `nbrtos\include\predef.h`.

This example demonstrates how to use the `UserAuthManager`, which will let you maintain user password/key information that can be used when authenticating users trying to log on to your device. In this example, we store the data in the UserParam space, but the `UserAuthManager` will let you determine where that information is saved and loaded from with the callbacks that are passed into the object during construction.

To use the example:

- Compile and load the application into your NetBurner device.
- Run MTTTY and connect to USB or Serial port to view status messages and send data to the SSH Client.
- Run a SSH Client like Putty, and connect to the NetBurner device.

12.42.5 SecureSerToEthFactoryApp

The NetBurner Serial-to-Ethernet Secure Factory Application is pre-programmed into NetBurner Serial to Ethernet devices. This application source code is provided for customers that wish to customize the application. It enables bi-directional serial to Ethernet communication through a variety of serial interfaces (some interfaces are platform specific).

- RS-232
- RS-485
- CAN Bus
- I2C
- Ethernet
- Wifi

Features include:

- Data transfers using TCP, UDP, SSH and TLS.
- Multiple methods of device configuration:
 - The device's web server interface (HTTP or HTTPS).
 - The device's Configuration Interface.
 - Through a serial port using an AT command set.
- Server and client certificate management for HTTPS and TLS data connections.
- DHCP and static IP addressing.
- Two to five serial ports.
- Support for the NetBurner virtual comm port driver (Windows only).
- Serial port configuration
- Data packetization configuration
- Network connect and disconnect messages
- Timeout options for data activity and connection overrides

Note

Please refer to the Secure Serial Factory App Users Manual for a detailed description of this application at www.netburner.com.

Hardware Platforms Include:

- SBE70LC
- SB800EX
- NANO54415
- SOMRT1061

The application will send data from the serial port to the Ethernet port and vice versa. be forwarded to the serial port, and vice versa. When using I2C, the program creates a dedicated TCP server for Ethernet-to-I2C communication.

12.43 SSL/TLS

Obtaining certificates:

- [Easy SSL/TLS Onboard Certificates](#)
- [exampleSSL-ACMEServlet](#)

SSL/TLS examples. Note that all references to SSL represent TLS.

- [FTPS Server](#)
- [HTML File Post](#)
- [HTML Form Post](#)
- [HTTPS Dual Cert](#)
- [HTTPS Upload Cert](#)
- [HTTPS Web Server Demo](#)
- [HTTPS GET Request](#)
- [SSL/TLS Client](#)
- [SSL/TLS Client Certificate](#)
- [SSL/TLS Client Verify Peer - Basic](#)
- [SSL/TLS Client Verify Peer - EFFS-STD](#)
- [SSL/TLS Receive Mail \(POP3\)](#)
- [SSL/TLS Send Mail](#)
- [SSL/TLS Send Mail w/ Attachment](#)
- [SSL/TLS Send Mail w/ EFFS Attachment](#)
- [SSL/TLS Server](#)
- [HTTPS Configuration Mirror](#)

12.43.1 Easy SSL/TLS Onboard Certificates

For ACME (Public Certificate Authority) Certificate Generation:

- [ACME Certificate Generation \(Easy Servlet\)](#)

For Self-Signed Certificate Generation:

- [On-board Cert Generation - Simple](#)
- [On-board Cert Generation - Advanced](#)
- [On-board Cert Generation - Compiled Certificate Authority](#)

12.43.1.1 ACME Certificate Generation (Easy Servlet)

`<NNDK install>\examples\SSL\acmeservlet`

SSL/TLS example program that demonstrates getting an ACME cert automatically. Will only work for a device accessible via a public IP and a public DNS entry. Make sure to change the `DEFAULT_CERT_COM_NAME` constant in `main.cpp` to match.

This example makes use of the [acmeRFC8555Servlet.h](#) builtin to the NNDK, which reduces how much code is required to add the functionality to your project and will more easily take advantage of future NNDK updates.

12.43.1.2 On-board Cert Generation - Simple

This example shows how to enable auto-generation of self-signed certificates. The certificate will enable secure communication to the system configuration web server and the HTTPS web server of the application. On-board generation of certificates are an alternative to creating your own self-signed certificates and uploading them to your NetBurner device. This simple example should cover most use cases. Please refer to the other examples for additional functionality.

Auto-generated certificates will operate as follows:

- If enabled and no certificate exists, a certificate will be created on first call to `SSL_accept()` or `SslInitServer()`.
- The Common Name (CN) will be the IP address of the device. Alternate names are also supported.
- The application must ensure it has the correct system time, otherwise the certificate dates will be invalid.
- Calling the function `EnableOnboardCertificateCreation()` enables certificate generation.
- If `ENABLE_AUTO_CERT_REGEN` is defined in `predef.h`, the certificate will update when it expires, creating a new 1 year certificate. Generation will occur on next SSL/TLS access.
- If `ENABLE_AUTO_CERT_REGEN` is defined in `predef.h`, `AUTO_CERT_GEN_CHECK` will dictate how frequently a certificate is checked for expiration. The default value is one minute.
- The certificate will update if the IP address changes to handle environments such as `DHCP` address assignments.

If the system time is incorrect, the certificate will be invalid.

Additional Examples:

Examples of a HTTPS server with a compiled-in certificate:

- `<NNDK install>\examples\ssl\sslserver`
- `<NNDK install>\examples\ssl\SslWebDemo`

Examples of uploading a certificate/key pair manually:

- `<NNDK install>\examples\ssl\HttpsDualCert`
- `<NNDK install>\examples\ssl\HttpsUploadCert`

12.43.1.3 On-board Cert Generation - Advanced

Please refer to the `ReadMe.txt` for the Simple version of this example for an operational description of the On-board certificate generation feature.

The simple auto-generate self-signed certificate example is what is normally used in applications. This example provide advanced options, such as interactive control to:

- Generate the certificate
- Delete the certificate
- View certificate expiration date
- Check for a valid certificate
- Manually enter the system time

12.43.1.4 On-board Cert Generation - Compiled Certificate Authority

Please refer to the `ReadMe.txt` for the Simple version of this example and for an operational description of the On-board certificate generation feature.

The simple auto-generate self-signed certificate example is what is normally used in applications. This example provides advanced users with a demonstration of how to write their own onboard certificate generation function. This includes signing the generated certificate with a compiled in Certificate Authority cert. To understand how to generate Certificate Authority certificate as well as how to compile it into your program, please see our documentation on creating self-signed certificates, found in the Programmers Guide.

For any network device, if you generate your own Certificate Authority (CA), you must accept responsibility for the security of the CA certificate. If a malicious party obtains your CA from the device or any other means, they would be able to use it to create their own "trusted" certificate and access your devices. This may be less of an issue if you are operating on a closed/private network, rather than devices on the Internet.

Taking full advantage of this example will also require some familiarity with the wolfSSL API.

12.43.2 FTPS Server

This example will create a simple FTPS Server running on the NetBurner device. The server will start and wait for a FTPS client connection on port 990. The goal of this example is strictly the encryption aspect; it can be extended to use the file systemZby combining it with the Embedded Flash File System (EFFS) examples, EFFS-FAT or EFFS-STD.

The server provides two functions:

1. Allows the FTPS Client to download a single file named ReadFile.txt
2. Allows the FTPS Client to upload a text file named WriteFile.txt, which will be displayed on the serial port. It is not stored since this simple examle does not use the file system.

The server uses a built in self-signed certificate and key. Status messages, including sockets in use, are displayed on the serial port.

To run the example:

- Run MTTY and connect to the debug serial port
- Run a program such as WinSCP that supports FTPS (not SFTP)
- Connect to the FTPS Server on the NetBurner device
- Select the ReadFile.txt file to download or view it
- Select the WriteFile.txt file in the FTPS Client and send it to the FTPS Server on the NetBurner device. It will be displayed on the serial port

12.43.3 HTML File Post

This example presents a web page with a field for selecting a file to upload to the NetBurner device. When the "Send File" button is selected, the upload is performed. The uploaded file is then displayed on the web page. A quick test is to send this example's ReadMe.txt file.

This example is similar to the `examples\web\HtmlFilePost`, with the addition of SSL/TLS capability.

Browsers are starting to require a valid certificate on the device, as well as the installation of the Certificate Authority (CA) certificate installed in the browser for self-signed certs. Receiving a warning message in the browser and selecting the option to continue anyway may work for variables posted in a form, but it will not work when posting a file.

12.43.4 HTML Form Post

- Similar to the `HtmlFormPost` in the `examples\web` folder, but works with SSL/TLS
- Uses the HTML POST command (the other is HTML GET) to send HTML form data from a web browser to the NetBurner device.
- Illustrates the use of the NetBurner POST callback objects, named `postForm1` and `postForm2` in this example, to intercept and process HTML Post data.
- Demonstrates how to handle multiple web pages with HTML forms and content delivery using the library functions `SendFullResponse()` and `RedirectResponse()`.

12.43.5 HTTPS Dual Cert

HTTPS Server Example for multiple certificates

Supported Platforms: MODM7AE70, SBE70LC, MOD5441X, NANO54415, SBE70LC

This example creates a web page that can be viewed as normal or encrypted with SSL/TLS. An example certificate is included in DEVICE.CRT and DEVICE.KEY. Load these files on the flash card prior to the device booting up. Since this is an example cert, the web browser will display warning messages to this effect. For this example select the "continue to page" options to allow the HTTPS for a single session.

In addition this example illustrates how to have both a permanent compiled-in certificate and key, as well as one that can be loaded from an external Flash card using the EDFS FAT file system. If a certificate and key are present on the Flash card named DEVICE.CRT and DEVICE.KEY, they will be used instead of the local, compiled-in certificate and key.

If you are using NBEclipse, then you will also need to tell the linker to include the FatFile.a library. To do this, complete the following steps:

- In NBEclipse, right-click on your project, and select "Properties"
- Select "C/C++ Builds -> Settings" on the left-hand side
- Select "GNU C/C++ Linker -> Libraries" under the "Tool Settings" tab
- In the "Libraries" list box, add "FatFile" by using the action icons provided in top-right corner of the list box

Example Features:

- Compiled-in certificate and key
- Optional Flash card certificate and key
- NTP client to set the time
- FTP to enable the upload of a certificate and key to a Flash card
- Flash card test code to verify the card can be read/written to
- Web page and links to load a HTTPS or HTTP version

12.43.6 HTTPS Upload Cert

This program demonstrates how to upload a user certificate and key to support SSL/TLS web page access. The uploaded certificate and key are stored in the on-chip flash memory using the standard file system (EDFS-STD). The serial port provides status messages on the application operation.

The application has a built-in certificate and key, ServerCert.cpp and ServerKey.cpp, to provide security before a user certificate and key are installed. You can generate a certificate and key by your own method, or using the makeca and makeserver scripts found in <nndk_install>\CreateCerts\<ECDSA or RSA>. The Certificate Authority is created by makeca, which is then used to sign the server certificate and key with makeserver.

The display on the web interface will indicate whether you are using the compiled certificate and key (listed as "Default"), or the uploaded version (listed as "User Installed").

To run the example:

- Create a server certificate and key
- Run MTTY to view status messages on the serial port
- Open the web page in a browser, which will be using the compiled in certificate and key if this is the first time
- Use the web interface to upload your own certificate and key

Note

Browsers are starting to require a valid certificate on the device, as well as the installation of the Certificate Authority (CA) certificate installed in the browser for self-signed certs. Receiving a warning message in the browser and selecting the option to continue anyway may work for variables posted in a form, but it will not work when posting a file.

12.43.7 HTTPS Web Server Demo

SSL/TLS Server example program with web page redirection for unauthorized access. The example demonstrates how you can have both secure and non-secure access to files and directories.

The application starts the web server with SSL/TLS capability. The directory structure is such that index.html and the files in the images subdirectory can be viewed with a http or https connection. However, files in the httpsdir directory (ie repeat.html) can only be viewed with a secure https connection.

```
html
|-- index.html
|-- images
    |-- (various image files)
|-- httpsdir
    |-- repeat.html
```

The `HTTP_ACCESS CheckHttpAccess(int sock, int access_level, HTTP_Request &Req)` function is used to authenticate the web page access. It will allow access or redirect depending on the file and access rights.

12.43.8 HTTPS GET Request

This example demonstrates how a SSL/TLS Client can retrieve a web page from a HTTPS server.

- Run the MTTY serial terminal
- When the application starts there will be a prompt to enter a HTTPS web site name (eg. www.google.com)
- The retrieved web site data will be displayed as text in MTTY

12.43.9 SSL/TLS Client

SSL/TLS Client Example

This example demonstrates how SSL/TLS Client connections can be made. It will attempt to connect to the specified SSL Server and keep track of the number successful and failed attempts. Status messages will be sent to both the SSL/TLS Server, and to the serial debug port on the NetBurner device.

You must modify the `SSL_SERVER_NAME` to match your SSL Server device.

Testing: One method of testing a SSL/TLS client is to use `openssl s_client`. A typical command to start the server at the time of this writing is: `openssl s_server -accept 4433 -cert Server.crt -key Server.key`

Where you supply the .crt and .key files created by the NetBurner tools, OpenSSL, or through a Certificate Authority. For more information please refer to the `openssl s_server` documentation online.

Certificate checking is disabled by default. To enable certificate checking you must:

1. Include a CA certificate list in your project
2. Uncomment `#define NB_SSL_CLIENT_CERTIFICATE_CHECKING_ENABLED` in `sslclient.cpp`
3. Rebuild the system libraries

12.43.10 SSL/TLS Client Certificate

PROGRAM DESCRIPTION: SSL Client Certificate Example

This example demonstrates:

1. How SSL Client connections can be made.
2. How to load and use Client Certificates.
3. This example will only work if you are connecting to a SSL server that is configured to request and receive client certificates. In this example the client certificate is compiled as part of the application.

The application will attempt to connect to the specified SSL Server and keep track of the number successful and failed attempts. Status messages will be sent to both the SSL Server, and to the serial debug serial port on the NetBurner device.

IMPORTANT: A Client Certificate is a very different thing than when a client checks a server certificate against a list of Certificate Authorities (CA):

Certificate Checking against a CA: In this mode the Client will check the CA portion of the server certificate against a list of CA's maintained by the client. If the CA's match, the connection is allowed. This mode requires a modification to [predef.h](#) to enable client certificate checking. This is NOT the purpose of this example application.

Sending a Client Certificate to the Server: In this mode, in addition to the server sending a certificate to the client as in the above case, the client is required to send a certificate to the server. That is the purpose of this example application.

CREATING A CERTIFICATE AND CA: Please refer to the NetBurner Security Library documentation for a detailed description. For the convenient of this example, we have created one for you.

12.43.11 SSL/TLS Client Verify Peer - Basic

This program will demonstrate how to use CA Lists for use in support of peer verification. One certificate is defined in [caList.h](#). This is the root certificate for GitHub. They are passed into the call to `SSL_connect()`, and the verify peer parameter in that function is set to true.

To test this example, use the command 'C' at the debug prompt, and then type the name of the site that you wish to test a connection to.

12.43.12 SSL/TLS Client Verify Peer - EFFS-STD

This program will demonstrate how to upload CA Lists to use in support of verify peer. The uploaded information is stored in the onchip flash memory using the standard file system. The serial port provides a debug menu.

We include `github.pem` with this example to use for your testing. Load this file onto the device through the web interface and then try to connect to GitHub.com through the serial menu. You should see a message stating that there's a good SSL connection if it's successful.

12.43.13 SSL/TLS Receive Mail (POP3)

This example demonstrates how to implement retrieving email from a server that requires SSL/TLS.

When trying to connect to a Google Account, you will likely need to enable less secure application access. If you use two-factor authentication with your account, you will need to setup an application password for the account being connected to. This can be done at the following URL: <https://myaccount.google.com/apppasswords>

Note that when setting this up, it will tell you that you do not need to save the password. For this example, this is not the case. The application password is not stored anywhere, and will need to be reentered for every request.

12.43.14 SSL/TLS Send Mail

This program illustrates how to send an email message to a server that uses SSL/TLS.

All the magic happens in the `webfuncs.cpp` file, this code just initializes the app

Note that this application uses a secure SSL/TLS connection when accessing the web server. All connections made through it will need to take place via HTTPS.

There are two ways the SSL/TLS SMTP handshake can happen, with or without "STARTTLS". With servers that don't require STARTTLS, all that needs to be done differently than a regular SMTP handshake is to connect using "SSL_connect" to port 465 or 587 (instead of a regular connect to port 25), and from there proceed like a normal SMTP handshake. This method is used when we know for sure the server accepts SSL/TLS mail and we definitely want to use SLL (since some server like Yahoo allow you to connect in both ways).

If we are not sure if a server supports SSL/TLS, or, we only want to use SSL/TLS if it is required, we use the STARTTLS method. With this method, the `send_mail` function first opens a connection to the regular SMTP port 25 and does an "EHLO". If the server has the key word "STARTTLS" in its response, it means that it supports TLS, from there, the client says "STARTTLS" and then calls the `SSL_negotiate` function which establishes a secure connection with the server. After the secure connection is established, we say "EHLO" again and proceed as normal.

Gmail requires SSL/TLS, so if we try to connect to it on port 25 (the non SLL port) it will say STARTTLS without giving the option AUTH, which means SSL/TLS is required and we must start the SSL/TLS negotiation. Yahoo allows both, but does not offer STARTTLS. This means that it doesn't let you know that SSL/TLS is available if connected to on the regular SMTP port, it expects you to connect to port 465 or 587 if you want to use SSL/TLS, and port 25 for non SSL/TLS.

When trying to connect to a Google Account, you will likely need to enable less secure application access. If you use two-factor authentication with your account, you will need to setup an application password for the account being connected to. This can be done at the following URL: <https://myaccount.google.com/apppasswords>

If you are using NBEclipse, then you will also need to tell the linker to include the `/nburn/platform/<platform>/original StdFFile.a` library. To do this, complete the following steps:

- In NBEclipse, right-click on your project, and select "Properties"
- Select "C/C++ Builds -> Settings" on the left-hand side
- Select "GNU C/C++ Linker -> Libraries" under the "Tool Settings" tab
- In the "Libraries" list box, add "StdFFile" by using the action icons provided in top-right corner of the list box

12.43.15 SSL/TLS Send Mail w/ Attachment

Send an email with a plain text attachment

Note that this application uses a secure SSL/TLS connection when accessing the web server. All connections made through it will need to take place via HTTPS.

This example illustrates how to send a MIME email attachment in plain text, without using the EFFS FAT32 file system (there is a different example for EFFS). Once the example is running, all interaction is done through the web page.

When trying to connect to a Google Account, you will likely need to enable less secure application access. If you use two-factor authentication with your account, you will need to setup an application password for the account being connected to. This can be done at the following URL: <https://myaccount.google.com/apppasswords>

The default STMP port value will be set to 465 for a connection using SSL/TLS. This example is not structured to handle a STARTTLS response. Please see the SslSendMail example for more information.

12.43.16 SSL/TLS Send Mail w/ EFFS Attchment

Supported Platforms: MOD5551X, NANO54415, MODM7AE70, SBE70LC

This example demonstrates how to attach files from the EFFS FAT32 file system to an email. Once the program starts, all interaction is done from the web page.

Note that this application uses a secure SSL connection when accessing the web server. All connections made through it will need to take place via HTTPS.

When trying to connect to a Google Account, you will likely need to enable less secure application access. If you use two-factor authentication with your account, you will need to setup an application password for the account being connected to. This can be done at the following URL: <https://myaccount.google.com/apppasswords>

The default STMP port value will be set to 465 for a connection using SSL/TLS. This example is not structured to handle a STARTTLS response. Please see the SslSendMail example for more information.

12.43.17 SSL/TLS Server

This program will create a SSL/TLS server task that uses Elliptic Curve Cryptographic (ECC) keys. To test the application you can use another NetBurner device configured as a client, or openssl. The command line options for openssl as of 13-Nov-2018 are: `openssl s_client -cipher ECDHE-ECDSA-AES256-GCM-SHA384 -connect <ip address>:<port>`

For example: `openssl s_client -cipher ECDHE-ECDSA-AES256-GCM-SHA384 -connect 10.1.1.191:8883`

If you need an RSA key for your specific application needs, you can generate them using the scripts found in `\nburn\CreateCerts\RSA`. Just replace `ServerKey.cpp` and `ServerCert.cpp` in this example with those that you generate from the scripts and rebuild the application. You can test this with the following OpenSSL commands.

`openssl s_client -connect <ip address>:<port>`

For example: `openssl s_client -connect 10.1.1.191:8883`

This example uses a simple `read()` function to receive data from a TCP client.

12.43.18 HTTPS Configuration Mirror

SSL/TLS Server example program with web page redirection for unauthorized access. The example demonstrates how you can have both secure and non-secure access to files and directories.

The application starts the web server with SSL/TLS capability. The directory structure is such that index.html and the files in the images subdirectory can be viewed with a http or https connection. However, files in the httpsdir directory (ie repeat.html) can only be viewed with a secure https connection.

```
html
|-- index.html
|-- images
    |-- (various image files)
|-- httpsdir
    |-- repeat.html
```

The `HTTP_ACCESS CheckHttpAccess(int sock, int access_level, HTTP_Request &Req)` function is used to authenticate the web page access. It will allow access or redirect depending on the file and access rights.

12.44 Stack Protection

Demonstrate various stack overflow/underflow protection methods.

To run this example, the following lines must be uncommented in `\nburn\nbrtos\include\predef.h` to enable stack checking features:

```
#define NBRtos_STACKCHECK (1)
#define NBRtos_STACKOVERFLOW (1)
#define NBRtos_STACKUNDERFLOW (1)
```

12.45 Syslog

The Syslog utility enables you to send logging information to a destination host computer using UDP (port number 514). This example uses syslog to send a simple counting variable to a host computer.

To run the example:

1. Verify you have proper network communication with you NetBurner device. It must have an IP address and mask.
2. Modify the source code line: `SysLogAddress = AsciiToIp("10.1.1.191");` so that it specifies the address of your computer. If this line is commented out and no SysLogAddress is specified, then the syslog data will be sent as a UDP broadcast.
3. Run the NetBurner "UDP Terminal Tool" application. Make sure the local listening port field is set to 514, the default syslog port.
4. Download and run the application on your NetBurner device.

12.46 System Diagnostics

By including the function `EnableSystemDiagnostics()` in your application, you can view system diagnostic information by going to the device's Configuration Server web page and clicking on the "Diagnostics" button.

This example demonstrates how to add your own additional variables to the diagnostic display, such as application integers, floats, strings, definitions, etc. To do so:

- Add `#include <diagnostics.h>`
- Declare the corresponding `DiagVarMon()` function. For example, to add an integer variable myInt you would declare: `static DiagVarMon MyIntMon("My Int", myInt);` The first parameter is the name or description you wish to use to identify the variable.

12.47 TCP

TCP Examples:

- [TCP No Block Connect Test](#)
- [TCP Keepalive](#)
- [TCP Client](#)
- [Multiple TCP Interface Test](#)
- [TCP Multi-Socket Server](#)
- [TCP Resource Information](#)
- [TCP Server](#)
- [TCP Server Using Via](#)
- [TCP Speed Test](#)
- [TCP Stress Test](#)

12.47.1 TCP No Block Connect Test

The standard TCP connect call will block until the connection is either made or fails. The non-blocking connect call will initiate a TCP connection and return immediately.

12.47.2 TCP Keepalive

This example program will create a TCP server that also implements keep alive functionality with the TCP client. Keep-alive is implemented with the `TcpGetLastRxTime()` and `TcpSendKeepAlive()` functions. `TcpGetLastRxTime()` returns the number of time ticks since the last time a packet was received. `TcpSendKeepAlive()` sends a keep-alive packet to the client, which is used when no data has been transmitted within the timeout period.

The general concept is to call `TcpGetLastRxTime()`, call `TcpSendKeepAlive()`, wait a bit, then call `TcpSendKeepAlive()` a second time and verify the number of time ticks is different. If not, no packets were received and the client is not responding. Make sure to allow time for the client to respond to the keep alive packet. Do not call `TcpGetLastRxTime` more often than once every second to avoid performance issues.

This example creates a TCP server task that listens on port 23 by default. The server blocks with "ReadWithTimeOut" until data is received or the timer times out. If a timeout occurs the time of the last received packet is recorded and a keep-alive packet is sent. Then, the server goes back to waiting for a read again. If ReadWithTimeOut times out a second time, the value of the last received TCP packet is checked again. If the client is still active the value of lastRxTime will be different than the previous value (due to the keep-alive packet that was sent). If the client did not respond to the keep-alive packet the number will remain the same and the client is assumed to be non-responsive, and the connection is closed.

To test the application you can use a TCP client such as telnet or putty. For example, from a windows command prompt, type `telnet <ip address of NetBurner>`. Status messages are sent to the debug/console serial port.

12.47.3 TCP Client

This program demonstrates how to create a TCP Client. All interaction is through the web page interface, which enables you to type a message as well as the IP address and port number of the destination TCP server. You should be able to use any TCP server. If you do not have one, we have a windows example TCP server in the `\nburn\pctools\TCP\TcpServerWin` directory (as well as source code).

12.47.4 Multiple TCP Interface Test

TCP Multiple Interface Test

12.47.5 TCP Multi-Socket Server

This example creates a TCP server that listens on the specified TCP port number and can handle multiple TCP connections simultaneously (10 in this example). The `select()` function is a great way method to pend and process multiple connections.

An easy way to test the example is to use multiple Telnet sessions to create simultaneous connections to the NetBurner device. Status messages are sent out stdio to the debug serial port, and to the client TCP connections.

12.47.6 TCP Resource Information

This example demonstrates the use of functions to obtain the number of free system buffers and the number of free network sockets. A socket will be consumed when you listen or connect. For example, the web server will consume one socket listening to port 80 for incoming connections.

If the system is out of buffers or sockets, it will not be able to accept any incoming connections or make any outgoing connections.

`int32_t GetFreeCount()` returns the number of free system buffers
`int32_t GetFreeSocketCount()` returns the number of free sockets/file descriptors, not included extra fds
`int32_t GetFreeExtraFDCount()` returns the number of extra file descriptors

12.47.7 TCP Server

This program will create a TCP server task, which listens on port 23 by default. To test the application you can use Telnet. For example, from a windows command prompt, type: `telnet <ip address>`

This example uses a simple `read()` function to receive data from a TCP client. Refer to the TCP Multi Socket Server example to handle multiple client connections.

12.47.8 TCP Server Using Via

This example is based on the TCP Multi-Socket Server example, with the addition of the `listenvia()` function call to specify a specific network interface for multi-interface devices.

This program will create a TCP server task, with multiple listening sockets, one listening on all interfaces, and an additional socket each listening on a specific network interface. By default, these sockets listen on port 23 and incrementing from there. To test the application you can use Telnet. For example, from the command line, type:

```
telnet <ip address> <port>
```

This example uses the `select()` method to handle the multiple sockets within the context of a single task.

12.47.9 TCP Speed Test

This program will test the receive speed of the NetBurner device. To run the program:

- Run MTTY and connect to the debug serial port
- Build and download this example application
- Run the TcpSpeedTest.exe PC application, found in the "pc" subdir in this example in a windows command prompt window
- The test results will be displayed in MTTY and in the command prompt window

Executing TcpSpeedTest.exe from a PC:

- Need a NetBurner device running it's speed test code on the same LAN
- Open a command prompt, type `./TcpSpeedTest <ip address>` where "ip address" is the address of the NetBurner device.
- The "-r" command line option will repeat forever or until you use `ctrl-c` to exit.

12.47.10 TCP Stress Test

Example to test various response times. Work in conjunction with a windows program to exercise the test cases:

- Listen for an incoming connection and exchange data
- Listen for an incoming request, then make an outgoing request and exchange data
- Worst case time for sending and receiving one byte at a time both directions
- Response time of the `select()` function to block on multiple fds
- Bulk data transfer time

Time for the various tests will be in multiples of a time tick, which is by default 20 ticks per second (TICKS_PER_SECOND).

Be sure not to include the pc folder in your NetBurner project. It is a windows program.

12.48 Telnet Command

This example shows how to use the Command Processor Library, which will accept and process user commands. Connections can be made to the command processor through the serial port, or through a telnet connection. TCP connections may also be used.

To use the Command Processor Library, a set of callback functions are defined to accept user connections, handle authentication, handle disconnections, provide a prompt, and of course to process the commands.

12.49 TFTP - Trivial File Transfer Protocol

This example program will use a NetBurner device to communicate with the NetBurner TFTP Server running on a PC. To run the example:

1. The TFTP Server on the PC must be started and configured to handle both reads and writes.
2. You must specify the TFTP server in the NetBurner device using IPSetp or through the monitor

12.50 Time Functions

Example of how to set and read system time.

Example of system time functions:

- Set system time from a NTP server or manual entry (see also: RTC example)
- Use of time functions such as `time()`, `mktime()`, `localtime()`, etc
- How to display date and time
- Time zones and use of `tzsetchar()` to set a time zone
- Use of `time_t` and `tm` structure

12.51 Timers

System timer examples:

- [Timer](#)
- [Interval Timer](#)
- [Stopwatch Timer](#)

12.51.1 Timer

The HiResDelay class uses a hardware timer to provide a microsecond delay function.

12.51.2 Interval Timer

The Interval Timer user a processor hardware timer to schedule periodic interrupts. This can be useful for applications that need to do something at reliable intervals.

The example demonstrates how to:

- Create an IntervalTimer object
- Trigger an interrupt and access an interrupt service routine
- Post a semaphore
- Post a flag

The default for the timer constructor is to use the next available system timer, but you can also specify a specific timer as an optional parameter. Depending on the application requirements, the system may also use one or more of the available timers.

Warning

Always check the return value when creating a timer object. A value of less than 0 means a timer could not be allocated.

Available Timers MODM7AE70: 0 - 11 MOD54415, MOD54417, NANO54415, SB800EX: 1-3 MODRT1061: 0 - 20

12.51.3 Stopwatch Timer

A [StopWatch](#) object is used to time events. Once the object has been created, the Start and Stop member functions are used to control timing events.

12.52 UDP

The UDP API includes both socket based and object based (UDP Packet) implementations.

UDP Examples:

- [UDP to Serial](#)
- [UDP Notify Callback Function](#)
- [UDP C++ Packet Class](#)
- [UDP Echo](#)
- [UDP Send/Receive](#)
- [UDP Sockets](#)
- [UDP Sockets Via](#)

12.52.1 UDP to Serial

This program will send/receive data between a UDP program, such as the NetBurner UDP Terminal, and a serial port (such as the MTTY program). The UDP configuration parameters are handled through the web page configuration interface.

12.52.2 UDP Notify Callback Function

This example illustrates how to use a callback function to be notified of any incoming UDP packets. The key components are:

- Standard UDP packet class
- A callback function to be executed when data is available
- Using the [RegisterUDPFifoWithNotify\(\)](#) instead of [RegisterUDPFifo\(\)](#)

12.52.3 UDP C++ Packet Class

This application will send/receive UDP packets with another host on a network, such as a PC. Use the MTTTY serial port program to access the menu and prompts to specify the destination IP address and port number.

NetBurner supplies an API for handling UDP as a C++ Class using [UDPPacket](#), or you can use a UDP sockets API (see UDP socket example).

For an external UDP host you can use the NetBurner Java example, or the NetBurner UDP terminal program.

12.52.4 UDP Echo

This example program will receive a UDP packet from another device or host computer, and then send a response. To run the example, connect a serial port from your PC to the debug serial port on your NetBurner device and run a terminal program such as MTTTY. On the PC, run the NetBurner UDP Terminal (be sure to set the IP address and port numbers to match). Send data from the NetBurner UDP Terminal, and observe that the packet is received in MTTTY. Then observe the response from the device in the NetBurner UDP Terminal.

12.52.5 UDP Send/Receive

This example program will receive a UDP packet from another device or host computer, and then send a response. UDP is handled using the UDP C++ Class.

Note there is also an API for handling UDP using a socket interface.

To run the example, connect a serial port from your PC to the debug serial port on your NetBurner device and run a terminal program such as MTTTY.

On the PC, run the NetBurner UDP Terminal (be sure to set the IP address and port numbers to match) or some other UDP program of your choice. You will then be able to type characters in the UDP Terminal and see them in MTTTY, and vice versa.

You will be prompted for the port number to send/receive data and the destination IP address of the other device or host. Note that the application uses the same port number to send and receive data, but you can use any other port number you wish.

The application will create a thread to receive packets and display them on the debug port, while the main task will take any data you type in to the MTTTY terminal and send it as a UDP packet to the destination IP address.

12.52.6 UDP Sockets

This application will send/receive UDP packets with another host on a network using the UDP Sockets API. Use the MTTTY serial port program to access the menu and prompts to specify the destination IP address and port number.

Note there is also an API for handling UDP as a C++ Class using [UDPPacket](#).

For an external UDP host you can use the NetBurner Java example, or the NetBurner UDP terminal program.

12.52.7 UDP Sockets Via

This application will send/receive UDP packets with another host on a network using the UDP Sockets API. This opens multiple sockets for all different interfaces. Use the MTTTY serial port program to access the menu and prompts to specify the destination IP address. It also demonstrates using Select for UDP receive.

There is also an API for handling UDP as a C++ Class using [UDPPacket](#)

For an external UDP host you can use the NetBurner Java example, or the NetBurner UDP terminal program.

12.53 VLAN

Creates 3 VLAN interfaces:

- Ethernet 0, [DHCP](#), VLAN ID 1
- Ethernet 0, [DHCP](#), VLAN ID 2
- Ethernet 0, Static IP, VLAN ID 10

The serial port interface provides an interactive menu to display interface and VLAN information, as well as other system parameters.

To build this example MULTIHOME must be enabled in [predef.h](#). Rather than change the file in `\nburn\nbrtos\include`, use the override feature and add [predef.h](#) to your project.

12.54 Web Server

Web Server Examples:

- [Ajax Graph](#)
- [Bootstrap Hello World](#)
- [HTML File Post](#)
- [Flash Form](#)
- [GIF Canvas](#)
- [HTML Application File Post](#)
- [HTML Cookie](#)
- [HTML Form Post](#)
- [HTML Form Post 2.X Compatible](#)
- [HTML Password](#)
- [HTML Server GET Request](#)
- [HTMLVariables](#)
- [Serial Webserver](#)
- [Signed Application](#)
- [Simple HTML](#)
- [TicTacToe](#)

12.54.1 Ajax Graph

This example demonstrates the code to create a webpage with a dynamic graph, generated by data from the Net↔ Burner device. Specifically, it has been designed to imitate the data formats found in log files, where ordering and frequency are varied between data sources.

The vast majority of the example is simply the support code needed to generate the random data. This code is located in the other support files. The locations that actually are relevant to the AJAX portion of the example are:

```
main.cpp: getSensorData () DumpLogData ()
```

```
ticks.html: <!--FUNCTIONCALL getHTMLTicks -->
```

```
data.html: <!--CPPCALL getSensorData () -->
```

index.html: Basically, all the Javascript.

12.54.2 Bootstrap Hello World

The Bootstrap HelloWorld Example demonstrates how easy it is to utilize Twitter Bootstrap (<http://twitter.github.io/bootstrap/>) on a NetBurner device. This example loads a simple "Hello World" web page on to the device, along with the Twitter Bootstrap framework (version 4.0).

12.54.3 HTML File Post

This example presents a web page with a field for selecting a file to upload to the NetBurner device. When the "Send File" button is selected, the upload is performed. The uploaded file is then displayed on the web page.

12.54.4 Flash Form

The FlashForm example demonstrates three different capabilities:

1. Dynamic HTML
2. HTML Form processing
3. User Flash parameter storage. Note that as of the 3.x release, we recommend you use the configuration server/storage.

All the processing happens when a web browser posts a form, and all the comments are in the formcode.cpp source file.

12.54.5 GIF Canvas

This example program describes how to programmatically create images and text. This file, main.cpp, starts the application, network services and web server. The functions that create the images and interact with the web browser are located in drawimage.cpp.

To run this application compile and download the program file, then use your web browser to connect to the NetBurner device.

12.54.6 HTML Application File Post

This example presents a web page where the user can post a file to update the code in the device. Optionally you can uncomment:

```
#define I_WANT_TO_AUTHENTICATE_UPDATE  
to enforce a username password.
```

12.54.7 HTML Cookie

This example shows how to implement cookies with the NetBurner web server. The example program works as follows:

- Three web pages are created: an index page, a page to set the cookie value to "MyCookie", and a page to view the cookie value.
- When you run the program open a web browser and go to the index page.
- Select the "set cookie" link to set the cookie. Note that if you select "show cookie" before setting the value, no value will be displayed.
- Select the "show cookie" link to view the cookie

A cookie will apply to a "site". In this example a "site" will probably be the IP address of your NetBurner device. The cookie will be sent as part of the HTML header for any page requested from the "site".

12.54.8 HTML Form Post

- Uses the HTML POST command (the other is HTML GET) to send HTML form data from a web browser to the NetBurner device.
- Illustrates the use of the NetBurner POST callback objects, named `postForm1` and `postForm2` in this example, to intercept and process HTML Post data.
- Demonstrates how to handle multiple web pages with HTML forms and content delivery using the library functions [SendFullResponse\(\)](#) and [RedirectResponse\(\)](#).

12.54.9 HTML Form Post 2.X Compatible

The standard HTTP POST methodology in 3.x should be used whenever creating a new project. The 3.X methods enable cleaner code, less URL parsing, and better performance.

For customers migrating large and complex applications from legacy NNDK 2.X tools and platforms to NNDK 3.X, it is possible to create a HTTP POST callback function that in turn calls a `MyDoPost()` style 2.X function. This example assumes familiarity with the NNDK 3.X HTTP POST methods.

- A NNDK 3.X HTTP POST callback function is declared with a wildcard mask ("*") so that it is called for all HTTP POST operations.
- Strings are created for the URL containing the form action name and the posted form data
- The 2.X style `MyDoPost()` function is called with the URL and data strings
- The `ExtractPostData()` function is copied from the 2.X tools and included as a function in the application

Once the example has been loaded, interaction is through the device's web page. There are two web pages with forms for data entry, and a summary page at the end to display the assigned values from the post. Status messages are displayed on the serial port that can be viewed with a serial terminal, such as the MTTY utility.

While every attempt has been made to ensure compatibility, every application must be tested to verify proper operation. Also, this example will not work with multi-part forms.

12.54.10 HTML Password

Demonstrates how to use user names, passwords and access groups. The application consists of an index page with links to three additional pages with access group numbers 0, 1 and 2.

- Group 0 = Open access
- Group 1 = Admin access
- Group 2 = User access

The function `HTTP_ACCESS CheckHttpAccess(int sock, int access_level, HTTP_Request & Req)` is used to authenticate the user names and passwords.

Note: A web browser will cache the username and password once entered. To force a password request again you will need to clear the browser cache, restart the browser, or open a new private browsing session.

12.54.11 HTML Server GET Request

Demonstrates how to use web server GET function callbacks to intercept browser GET requests. This mechanism can be used to enable the application to add custom processing and dynamic web content when a specific web page our URL is requested, or to add custom processing for all GET requests.

12.54.12 HTMLVariables

This example illustrates how to use dynamic HTML content with variables and function call parameters embedded in HTML code. The HTML tags `VARIABLE` and `FUNCTIONCALL` enable you to display application variables and call application functions directly from the HTML code.

In this example, the device's IP, Mask, Gateway, and DNS Server are displayed dynamically on the web page. The page also displays an uptime counter which updates when the page is refreshed.

Note for NBEclipse Users: This example requires that the auto-generated file `htmldata.cpp` have a path to include the `htmlvar.h` header file. To add the path in NBEclipse:

Right-click on your project and select properties Select "C/C++ Build" options Select "GNU C++ Compiler" -> Directories Use the "+" in the include path box to add the project's "HtmlVariables\html" folder to the list of include paths.

12.54.13 Serial Webserver

The Serial Webserver is a simple example demonstrating receiving and replying to HTTP requests over a serial port, using the NetBurner web server implementation. The example will display a "Hello World" type message on the device's index page: `index.html`.

An valid HTTP GET request that is compatible with this application is the following:

Note

The webserver expects a double carriage return line feed

```
\GET /INDEX.HTML HTTP/1.1\r\n\r\n`
```

The expected response should look similar to the following:

```
HTTP/1.0 200 OK
Pragma: no-cache
MIME-version: 1.0
Content-Type: text/html
Content-length: 231

<html>
<head><link rel="stylesheet" type="text/css" href="style.css"></head>
<body>
<a href="http://www.netburner.com"></a>
<h1>Thank you for NetBurning!</h1>
</body>
</html>
```

12.54.14 Signed Application

Demonstrates the signed application update capability.

To use this you need to create a public/private key pair. It is VERY important that the private key is not stored on the device in order to be secure. The signing key needs to be different than all other certs and keys used on the device as a server, such as those for HTTPS.

From this public/private key pair, the public key needs to be stored in the application, and the private key needs to be stored in some other secure location. If the private key is lost, you will be unable to ever again update the device. To create the public key and compile it into the application, from the command line:

- `openssl genrsa -out signkey.pem 1024`
- `openssl rsa -in signkey.pem -pubout -out src/public.key`
- `set NB_SIGN_KEY = WHERE_EVER_THE_KEY_LIVES\signkey.pem`

This example includes a batch file named `makekey.bat` that executes the above steps.

Once the public key has been created, the following commands can be used from the command line to create the signed application and load it into the device:

- `make sign`
- `make loadsign`

When using NBEclipse:

- Make the public/private key pair as described above.
- In the directory where you have the public key, run `compfile public.key codekey_array codekey_len codekey.cpp`.
- Now include the `codekey.cpp` in your NBEclipse project.

After NBEclipse has built your project:

1. Create an External Tool Configuration with Run->External Tools->External Tools Configurations.
2. In the new external tool configuration, specify the following: – Name: Sign – Location: "\${env_var:NNDK_ROOT}\pcbin\nbsign.exe" – Working Directory: Browse Workspace and select your project – Arguments: -k <full path to private key.pem> -in Release\${project_name}.bin -o Release\${project_name}.signed.bin
3. Project can now be signed by running the Sign External Tool

12.54.15 Simple HTML

The Simple HTML Example is a basic demonstration of the NetBurner web server implementation, and is a good starting point for custom applications. The example will display a "Hello World" type message on the device's index page: index.html.

12.54.16 TicTacToe

The TicTacToe application provides a number of simple examples:

- Play tic tac toe, of course
- Manipulate the LEDs on the NetBurner development board. This is an example of URL Encoding.
- Echo web browser requests, so you can see what is sent to the web server.
- Example of a meta tag to create a "reloading web page", which refreshes itself at 1 second intervals.

12.55 Web Client

Web Socket Examples:

- [Earthquake](#)
- [Find My IP](#)
- [Find My IP Task](#)
- [Message Passer](#)
- [MessagePasserTask JSON](#)

12.55.1 Earthquake

Simple program that demonstrates retrieving a JSON object from a site and using it to present the user with dynamic output; in this case obtaining the number of earthquakes that have occurred today and their details.

12.55.2 Find My IP

This program starts a separate, higher-priority task that navigates to a website and retrieves information; in this case we navigate to a site and retrieve the IP address that we connected with.

12.55.3 Find My IP Task

This program starts a separate, higher-priority task that navigates to a website and retrieves information; in this case we navigate to a site and retrieve the IP address that we connected with.

12.55.4 Message Passer

Message Passer example that checks the current time.

12.55.5 MessagePasserTask JSON

Message Passer Task to send a JSON object.

12.56 Web Sockets

Web Socket Examples:

- [Web Socket Connect](#)
- [Web Socket Console](#)
- [Web Socket DIP Switch](#)
- [Web Socket Echo](#)
- [HTTPS WebSocket Demo](#)

12.56.1 Web Socket Connect

This is an example that demonstrates websocket connections.

12.56.2 Web Socket Console

Web Sockets Console example

12.56.3 Web Socket DIP Switch

Supported Platforms: MODM7AE70, MOD5441x, NANO54415

This program illustrates how to use the NetBurner WebSocket class to display the state of the DIP switches on the MOD-DEV-70CR in real-time on a webpage. That means as soon as you flip the DIP switches on the development board, the state will change on the webpage without having to refresh the page.

The application continuously polls the DIP switches and sends the state of the DIP switches via a websocket to the client. It's not the most efficient implementation when considering CPU utilization but this app demonstrates the capabilities of a WebSocket to allow the server(NetBurner device) to send the state of a variable to the client(webpage) with low latency and minimal packet size. This app also illustrates how to use the NetBurner JSON library to build and send JSON objects from the NetBurner device to the client. In this case, JSON objects are used to pass the state of the DIP switches to the webpage.

12.56.4 Web Socket Echo

Web Sockets Echo example

12.56.5 HTTPS WebSocket Demo

SSL/TLS WebSocket example program with web page redirection for unauthorized access. The example demonstrates how you can have both secure and non-secure access to files and directories, alongside secure and non-secure access to WebSockets.

The application starts the web server with SSL/TLS capability. The directory structure is such that index.html, script.js, and the files in the images subdirectory can be viewed with a http or https connection. However, files in the httpsdir directory (ie ssl.html) can only be viewed with a secure https connection.

```
html
|-- httpsdir
|   |-- ssl.html
|-- images
|   |-- (various image files)
|-- index.html
|-- script.js
```

The `HTTP_ACCESS CheckHttpAccess(int sock, int access_level, HTTP_Request &Req)` function is used to authenticate the web page access. It will allow access or redirect depending on the file and access rights.

The `StartHttps()` function starts the webserver for both HTTP and WebSockets. If SSL-only access is desired, `StartHttps(443, 0)` can be used instead.

12.57 Wifi

Wifi Examples:

- [Wifi Config AP](#)
- [Configure AP with JSON](#)
- [Wifi Firmware Update](#)
- [Wifi Access Point](#)
- [Wifi Client](#)
- [Wifi Scan](#)

12.57.1 Wifi Config AP

Configure the wifi as an access point.

12.57.2 Configure AP with JSON

Configure the WiFi interface as an access point to provide the user a means to connect to local networks.

If no network SSID is provided to connect to upon boot, the application will start a WiFi Access Point. The NetBurner's WiFi Access Point can be used to scan for local networks. The NetBurner device hosts a webpage that allows the user to establish a connection to local networks after performing a scan.

The default WiFi access point SSID will be of the form "NB_<last 6 bytes of MAC>". For example, a NetBurner access point may look like "NB_012345". If you would like modify the prefix of the access point to include custom product branding, the prefix can be re-defined by un-commenting and modifying the following line located at the top of main.cpp:

```
extern const NB::SSID_t default_SSID_Prefix = { 4, "FOO_" };
```

For the user's convenience, the device's SSID and WiFi Interface IP address are printed out the serial port. These can be used to access the device's webpage, which allows the user to connect to a local network.

This list of networks is generated using JavaScript. JavaScript is used to parse a JSON object sent by the NetBurner, which contains the access point scan results.

12.57.3 Wifi Firmware Update

Update the firmware in the wifi module.

12.57.4 Wifi Access Point

This example shows how to run the wifi module in Access Point mode. It also launches a [DHCP](#) Server running on the wifi interface, making it easier for a client to configure when connecting to the access point.

To setup your access point properly, you will need to configure the IP address and Mask of the Wifi interface. This can be done using IPSetup. You will also need to set the start address for the [DHCP](#) server to begin assigning IP addresses to connected devices. The variable 'startAddr' is used to so in this application.

For example, a proper AP configuration would be a WiFi interface with an IP address of 192.168.0.1, Mask of 255.255.255.0, and a [DHCP](#) server start address of 192.168.0.2

12.57.5 Wifi Client

This example demonstrates how to connect to a wifi network and use the wifi driver object to access the status information of the wifi connection.

If you are using a 5270 or 5234 processor based design it also enables spread spectrum mode to reduce emissions that can interfere with the wifi radio. These platforms should be using a wifi module with an external antenna.

12.57.6 Wifi Scan

Scan for access points

Chapter 13

Deprecated List

Module [groupFtpServerCallback](#)

For NetBurner customers porting from the 2.x tools to 3.x: `FTP_FAIL` and `FTP_OK` were deprecated on Jan 16, 2008. These defines were removed and all server functions (denoted as `FTPD`) were modified to use `FTPD_OK` and `FTPD_FAIL`. This was necessary so that the FTP client and server header files could be used at the same time. If you have any errors in your application code, you can safely change all server functions from `FTP_OK/FAIL` to `FTPD_OK/FAIL`.

Member [OSCritEnter](#) ([OS_CRIT](#) *pCrit, [uint16_t](#) timeout)

This function is now deprecated. Please see [OS_CRIT](#) for current usage.

Chapter 14

NetBurner API

14.1 AES - Advanced Encryption Standard

Classes

- struct [aes_context](#)
AES context structure.

Functions

- void [aes_set_key](#) ([aes_context](#) *ctx, const unsigned char *key, int keysize)
AES key schedule.
- void [aes_encrypt](#) ([aes_context](#) *ctx, unsigned char input[16], unsigned char output[16])
AES block encryption (ECB mode)
- void [aes_decrypt](#) ([aes_context](#) *ctx, unsigned char input[16], unsigned char output[16])
AES block decryption (ECB mode)
- void [aes_cbc_encrypt](#) ([aes_context](#) *ctx, unsigned char iv[16], unsigned char *input, unsigned char *output, int len)
AES-CBC buffer encryption.
- void [aes_cbc_decrypt](#) ([aes_context](#) *ctx, unsigned char iv[16], unsigned char *input, unsigned char *output, int len)
AES-CBC buffer decryption.
- int [aes_self_test](#) (int verbose)
Checkup routine.

14.1.1 Detailed Description

```
#include < aes.h >
```

Function to implement the symmetric block cyper AES

14.1.2 Function Documentation

14.1.2.1 aes_cbc_decrypt()

```
void aes_cbc_decrypt (  
    aes\_context * ctx,  
    unsigned char iv[16],  
    unsigned char * input,  
    unsigned char * output,  
    int len )
```

```
#include < aes.h >
```

AES-CBC buffer decryption.

Parameters

<i>ctx</i>	AES context
<i>iv</i>	initialization vector (modified after use)
<i>input</i>	buffer holding the ciphertext
<i>output</i>	buffer holding the plaintext
<i>len</i>	length of the data to be decrypted

14.1.2.2 aes_cbc_encrypt()

```
void aes_cbc_encrypt (
    aes_context * ctx,
    unsigned char iv[16],
    unsigned char * input,
    unsigned char * output,
    int len )
```

```
#include <aes.h>
```

AES-CBC buffer encryption.

Parameters

<i>ctx</i>	AES context
<i>iv</i>	initialization vector (modified after use)
<i>input</i>	buffer holding the plaintext
<i>output</i>	buffer holding the ciphertext
<i>len</i>	length of the data to be encrypted

14.1.2.3 aes_decrypt()

```
void aes_decrypt (
    aes_context * ctx,
    unsigned char input[16],
    unsigned char output[16] )
```

```
#include <aes.h>
```

AES block decryption (ECB mode)

Parameters

<i>ctx</i>	AES context
<i>input</i>	ciphertext block
<i>output</i>	plaintext block

14.1.2.4 aes_encrypt()

```
void aes_encrypt (
    aes_context * ctx,
    unsigned char input[16],
    unsigned char output[16] )
```

```
#include <aes.h>
```

AES block encryption (ECB mode)

Parameters

<i>ctx</i>	AES context
------------	-------------

Parameters

<i>input</i>	plaintext block
<i>output</i>	ciphertext block

14.1.2.5 aes_self_test()

```
int aes_self_test (
    int verbose )
#include <aes.h>
Checkup routine.
```

Returns

0 if successful, or 1 if the test failed

14.1.2.6 aes_set_key()

```
void aes_set_key (
    aes_context * ctx,
    const unsigned char * key,
    int keysize )
#include <aes.h>
AES key schedule.
```

Parameters

<i>ctx</i>	AES context to be initialized
<i>key</i>	the secret key
<i>keysize</i>	must be 128, 192 or 256

14.2 ARP - Address Resolution Protocol

Functions

- void [ShowArp](#) ()
Display ARP cache, output will be the stdio serial port.
- void [fShowArp](#) (FILE *fp)
Display ARP cache, output will be sent to the specified file pointer.
- BOOL [GetArpMacFromIp](#) (IPADDR4 ip, MACADR &ma)
Check to see if the specified IP address is in the ARP cache.
- void [sendGratuitousArp](#) (int interfaceNumber, IPADDR4 ip)
Send Gratuitous ARP Request.

14.2.1 Detailed Description

```
#include< arp.h >
```

The Address Resolution Protocol (ARP) is a protocol for mapping an Internet Protocol address (IP Address) to a physical machine address called the Media Access Control (MAC), that is recognized on the local network. An local ARP cache correlating machine IP address to MAC address is maintained on each local machine.

When a host such as a PC computer attempts to communicate with another device, ARP is used to resolve the IP address to the corresponding MAC address.

14.2.2 Function Documentation

14.2.2.1 fShowArp()

```
void fShowArp (
    FILE * fp )
#include <arp.h>
```

Display ARP cache, output will be sent to the specified file pointer.

Parameters

<i>*fp</i>	pointer to type FILE.
------------	-----------------------

See also

[ShowArp\(\)](#)

14.2.2.2 GetArpMacFromIp()

```
BOOL GetArpMacFromIp (
    IPADDR4 ip,
    MACADR & ma )
#include <arp.h>
```

Check to see if the specified IP address is in the ARP cache.

This function does not send an arp request, it only checks the arp cache. If you want it to send an arp you could do something like send a ping to the IP address before calling this function.

Parameters

<i>ip</i>	IP address to check for
<i>&ma</i>	MACADR structure to hold the result (C++ pass by reference)

Return values

<i>TRUE</i>	if found, otherwise FALSE.
-------------	----------------------------

14.2.2.3 sendGratuitousArp()

```
void sendGratuitousArp (
    int interfaceNumber,
    IPADDR4 ip )
#include <arp.h>
```

Send Gratuitous ARP Request.

Used after adding an interface or changing an IP address to update the ARP caches of other hosts on the network. Ensure the interface has a valid IP address before sending.

Parameters

<i>interfaceNumber</i>	Specified which network interface to send on.
<i>ip</i>	The interface's IP address

14.2.2.4 ShowArp()

```
void ShowArp ( )
```

```
#include <arp.h>
```

Display ARP cache, output will be the stdio serial port.

[fShowArp\(\)](#)

14.3 AT Commands

Functions for serial modem AT commands.

Macros

- #define **AT_COMMAND_REASON_START_AT** (1)
AT_COMMAND_REASON_START_AT.
- #define **AT_COMMAND_REASON_EXIT_AT** (2)
AT_COMMAND_REASON_EXIT_AT.
- #define **AT_COMMAND_REASON_NORMAL_COMMAND** (3)
AT_COMMAND_REASON_NORMAL_COMMAND.
- #define **AT_COMMAND_OK** (1)
AT_COMMAND_OK.
- #define **AT_COMMAND_EXIT** (2)
AT_COMMAND_EXIT.

Typedefs

- typedef int **ProcessATcommandFunc**(int uartnum, const char *pCommand, FILE *pResponseFile, int reason)
typedef for the AT command processing function

Functions

- void **EnableATCommands** (int port_number, **ProcessATcommandFunc** *pcmdf, int task_priority)
Enable AT command on the specific serial port, port must already be popen'd in interrupt mode.
- void **DisableATCommands** (int port_number)
Disable AT command.

14.3.1 Detailed Description

Functions for serial modem AT commands.

```
#include <atcommand.h >
```

14.3.2 Typedef Documentation

14.3.2.1 ProcessATcommandFunc

```
typedef int ProcessATcommandFunc(int uartnum, const char *pCommand, FILE *pResponseFile, int reason)
```

```
#include <atcommand.h>
```

typedef for the AT command processing function

Returns

AT_COMMAND_OK or AT_COMMAND_EXIT

14.4 Base64

Functions

- int [Base64Decode](#) (const char *input, uint8_t *outputbuf, const char *pEndMarker=NULL)
Decodes a null terminated Base64 string into bytes.
- int [Base64UrlDecode](#) (const char *input, uint8_t *outputbuf, const char *pEndMarker=NULL)
Decodes a null terminated Base64Url string into bytes.
- int [Base64Encode](#) (uint8_t *input, int inlen, char *outputbuf)
Encodes arbitrary binary bytes into Base64 string.
- int [Base64UrlEncode](#) (uint8_t *input, int inlen, char *outputbuf)
Encodes arbitrary binary bytes into Base64Url string.
- int [Base64StreamEncode](#) (int fd, uint8_t *input, int inlen, char *outBuf, int maxOutLen)
Encodes arbitrary binary bytes into Base64 string and writes them to a file descriptor.
- int [Base64UrlStreamEncode](#) (int fd, uint8_t *input, int inlen, char *outBuf, int maxOutLen)
Encodes arbitrary binary bytes into Base64Url string and writes them to a file descriptor.

14.4.1 Detailed Description

#include <[base64.h](#)>

Functions to encode/decode in Base64

14.4.2 Function Documentation

14.4.2.1 Base64Decode()

```
int Base64Decode (
    const char * input,
    uint8_t * outputbuf,
    const char * pEndMarker = NULL )
```

#include <[base64.h](#)>

Decodes a null terminated Base64 string into bytes.

Notes:

- outputbuf should be at least the size of input divided by 4, rounded up
- Does not null terminate results

Parameters

<i>input</i>	Base64 string
<i>outputbuf</i>	Resulting decoded data
<i>pEndMarker</i>	Pointer to the end of the string (in the event it is not terminated by either a null char or a base64 terminator)

Returns

Number of bytes returned in outputbuf

See also

[Base64Encode\(\)](#)

[Base64UrlDecode\(\)](#)

14.4.2.2 Base64Encode()

```
int Base64Encode (
    uint8_t * input,
    int inlen,
    char * outputbuf )
```

```
#include <base64.h>
```

Encodes arbitrary binary bytes into Base64 string.

Notes: Does not null terminate results but terminates with an '='

Parameters

<i>input</i>	Data
<i>inlen</i>	Length of data
<i>outputbuf</i>	Resulting encoded data

Returns

Number of bytes returned in outputbuf

See also

[Base64Decode\(\)](#)

[Base64StreamEncode\(\)](#)

[Base64UrlEncode\(\)](#)

14.4.2.3 Base64StreamEncode()

```
int Base64StreamEncode (
    int fd,
    uint8_t * input,
    int inlen,
    char * outBuf,
    int maxOutLen )
```

```
#include <base64.h>
```

Encodes arbitrary binary bytes into Base64 string and writes them to a file descriptor.

Notes: Does not null terminate results but terminates with an '='

Parameters

<i>fd</i>	Target File Descriptor
<i>input</i>	Data to be encoded
<i>inlen</i>	Length of data
<i>outBuf</i>	Temporary buffer to accumulate encoded data
<i>maxOutLen</i>	Maximum buffer space to accumulate data

Returns

Number of bytes returned in outputbuf

See also

[Base64Encode](#)

[Base64UrlStreamEncode](#)

14.4.2.4 Base64UrlDecode()

```
int Base64UrlDecode (
    const char * input,
    uint8_t * outputbuf,
    const char * pEndMarker = NULL )
```

#include <base64.h>

Decodes a null terminated Base64Url string into bytes.

Notes:

- outputbuf should be at least the size of input divided by 4, rounded up
- Does not null terminate results

Parameters

<i>input</i>	Base64Url string
<i>outputbuf</i>	Resulting decoded data
<i>pEndMarker</i>	Pointer to the end of the string (in the event it is not terminated by either a null char or a base64 terminator)

Returns

Number of bytes returned in outputbuf

See also

[Base64UrlEncode\(\)](#)

[Base64Decode\(\)](#)

14.4.2.5 Base64UrlEncode()

```
int Base64UrlEncode (
    uint8_t * input,
    int inlen,
    char * outputbuf )
```

#include <base64.h>

Encodes arbitrary binary bytes into Base64Url string.

Notes: Does not null terminate results but terminates with an '='

Parameters

<i>input</i>	Data
<i>inlen</i>	Length of data
<i>outputbuf</i>	Resulting encoded data

Returns

Number of bytes returned in outputbuf

See also

[Base64UrlDecode\(\)](#)

[Base64UrlStreamEncode\(\)](#)

[Base64Encode\(\)](#)

14.4.2.6 Base64UrlStreamEncode()

```
int Base64UrlStreamEncode (
    int fd,
    uint8_t * input,
    int inlen,
    char * outBuf,
    int maxOutLen )
```

```
#include <base64.h>
```

Encodes arbitrary binary bytes into Base64Url string and writes them to a file descriptor.

Notes: Does not null terminate results but terminates with an '='

Parameters

<i>fd</i>	Target File Descriptor
<i>input</i>	Data to be encoded
<i>inlen</i>	Length of data
<i>outBuf</i>	Temporary buffer to accumulate encoded data
<i>maxOutLen</i>	Maximum buffer space to accumulate data

Returns

Number of bytes returned in outputbuf

[Base64UrlEncode](#)

[Base64StreamEncode](#)

14.5 Buffers - System Buffer Pool

Functions

- uint16_t [GetFreeCount](#) ()
Returns the number of free buffers in the system. Buffers are used for both serial and network interfaces.
- void **ShowBuffer** (PoolPtr p)
Prints a pool buffer to stdout.

14.5.1 Detailed Description

```
#include< buffers.h >
```

Functions associated with the buffers allocated for use by network interfaces and serial ports. If a system runs out of buffers it will no longer be able to send or receive network data.

14.5.2 Function Documentation

14.5.2.1 GetFreeCount()

```
uint16_t GetFreeCount ( )
#include <buffers.h>
```

Returns the number of free buffers in the system. Buffers are used for both serial and network interfaces.

This function returns the number of free pool buffers, which are used for network and serial communication. The maximum number of buffers is defined in `\nburn\nbrtos\include\constants.h`:

```
#define BUFFER_POOL_SIZE (128)
```

The size of each buffer is defined as:

```
#define ETHER_BUFFER_SIZE 1548
```

If the number of free buffers reaches zero, then no further network communication will be possible until some buffers are freed. This is a good function to use as a debug tool for detecting buffer leaks in your application.

Serial ports also use buffers, which are allocated in constants.h:

```
#define SERIAL_TX_BUFFERS (2)
#define SERIAL_RX_BUFFERS (2)
```

Each serial port buffer is equal in size to an Ethernet buffer.

Returns

The number of free buffers in the system.

14.6 CAN

Topics

- [ColdFire MCF5441x Platforms](#)
- [MODM7AE70](#)

14.6.1 Detailed Description

Controller Area Network (CAN) API for NetBurner Platforms

14.6.2 ColdFire MCF5441x Platforms

Classes

- class [canMCF5441x::CanRxMessage](#)
Class to hold received CAN messages.

14.6.2.1 Detailed Description

Control Area Network (CAN) for ColdFire MCF5441x platforms including MOD54415, MOD54417, NANO54415 and SB800EX.

14.6.3 MODM7AE70

Classes

- class [mcanMODM7AE70::mcan_module](#)
MCAN Module Class.
- class [mcanMODM7AE70::mcan_config](#)
MCAN configuration structure.
- class [mcanMODM7AE70::CanRxMessage](#)
Class to hold received CAN messages.

MCAN Constants

- const uint32_t [mcanMODM7AE70::CONF_MCAN_RX_FIFO_0_NUM](#) = 32
Range: 1..64.
- const uint32_t [mcanMODM7AE70::CONF_MCAN_RX_FIFO_1_NUM](#) = 1
Range: 1..64.
- const uint32_t [mcanMODM7AE70::CONF_MCAN_RX_BUFFER_NUM](#) = 1
Range: 1..64.
- const uint32_t [mcanMODM7AE70::CONF_MCAN_TX_BUFFER_NUM](#) = 8
Range: 1..16.
- const uint32_t [mcanMODM7AE70::CONF_MCAN_TX_FIFO_QUEUE_NUM](#) = 1
Range: 1..16.
- const uint32_t [mcanMODM7AE70::CONF_MCAN_TX_EVENT_FIFO](#) = 8

- *Range: 1..32.*
- `const uint32_t mcANMODM7AE70::CONF_MCAN_RX_STANDARD_ID_FILTER_NUM = 32`
Range: 1..128.
- `const uint32_t mcANMODM7AE70::CONF_MCAN_RX_EXTENDED_ID_FILTER_NUM = 32`
Range: 1..64.
- `#define CAN_DATA_STORE_SIZE (512)`
Receive OS_FIFO Buffer Size.

Helper Macros

- `#define CAN_EXTENDED_ID_BIT (0x20000000)`
The single bit used by this API to indicate an extended ID.
- `#define ExtToNbId(id) (id | CAN_EXTENDED_ID_BIT)`
Convert an ID to an extended ID.
- `#define NormToNbId(id) (id & 0x7ff)`
Convert a normal ID in the range of 0 to 2048 to the range of 0 to 1024.
- `#define IsNbIdExt(id) ((id & CAN_EXTENDED_ID_BIT) != 0)`
Check for an extended MCAN ID.
- `#define NbToExtId(id) (id & 0x1FFFFFFF)`
Remove the API extended flage from the ID.
- `#define NbToNormId(id) (id & 0x7FF)`
Shift a Normal ID so it has a value from 0 to 1023.

14.6.3.1 Detailed Description

Control Area Network (MCAN) Low Level Driver for MODM7AE70

The Controller Area Network (MCAN) performs communication according to ISO 11898-1:2015 and to Bosch CANFD specification. Additional transceiver hardware is required for connection to the physical layer. All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN core to the Message RAM, as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN core, as well as providing transmit status information.

Acceptance filtering is implemented by a combination of up to 128 filter elements, where each element can be configured as a range, as a bit mask, or as a dedicated ID filter.

There are two types of CAN identifiers that define different formats of the message frame, with the main difference being the identifier length. The two CAN protocol versions are:

- Version 2.0A, Normal or Standard CAN, supporting messages with 11-bit identifiers.
- Version 2.0B, Extended CAN, supporting messages with 29-bit identifiers consisting of an 11-bit base identifier for compatibility with Version 2.0A and an 18-bit extension identifier.

Note

Detailed information on the MCAN operation and features is located in the Microchip SAME70 Family Data Sheet located in your `\nburn\docs\Microchip` folder, chapter 49.

14.6.3.2 Macro Definition Documentation

14.6.3.2.1 IsNbIdExt

```
#define IsNbIdExt(  
    id ) ( (id & CAN_EXTENDED_ID_BIT) != 0)
```

```
#include <mcAN.h>
```

Check for an extended MCAN ID.

Returns non zero if the ID is an extended ID

14.6.3.2.2 NbToNormId

```
#define NbToNormId(
    id ) (id & 0x7FF)
```

```
#include <mcans.h>
```

Shift a Normal ID so it has a value from 0 to 1023.

Some CAN systems will treat normal ID's as an integer from 0 to 2048. Other systems may treat normal ID's as 28 bit values where the bottom 17 bits are zero. This macro will convert the NetBurner normal ID format to the 0 to 2048 format.

14.7 Command Processor

Topics

- [Command Processor Disconnect Causes](#)
- [Command Processor Listen Channels](#)
- [Command Processor Response Codes](#)

Functions

- int [CmdStartCommandProcessor](#) (int priority)
Start the command processor.
- int [CmdAddCommandFd](#) (int fd, bool require_auth, bool time_out_conn, bool local_echo=true)
Add an established FD connection to the list of fd's managed by the command processor.
- int [CmdRemoveCommandFd](#) (int fd)
Remove an established FD (either a TCP session, a serial connection, or an SSH session).
- int [CmdListenOnTcpPort](#) (uint16_t port, int do_telnet_processing, int max_connections)
Start listening for a connection over TCP.
- int [CmdListenQuietOnTcpPort](#) (uint16_t port, int do_telnet_processing, int max_connections)
Start listening for a connection over TCP, but without the siggnon or password.
- int [CmdListenOnSshPort](#) (uint16_t port, int max_connections)
Start listening for a connection over SSH.
- int [CmdListenQuietOnSshPort](#) (uint16_t port, int max_connections)
Start listening for a connection over SSH, but without the siggnon or password.
- int [CmdStopListeningOnTcpPort](#) (uint16_t port)
Stop Listening for connections on the specified port. Also closes all open connections that were based on that port.
- int [CmdStopListeningOnSshPort](#) (uint16_t port)
Stop Listening for connections on the specified port. Also closes all open connections that were based on that port.
- void [SendToAll](#) (const char *buffer, int len, bool include_serial_ports)
Send a message to all connected sockets, excluding "Listening sockets".

Variables

- int(* [CmdAuthenticateFunc](#))(const char *name, const char *passwd)
External Authentication function CALLBACK for TCP connections, used to verify username and password. If this function pointer is not NULL then each new Telnet session will be asked to authenticate.
- int(* [CmdAuthenticateSshFunc](#))(const char *name, const char *authVal, [AuthType](#) authType)
External Authentication function CALLBACK for SSH connections, used to verify username and password. If this function pointer is not NULL then each new SSH session will be asked to authenticate. If this function pointer is NULL, it tries to use CmdAuthenticateFunc instead.
- int(* [CmdCmd_func](#))(const char *command, FILE *fRespondto, void *pData)
The command processing callback function for handling string commands.
- int(* [CmdChar_func](#))(char command, FILE *fRespondto, void *pData)
The command processing callback function for handling single character commands. If this is implemented does not do echo or line editing this is the responsibility of the application programmer.

- void `(* CmdConnect_func)(FILE *fRespondto)`
Connect callback function. If this function is not NULL, then the system will call this function every time a new session is started.
- void `(* CmdPrompt_func)(FILE *fRespondto, void *pData)`
Prompt callback function. If this function is not NULL, then the system will call this function every time a new prompt line needs to be displayed.
- void `(* CmdDisconnect_func)(FILE *fRespondto, int cause, void *pData)`
Dis-Connect callback function, if this function is not NULL then the system will call this function every time a session is terminated.
- int `CmdIdleTimeout`
- const char * `Cmdlogin_prompt`
If this is defined, then it will be sent to the socket on connection before Authentication is tried.

14.7.1 Detailed Description

```
#include <command.h >
```

This is is NetBurner's Command Processor Library. It operates as a task and reads input one line at a time from multiple sources. When it has gathered a whole line, it sends it to a command processor that is defined by the user.

14.7.2 Function Documentation

14.7.2.1 CmdAddCommandFd()

```
int CmdAddCommandFd (
    int fd,
    bool require_auth,
    bool time_out_conn,
    bool local_echo = true )
#include <command.h>
```

Add an established FD connection to the list of fd's managed by the command processor.

Parameters

<code>fd</code>	The file descriptor.
<code>require_auth</code>	Do we Authenticate the connection on this FD?
<code>time_out_conn</code>	Do we time out the connection on this FD?
<code>local_echo</code>	Do we provide a local echo for this FD (default is true)?

Return values

<code>CMD_OK</code>	Command processor task started properly.
<code>CMD_FAIL</code>	Command processor task failed to start.
<code>CMD_TO_MANY_FDS</code>	Too many file descriptors are currently in use.

14.7.2.2 CmdListenOnSshPort()

```
int CmdListenOnSshPort (
    uint16_t port,
    int max_connections )
#include <command.h>
```

Start listening for a connection over SSH.

Parameters

<i>port</i>	The port number to listen on.
<i>max_connections</i>	What are the max number of connections we should allow on this port?

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_TO_MANY_FDS</i>	Too many file descriptors are currently in use.
<i>CMD_FAILED_SSH_KEY_GEN</i>	Unable to generate the key needed for SSH communication.

14.7.2.3 CmdListenOnTcpPort()

```
int CmdListenOnTcpPort (
    uint16_t port,
    int do_telnet_processing,
    int max_connections )
```

```
#include <command.h>
```

Start listening for a connection over TCP.

Parameters

<i>port</i>	The port number to listen on.
<i>do_telnet_processing</i>	Should we treat the port as telnet and process telnet negotiations?
<i>max_connections</i>	What are the max number of connections we should allow on this port?

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_TO_MANY_FDS</i>	Too many file descriptors are currently in use.

14.7.2.4 CmdListenQuietOnSshPort()

```
int CmdListenQuietOnSshPort (
    uint16_t port,
    int max_connections )
```

```
#include <command.h>
```

Start listening for a connection over SSH, but without the signon or password.

Parameters

<i>port</i>	The port number to listen on.
<i>max_connections</i>	What are the max number of connections we should allow on this port?

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_TO_MANY_FDS</i>	Too many file descriptors are currently in use.
<i>CMD_FAILED_SSH_KEY_GEN</i>	Unable to generate the key needed for SSH communication.

14.7.2.5 CmdListenQuietOnTcpPort()

```
int CmdListenQuietOnTcpPort (
    uint16_t port,
    int do_telnet_processing,
    int max_connections )
```

```
#include <command.h>
```

Start listening for a connection over TCP, but without the siggnon or password.

Parameters

<i>port</i>	The port number to listen on.
<i>do_telnet_processing</i>	Should we treat the port as telnet and process telnet negotiations?
<i>max_connections</i>	What are the max number of connections we should allow on this port?

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_TO_MANY_FDS</i>	Too many file descriptors are currently in use.

14.7.2.6 CmdRemoveCommandFd()

```
int CmdRemoveCommandFd (
    int fd )
```

```
#include <command.h>
```

Remove an established FD (either a TCP session, a serial connection, or an SSH session).

Parameters

<i>fd</i>	The file descriptor to remove.
-----------	--------------------------------

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_FAIL</i>	Failed to remove the file descriptor.

14.7.2.7 CmdStartCommandProcessor()

```
int CmdStartCommandProcessor (
    int priority )
```

```
#include <command.h>
```

Start the command processor.

Parameters

<i>priority</i>	The NBRTOS task priority to run at.
-----------------	-------------------------------------

Return values

<i>CMD_OK</i>	Command processor task started properly.
<i>CMD_FAIL</i>	Command processor task failed to start.

14.7.2.8 CmdStopListeningOnSshPort()

```
int CmdStopListeningOnSshPort (
    uint16_t port )
```

```
#include <command.h>
```

Stop Listening for connections on the specified port. Also closes all open connections that were based on that port.

Parameters

<i>port</i>	The port number to listen on.
-------------	-------------------------------

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_FAIL</i>	Port requested wasn't listening for a connection.

14.7.2.9 CmdStopListeningOnTcpPort()

```
int CmdStopListeningOnTcpPort (
    uint16_t port )
```

```
#include <command.h>
```

Stop Listening for connections on the specified port. Also closes all open connections that were based on that port.

Parameters

<i>port</i>	The port number to listen on.
-------------	-------------------------------

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_FAIL</i>	Port requested wasn't listening for a connection.

14.7.2.10 SendToAll()

```
void SendToAll (
    const char * buffer,
    int len,
    bool include_serial_ports )
```

```
#include <command.h>
```

Send a message to all connected sockets, excluding "Listening sockets".

Parameters

<i>buffer</i>	A buffer holding the message to send.
<i>len</i>	The length of the buffer to send.
<i>include_serial_ports</i>	Also send to serial ports?

14.7.3 Variable Documentation

14.7.3.1 CmdAuthenticateFunc

```
int(* CmdAuthenticateFunc) (const char *name, const char *passwd) (
```

```

        const char * name,
        const char * passwd ) [extern]
#include <command.h>

```

External Authentication function CALLBACK for TCP connections, used to verify username and password. If this function pointer is not NULL then each new Telnet session will be asked to authenticate.

Parameters

<i>name</i>	The user name trying to authenticate.
<i>passwd</i>	The password provided for the user.

Return values

<i>CMD_OK</i>	If the authentication was successful.
<i>CMD_CLOSE</i>	If the authentication was not successful.

14.7.3.2 CmdAuthenticateSshFunc

```

int(* CmdAuthenticateSshFunc) (const char *name, const char *authVal, AuthType authType) (
        const char * name,
        const char * authVal,
        AuthType authType ) [extern]
#include <command.h>

```

External Authentication function CALLBACK for SSH connections, used to verify username and password. If this function pointer is not NULL then each new SSH session will be asked to authenticate. If this function pointer is NULL, it tries to use CmdAuthenticateFunc instead.

Parameters

<i>name</i>	The user name trying to authenticate.
<i>authVal</i>	The authorization value provided for the user.
<i>authType</i>	The type of authorization value passed in.

Return values

<i>CMD_OK</i>	If the authentication was successful.
<i>CMD_CLOSE</i>	If the authentication was not successful.

14.7.3.3 CmdChar_func

```

int(* CmdChar_func) (char command, FILE *fRespondto, void *pData) (
        char command,
        FILE * fRespondto,
        void * pData ) [extern]
#include <command.h>

```

The command processing callback function for handling single character commands. If this is implemented does not do echo or line editing this is the responsibility of the application programmer.

Parameters

<i>command</i>	The single command character.
<i>fRespondto</i>	The FILE * all responses should be set to (use fprintf).
<i>pData</i>	Any data that is associated from the session. This is returned by CmdConnect_func.

Return values

<i>CMD_OK</i>	If the command was okay.
<i>CMD_CLOSE</i>	If the command causes the session to terminate (Close).

See also

[CmdCmd_func](#)

[CmdConnect_func](#)

14.7.3.4 CmdCmd_func

```
int (* CmdCmd_func) (const char *command, FILE *fRespondto, void *pData) (
    const char * command,
    FILE * fRespondto,
    void * pData ) [extern]
```

```
#include <command.h>
```

The command processing callback function for handling string commands.

Parameters

<i>command</i>	A pointer to the null terminated ASCII text of the command.
<i>fRespondto</i>	The FILE * all responses should be set to (use fprintf).
<i>pData</i>	Any data that is associated from the session and is returned by CmdConnect_func.

Return values

<i>CMD_OK</i>	If the command was okay.
<i>CMD_CLOSE</i>	If the command causes the session to terminate (Close).

See also

[CmdChar_func](#)

[CmdConnect_func](#)

14.7.3.5 CmdConnect_func

```
void (* CmdConnect_func) (FILE *fRespondto) (
    FILE * fRespondto ) [extern]
```

```
#include <command.h>
```

Connect callback function. If this function is not NULL, then the system will call this function every time a new session is started.

Parameters

<i>fRespondto</i>	The FILE * all responses should be set to (use fprintf).
-------------------	--

Return values

<i>Returns</i>	an arbitrary void* data item to be associated with the session. This data item is the same pData item used in other callback functions such as CmdPrompt_func.
----------------	--

[CmdChar_func](#)

14.7.3.6 CmdDisconnect_func

```
void(* CmdDisconnect_func) (FILE *fRespondto, int cause, void *pData) (
    FILE * fRespondto,
    int cause,
    void * pData ) [extern]
```

```
#include <command.h>
```

Dis-Connect callback function, if this function is not NULL then the system will call this function every time a session is terminated.

Parameters

<i>fRespondto</i>	The FILE * all responses should be set to (use fprintf).
<i>cause</i>	Why it disconnected. Can be any value from Command Processor Disconnect Causes .
<i>pData</i>	Any data that is associated from the session. This is returned by CmdConnect_func.

See also

[CmdConnect_func](#)

14.7.3.7 CmdIdleTimeout

```
int CmdIdleTimeout [extern]
```

```
#include <command.h>
```

User defined value that specifies the number of seconds a connection is idle before it is terminated due to inactivity.

14.7.3.8 CmdPrompt_func

```
void(* CmdPrompt_func) (FILE *fRespondto, void *pData) (
    FILE * fRespondto,
    void * pData ) [extern]
```

```
#include <command.h>
```

Prompt callback function. If this function is not NULL, then the system will call this function every time a new prompt line needs to be displayed.

Parameters

<i>fRespondto</i>	The FILE * all responses should be set to (use fprintf).
<i>pData</i>	Any data that is associated from the session. This is returned by CmdConnect_func.

[CmdConnect_func](#)

14.7.4 Command Processor Disconnect Causes

Macros

- #define **CMD_DIS_CAUSE_TIMEOUT** (1)
Connection timed out.
- #define **CMD_DIS_CAUSE_CLOSED** (2)

Connection closed.

- #define **CMD_DIS_SOCKET_CLOSED** (3)
Socket closed. Don't send a response for this case.
- #define **CMD_DIS_AUTH_FAILED** (4)
Authorization failed. Don't send a response for this case.

14.7.4.1 Detailed Description

Possible causes given for disconnects.

14.7.5 Command Processor Listen Channels

Enumerations

- enum `ListenOn` : `int8_t { eListenOnTcp = 1 , eListenOnSsh = 2 }`
The various remote channels that the command processor can listen to.

14.7.5.1 Detailed Description

14.7.5.2 Enumeration Type Documentation

14.7.5.2.1 ListenOn

```
enum ListenOn : int8_t
#include <command.h>
```

The various remote channels that the command processor can listen to.

Enumerator

eListenOnTcp	Listen on TCP.
eListenOnSsh	Listen on SSH.

14.7.6 Command Processor Response Codes

Macros

- #define **CMD_OK** (0)
Function was executed properly.
- #define **CMD_CLOSE** (1)
Connection closed.
- #define **CMD_FAIL** (2)
General function failed.
- #define **CMD_AUTH_FAIL** (3)
Authorization failed.
- #define **CMD_TO_MANY_FDS** (4)
Too many file descriptors currently in use.
- #define **CMD_FAILED_SSH_KEY_GEN** (5)
Unable to correctly generate key needed for SSH connections.

14.7.6.1 Detailed Description

Valid return codes that can be returned by the NetBurner Command Processor functions.

14.8 Configuration System

Configuration System Variables.

Topics

- [Configuration Network Objects](#)
- [Configuration Server](#)
- [Configuration Time Objects](#)
- [Configuration Variables](#)

Configuration System Variables.

14.8.1 Detailed Description

Configuration System Variables.

```
#include< config\_obj.h >
```

14.8.2 Configuration Network Objects

Classes

- class [config_localname](#)
Configure device network name.
- class [CUR_IPADDR4](#)
- class [I4Record](#)
- class [Dynamic_IPADDR](#)
Dynamic_IPADDR.
- class [I6Record](#)

14.8.2.1 Detailed Description

```
#include< config\_netobj.h >
```

14.8.3 Configuration Server

Classes

- class [WebConfigServlet](#)
Class to run web configurator.

Functions

- void [EnableConfigMirror](#) ()
Enable the configuration mirror.
- void [SaveConfigToStorage](#) ()
Write all pending data to flash memory.
- size_t [ConfigSize](#) ()
Returns the number of bytes currently in use by configuration flash.
- size_t [ConfigMaxSize](#) ()
Returns the number of bytes available in configuration flash.

14.8.3.1 Detailed Description

```
#include <config_server.h >
```

The configuration server manages the configuration variables, which can be used internally, or optionally presented on a configuration server web page. Please refer to the configuration object section for more details.

There is a default factory web interface that is normally running on the device as a user interface to set configuration options. Enabling the Configuration Mirror provides a method to replace the factory interface with your own custom interface. This is an easy way to use your company brand on the device.

Any time a configuration variable is modified, it is marked as pending. Modified values will not be written to flash memory until a call to [SaveConfigToStorage\(\)](#) is executed. Note that if a user clicks on the Update button on the configuration web page, values will be written to flash.

14.8.3.2 Function Documentation

14.8.3.2.1 ConfigMaxSize()

```
size_t ConfigMaxSize ( )
#include <config_server.h>
```

Returns the number of bytes available in configuration flash.

Returns

The maximum number of bytes available. This function is implemented in hal.cpp

14.8.3.2.2 ConfigSize()

```
size_t ConfigSize ( )
#include <config_server.h>
```

Returns the number of bytes currently in use by configuration flash.

Returns

Number of bytes in use

14.8.3.2.3 EnableConfigMirror()

```
void EnableConfigMirror ( )
#include <config_server.h>
```

Enable the configuration mirror.

When enabled, the application configuration web interface will replace the default system web interface. In this way you can easily customize and brand the configuration web interface for your company.

Note

This is an empty function. To enable the config mirror, it needs to be called within the application code, which in turn forces the function to be linked during compilation. The linking is what enables the config mirror.

14.8.3.2.4 SaveConfigToStorage()

```
void SaveConfigToStorage ( )
#include <config_server.h>
```

Write all pending data to flash memory.

Checks the pending flag of all configuration system objects and writes updates to flash memory

14.8.4 Configuration Time Objects

Classes

- class [config_time_t](#)
Class to hold time configuration.

14.8.4.1 Detailed Description

```
#include< config_time.h >
```

14.8.5 Configuration Variables

Configuration System Variables.

Topics

- [Configuration Variable Flags](#)

Classes

- class [config_obj](#)
Base class used to create configuration objects.
- class [config_value](#)
Base class used to create a configuration value.
- class [config_uint](#)
Unsigned 32-bit Integer Configuration Variable.
- class [config_int](#)
Signed 32-bit Integer Configuration Variable.
- class [config_double](#)
Double Float Configuration Variable.
- class [config_bool](#)
Boolean Configuration Variable.
- class [config_string](#)
String Configuration Variable.
- class [config_pass](#)
Password string Configuration Variable.
- class [config_IPADDR4](#)
Configuration Variable for IPADDR4 (IPv4) object types.
- class [config_IPADDR](#)
Configuration Variable for IPADDR (IPv6) object type.
- class [config_MACADR](#)
Configuration Variable for MACADR object type.
- class [config_chooser](#)
Chooser Configuration Variable - Select From a List of Items.

Functions

- void **SaveConfigToStorage** ()
Save configuration to flash storage.

14.8.5.1 Detailed Description

Configuration System Variables.

```
#include< config_obj.h >
```

Configuration variable objects are part of the NetBurner 3.x configuration system. The use of configuration objects facilitates a much easier method to create and store non-volatile information for both system configuration and for user application configuration and storage. They use a JSON interface so the information can be easily downloaded

to save a configuration, or uploaded to configure the entire device at one time, such as in production bring-up. This includes system configuration such as IP addresses, and also any settings specific to your application.

The JSON value types include: integer, unsigned integer, float, boolean and string. There are also objects for IPv4 IP, IPv6 IP, MAC addresses, passwords, and selection lists options. In JSON everything is represented as a string, so there are object member functions to convert between values. These functions make use of the [NBString](#) class. For customers using the 2.x tools, the User Parameter flash sector method is still available, but we do recommend converting to the new configuration system. In 3.x you have the ability to access the data through a web configuration page and also through JSON, but you can certainly choose not to use those features and treat the configuration system as internal storage, and any configuration can be done through your application just as with the 2.x tool set.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

14.8.5.2 Configuration Variable Flags

Variables

- `const uint32_t fConfigValueLeaf = 0x01`
Value is a leaf.
- `const uint32_t fConfigReadOnly = 0x02`
Variable is read-only.
- `const uint32_t fConfigModified = 0x04`
Variable has been modified, but not yet saved.
- `const uint32_t fConfigHidden = 0x08`
Not visible to configuration web server display.
- `const uint32_t fConfigNoSave = 0x10`
Do not save to flash memory when save functions are called.
- `const uint32_t fConfigNoObscure = 0x20`
Do not obscure the value.
- `const uint32_t fConfigNeedReboot = 0x40`
System reboot required for changes to take effect.
- `const uint32_t fConfigNoReload = 0x80`
Disable reloading value from flash during a call to ReloadFromFlash.
- `const uint32_t fConfigDetached = 0x100`
Disable reloading value from flash during a call to ReloadFromFlash.
- `const uint32_t fConfigIsDefault = 0x200`
Value is unchanged from the default, i.e. was never set.

14.8.5.2.1 Detailed Description

Specifies the characteristics of a configuration variable, such as read-only, hidden, etc.

14.9 Constants

NetBurner System Constants.

Macros

- `#define TICK_IRQ_LEVEL (5)`
System clock IRQ level.
- `#define SERIAL_IRQ_LEVEL (3)`
- `#define SERIAL_VECTOR_BASE (64)`

- #define **TICKS_PER_SECOND** (20)
System clock ticks per second.
- #define **OS_MAX_TASKS** 32
Max number of system tasks.
- #define **OS_MAX_PRIOS** 64
Maximum number of system priorities.
- #define **SSH_TASK_PRIORITY** (56)
ief SSH server must be lower than main for progress displays

Ethernet buffer defines

OS Maximum Interrupt Level

OS_MAX_IRQ_MASK - Optional, Maximum IRQ level that the RTOS is allowed to mask. RTOS objects may not be used in ISRs above this level.

- #define **ETHER_BUFFER_SIZE** 1548
- #define **ETH_MAX_PAYLOAD** (1500)
- #define **ETH_MAX_SIZE** (1522)
- #define **ETH_MIN_SIZE** (46)
- #define **IP_HEADER_SIZE** (20)
- #define **UDP_HEADER_SIZE** (8)
- #define **MAX_UDPDATA** (**ETH_MAX_PAYLOAD** - (**IP_HEADER_SIZE** + **UDP_HEADER_SIZE**))
- #define **SERIAL_TX_BUFFERS** (2)
ETHERN_BUFFER_SIZE = bytes of serial TX fifo.
- #define **SERIAL_RX_BUFFERS** (2)
ETHERN_BUFFER_SIZE = bytes of serial RX fifo.
- #define **stdin_buffer_size** (200)

System task priorities

Restating the NBRtos RTOS Library document (NBRtosLibrary.pdf) Lowest priority is OS_MAX_PRIOS-1, 1 is the highest. There can only be one task at each priority level. Idle task is created at priority 63.

UserMain is created at priority 10. It is recommended and is supported by examples and default projects that a call to OSChangePrio(MAIN_PRIO); be made to lower the priority to the range recommended for the main application.

Factory applications use priorities 46 through 56.

Netburner Runtime library support and driver tasks use 36 through 45.

Care should be taken in use of priorities it can affect reliability and performance.

- #define **MAIN_PRIO** (50)
Recommend UserMain priority.

Runtime library driver and support task priorities

- `#define USB_HW_PRIO` (45)
- `#define PPP_PRIO` (44)
- `#define SECURITY_TASK_PRIO` (43)
- `#define WIFI_STATION_TASK_PRIO` (42)
- `#define WIFI_TASK_PRIO` (41)
- `#define CONFIG_SERVER_PRIO` (40)
- `#define HTTP_PRIO` (39)
- `#define ETHER_SEND_PRIO` (38)

14.9.1 Detailed Description

NetBurner System Constants.
`#include <constants.h>`

14.9.2 Macro Definition Documentation

14.9.2.1 TICKS_PER_SECOND

```
#define TICKS_PER_SECOND (20)
#include <constants.h>
```

System clock ticks per second.

PLEASE READ THIS BEFORE MODIFYING TICKS_PER_SECOND

Before you change this value understand what changing it does. Making it faster only slows things down. It does not speed up task switches, it only changes the granularity of time delays and timeouts. Task switches happen much much faster than the tick interval. They happen as soon as one task blocks or an interrupt /or task causes a higher priority task to be unblocked. The Time tick has NOTHING to do with task switches.

If you change it to the maximum 200 you have increased the RTOS overhead by a factor of 10 and have actually slowed your system.

14.10 DHCP

Topics

- [DHCP Server](#)
- [DHCPv4 Client](#)
- [DHCPv6 Client](#)

14.10.1 Detailed Description

[DHCP](#) Client functions. Refer to DHCPv4 or DHCPv6 documents for IPv4 or IPv6.

The [DHCP](#) client services are automatically controlled by the configuration option when the `init()` function is called in an application. Options are:

- [DHCP](#)

- [DHCP](#) with Static Fallback
- Static

You may also create your own [DHCP](#) objects.

14.10.2 DHCP Server

Namespaces

- namespace [DHCP](#)
DHCP Namespace.

Functions

- bool [AddStandardDHCP](#)Server (int intf=0, [IPADDR4](#) startAddr=[IPADDR4::NullIP\(\)](#))
Starts a standard allocator DHCP server.

14.10.2.1 Detailed Description

```
#include< dhcpcd.h >
```

Adding a [DHCP](#) server will enable your NetBurner device to serve IPv4 addresses. This can be useful in circumstances such as direct connections between 2 devices.

14.10.2.2 Function Documentation

14.10.2.2.1 AddStandardDHCP

Server()

```
bool AddStandardDHCP
```

Server (
 int intf = 0,
 [IPADDR4](#) startAddr = [IPADDR4::NullIP\(\)](#))

```
#include <dhcpcd.h>
```

Starts a standard allocator [DHCP](#) server.

Also checks for existing [DHCP](#) servers on the specified network interface.

Parameters

<i>intf</i>	The interface to use. If no parameter is specified the default value is 0 which will use the first system interface.
<i>startAddr</i>	The starting IP address. If no parameter is specified the default range of 192.168.1.100 to 192.168.1.249 will be used.

Return values

<i>true</i>	Success
<i>false</i>	A server already exists or error starting the server

14.10.3 DHCPv4 Client

Topics

- [DHCP State](#)

Classes

- class [DhcpObject](#)
DHCP client class.

Functions

- `int32_t GetInterfaceDHCPState` (int interface=0)
Returns current state of the *DHCP* lease, with optional interface parameter.
- `int32_t WaitForDHCPInterface` (int interface=0, uint16_t TicksToWait=10 **TICKS_PER_SECOND*)
Wait until a *DHCP* lease is obtained, or the timeout occurs.

14.10.3.1 Detailed Description

#include <[dhcpclient.h](#)>

14.10.3.2 Function Documentation

14.10.3.2.1 GetInterfaceDHCPState()

```
int32_t GetInterfaceDHCPState (
    int interface = 0 )
```

#include <[dhcpclient.h](#)>

Returns current state of the *DHCP* lease, with optional interface parameter.

The `DhcpObject::GetDHCPState()` function is a member function of the *DHCP* client class.

Returns

[DHCP State](#)

See also

[DhcpObject::GetDHCPState](#)

14.10.3.2.2 WaitForDHCPInterface()

```
int32_t WaitForDHCPInterface (
    int interface = 0,
    uint16_t TicksToWait = 10 *TICKS_PER_SECOND )
```

#include <[dhcpclient.h](#)>

Wait until a *DHCP* lease is obtained, or the timeout occurs.

Parameters

<i>interface</i>	The network interface to wait on.
<i>TicksToWait</i>	The number of system Time Ticks to wait. The <i>TICKS_PER_SECOND</i> constant can be used to more easily specify a number of seconds. If not specified, the default timeout is 10 seconds.

Returns

[DHCP State](#)

See also

[DhcpObject::GetDHCPState](#)

14.10.3.3 DHCP State

Macros

- #define **SDHCP_NOTSTARTED** 0
The System has not been initialized.
- #define **SDHCP_DISCOVER** 1

- *The system is discovering the [DHCP](#) servers.*
- **#define SDHCP_OFFER 2**
The system has responded to an OFFER.
- **#define SDHCP_ACK 3**
The System has Acknowledged the OFFER.
- **#define SDHCP_INIT 4**
The System is reinitializing.
- **#define SDHCP_CMPL 5**
The System has obtained a valid [DHCP](#) lease.
- **#define SDHCP_RENEW 6**
The System is in the process of renewing.
- **#define SDHCP_REBIND 7**
The System has failed the Renew and is trying to Rebind.
- **#define SDHCP_RELEASE 8**
The System is trying to release the Lease.
- **#define SBOOTP_TRANSMITTING 9**
Trying BOOTP.
- **#define SBOOTP_DONE 10**
BOOTP complete.
- **#define SDHCP_FAILED 11**
[DHCP](#) attempt failed - could not obtain a [DHCP](#) lease.

14.10.3.3.1 Detailed Description

14.10.4 DHCPv6 Client

Functions

- void [InitIPv6](#) (int ifc=0)
- void [ShowAllIPv6Info](#) ()
- void [StartDHCPv6_Solicit](#) (int ifnum=-1)
Manually starts the DHCPv6 Client in Full Solicitation mode.
- void [StartDHCPv6_InfoReq](#) (int ifnum=-1)
Manually starts the DHCPv6 Client in Full Solicitation mode.
- void [StartDHCPv6](#) (int ifnum=-1)
Manually starts the DHCPv6 Client in Information Request mode.
- bool [AddStaticIPv6Address](#) (const [IPADDR6](#) &ip, int ifnum=-1)
Add a static IPv6 address to an interface.
- bool [RemoveStaticIPv6Address](#) (const [IPADDR6](#) &ip, int ifnum=-1)
Add a static IPv6 address to an interface.

14.10.4.1 Detailed Description

```
#include < ipv6\_intf.h >
```

14.10.4.2 Function Documentation

14.10.4.2.1 AddStaticIPv6Address()

```
bool AddStaticIPv6Address (
    const IPADDR6 & ip,
    int ifnum = -1 )
#include <ipv6\_intf.h>
Add a static IPv6 address to an interface.
```

Parameters

<i>ip</i>	The IP address to add.
<i>ifnum</i>	The desired IPv6Interface to operate on. A negative value will use the first interface.

Return values

<i>true</i>	IP address successfully added
<i>false</i>	Error

See also

[RemoveStaticIPv6Address\(\)](#)

14.10.4.2.2 InitIPv6()

```
void InitIPv6 (
    int ifc = 0 )
#include <ipv6_intf.h>
```

14.10.4.2.3 RemoveStaticIPv6Address()

```
bool RemoveStaticIPv6Address (
    const IPADDR6 & ip,
    int ifnum = -1 )
#include <ipv6_intf.h>
```

Add a static IPv6 address to an interface.

Parameters

<i>ip</i>	The IP address to remove.
<i>ifnum</i>	The desired IPv6Interface to operate on. A negative value will use the first interface.

Return values

<i>true</i>	IP address successfully removed
<i>false</i>	Error

See also

[AddStaticIPv6Address\(\)](#)

14.10.4.2.4 ShowAllV6Info()

```
void ShowAllV6Info ( )
#include <ipv6_intf.h>
```

14.10.4.2.5 StartDHCPv6()

```
void StartDHCPv6 (
    int ifnum = -1 ) [inline]
#include <ipv6_intf.h>
```

Manually starts the DHCPv6 Client in Information Request mode.

Parameters

<i>ifnum</i>	The desired IPv6Interface to operate on. A negative value indicates all interfaces
--------------	--

See also

[StartDHCPv6_Solicit\(\)](#)

14.10.4.2.6 StartDHCPv6_InfoReq()

```
void StartDHCPv6_InfoReq (
    int ifnum = -1 )
#include <ipv6_intf.h>
```

Manually starts the DHCPv6 Client in Full Solicitation mode.

Parameters

<i>ifnum</i>	The desired IPv6Interface to operate on. A negative value indicates all interfaces
--------------	--

14.10.4.2.7 StartDHCPv6_Solicit()

```
void StartDHCPv6_Solicit (
    int ifnum = -1 )
#include <ipv6_intf.h>
```

Manually starts the DHCPv6 Client in Full Solicitation mode.

Parameters

<i>ifnum</i>	The desired IPv6Interface to operate on. A negative value indicates all interfaces
--------------	--

See also

[StartDHCPv6\(\)](#)

14.11 DNS - Domain Name System

Topics

- [DNS Record Types](#)
- [DNS Return Codes](#)

Functions

- bool [IsNameIPAddress](#) (const char *name)

Determine if the name is a valid IP Address and does not need to be looked up.
- int [fd_dns_part1](#) (const char *name, const [IPADDR](#) &dns_server, uint16_t TYPE=[DNS_A](#), uint16_t TYPE2=0, int ifn=-1)

Open a UDP socket and initiate a DNS lookup.
- bool [fd_dns_processresult](#) (int fd, const char *name, [IPADDR](#) &addr_out, uint16_t TYPE=[DNS_A](#), uint16_t TYPE2=[DNS_AAAA](#), uint32_t *ttl=0)

Process any responses on the UDP socket opened for DNS.
- int [fd_outstanding_Responses](#) (int fd)

Check to see if there are any outstanding DNS requests.
- bool [AnyDNSInterFaceActive](#) ()

Determine if we have an active DNS route; DNS server is set for an active interface.

- int [GetHostByName](#) (const char *name, [IPADDR](#) *plpaddr, const [IPADDR](#) &dns_server, const [TickTimeout](#) tout, uint16_t TYPE1=[DNS_A](#), uint16_t TYPE2=extra_dns_t, uint32_t *ttl=NULL)

Get the IP address associated with the specified domain name.

- int [GetHostByNameViaIfNum](#) (const char *name, [IPADDR](#) *plpaddr, const [IPADDR](#) &dns_server, int ifn, const [TickTimeout](#) &tout, uint16_t TYPE1=[DNS_A](#), uint16_t TYPE2=extra_dns_t, uint32_t *ttl=NULL)

Get the IP address associated with the specified domain name on a specific interface.

14.11.1 Detailed Description

```
#include < dns.h >
```

The current DNS system is agnostic about the use of [IPADDR](#), [IPADDR6](#) or [IPADDR4](#). The capability of C++ is such that you pass in any of those types and the compiler will select the correct function for that type. This is a change from tools versions 3.4.0 and earlier in which explicit IPv4 and IPv6 functions were used.

Note

While we are pointing out the automatic functionality in this DNS API, the same is true for most functions, structures and classes throughout the NetBurner API libraries.

The DNS system can be accessed as a blocking or synchronous operation with: [GetHostByName\(\)](#). If you want to do asynchronous non-blocking lookups, please refer to the functions:

- [fd_dns_part1\(\)](#)
- [fd_dns_processresult\(\)](#)

14.11.2 Function Documentation

14.11.2.1 AnyDNSInterFaceActive()

```
bool AnyDNSInterFaceActive ( )
#include <dns.h>
```

Determine if we have an active DNS route; DNS server is set for an active interface.

Returns

true if active DNS is available somewhere

See also

[GetHostByName\(\)](#)
[InterfaceLinkActive\(int interface\);](#)

14.11.2.2 fd_dns_part1()

```
int fd_dns_part1 (
    const char * name,
    const IPADDR & dns_server,
    uint16_t TYPE = DNS\_A,
    uint16_t TYPE2 = 0,
    int ifn = -1 )
```

```
#include <dns.h>
```

Open a UDP socket and initiate a DNS lookup.

This socket can be put in a select and used for asynchronous DNS lookups. Opens a UDP receive FD and sends DNS queries.

Parameters

<i>name</i>	Pointer to domain name to resolve
-------------	-----------------------------------

Parameters

<i>dns_server</i>	Reference to the DNS server to use. Pass INADDR_ANY to use the DNS server associated with the interface.
<i>TYPE</i>	Optional DNS record type. If no type is specified the default is IPv4 DNS_A
<i>TYPE2</i>	Optional 2nd DNS record type. If no type is specified the default is no look up
<i>ifn</i>	Which interface to use -1 uses the default active DNS interface

Returns

fd The file descriptor of the udp socket. [DNS Return Codes](#)

See also

[fd_dns_processresult\(\)](#), [fd_outstanding_Responses\(\)](#), [GetHostByName\(\)](#),

14.11.2.3 fd_dns_processresult()

```
bool fd_dns_processresult (
    int fd,
    const char * name,
    IPADDR & addr_out,
    uint16_t TYPE = DNS_A,
    uint16_t TYPE2 = DNS_AAAA,
    uint32_t * ttl = 0 )
```

#include <[dns.h](#)>

Process any responses on the UDP socket opened for DNS.

This should only be called when the socket has data, otherwise it will block.

Parameters

<i>fd</i>	The file descriptor opened with fd_dns_part1
<i>name</i>	Pointer to domain name to resolve
<i>addr_out</i>	Reference to IPADDR variable to hold the result
<i>TYPE</i>	DNS record type. If no type is specified the default is IPv4 DNS_A
<i>TYPE2</i>	2nd DNS record type. If no type is specified the default is no look up
<i>ttl</i>	Optional pointer to return variable for TimeToLive value for DNS record

Returns

true if resolution was successful

See also

[fd_dns_part1\(\)](#), [fd_outstanding_Responses\(\)](#), [GetHostByName\(\)](#),

14.11.2.4 fd_outstanding_Responses()

```
int fd_outstanding_Responses (
    int fd )
```

#include <[dns.h](#)>

Check to see if there are any outstanding DNS requests.

If this returns 0 then all DNS responses have been processed and one can assume there is no such name.

Parameters

<i>fd</i>	The file descriptor opened with <code>fd_dns_part1</code>
-----------	---

Returns

The number of outstanding DNS requests that have not been answered.

See also

[fd_dns_part1\(\)](#), [fd_dns_processresult\(\)](#), [GetHostByName\(\)](#),

14.11.2.5 GetHostByName()

```
int GetHostByName (
    const char * name,
    IPADDR * pIpaddr,
    const IPADDR & dns_server,
    const TickTimeout tout,
    uint16_t TYPE1 = DNS_A,
    uint16_t TYPE2 = extra_dns_t,
    uint32_t * ttl = NULL ) [inline]
```

```
#include <dns.h>
```

Get the IP address associated with the specified domain name.

Calling [GetHostByName\(\)](#) in dual stack mode will automatically call the correct IPv4 or IPv6 function.

The function will attempt to retrieve record type 1 first. If successful the function returns. If the attempt using type 1 fails, the function will attempt to get a record using the type 2 parameter. For example, lets say you wish your code to use IPv6, but its OK to fall back to IPv4. You can set type 1 to DNS_AAAA and type2 to DNS_A.

Parameters

<i>*name</i>	Pointer to domain name to resolve
<i>*pIpaddr</i>	Pointer to variable of type IPADDR (or IPADDR4) to store resultant IP address.
<i>&dns_server</i>	Specified the DNS server to use. Pass INADDR_ANY to use the DNS server associated with the interface.
<i>tout</i>	Number of time ticks to wait of type TickTimeout
<i>TYPE1</i>	Optional record type. If not specified will default to IPv4 DNS_A
<i>TYPE2</i>	Optional record type. If not specified will default to IPv6 DNS_AAAA
<i>ttl</i>	Optional pointer to return variable for TimeToLive value for DNS record

Returns

[DNS Return Codes](#)

See also

[GetHostByName4\(\)](#)

[GetHostByName6\(\)](#)

14.11.2.6 GetHostByNameViaIfNum()

```
int GetHostByNameViaIfNum (
    const char * name,
    IPADDR * pIpaddr,
    const IPADDR & dns_server,
    int ifn,
```

```

    const TickTimeout & tout,
    uint16_t TYPE1 = DNS_A,
    uint16_t TYPE2 = extra_dns_t,
    uint32_t * ttl = NULL ) [inline]
#include <dns.h>

```

Get the IP address associated with the specified domain name on a specific interface.

Calling [GetHostByName\(\)](#) in dual stack mode will automatically call the correct IPv4 or IPv6 function.

The function will attempt to retrieve record type 1 first. If successful the function returns. If the attempt using type 1 fails, the function will attempt to get a record using the type 2 parameter. For example, lets say you wish your code to use IPv6, but its OK to fall back to IPv4. You can set type 1 to DNS_AAAA and type2 to DNS_A.

Parameters

<i>*name</i>	Pointer to domain name to resolve
<i>*paddr</i>	Pointer to variable of type IPADDR to store resultant IP address
<i>&dns_server</i>	Specified the DNS server to use. Pass INADDR_ANY to use the DNS server associated with the interface.
<i>tout</i>	A reference to the number of time ticks to wait of type TickTimeout
<i>TYPE1</i>	Optional record type. If not specified will default to IPv4 DNS_A
<i>TYPE2</i>	Optional record type. If not specified will default to IPv6 DNS_AAAA
<i>ifn</i>	Interface number
<i>ttl</i>	Optional pointer to return variable for TimeToLive value for DNS record

Returns

[DNS Return Codes](#)

[GetHostByName4VialfNum\(\)](#)

[GetHostByNameVialfNum\(\)](#)

14.11.2.7 IsNameIPAddress()

```

bool IsNameIPAddress (
    const char * name )
#include <dns.h>

```

Determine if the name is a valid IP Address and does not need to be looked up.

Parameters

<i>*name</i>	Pointer to domain name to check
--------------	---------------------------------

Returns

true If it is a valid IP address

See also

[GetHostByName\(\)](#), [GetHostByName4VialfNum\(\)](#), [GetHostByName6\(\)](#)

14.11.3 DNS Record Types

Macros

- `#define DNS_A 1`
32-bit IPv4 address

- #define **DNS_CNAME** 5
Canonical name record.
- #define **DNS_MB** 7
Mailing list subscriber list.
- #define **DNS_MG** 8
Mailing list subscriber list.
- #define **DNS_MX** 15
Mail exchange record.
- #define **DNS_AAAA** 28
128-bit IPv6 address

14.11.3.1 Detailed Description

DNS record types from RFC1035

14.11.4 DNS Return Codes

Macros

- #define **DNS_OK** (0)
Success.
- #define **DNS_TIMEOUT** (1)
Request timed out.
- #define **DNS_NOSUCHNAME** (2)
Name not found.
- #define **DNS_ERR** (3)
Other error.

14.11.4.1 Detailed Description

14.12 Device Interrupts

Macros

- #define **DEVICE_INTERRUPT_MAXIMUM** (8)
Fixed interrupt sources.

Typedefs

- typedef enum [_DeviceInterruptTrigger](#) **DeviceInterruptTrigger**
DeviceSetupIsr interrupt trigger.
- typedef void **DeviceIsrFn**()
ISR function.

Enumerations

- enum [_DeviceInterruptTrigger](#) {
[InterruptTriggerNone](#) , [InterruptTriggerSensitive](#) , [InterruptTriggerRisingEdge](#) , [InterruptTriggerFallingEdge](#) ,
[InterruptTriggerBothEdge](#) }
- DeviceSetupIsr interrupt trigger.*

Functions

- BOOL [DeviceIsValid](#) (int irq)
Verify availability and support for device. (Only verifies IRQ is valid)
- BOOL [DeviceSetupIsr](#) (int irq, [DeviceInterruptTrigger](#) trigger, DeviceIsrFnPtr isrPtr)
Set interrupt controller and attach function to interrupt.
- void [DeviceAckInterrupt](#) (int irq)
Acknowledge interrupt.
- void [DeviceDisableInterrupt](#) (int irq)
Disable interrupt.
- void [DeviceEnableInterrupt](#) (int irq)
Enable interrupt.
- OS_SEM * [DeviceGetQspiSem](#) (void)
Acquire QSPI semaphore for sharing access to SPI devices.
- OS_SEM * [DeviceGetI2cSem](#) (void)
Acquire I2C semaphore for sharing access to I2C devices.

14.12.1 Detailed Description

```
#include <device.h >
```

14.12.2 Enumeration Type Documentation

14.12.2.1 _DeviceInterruptTrigger

```
enum _DeviceInterruptTrigger
#include <device.h>
DeviceSetupIsr interrupt trigger.
```

Enumerator

InterruptTriggerNone	No interrupt level.
InterruptTriggerSensitive	Trigger-sensitive interrupt.
InterruptTriggerRisingEdge	Rising edge triggered interrupt.
InterruptTriggerFallingEdge	Falling edge triggered interrupt.
InterruptTriggerBothEdge	Both rising and falling edge triggered.

14.12.3 Function Documentation

14.12.3.1 DeviceAckInterrupt()

```
void DeviceAckInterrupt (
    int irq )
#include <device.h>
Acknowledge interrupt.
```

Parameters

<i>irq</i>	Fixed level interrupt source
------------	------------------------------

14.12.3.2 DeviceDisableInterrupt()

```
void DeviceDisableInterrupt (
    int irq )
#include <device.h>
Disable interrupt.
```

Parameters

<i>irq</i>	Fixed level interrupt source
------------	------------------------------

14.12.3.3 DeviceEnableInterrupt()

```
void DeviceEnableInterrupt (
    int irq )
#include <device.h>
Enable interrupt.
```

Parameters

<i>irq</i>	Fixed level interrupt source
------------	------------------------------

14.12.3.4 DeviceGetI2cSem()

```
OS_SEM * DeviceGetI2cSem (
    void )
#include <device.h>
Acquire I2C semaphore for sharing access to I2C devices.
```

Returns

Semaphore

Return values

<i>NULL</i>	for non-existent device
-------------	-------------------------

14.12.3.5 DeviceGetQspiSem()

```
OS_SEM * DeviceGetQspiSem (
    void )
#include <device.h>
Acquire QSPI semaphore for sharing access to SPI devices.
```

Returns

Semaphore

Return values

<i>NULL</i>	for non-existent device
-------------	-------------------------

14.12.3.6 DeviceIsValid()

```

BOOL DeviceIsValid (
    int irq )
#include <device.h>
Verify availability and support for device. (Only verifies IRQ is valid)

```

Parameters

<i>irq</i>	Fixed level interrupt source
------------	------------------------------

Return values

<i>TRUE</i>	Support and available on module
<i>FALSE</i>	Option not supported

14.12.3.7 DeviceSetupIsr()

```

BOOL DeviceSetupIsr (
    int irq,
    DeviceInterruptTrigger trigger,
    DeviceIsrFnPtr isrPtr )
#include <device.h>
Set interrupt controller and attach function to interrupt.

```

Parameters

<i>irq</i>	Fixed level interrupt source
<i>trigger</i>	Triggering edge level
<i>isrPtr</i>	ISR function

Return values

<i>TRUE</i>	Set
<i>FALSE</i>	Not valid interrupt source

14.13 Diagnostics (DIAG) System**Classes**

- class [DiagItemClass](#)
Diagnostics item.
- class [DiagCallBack](#)
Call back and generate the specific diagnostic element when requested.
- class [DiagVarMon](#)
Report the value of some numeric type.
- class [DiagStrMon](#)
Report the value of a string.
- class [DiagPtrMon](#)
Report the value of a pointer.

Functions

- bool **SendDiagReport** (const char *pUrl, const char *pUser=0, const char *pPass=0)
Set up to send the diagnostic report as a JSON blob to some external URL.
- bool **SendDiagReport** (ParsedURI &uri, const char *pUser=0, const char *pPass=0)
Set up to send the diagnostic report as a JSON blob to some external URL.

14.13.1 Detailed Description

#include< [diagnostics.h](#) >

The functions in this header are used to add diagnostic reports to the diagnostics tab under the config page when [diagnostics.h](#) is included and [EnableSystemDiagnostics\(\)](#) is called.

The resulting JSON blob can be accessed directly (replace 10.1.1.100 with your IP or dns name) <http://10.1.1.100:20034/DIAG>

You can also access subgroups directly from the diagnostics: <http://10.1.1.100:20034/DIAG/Buffers> or <http://10.1.1.100:20034/DIAG/Tasks>

Examples

If I have a `uint32_t` called `myVar` I want to monitor:

```
DiagVarMon MyVarMon("MyVarName", myVar);
```

If I have char buffer holding the name of the current mode:

```
DiagStrMon MyStrMon("CurMode", cur_mode);
```

If I want to output a complex JSON object for a custom report, I can write a routine that outputs this object to an fd:

```
void MyCustomReport(int fd);
DiagCallBack MyReporter("MyReportName", MyCustomReport);
```

14.13.2 Function Documentation

14.13.2.1 SendDiagReport()

```
bool SendDiagReport (
    ParsedURI & uri,
    const char * pUser = 0,
    const char * pPass = 0 )
```

#include <[diagnostics.h](#)>

Set up to send the diagnostic report as a JSON blob to some external URL.

14.14 EFFS - Embedded Flash File System

Topics

- [EFFS-STD Flash File System](#)
- [FAT File System](#)

14.14.1 Detailed Description

#include< [api_f.h](#) >

#include< [fsf.h](#) >

Two Embedded Flash File Systems are supported:

- FAT32 File System (EFFS-FAT), a FAT32 file system used on external flash memory cards and ram drives.
- Standard File System (EFFS-STD), a power-fail safe file system that resides in the flash on the module.

14.14.2 EFFS-STD Flash File System

Topics

- [STD File System Seek Codes](#)

Macros

- #define `fs_getfreespace`(drivenum, space) fsm_getfreespace(drivenum, space)
Provides information about the drive space usage.
- #define `fs_mkdir`(dirname) fsm_mkdir(dirname)
Makes a new directory.
- #define `fs_chdir`(dirname) fsm_chdir(dirname)
Change the directory.
- #define `fs_rmdir`(dirname) fsm_rmdir(dirname)
Removes a directory.
- #define `fs_delete`(filename) fsm_delete(filename)
Deletes a file.
- #define `fs_findfirst`(filename, find) fsm_findfirst(filename, find)
Find the first file or subdirectory in a specified directory.
- #define `fs_findnext`(find) fsm_findnext(find)
Finds the next file or subdirectory in a specified directory after a previous call to `fs_findfirst()` or `fs_findnext()`.
- #define `fs_open`(filename, mode) fsm_open(filename, mode)
Opens a file in the file system.
- #define `fs_close`(filehandle) fsm_close(filehandle)
Closes an opened file.
- #define `fs_write`(buf, size, size_st, filehandle) fsm_write(buf, size, size_st, filehandle)
Write data to the file at the current position.
- #define `fs_read`(buf, size, size_st, filehandle) fsm_read(buf, size, size_st, filehandle)
Read data from the current position in a file.
- #define `fs_seek`(filehandle, offset, whence) fsm_seek(filehandle, offset, whence)
Move the stream position of an open file.
- #define `fs_eof`(filehandle) fsm_eof(filehandle)
Check whether the current position in the open target file is the end of the file.
- #define `fs_rewind`(filehandle) fsm_rewind(filehandle)
Sets the file position in the open target file to the start of the file.
- #define `fs_settimedate`(filename, ctime, cdate) fsm_settimedate(filename, ctime, cdate)
Set the time and date of a file or directory.
- #define `fs_gettimedate`(filename, pctime, pctime) fsm_gettimedate(filename, pctime, pctime)
Get the time and date of a file or directory.

14.14.2.1 Detailed Description

```
#include <fsf.h >
```

The Standard Embedded Flash File System, EFFS-STD

14.14.2.2 Macro Definition Documentation

14.14.2.2.1 fs_chdir

```
#define fs_chdir(  
    dirname ) fsm_chdir(dirname)
```

```
#include <fsf.h>
```

Change the directory.

Parameters

<i>dirname</i>	The directory to change to.
----------------	-----------------------------

Return values

<i>FS_NOERR</i>	If able to change to the directory
<i>IFS_NOERR</i>	If unable to change to the directory

See also

[fs_mkdir\(\)](#)

[fs_rmdir\(\)](#)

14.14.2.2.2 fs_close

```
#define fs_close(  
    filehandle ) fsm_close(filehandle)
```

```
#include <fsf.h>
```

Closes an opened file.

Parameters

<i>filehandle</i>	A handle to the file to close.
-------------------	--------------------------------

Return values

<i>FS_NOERR</i>	If able to close the file
<i>IFS_NOERR</i>	If unable to close the file

14.14.2.2.3 fs_delete

```
#define fs_delete(  
    filename ) fsm_delete(filename)
```

```
#include <fsf.h>
```

Deletes a file.

A read-only or open file cannot be deleted.

Parameters

<i>filename</i>	The name of the file to be deleted.
-----------------	-------------------------------------

Return values

<i>FS_NOERR</i>	If able to delete the file
<i>IFS_NOERR</i>	If unable to delete the file

14.14.2.2.4 fs_eof

```
#define fs_eof(  
    filehandle ) fsm_eof(filehandle)
```

```
#include <fsf.h>
```

Check whether the current position in the open target file is the end of the file.

Parameters

<i>filehandle</i>	A handle to the file to check.
-------------------	--------------------------------

Return values

0	Nothing at the end of the file
!0	The end of the file, or an error

14.14.2.2.5 fs_findfirst

```
#define fs_findfirst(  
    filename,  
    find ) fsm_findfirst(filename, find)
```

```
#include <fsf.h>
```

Find the first file or subdirectory in a specified directory.

Note: If this is called with "*" and this is not the root directory, the first entry found will be ".", which is the current directory.

Parameters

<i>filename</i>	The name of the file to find.
<i>find</i>	Where to store the found information.

Return values

<i>FS_NOERR</i>	If the file was found
<i>IFS_NOERR</i>	If the file wasn't found or there are errors

See also

[fs_findnext\(\)](#)

14.14.2.2.6 fs_findnext

```
#define fs_findnext(  
    find ) fsm_findnext(find)
```

```
#include <fsf.h>
```

Finds the next file or subdirectory in a specified directory after a previous call to [fs_findfirst\(\)](#) or [fs_findnext\(\)](#).

Note: If this is called with "*" and this is not the root directory, the first entry found will be ".", which is the current directory.

Parameters

<i>find</i>	Where to store the found information.
-------------	---------------------------------------

Return values

<i>FS_NOERR</i>	If the file was found
-----------------	-----------------------

Return values

<i>IFS_NOERR</i>	If the file wasn't found or there are errors
------------------	--

See also

[fs_findfirst\(\)](#)

14.14.2.2.7 fs_getfreespace

```
#define fs_getfreespace(
    drivenum,
    space ) fsm_getfreespace(drivenum, space)
#include <fsf.h>
```

Provides information about the drive space usage.

Parameters

<i>drivenum</i>	The drive number to get space usage for.
<i>space</i>	The structure to store the usage information in.

Return values

<i>FS_NOERR</i>	If able to get the drive space usage
<i>IFS_NOERR</i>	If unable to get the drive space usage

14.14.2.2.8 fs_gettimedate

```
#define fs_gettimedate(
    filename,
    pctime,
    pcdate ) fsm_gettimedate(filename, pctime, pcdate)
#include <fsf.h>
```

Get the time and date of a file or directory.

Parameters

<i>filename</i>	The name of the file or directory to modify.
<i>pctime</i>	A pointer to store the creation time of the file or directory.
<i>pcdate</i>	A pointer to store the creation date of the file or directory.

Return values

<i>FS_NOERR</i>	If able to get time and date
<i>IFS_NOERR</i>	If unable to get time and date

14.14.2.2.9 fs_mkdir

```
#define fs_mkdir(
    dirname ) fsm_mkdir(dirname)
#include <fsf.h>
```

Makes a new directory.

Parameters

<i>dirname</i>	The name to use for the new directory.
----------------	--

Return values

<i>FS_NOERR</i>	If able to make the directory
<i>IFS_NOERR</i>	If unable to make the directory

See also

[fs_chdir\(\)](#)

[fs_rmdir\(\)](#)

14.14.2.2.10 fs_open

```
#define fs_open(  
    filename,  
    mode ) fsm_open(filename, mode)
```

```
#include <fsf.h>
```

Opens a file in the file system.

Parameters

<i>filename</i>	The name of the file to open.
<i>mode</i>	The mode to open the file in. The following options are available: <ul style="list-style-type: none"> "r": Reading. The stream is positioned at the beginning of the file. "r+": Reading and writing. The stream is positioned at the beginning of the file. "w": Truncate file to 0 length or create for writing. The stream is positioned at the beginning of the file. "w+": Reading and writing. Create if it doesn't exist, or truncate if it does. The stream is positioned at the beginning of the file. "a": Append, and create if it doesn't exist. The stream is positioned at the end of the file. "a+": Reading and appending, and create if it doesn't exist. The stream is positioned at the end of the file.

Return values

<i>FS_FILE*</i>	Pointer to the file if it could be opened
<i>0</i>	If it a file could not be opened

See also

[fs_close\(\)](#)

14.14.2.2.11 fs_read

```
#define fs_read(  
    buf,
```

```

        size,
        size_st,
        filehandle ) fsm_read(buf, size, size_st, filehandle)
#include <fsf.h>

```

Read data from the current position in a file.

Parameters

<i>buf</i>	A pointer where the data should be read.
<i>size</i>	The size of the items to be read.
<i>size_st</i>	The number of items to be read.
<i>filehandle</i>	A handle to the file to read to.

Returns

The number of items read.

14.14.2.2.12 fs_rewind

```

#define fs_rewind(
        filehandle ) fsm_rewind(filehandle)
#include <fsf.h>

```

Sets the file position in the open target file to the start of the file.

Parameters

<i>filehandle</i>	A handle to the file operate on.
-------------------	----------------------------------

Return values

<i>FS_NOERR</i>	If successful
<i>IFS_NOERR</i>	If there was an error

14.14.2.2.13 fs_rmdir

```

#define fs_rmdir(
        dirname ) fsm_rmdir(dirname)
#include <fsf.h>

```

Removes a directory.

Note: The target directory must be empty, otherwise an error code is returned.

Parameters

<i>dirname</i>	The name of the directory to remove.
----------------	--------------------------------------

Return values

<i>FS_NOERR</i>	If able to get the drive space usage
<i>IFS_NOERR</i>	If unable to get the drive space usage

See also

[fs_chdir\(\)](#)

[fs_mkdir\(\)](#)

14.14.2.2.14 fs_seek

```
#define fs_seek(  
    filehandle,  
    offset,  
    whence ) fsm_seek(filehandle, offset, whence)
```

```
#include <fsf.h>
```

Move the stream position of an open file.

Parameters

<i>filehandle</i>	A handle to the file to move the position of.
<i>offset</i>	The relative byte position according to whence.
<i>whence</i>	Where to calculate the offset from. Can be a value from fSeekCodeGroup.

Return values

<i>FS_NOERR</i>	If the seek operation was successful
<i>IFS_NOERR</i>	If there was an error

14.14.2.2.15 fs_settimedate

```
#define fs_settimedate(  
    filename,  
    ctime,  
    cdate ) fsm_settimedate(filename, ctime, cdate)
```

```
#include <fsf.h>
```

Set the time and date of a file or directory.

Parameters

<i>filename</i>	The name of the file or directory to modify.
<i>ctime</i>	The creation time of the file or directory.
<i>cdate</i>	The creation date of the file or directory.

Return values

<i>FS_NOERR</i>	If able to set time and date
<i>IFS_NOERR</i>	If unable to set time and date

14.14.2.2.16 fs_write

```
#define fs_write(  
    buf,  
    size,  
    size_st,  
    filehandle ) fsm_write(buf, size, size_st, filehandle)
```

```
#include <fsf.h>
```

Write data to the file at the current position.

Parameters

<i>buf</i>	A pointer to the data to write.
<i>size</i>	The size of the items to write.
<i>size_st</i>	The number of items to write.
<i>filehandle</i>	A handle to the file to write to.

Returns

The number of items written.

14.14.2.3 STD File System Seek Codes

Macros

- #define **FS_SEEK_SET** 0
Beginning of file.
- #define **FS_SEEK_CUR** 1
Current position of the file pointer.
- #define **FS_SEEK_END** 2
End of file.

14.14.2.3.1 Detailed Description

```
#include< fsf.h >
```

The codes used when calling `f_seek()`.

14.14.3 FAT File System

Topics

- [FAT File System Seek Codes](#)

Macros

- #define **f_delvolume**(drvnumber) fm_delvolume(drvnumber)
Un-mounts a flash card.
- #define **f_getfreespace**(drivenum, pspace) fm_getfreespace(drivenum, pspace)
Provides information about the drive space usage.
- #define **f_chdir**(dirname) fm_chdir(dirname)
Change the directory.
- #define **f_mkdir**(dirname) fm_mkdir(dirname)
Makes a new directory.
- #define **f_rmdir**(dirname) fm_rmdir(dirname)
Removes a directory.
- #define **f_findfirst**(filename, find) fm_findfirst(filename, find)
Find the first file or subdirectory in a specified directory.
- #define **f_findnext**(find) fm_findnext(find)
Finds the next file or subdirectory in a specified directory after a previous call to `f_findfirst()` or `f_findnext()`.
- #define **f_close**(filehandle) fm_close(filehandle)
Closes an opened file.

- #define `f_open`(filename, mode) `fm_open`(filename, mode)
Opens a file in the file system.
- #define `f_read`(buf, size, size_st, filehandle) `fm_read`(buf, size, size_st, filehandle)
Read data from the current position in a file.
- #define `f_write`(buf, size, size_st, filehandle) `fm_write`(buf, size, size_st, filehandle)
Write data to the file at the current position.
- #define `f_seek`(filehandle, offset, whence) `fm_seek`(filehandle, offset, whence)
Move the stream position of an open file.
- #define `f_rewind`(filehandle) `fm_rewind`(filehandle)
Sets the file position in the open target file to the start of the file.
- #define `f_eof`(filehandle) `fm_eof`(filehandle)
Check whether the current position in the open target file is the end of the file.
- #define `f_gettimedate`(filename, pctime, pcdatetime) `fm_gettimedate`(filename, pctime, pcdatetime)
Get the time and date of a file or directory.
- #define `f_settimedate`(filename, ctime, cdatetime) `fm_settimedate`(filename, ctime, cdatetime)
Set the time and date of a file or directory.
- #define `f_delete`(filename) `fm_delete`(filename)
Deletes a file.

Functions

- int `f_enterFS` (void)
Adds a new task priority to the task list used by the file system.
- void `f_releaseFS` (void)
Removes a task priority from the task list used by the file system.

14.14.3.1 Detailed Description

#include < [api_f.h](#) >

The FAT32 Embedded Flash File System for Flash Cards, EFFS-FAT

14.14.3.2 Macro Definition Documentation

14.14.3.2.1 f_chdir

```
#define f_chdir(  
    dirname ) fm_chdir(dirname)
```

#include <[api_f.h](#)>

Change the directory.

Parameters

<i>dirname</i>	The directory to change to.
----------------	-----------------------------

Return values

<code>F_NO_ERROR</code>	If able to change to the directory
<code>!F_NO_ERROR</code>	If unable to change to the directory

See also

[f_mkdir\(\)](#)
[f_rmdir\(\)](#)

14.14.3.2.2 f_close

```
#define f_close(  
    filehandle ) fm_close(filehandle)
```

```
#include <api_f.h>
```

Closes an opened file.

Parameters

<i>filehandle</i>	A handle to the file to close.
-------------------	--------------------------------

Return values

<i>F_NO_ERROR</i>	If able to close the file
<i>!F_NO_ERROR</i>	If unable to close the file

14.14.3.2.3 f_delete

```
#define f_delete(  
    filename ) fm_delete(filename)
```

```
#include <api_f.h>
```

Deletes a file.

A read-only or open file cannot be deleted.

Parameters

<i>filename</i>	The name of the file to be deleted.
-----------------	-------------------------------------

Return values

<i>F_NO_ERROR</i>	If able to delete the file
<i>!F_NO_ERROR</i>	If unable to delete the file

14.14.3.2.4 f_delvolume

```
#define f_delvolume(  
    drvnumber ) fm_delvolume(drvnumber)
```

```
#include <api_f.h>
```

Un-mounts a flash card.

Parameters

<i>drvnumber</i>	The drive to be un-mount.
------------------	---------------------------

14.14.3.2.5 f_eof

```
#define f_eof(  
    filehandle ) fm_eof(filehandle)
```

```
#include <api_f.h>
```

Check whether the current position in the open target file is the end of the file.

Parameters

<i>filehandle</i>	A handle to the file to check.
-------------------	--------------------------------

Return values

<i>0</i>	Nothing at the end of the file
<i>!0</i>	The end of the file, or an error

14.14.3.2.6 f_findfirst

```
#define f_findfirst(
    filename,
    find ) fm_findfirst(filename, find)
#include <api_f.h>
```

Find the first file or subdirectory in a specified directory.

Note: If this is called with "*" and this is not the root directory, the first entry found will be ".", which is the current directory.

Parameters

<i>filename</i>	The name of the file to find.
<i>find</i>	Where to store the found information.

Return values

<i>F_NO_ERROR</i>	If the file was found
<i>!F_NO_ERROR</i>	If the file wasn't found or there are errors

See also

[f_findnext\(\)](#)

14.14.3.2.7 f_findnext

```
#define f_findnext(
    find ) fm_findnext(find)
#include <api_f.h>
```

Finds the next file or subdirectory in a specified directory after a previous call to [f_findfirst\(\)](#) or [f_findnext\(\)](#).

Note: If this is called with "*" and this is not the root directory, the first entry found will be ".", which is the current directory.

Parameters

<i>find</i>	Where to store the found information.
-------------	---------------------------------------

Return values

<i>F_NO_ERROR</i>	If the file was found
<i>!F_NO_ERROR</i>	If the file wasn't found or there are errors

See also

[f_findfirst\(\)](#)

14.14.3.2.8 f_getfreespace

```
#define f_getfreespace(
    drivenum,
    pspace ) fm_getfreespace(drivenum, pspace)
#include <api_f.h>
```

Provides information about the drive space usage.

Parameters

<i>drivenum</i>	The drive number to get space usage for.
<i>pspace</i>	The structure to store the usage information in.

Return values

<i>F_NO_ERROR</i>	If able to get the drive space usage
<i>!F_NO_ERROR</i>	If unable to get the drive space usage

14.14.3.2.9 f_gettimedate

```
#define f_gettimedate(
    filename,
    pctime,
    pcdate ) fm_gettimedate(filename, pctime, pcdate)
#include <api_f.h>
```

Get the time and date of a file or directory.

Parameters

	<i>filename</i>	The name of the file or directory to modify.
out	<i>pctime</i>	A pointer to store the creation time of the file or directory.
out	<i>pcdate</i>	A pointer to store the creation date of the file or directory.

Return values

<i>F_NO_ERROR</i>	If able to get time and date
<i>!F_NO_ERROR</i>	If unable to get time and date

14.14.3.2.10 f_mkdir

```
#define f_mkdir(
    dirname ) fm_mkdir(dirname)
#include <api_f.h>
```

Makes a new directory.

Parameters

<i>dirname</i>	The name to use for the new directory.
----------------	--

Return values

<code>F_NO_ERROR</code>	If able to make the directory
<code>!F_NO_ERROR</code>	If unable to make the directory

See also

[f_chdir\(\)](#)[f_rmdir\(\)](#)**14.14.3.2.11 f_open**

```
#define f_open(
    filename,
    mode ) fm_open(filename, mode)
```

```
#include <api_f.h>
```

Opens a file in the file system.

Parameters

<i>filename</i>	The name of the file to open.
<i>mode</i>	The mode to open the file in. The following options are available: <ul style="list-style-type: none"> • "r": Reading. The stream is positioned at the beginning of the file. • "r+": Reading and writing. The stream is positioned at the beginning of the file. • "w": Truncate file to 0 length or create for writing. The stream is positioned at the beginning of the file. • "w+": Reading and writing. Create if it doesn't exist, or truncate if it does. The stream is positioned at the beginning of the file. • "a": Append, and create if it doesn't exist. The stream is positioned at the end of the file. • "a+": Reading and appending, and create if it doesn't exist. The stream is positioned at the end of the file.

Return values

<code>F_FILE*</code>	Pointer to the file if it could be opened
<code>0</code>	If it a file could not be opened

See also

[f_close\(\)](#)**14.14.3.2.12 f_read**

```
#define f_read(
    buf,
    size,
    size_st,
    filehandle ) fm_read(buf, size, size_st, filehandle)
```

```
#include <api_f.h>
```

Read data from the current position in a file.

Parameters

<i>buf</i>	A pointer where the data should be read.
<i>size</i>	The size of the items to be read.
<i>size_st</i>	The number of items to be read.
<i>filehandle</i>	A handle to the file to read to.

Returns

The number of items read.

14.14.3.2.13 f_rewind

```
#define f_rewind(  
    filehandle ) fm_rewind(filehandle)  
#include <api_f.h>
```

Sets the file position in the open target file to the start of the file.

Parameters

<i>filehandle</i>	A handle to the file operate on.
-------------------	----------------------------------

Return values

<i>F_NO_ERROR</i>	If successful
<i>!F_NO_ERROR</i>	If there was an error

14.14.3.2.14 f_rmdir

```
#define f_rmdir(  
    dirname ) fm_rmdir(dirname)  
#include <api_f.h>
```

Removes a directory.

Note: The target directory must be empty, otherwise an error code is returned.

Parameters

<i>dirname</i>	The name of the directory to remove.
----------------	--------------------------------------

Return values

<i>F_NO_ERROR</i>	If able to remove the directory
<i>!F_NO_ERROR</i>	If unable to remove the directory

See also

[f_chdir\(\)](#)

[f_mkdir\(\)](#)

14.14.3.2.15 f_seek

```
#define f_seek(  
    filehandle,
```

```

        offset,
        whence ) fm_seek(filehandle, offset, whence)
#include <api_f.h>

```

Move the stream position of an open file.

Parameters

<i>filehandle</i>	A handle to the file to move the position of.
<i>offset</i>	The relative byte position according to whence.
<i>whence</i>	Where to calculate the offset from. Can be a value from FAT File System Seek Codes .

Return values

<i>F_NO_ERROR</i>	If the seek operation was successful
<i>!F_NO_ERROR</i>	If there was an error

14.14.3.2.16 f_settimate

```

#define f_settimate(
    filename,
    ctime,
    cdate ) fm_settimate(filename, ctime, cdate)
#include <api_f.h>

```

Set the time and date of a file or directory.

Parameters

<i>filename</i>	The name of the file or directory to modify.
<i>ctime</i>	The creation time of the file or directory.
<i>cdate</i>	The creation date of the file or directory.

Return values

<i>F_NO_ERROR</i>	If able to set time and date
<i>!F_NO_ERROR</i>	If unable to set time and date

14.14.3.2.17 f_write

```

#define f_write(
    buf,
    size,
    size_st,
    filehandle ) fm_write(buf, size, size_st, filehandle)
#include <api_f.h>

```

Write data to the file at the current position.

Parameters

<i>buf</i>	A pointer to the data to write.
<i>size</i>	The size of the items to write.
<i>size_st</i>	The number of items to write.
<i>filehandle</i>	A handle to the file to write to.

Returns

The number of items written.

14.14.3.3 Function Documentation**14.14.3.3.1 f_enterFS()**

```
int f_enterFS (
    void ) [extern]
#include <api_f.h>
```

Adds a new task priority to the task list used by the file system.

This function needs to be called when a new task wants to use the file system, before any other calls to other file system functions. Up to 10 tasks can be assigned to use the file system at any given time.

Note: The task priority level is associated with the task list, not the task itself. This means that a task switched priority levels and still wants to use the file system, it will need to be called again.

Return values

0	If successful
!0	If there were errors

See also

[f_releaseFS\(\)](#)

14.14.3.3.2 f_releaseFS()

```
void f_releaseFS (
    void ) [extern]
#include <api_f.h>
```

Removes a task priority from the task list used by the file system.

When a task no longer needs to use the file system, or prior to task changing priorities, this should be called. In the case of a task changing priorities, if access to the file system is still desired, another call to [f_enterFS\(\)](#) should be made.

14.14.3.4 FAT File System Seek Codes**Macros**

- #define **F_SEEK_SET** FN_SEEK_SET
Beginning of file.
- #define **F_SEEK_END** FN_SEEK_END
End of file.
- #define **F_SEEK_CUR** FN_SEEK_CUR
Current position of the file pointer.

14.14.3.4.1 Detailed Description

```
#include< api_f.h >
```

The codes used when calling [f_seek\(\)](#).

14.15 Ethernet

Topics

- [Ethernet I/O Counters](#)

Classes

- struct [_EthernetFrameHeader](#)
Ethernet Type II Frame Header.

Macros

- #define [NO_AUTOMATIC_2ND_ETHERNET](#) extern const bool bAutomatic2ndEther = false;
Disable automatic initialization of second Ethernet interface.

Typedefs

- typedef struct [_EthernetFrameHeader](#) **EthernetFrameHeader**
Ethernet Type II Frame Header.

Functions

- void [AddEthernetInterfaces](#) ()
Add an Ethernet interface.
- void [ManualEthernetConfig](#) (int interface, BOOL speed100Mbit, BOOL fullDuplex, BOOL autoNegotiate)
Manually configure Ethernet speed and duplex settings.
- void [DisablePHY](#) (int ifn)
Disable the specified Ethernet PHY.
- void [EnablePHY](#) (int ifn)
Disable the specified Ethernet PHY.

Ethernet Interface Types

EtherType Field (Ethernet Version II)

- #define **ETHERNET_ETHERTYPE_IPv4** (uint16_t)(0x0800)
Internet Protocol, Version 4 (IPv4)
- #define **ETHERNET_ETHERTYPE_ARP** (uint16_t)(0x0806)
Address Resolution Protocol (ARP)
- #define **ETHERNET_ETHERTYPE_IPv6** (uint16_t)(0x86DD)
Internet Protocol, Version 6 (IPv6)
- #define **ETHERNET_ETHERTYPE_AARP** (uint16_t)(0x80F3)
AppleTalk Address Resolution Prot. (AARP)
- #define **ETHERNET_ETHERTYPE_IPX** (uint16_t)(0x8137)
Novell Internet Packet Exchange (IPX) (alt.)
- #define **ETHERNET_ETHERTYPE_EAPOL** (uint16_t)(0x888E)
Extensible Authorization Protocol (EAP) over LAN.
- #define **ETHERNET_ETHERTYPE_VLAN** (uint16_t)(0x8100)
Virtual Private Network (VLAN)

14.15.1 Detailed Description

#include< [ethernet.h](#) >

Functions to add, configure and disable Ethernet interfaces

14.15.2 Macro Definition Documentation

14.15.2.1 NO_AUTOMATIC_2ND_ETHERNET

```
#define NO_AUTOMATIC_2ND_ETHERNET extern const bool bAutomatic2ndEther = false;
#include <ethernet.h>
```

Disable automatic initialization of second Ethernet interface.

Include this macro in UserMain to prevent automatic system addition and initialization of the second Ethernet interface on dual Ethernet devices.

14.15.3 Function Documentation

14.15.3.1 AddEthernetInterfaces()

```
void AddEthernetInterfaces ( )
#include <ethernet.h>
```

Add an Ethernet interface.

The default system behavior is all Ethernet interfaces will automatically be added and initialized. Interface numbers range from 1 to (MAX_INTERFACES - 1)

14.15.3.2 DisablePHY()

```
void DisablePHY (
    int ifn )
#include <ethernet.h>
```

Disable the specified Ethernet PHY.

Typically used for low power mode.

Parameters

<i>ifn</i>	Interface number to disable
------------	-----------------------------

See also

[EnablePHY](#)

14.15.3.3 EnablePHY()

```
void EnablePHY (
    int ifn )
#include <ethernet.h>
```

Disable the specified Ethernet PHY.

Enable an Ethernet PHY previously disabled by [DisablePHY\(\)](#)

Parameters

<i>ifn</i>	Interface number to enable
------------	----------------------------

See also

[DisablePHY\(\)](#)

14.15.3.4 ManualEthernetConfig()

```
void ManualEthernetConfig (
    int interface,
    BOOL speed100Mbit,
    BOOL fullDuplex,
    BOOL autoNegotiate )
```

```
#include <ethernet.h>
```

Manually configure Ethernet speed and duplex settings.

The default setting to establish an Ethernet link is autonegotiate. This function can be used to disable autonegotiate and set the Ethernet link speed and duplex.

Warning

With autonegotiate disabled, the other Ethernet host must also be configured manually with the same settings. If the other host is set to autonegotiate, the link will have undefined behavior and data loss.

Parameters

<i>interface</i>	The network interface to modify. The first interface number is 1
<i>speed100Mbit</i>	True = 100Mbps, False = 10Mbps
<i>fullDuplex</i>	True = full duplex, False = half duplex
<i>autoNegotiate</i>	True = enabled, False = disabled. If enabled, will override manual settings.

14.16 External Bus Interface (EBI)

Classes

- struct [EBI_CS_cfg_t](#)
Configuration structure for an External Bus Interface (EBI) chip select.

Enumerations

- enum [EBI_CS_BusWidth_t](#) { [EBI_BUS_WIDTH_8](#) = 0 , [EBI_BUS_WIDTH_16](#) = 1 }
- enum [EBI_CS_ByteAccess_t](#) { [EBI_BYTE_ACCESS_SELECT](#) = 0 , [EBI_BYTE_ACCESS_WRITE](#) = 1 }
- enum [EBI_CS_NWait_t](#) { [EBI_NWAIT_DISABLED](#) = 0 , [EBI_NWAIT_FROZEN](#) = 2 , [EBI_NWAIT_READY](#) = 3 }
- enum [EBI_CS_WrMode_t](#)
- enum [EBI_CS_RdMode_t](#)

Functions

- void [ConfigureEBI_CSPin](#) (int csNum)
Configure the I/O pin for a given Chip Select for the external data bus.
- void [ConfigureEBI_NWRPin](#) ()
Configure the I/O pin for the active low write/read (NWR) bus signal.
- void [ConfigureEBI_NRDPin](#) ()
Configure the I/O pin for the active low read (NRD) bus signal.
- void [ConfigureEBI_CS](#) (uint32_t csNum, const [EBI_CS_cfg_t](#) &&cfg)
Configure the given Chip Select for the external data bus.
- void [ConfigureEBI_CS](#) (uint32_t csNum, const [EBI_CS_cfg_t](#) &cfg)
Configure the given Chip Select for the external data bus.

Variables

- `uint8_t EBI_CS_cfg_t::ncs_rd_setup`
- `uint8_t EBI_CS_cfg_t::nrd_setup`
- `uint8_t EBI_CS_cfg_t::ncs_wr_setup`
- `uint8_t EBI_CS_cfg_t::nwe_setup`
- `uint8_t EBI_CS_cfg_t::ncs_rd_pulse`
- `uint8_t EBI_CS_cfg_t::nrd_pulse`
- `uint8_t EBI_CS_cfg_t::ncs_wr_pulse`

- `uint16_t EBI_CS_cfg_t::nrd_cycles`
- `uint16_t EBI_CS_cfg_t::nwe_cycles`
- `uint8_t EBI_CS_cfg_t::tdf_cycles`
- `EBI_CS_BusWidth_t EBI_CS_cfg_t::busWidth`
- `EBI_CS_ByteAccess_t EBI_CS_cfg_t::byteAccess`
- `EBI_CS_NWait_t EBI_CS_cfg_t::nWait`
- `EBI_CS_WrMode_t EBI_CS_cfg_t::wrMode`
- `EBI_CS_RdMode_t EBI_CS_cfg_t::rdMode`

14.16.1 Detailed Description

The Microchip SAME70 EBI peripheral is a parallel communication port that can only operate in "host" mode to communicate with "slave" devices. The EBI peripheral consists of a set of up to 16 data signals, up to 24 address signals and up to 10 different control signals. Some of the benefits of using the EBI bus are that it has high performance in both throughput and latency. It is directly memory mapped to the processor so it is very easy to use in software once configured. The downsides are mostly that it has many signals which will greatly complicate hardware designs and increase the size of external peripheral chips.

The EBI peripheral is highly configurable to fit the specifications of many types of external devices.

A consequence to this high configurability is that there are many timing parameters which makes configuration complicated. The NetBurner examples specify a conservative set of timing parameters with the goal of being compatible with a wide range of peripherals such as FPGAs, CPLDs, buffers, latches displays, flash memory and SRAM. Once successful communication is obtained with the slave target device, these default settings should be refined to increase the performance to match the device you are interfacing with.

Advanced EBI functionality is currently not supported by this examples or this driver. Advanced functionality includes interfacing with SDRAM or NAND memories. Page mode, burst operations and scrambling functionality are all not currently configurable via this driver.

In most applications you will only need to verify the last 5 parameters meet your peripheral requirements: bus width (8 or 16), byte Access 16-bit mode only), timing parameters, read mode (chip select or read signal) and write mode (chip select or write signal).

There are 3 sources of information that are very useful for understanding the EBI:

1. The EBI section of the Microchip SAME70 manual located in "`\nburn\docs`". It is very important to do this as the first step to understand the signal terminology in the examples and header files. Additionally the Static Memory Controller chapter in this processor manual is essential as it explains all the settings and timing parameters exposed by this driver.
2. The NetBurner EBI examples described in the manual and located in "`\nburn\examples\PlatformSpecific\MODM7AE70`".
3. The SAME70 `ebi.h` header file located in "`\nburn\arch\cortex-m7\cpu\SAME70\include`".

The EBI supports Chip Selects as well as Read and Write signals to interface with peripherals. The basic procedure for configuring the bus is:

- As noted in the examples, the MODM7AE70 has onboard bus buffers to reduce noise and help signal integrity. The following 4 signals must always be configured for EBI functionality as they are control the enable/disable and direction control of the bus buffer ICs:

```
P1[5].function(PINP1_5_NCS2); // chip select 2, active low
P1[6].function(PINP1_6_NCS0); // chip select 0, active low
P1[7].function(PINP1_7_NCS3); // chip select 3, active low
P1[8].function(PINP1_8_NRD); // Bus read, active low
```

- Declare a Configuration Structure of type [EBI_CS_cfg_t](#). An easy way is to copy one from the examples. Then modify any parameters necessary to meet your specific peripheral requirements, such as bus width, byte access in 16-bit mode, timing parameters, etc.
- Configure the desired chip select using the [ConfigureEBI_CS\(\)](#) function. Note that when enabling the EBI, the MODM7AE70 module requires all three chip selects (NCS0, NCS02, NCS03) to be assigned as chip selects. Additionally the NRD signal must also be configured for NRD bus operation. All of these signals are used for controlling the enable/direction logic of the external bus buffer hardware - they cannot use their alternate functions. Each chip select has a predefined fixed 16MB address range ([MODM7AE70 Memory Map](#)). The NetBurner API supplied predefined base address variables to make access easier as demonstrated in the EBI examples:

EBI examples:

```
extern volatile uint8_t ebi_0_base[]; // Chip select 0
extern volatile uint8_t ebi_1_base[]; // Chip select 1
extern volatile uint8_t ebi_2_base[]; // Chip select 2
extern volatile uint8_t ebi_3_base[]; // Chip select 3
```

In this way you can do a bus write with code such as (please refer to EBI examples for latest code):

```
const uint8_t EBITestData8 = 0x5A; // Data byte for testing
const uint32_t EBITestAddressOffset = 0xA5A5; // Address offset from chip select base address

ebi_0_base[EBITestAddressOffset] = EBITestData8; // Write data to EBI, chip select 0
ebi_0_base[0xA5A5] = 0x5A; // Same write with hard coded values

uint32_t EBIdata = ebi_0_base[EBITestAddressOffset]; // Read data from EBI, chip select 0
```

Warning

When enabling the EBI for the MODM7AE70 module, NCS0, NCS2, NCS3 and NRD must all be configured for their bus functionality as chip selects or nRead signals, even if not used by your application - they cannot be assigned their alternate functions. Additionally the "void EnableExtBusBuff(bool enable);" function from bsp.h must be used to enable the external bus buffer hardware.

14.16.2 Enumeration Type Documentation

14.16.2.1 EBI_CS_BusWidth_t

```
enum EBI_CS_BusWidth_t
#include <ebi.h>
Data bus width, 8 or 16 bits.
```

Enumerator

EBI_BUS_WIDTH_8	8-bit bus
EBI_BUS_WIDTH_16	16-bit bus

14.16.2.2 EBI_CS_ByteAccess_t

```
enum EBI_CS_ByteAccess_t
#include <ebi.h>
Byte Access. Used only in 16-bit mode to access low or high byte on data bus.
```

Enumerator

EBI_BYTE_ACCESS_SELECT	Use chip select for 8-bit access.
EBI_BYTE_ACCESS_WRITE	Use write signal for 8-bit access.

14.16.2.3 EBI_CS_NWait_t

```
enum EBI_CS_NWait_t
#include <ebi.h>
```

NWAIT signal mode. Used to extend read/write pulse by the bus device. Normally used with slow flash memory, otherwise disabled.

Any access can be extended by an external device using the NWAIT input signal of the SMC. The SMC_MODE.EXNW_MODE field on the corresponding chip select must be set either to "10" (Frozen mode) or "11" (Ready mode). When SMC_MODE.EXNW_MODE is set to "00" (disabled), the NWAIT signal is simply ignored on the corresponding chip select. The NWAIT signal delays the read or write operation in regards to the read or write controlling signal, depending on the Read and Write modes of the corresponding chip select.

Enumerator

EBI_NWAIT_DISABLED	Disabled.
EBI_NWAIT_FROZEN	Frozen mode.
EBI_NWAIT_READY	Ready mode.

14.16.2.4 EBI_CS_RdMode_t

```
enum EBI_CS_RdMode_t
#include <ebi.h>
```

Read signal selection. NCS for chip select, or NRD for write enable signal.

14.16.2.5 EBI_CS_WrMode_t

```
enum EBI_CS_WrMode_t
#include <ebi.h>
```

Write signal selection. NCS for chip select, or NWE for write enable signal.

14.16.3 Function Documentation

14.16.3.1 ConfigureEBI_CS() [1/2]

```
void ConfigureEBI_CS (
    uint32_t csNum,
    const EBI_CS_cfg_t && cfg )
#include <ebi.h>
```

Configure the given Chip Select for the external data bus.

Parameters

<i>csNum</i>	The EBI Chip Select to configure.
<i>cfg</i>	The structure containing the configuration to use.

14.16.3.2 ConfigureEBI_CS() [2/2]

```
void ConfigureEBI_CS (
    uint32_t csNum,
    const EBI_CS_cfg_t & cfg )
#include <ebi.h>
```

Configure the given Chip Select for the external data bus.

Parameters

<i>csNum</i>	The EBI Chip Select to configure.
<i>cfg</i>	The structure containing the configuration to use.

14.16.3.3 ConfigureEBI_CSPin()

```
void ConfigureEBI_CSPin (
    int csNum )
#include <ebi.h>
Configure the I/O pin for a given Chip Select for the external data bus.
```

Parameters

<i>csNum</i>	The chip select to configure.
--------------	-------------------------------

14.16.4 Variable Documentation

14.16.4.1 busWidth

`EBI_CS_cfg_t::busWidth`
Data bus width

14.16.4.2 byteAccess

`EBI_CS_cfg_t::byteAccess`
Byte Access mode, only used for 16-bit bus

14.16.4.3 ncs_rd_pulse

`EBI_CS_cfg_t::ncs_rd_pulse`
NCS pulse length = (256* ncs_rd_pulse[6] + ncs_rd_pulse[5:0]) clock cycles

14.16.4.4 ncs_rd_setup

`EBI_CS_cfg_t::ncs_rd_setup`
NCS setup length = (128* ncs_rd_setup[5] + ncs_rd_setup[4:0]) clock cycles

14.16.4.5 ncs_wr_pulse

`EBI_CS_cfg_t::ncs_wr_pulse`
NCS pulse length = (256* ncs_wr_pulse[6] + ncs_wr_pulse[5:0]) clock cycles

14.16.4.6 ncs_wr_setup

`EBI_CS_cfg_t::ncs_wr_setup`
NCS setup length = (128* ncs_wr_setup[5] + ncs_wr_setup[4:0]) clock cycles

14.16.4.7 nrd_cycles

`EBI_CS_cfg_t::nrd_cycles`
The total read cycle length is the total duration in clock cycles of the read cycle. It is equal to the sum of the setup, pulse and hold steps of the NRD and NCS signals. It is defined as: Read cycle length = (nrd_cycles[8:7]*256 + nrd_cycles[6:0]) clock cycles

14.16.4.8 nrd_pulse

`EBI_CS_cfg_t::nrd_pulse`
NRD pulse length = (256* nrd_pulse[6] + nrd_pulse[5:0]) clock cycles

14.16.4.9 nrd_setup

`EBI_CS_cfg_t::nrd_setup`
NRD setup length = (128* nrd_setup[5] + nrd_setup[4:0]) clock cycles

14.16.4.10 nWait

EBI_CS_cfg_t::nWait

NWAIT signal mode. Used to extend read/write pulse by the bus device.

14.16.4.11 nwe_cycles

EBI_CS_cfg_t::nwe_cycles

The total write cycle length is the total duration in clock cycles of the write cycle. It is equal to the sum of the setup, pulse and hold steps of the NWE and NCS signals. It is defined as: Write cycle length = (nwe_cycles[8:7]*256 + nwe_cycles[6:0]) clock cycles

14.16.4.12 nwe_pulse

EBI_CS_cfg_t::nwe_pulse

NWE pulse length = (256* nwe_pulse[6] + nwe_pulse[5:0]) clock cycles

14.16.4.13 nwe_setup

EBI_CS_cfg_t::nwe_setup

NWE setup length = (128* nwe_setup[5] + nwe_setup[4:0]) clock cycles

14.16.4.14 rdMode

EBI_CS_cfg_t::rdMode

Configures which signal is used to signal a bus read.

14.16.4.15 tdf_cycles

EBI_CS_cfg_t::tdf_cycles

The number of clock cycles required by the external device to release the data after the rising edge of the read controlling signal. The SMC always provide one full cycle of bus turnaround after the TDF_CYCLES period. Note: Valid range => 0-15

14.16.4.16 wrMode

EBI_CS_cfg_t::wrMode

Configures which signal is used to signal a bus write.

14.17 Extra File Descriptors**Functions**

- int [GetExtraFD](#) (void *extra_data, struct IoExpandStruct *pFuncs)

Returns a file descriptor for the structure passed as the IoExpandStruct. [FreeExtraFd](#)() will release the fd back to the pool of available fds.
- void * [GetExtraData](#) (int fd)

Returns the extra structure value from IoExpandStruct associated with the file descriptor.
- void [FreeExtraFd](#) (int fd)

Free a file descriptor and associated resources.
- int [GetFreeExtraFDCount](#) ()

Returns the number of free file descriptors.
- int [GetFreeSocketCount](#) (void)

Returns the number of free sockets.

14.17.1 Detailed Description

```
#include <iointernal.h >
```

The NetBurner environment integrates the RTOS, TCP/IP stack, and other peripherals with a file I/O system based on file descriptors. A file descriptor can be described as a handle to a network socket, serial port, system peripheral, or any other object that can be read or written to. Most of the API functions pass a file descriptor as a parameter to such an object. These function are available if you wish to use the file descriptor system capabilities for your own application purposes. Please refer to the File Descriptor section in the Programmers Guide.

14.17.2 Function Documentation

14.17.2.1 FreeExtraFd()

```
void FreeExtraFd (
    int fd )
```

```
#include <iointernal.h>
```

Free a file descriptor and associated resources.

Parameters

<i>fd</i>	File descriptor
-----------	-----------------

14.17.2.2 GetExtraData()

```
void * GetExtraData (
    int fd )
```

```
#include <iointernal.h>
```

Returns the `extra` structure value from `IoExpandStruct` associated with the file descriptor.

Parameters

<i>fd</i>	File descriptor
-----------	-----------------

Return values

<i>Value</i>	of the <code>extra</code> member of the structure
--------------	---

14.17.2.3 GetExtraFD()

```
int GetExtraFD (
    void * extra_data,
    struct IoExpandStruct * pFuncs )
```

```
#include <iointernal.h>
```

Returns a file descriptor for the structure passed as the `IoExpandStruct`. `FreeExtraFd()` will release the `fd` back to the pool of available `fds`.

Parameters

<i>extra_data</i>	The optional <code>extra_data</code> void pointer can be used to pass data into the file descriptor
<i>*pFuncs</i>	Structure containing callback functions for such things as read, write, close, and the <code>extra_data</code> variable

Return values

<i>Value</i>	greater than 0, representing the file descriptor on success
-1	on failure

14.17.2.4 GetFreeExtraFDCount()

```
int GetFreeExtraFDCount ( )
#include <iointernal.h>
Returns the number of free file descriptors.
```

Return values

<i>Number</i>	of free extra file descriptors
---------------	--------------------------------

14.17.2.5 GetFreeSocketCount()

```
int GetFreeSocketCount (
    void )
#include <iointernal.h>
Returns the number of free sockets.
```

Return values

<i>Number</i>	of free sockets
---------------	-----------------

14.18 FTP Client**Functions**

- int **FTP_InitializeSession** (IPADDR4 server_address, uint16_t port, PCSTR UserName, PCSTR Password, uint32_t time_out)
Initialize a FTP session with a FTP server.
- int **FTP_CloseSession** (int session)
Close a FTP session.
- int **FTPGetDir** (int ftp_Session, char *dir_buf, int nbytes, uint16_t timeout)
Get the current working directory.
- int **FTPSetDir** (int ftp_Session, const char *new_dir, uint16_t timeout)
Set the current working directory.
- int **FTPDeleteDir** (int ftp_Session, const char *dir_to_delete, uint16_t timeout)
Delete a directory.
- int **FTPMakeDir** (int ftp_Session, const char *dir_to_make, uint16_t timeout)
Create a new directory.
- int **FTPUpDir** (int ftp_Session, uint16_t timeout)
Move up one directory level.
- int **FTPDeleteFile** (int ftp_Session, const char *file_name, uint16_t timeout)
Delete a file.
- int **FTPRenameFile** (int ftp_Session, const char *old_file_name, const char *new_file_name, uint16_t time-out)
Rename a file.
- int **FTPSendFile** (int ftp_Session, const char *full_file_name, BOOL bBinaryMode, uint16_t timeout)

- Initialize the process to send a file to s FTP server.*

 - int [FTPGetFile](#) (int ftp_Session, const char *full_file_name, BOOL bBinaryMode, uint16_t timeout)

Initialize the process to get a file from a FTP server.

 - int [FTPGetList](#) (int ftp_Session, const char *full_dir_name, uint16_t timeout)

Initialize the process to receive a directory listing from a FTP server.

 - int [FTPGetFileNames](#) (int ftp_Session, const char *full_dir_name, uint16_t timeout)

Initialize the process to receive just the file names in a directory from a FTP server.

 - int [FTPRawCommand](#) (int ftp_Session, const char *cmd, char *cmd_buf, int nbytes, uint16_t timeout)

Send a FTP command to the FTP server.

 - int [FTPGetCommandResult](#) (int ftp_Session, char *cmd_buf, int nbytes, uint16_t timeout)

Returns the result of the last FTP operation.

 - int [FTPRawStreamCommand](#) (int ftp_Session, const char *cmd, int *pResult, char *cmd_buf, int nbytes, uint16_t timeout)

Send a command and receive a response over a stream connection.

 - void [FTPActiveMode](#) (int ftp_Session)

Set mode to active.

 - void [FTPPassiveMode](#) (int ftp_Session)

Set mode to passive.

FTP Client Return Codes

- #define [FTP_OK](#) (0)
OK.
- #define [FTP_TIMEOUT](#) (-1)
Timeout.
- #define [FTP_PASSWORDERROR](#) (-2)
Password error.
- #define [FTP_CONNECTFAIL](#) (-3)
Connection failed.
- #define [FTP_COMMANDFAIL](#) (-4)
Command failed.
- #define [FTP_COMMANDERROR](#) (-4)
Command error.
- #define [FTP_BADSESSION](#) (-5)
Bad session.
- #define [FTP_NETWORKERROR](#) (-6)
Network error.

14.18.1 Detailed Description

```
#include <ftp.h >
```

The NetBurner FTP Client Group

14.18.2 Function Documentation

14.18.2.1 FTP_CloseSession()

```
int FTP_CloseSession (
    int session )
```

```
#include <ftp.h>
```

Close a FTP session.

Parameters

<i>session</i>	FTP session number to close
----------------	-----------------------------

Returns

[ftpClientReturnCodes](#)

See also

[FTP_InitializeSession\(\)](#)

14.18.2.2 FTP_InitializeSession()

```
int FTP_InitializeSession (
    IPADDR4 server_address,
    uint16_t port,
    PCSTR UserName,
    PCSTR Password,
    uint32_t time_out )
```

```
#include <ftp.h>
```

Initialize a FTP session with a FTP server.

Open a connection to a FTP server and log in with the specified username and password. The session number returned from this call can be used with the file and directory functions.

Parameters

<i>server_address</i>	The IP address of the FTP server
<i>port</i>	The listen port number of the FTP server. Typically 21.
<i>UserName</i>	Log-in username
<i>Password</i>	Log-in password
<i>time_out</i>	Timeout in system Time Ticks

Returns

A value greater than 0 is a FTP session handle, otherwise [ftpClientReturnCodes](#)

See also

[FTP_CloseSession\(\)](#)

14.18.2.3 FTPActiveMode()

```
void FTPActiveMode (
    int ftp_Session )
```

```
#include <ftp.h>
```

Set mode to active.

Parameters

<i>ftp_Session</i>	FTP session number
--------------------	--------------------

14.18.2.4 FTPDeleteDir()

```
int FTPDeleteDir (
```

```

        int ftp_Session,
        const char * dir_to_delete,
        uint16_t timeout )
#include <ftp.h>
Delete a directory.

```

Parameters

<i>ftp_Session</i>	FTP session number
<i>dir_to_delete</i>	Directory to delete
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.18.2.5 FTPDeleteFile()

```

int FTPDeleteFile (
    int ftp_Session,
    const char * file_name,
    uint16_t timeout )
#include <ftp.h>
Delete a file.

```

Parameters

<i>ftp_Session</i>	FTP session number
<i>file_name</i>	Name of file to delete
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.18.2.6 FTPGetCommandResult()

```

int FTPGetCommandResult (
    int ftp_Session,
    char * cmd_buf,
    int nbytes,
    uint16_t timeout )
#include <ftp.h>

```

Returns the result of the last FTP operation.

Queries the FTP server for the last FTP operation status.

Must be called after the following functions are used:

- [FTPGetList\(\)](#)
- [FTPFileNames\(\)](#)
- [FTPGetFile\(\)](#)
- [FTPSendFile\(\)](#)

Parameters

<i>ftp_Session</i>	FTP session number
<i>cmd_buf</i>	The buffer to hold the ASCII FTP server response. See FTP Server return codes for details.
<i>nbytes</i>	The maximum number of bytes <i>cmd_buf</i> can hold
<i>timeout</i>	Timeout in system Time Ticks

Returns

The FTP server response number on success, otherwise `ftpClientReturnCodes`

14.18.2.7 FTPGetDir()

```
int FTPGetDir (
    int ftp_Session,
    char * dir_buf,
    int nbytes,
    uint16_t timeout )
```

```
#include <ftp.h>
```

Get the current working directory.

Parameters

<i>ftp_Session</i>	FTP session number
<i>dir_buf</i>	The buffer to copy the directory information into
<i>nbytes</i>	Maximum number of bytes in the <i>dir_buf</i>
<i>timeout</i>	Timeout in system Time Ticks

Returns

`ftpClientReturnCodes`

14.18.2.8 FTPGetFile()

```
int FTPGetFile (
    int ftp_Session,
    const char * full_file_name,
    BOOL bBinaryMode,
    uint16_t timeout )
```

```
#include <ftp.h>
```

Initialize the process to get a file from a FTP server.

This function opens a TCP connection to a FTP server so that a file may be read. it will return a file descriptor that can then be used to read the file data using file I/O functions such as: `read()` and `ReadWithTimeout()`.

IMPORTANT After reading the file data you must do 2 things:

- The TCP connection must be closed with the `close()` function.
- `FTPGetCommandResult()` must be called to check the result of the operation.

Parameters

<i>ftp_Session</i>	FTP session number
<i>full_file_name</i>	Full file name being read, including the path
<i>bBinaryMode</i>	True = read file as binary data, False = read file as ASCII data
<i>timeout</i>	Timeout in system Time Ticks

Returns

TCP file descriptor if greater than 0, otherwise [ftpClientReturnCodes](#)

```
int fd = FTPGetFile(ftp, "testfile.txt", FALSE, 5 * TICKS_PER_SECOND); // Send file in ASCII mode
if (fd > 0)
{
    // Code to read all data from the file descriptor goes here
    close(fd);

    int rv = FTPGetCommandResult(ftpSession, resultBuffer, 80, 5 * TICKS_PER*SECOND );

    if ( rv != 226) // Return code 226 = Closing data connection. Requested file action successful.
        iprintf("Read error result = %d %s\r\n", rv, resultBuffer);
}
else
{
    iprintf("Failed to read file\r\n");
}
}
```

14.18.2.9 FTPGetFileNames()

```
int FTPGetFileNames (
    int ftp_Session,
    const char * full_dir_name,
    uint16_t timeout )
#include <ftp.h>
```

Initialize the process to receive just the file names in a directory from a FTP server.

This function opens a TCP connection to a FTP server so that a list of file names may be read. it will return a file descriptor that can then be used to read the file data using file I/O functions such as: [read\(\)](#) and [ReadWithTimeout\(\)](#). IMPORTANT After reading the file data you must do 2 things:

- The TCP connection must be closed with the [close\(\)](#) function.
- [FTPGetCommandResult\(\)](#) must be called to check the result of the operation.

Parameters

<i>ftp_Session</i>	FTP session number
<i>full_dir_name</i>	Full directory name to read, including the path
<i>timeout</i>	Timeout in system Time Ticks

Returns

TCP file descriptor if greater than 0, otherwise [ftpClientReturnCodes](#)

14.18.2.10 FTPGetList()

```
int FTPGetList (
    int ftp_Session,
    const char * full_dir_name,
    uint16_t timeout )
#include <ftp.h>
```

Initialize the process to receive a directory listing from a FTP server.

This function opens a TCP connection to a FTP server so that a directory list may be read. it will return a file descriptor that can then be used to read the file data using file I/O functions such as: [read\(\)](#) and [ReadWithTimeout\(\)](#). IMPORTANT After reading the file data you must do 2 things:

- The TCP connection must be closed with the [close\(\)](#) function.
- [FTPGetCommandResult\(\)](#) must be called to check the result of the operation.

Parameters

<i>ftp_Session</i>	FTP session number
<i>full_dir_name</i>	Full directory name to read, including the path
<i>timeout</i>	Timeout in system Time Ticks

Returns

TCP file descriptor if greater than 0, otherwise ftpClientReturnCodes

14.18.2.11 FTPMakeDir()

```
int FTPMakeDir (
    int ftp_Session,
    const char * dir_to_make,
    uint16_t timeout )
```

#include <ftp.h>

Create a new directory.

Parameters

<i>ftp_Session</i>	FTP session number
<i>dir_to_make</i>	Directory to create
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.18.2.12 FTPPassiveMode()

```
void FTPPassiveMode (
    int ftp_Session )
```

#include <ftp.h>

Set mode to passive.

Parameters

<i>ftp_Session</i>	FTP session number
--------------------	--------------------

14.18.2.13 FTPRawCommand()

```
int FTPRawCommand (
    int ftp_Session,
    const char * cmd,
    char * cmd_buf,
    int nbytes,
    uint16_t timeout )
```

#include <ftp.h>

Send a FTP command to the FTP server.

Parameters

<i>ftp_Session</i>	FTP session number.
<i>cmd</i>	The command to send. Do not include termination such as \r\n.

Parameters

<i>cmd_buf</i>	The buffer to hold the FTP server response, in ASCII.
<i>nbytes</i>	The maximum number of bytes the <i>cmd_buf</i> can hold.
<i>timeout</i>	Timeout in system Time Ticks.

Returns

The FTP server response code if greater than 0, otherwise `ftpClientReturnCodes`

14.18.2.14 FTPRawStreamCommand()

```
int FTPRawStreamCommand (
    int ftp_Session,
    const char * cmd,
    int * pResult,
    char * cmd_buf,
    int nbytes,
    uint16_t timeout )
```

```
#include <ftp.h>
```

Send a command and receive a response over a stream connection.

The FTP server will close the connection after all the data has been read. This function is the basis for such functions as [FTPGetList\(\)](#) and [FTPGetFiles\(\)](#).

IMPORTANT After reading the file data you must call [FTPGetCommandResult\(\)](#) to check the result of the operation.

Parameters

<i>ftp_Session</i>	FTP session number
<i>cmd</i>	Command to send
<i>pResult</i>	The server response code integer value
<i>cmd_buf</i>	The server response code ASCII value (including <code>\r\n</code>)
<i>nbytes</i>	Maximum number of bytes <i>cmd_buf</i> can hold
<i>timeout</i>	Timeout in system Time Ticks

Returns

TCP file descriptor if greater than 0, otherwise `ftpClientReturnCodes`

14.18.2.15 FTPRenameFile()

```
int FTPRenameFile (
    int ftp_Session,
    const char * old_file_name,
    const char * new_file_name,
    uint16_t timeout )
```

```
#include <ftp.h>
```

Rename a file.

Parameters

<i>ftp_Session</i>	FTP session number
<i>old_file_name</i>	Name of file to rename
<i>new_file_name</i>	New name of file
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.18.2.16 FTPSendFile()

```
int FTPSendFile (
    int ftp_Session,
    const char * full_file_name,
    BOOL bBinaryMode,
    uint16_t timeout )
```

```
#include <ftp.h>
```

Initialize the process to send a file to s FTP server.

This function opens a TCP connection to a FTP server so that a file may be sent. it will return a file descriptor that can then be used to send the file data using file I/O write functions such as: [write\(\)](#), [writeall\(\)](#), [writestring\(\)](#), etc.

IMPORTANT After sending the file data you must do 2 things:

- The TCP connection must be closed with the [close\(\)](#) function.
- [FTPGetCommandResult\(\)](#) must be called to check the result of the operation.

Parameters

<i>ftp_Session</i>	FTP session number
<i>full_file_name</i>	Name of the file being sent
<i>bBinaryMode</i>	True = send file as binary data, False = send file as ASCII data
<i>timeout</i>	Timeout in system Time Ticks

Returns

TCP file descriptor if greater than 0, otherwise [ftpClientReturnCodes](#)

```
int fd = FTPSendFile(ftp, "testfile.txt", FALSE, 5 * TICKS_PER_SECOND);    // Send file in ASCII mode

if (fd > 0)
{
    writestring(fd, "This is a test file\r\n");
    writestring(fd, "This is line 2 of the test file\r\n");
    writestring(fd, "Last Line\r\n");
    close(fd);

    int rv = FTPGetCommandResult(ftpSession, resultBuffer, 80, 5 * TICKS_PER*SECOND );

    if ( rv != 226)    // Return code 226 = Closing data connection. Requested file action successful.
        fprintf("Write error result = %d %s\r\n", rv, resultBuffer);
}
else
{
    fprintf("Failed to send file\r\n");
}
}
```

14.18.2.17 FTPSetDir()

```
int FTPSetDir (
    int ftp_Session,
    const char * new_dir,
    uint16_t timeout )
```

```
#include <ftp.h>
```

Set the current working directory.

Parameters

<i>ftp_Session</i>	FTP session number
<i>new_dir</i>	Directory path to set
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.18.2.18 FTPUpDir()

```
int FTPUpDir (
    int ftp_Session,
    uint16_t timeout )
```

#include <ftp.h>

Move up one directory level.

Parameters

<i>ftp_Session</i>	FTP session number
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.19 FTP Server**Topics**

- [FTP Server Callback](#)
Core Functions for running a FTP Server on a NetBurner device.
- [FTP Server with EFFS-FAT](#)
- [FTP Server with EFFS-STD](#)

14.19.1 Detailed Description

There are two APIs to implement an FTP Server:

- The FTP Server Callback API, which enables an application to create an FTP Server and process commands in any manor with the associated callback functions.
- The FTP Server File System (EFFS) API, which utilizes the FTP Callback API to implement a FTP Server using the EFFS-FAT or EFFS-STD file system. This is the most commonly used implementation.

14.19.2 FTP Server Callback

Core Functions for running a FTP Server on a NetBurner device.

Topics

- [FTP Server Core Return Codes](#)
- [FTP Server File Return Codes](#)

Initialization functions

- typedef void [FTPDCallBackReportFunc](#)(int handle, const char *name_to_report)
FTP Session callback typedef Typedef for all directory reporting callbacks This callback type definition is used by the directory reporting functions.
- int [FTPStartSSL](#) (uint16_t port, uint8_t server_priority, bool enableFTPS=false, bool encryptData=false)
Starts the FTP Server task (SSL) Listens for incoming connections. Only one instance of the FTPD is allowed.
- int [FTPStart](#) (uint16_t port, uint8_t server_priority)

Starts the FTP Server task (non-SSL/TLS) Listens for incoming connections. Only one instance of the FTPD is allowed. If FTPD SSL support exists, `FTPDStartSSL()` may be used instead.

- int `FTPDStopReq ()`

Stops the FTP Server task Sends a stop request to the currently running FTPD.

FTP Session callback functions that must be implemented by the programmer

- void * `FTPDSessionStart` (const char *user, const char *passwd, const IPADDR4 hi_ip)

Start an FTP user session (User) This function is called following the creation of a new FTP session. The function needs to determine the validity of the user/password pair. The returned void pointer will be passed to all access functions, which will be asked to determine the validity of the operation based on the permissions associated with the return value.

- void `FTPDSessionEnd` (void *pSession)

Indicate an FTP user session will be terminated. This callback function gives the user program the opportunity to clean up any storage associated with the void pointer returned from the `FTPDSessionStart()` call.

FTP Directory callback functions that must be implemented by the programmer

- int `FTPD_DirectoryExists` (const char *full_directory, void *pSession)

Called by the FTP Server to test for the existence of a directory Called by the FTP Server as the result of an attempt to change to a new directory. This function can also be used to validate the permissions of the session. This function must be implemented by the programmer.

- int `FTPD_CreateSubDirectory` (const char *current_directory, const char *new_dir, void *pSession)

Called by the FTP Server to create a directory Called by the FTP Server as the result of an attempt to create a new directory. This function can also be used to validate the permissions of the session. This function must be implemented by the programmer.

- int `FTPD_DeleteSubDirectory` (const char *current_directory, const char *sub_dir, void *pSession)

Called by the FTP Server to delete a directory Called by the FTP Server as the result of an attempt to delete a subdirectory. This function call can be used to validate the permissions of this session. This function must be implemented by the programmer.

- int `FTPD_ListSubDirectories` (const char *current_directory, void *pSession, `FTPDCallBackReportFunc` *pFunc, int handle)

Called by the FTP Server to list all subdirectories under the current directory Called by the FTP Server as the result of a client's attempt to list the contents of a directory. This function must be implemented by the programmer.

FTP file callback functions that must be implemented by the programmer

- int `FTPD_FileExists` (const char *full_directory, const char *file_name, void *pSession)

Report on the whether or not a file exists Check for the existence of a file, usually just before an attempt is made to download the file. This function must be implemented by the programmer.

- int `FTPD_GetFileSize` (const char *full_directory, const char *file_name)

Returns the size of a specific file.

- int `FTPD_SendFileToClient` (const char *full_directory, const char *file_name, void *pSession, int fd)

Send the contents of a file to a file descriptor Send a file to a FTP client. This function must be implemented by the programmer.

- int `FTPD_AbleToCreateFile` (const char *full_directory, const char *file_name, void *pSession)

Report on the ability to create/receive a file Determine if a file can be created. This function must be implemented by the programmer.

- int `FTPD_GetFileFromClient` (const char *full_directory, const char *file_name, void *pSession, int fd)

Create/get a file Receive a file from the FTP client. This function must be implemented by the programmer.

- int `FTPD_DeleteFile` (const char *current_directory, const char *file_name, void *pSession)

Delete a file Delete a file. This function must be implemented by the programmer.

- int `FTPD_Rename` (const char *current_directory, const char *cur_file_name, const char *new_file_name, void *pSession)

Rename a file Rename a file. This function must be implemented by the programmer.

- int `FTPListFile` (const char *current_directory, void *pSession, `FTPDCallBackReportFunc` *pFunc, int handle)

Lists all files in the current directory List all files in the current directory. This function must be implemented by the programmer.

14.19.2.1 Detailed Description

Core Functions for running a FTP Server on a NetBurner device.

```
#include <ftpd.h >
```

The FTP Server Core Functions described in this section consist of function to start and stop the FTP server, and callback functions to handle FTP processing such as: session handling, directory and file creation, deletion and listings, etc. These core callback functions enable applications to create a FTP server in many different ways, with or without a file system.

Without a file system. Real time processing of files sent or received. For example, application data can be sent in response to a FTP client request as a text file by specifying the file type as .txt and sending the data. There are examples of this method in the "\nburn\examples\FTP" folder.

With a file system. There are 3 choices on your NetBurner platform: external flash cards (EFFS-FAT), on-chip flash memory (EFFS-STD), and ram drives. Examples of these methods are located in the "\nburn\examples\EFFS" folder. When using a file system these core functions do not need to be used directly. Since the choice has been made to use a file system rather than the callback functions, applications should use the functions described in the examples since the work of linking the callbacks to the file system has already been done for you.

Deprecated For NetBurner customers porting from the 2.x tools to 3.x: `FTP_FAIL` and `FTP_OK` were deprecated on Jan 16, 2008. These defines were removed and all server functions (denoted as `FTPD`) were modified to use `FTPD_OK` and `FTPD_FAIL`. This was necessary so that the FTP client and server header files could be used at the same time. If you have any errors in your application code, you can safely change all server functions from `FTP_OK/FAIL` to `FTPD_OK/FAIL`.

14.19.2.2 Typedef Documentation

14.19.2.2.1 FTPDCallBackReportFunc

```
typedef void FTPDCallBackReportFunc(int handle, const char *name_to_report)
#include <ftpd.h>
```

FTP Session callback typedef Typedef for all directory reporting callbacks This callback type definition is used by the directory reporting functions.

Parameters

<i>handle</i>	The handle passed into the listing function
<i>name_to_report</i>	The file name to report for use in a directory listing

Return values

<code>FTPD_RUNNING</code>	- The FTPD is already running
<code>FTPD_LISTEN_ERR</code>	- The listen socket was not able to be opened
<code>FTPD_OK</code>	- The FTPD was successfully started
<code>FTPD_FAIL</code>	- The FTPD task could not be created

See also

14.19.2.3 Function Documentation

14.19.2.3.1 FTPD_AbleToCreateFile()

```
int FTPD_AbleToCreateFile (
    const char * full_directory,
    const char * file_name,
    void * pSession )
```

```
#include <ftpd.h>
```

Report on the ability to create/receive a file Determine if a file can be created. This function must be implemented by the programmer.

Parameters

<i>full_directory</i>	The current value of the session directory
<i>file_name</i>	The name of the file to create
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

Return values

<i>FTPD_OK</i>	The requested file can be written/created
<i>FTPD_FAIL</i>	The requested file could not be created

See also

[FTPD_FileExists](#), [FTPD_SendFileToClient](#), [FTPD_GetFileFromClient](#), [FTPD_DeleteFile](#), [FTPD_ListFile](#)

14.19.2.3.2 FTPD_CreateSubDirectory()

```
int FTPD_CreateSubDirectory (
    const char * current_directory,
    const char * new_dir,
    void * pSession )
```

```
#include <ftpd.h>
```

Called by the FTP Server to create a directory Called by the FTP Server as the result of an attempt to create a new directory. This function can also be used to validate the permissions of the session. This function must be implemented by the programmer.

Parameters

<i>current_directory</i>	The current value of the session directory
<i>new_dir</i>	The directory to create under the current_directory
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

Return values

<i>FTPD_OK</i>	The requested directory was created
<i>FTPD_FAIL</i>	The requested directory could not be created

See also

[FTPD_DirectoryExists](#), [FTPD_DeleteSubDirectory](#)

14.19.2.3.3 FTPD_DeleteFile()

```
int FTPD_DeleteFile (
    const char * current_directory,
    const char * file_name,
    void * pSession )
```

```
#include <ftpd.h>
```

Delete a file Delete a file. This function must be implemented by the programmer.

Parameters

<i>current_directory</i>	The current value of the session directory
<i>file_name</i>	The name of the file to delete
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

Return values

<i>FTPD_OK</i>	The requested file was deleted
<i>FTPD_FAIL</i>	The requested file could not be deleted

See also

[FTPD_FileExists](#), [FTPD_SendFileToClient](#), [FTPD_AbleToCreateFile](#), [FTPD_GetFileFromClient](#), [FTPD_ListFile](#)

14.19.2.3.4 FTPD_DeleteSubDirectory()

```
int FTPD_DeleteSubDirectory (
    const char * current_directory,
    const char * sub_dir,
    void * pSession )
```

```
#include <ftpd.h>
```

Called by the FTP Server to delete a directory Called by the FTP Server as the result of an attempt to delete a subdirectory. This function call can be used to validate the permissions of this session. This function must be implemented by the programmer.

Parameters

<i>current_directory</i>	The current value of the session current directory
<i>sub_dir</i>	The directory to delete under the current_directory
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call at the beginning of the session

Return values

<i>FTPD_OK</i>	The requested directory was deleted
<i>FTPD_FAIL</i>	The requested directory could not be deleted

See also

[FTPD_DirectoryExists](#), [FTPD_CreateSubDirectory](#)

14.19.2.3.5 FTPD_DirectoryExists()

```
int FTPD_DirectoryExists (
    const char * full_directory,
    void * pSession )
```

```
#include <ftpd.h>
```

Called by the FTP Server to test for the existence of a directory. Called by the FTP Server as the result of an attempt to change to a new directory. This function can also be used to validate the permissions of the session. This function must be implemented by the programmer.

Parameters

<i>full_directory</i>	Name of the new directory to test
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

Return values

<i>FTPD_OK</i>	The requested directory exists
<i>FTPD_FAIL</i>	The requested directory does not exist, or access is not permitted for the user

See also

[FTPD_CreateSubDirectory](#), [FTPD_DeleteSubDirectory](#)

14.19.2.3.6 FTPD_FileExists()

```
int FTPD_FileExists (
    const char * full_directory,
    const char * file_name,
    void * pSession )
```

```
#include <ftpd.h>
```

Report on the whether or not a file exists. Check for the existence of a file, usually just before an attempt is made to download the file. This function must be implemented by the programmer.

Parameters

<i>full_directory</i>	The current value of the session directory
<i>file_name</i>	The name of the file to check
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

Return values

<i>FTPD_OK</i>	The requested file exists
<i>FTPD_FAIL</i>	The requested file does not exist

See also

[FTPD_FileExists](#), [FTPD_SendFileToClient](#), [FTPD_AbleToCreateFile](#), [FTPD_GetFileFromClient](#), [FTPD_DeleteFile](#), [FTPD_ListFile](#)

14.19.2.3.7 FTPD_GetFileFromClient()

```
int FTPD_GetFileFromClient (
    const char * full_directory,
    const char * file_name,
    void * pSession,
    int fd )
```

```
#include <ftpd.h>
```

Create/get a file Receive a file from the FTP client. This function must be implemented by the programmer.

Parameters

<i>full_directory</i>	The current value of the session directory
<i>file_name</i>	The name of the file to create
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call
<i>fd</i>	The file descriptor that will be used to receive the file

Return values

<i>FTPD_OK</i>	The requested file was written/created
<i>FTPD_FAIL</i>	The requested file was not created

See also

[FTPD_FileExists](#), [FTPD_SendFileToClient](#), [FTPD_AbleToCreateFile](#), [FTPD_DeleteFile](#), [FTPD_ListFile](#)

14.19.2.3.8 FTPD_GetFileSize()

```
int FTPD_GetFileSize (
    const char * full_directory,
    const char * file_name )
```

```
#include <ftpd.h>
```

Returns the size of a specific file.

Returns

file size

Return values

<i>FTPD_FILE_SIZE_UNKNOWN</i>	
<i>FTPD_FILE_SIZE_NOSUCH_FILE</i>	

14.19.2.3.9 FTPD_ListFile()

```
int FTPD_ListFile (
    const char * current_directory,
    void * pSession,
    FTPDCallbackReportFunct * pFunc,
    int handle )
```

```
#include <ftpd.h>
```

Lists all files in the current directory List all files in the current directory. This function must be implemented by the programmer.

Example: Everything inside the callback function stub must be supplied by the programmer.

The FTP server will automatically call this function and provide values for the function variables. It is the programmer's responsibility to execute `pFunc()` with the provided handle and a pointer to the string representing the file name. `pFunc()` must be executed once for each file name. In this example, the variables `number_of_directories` and `FileNames[]` must be declared and initialized elsewhere in the application program.

```
int FTPD_ListFile(const char * current_directory, void * pSession, FTPDCallBackReportFunct * pFunc, int handle)
{
    for (int n = 0; n < numberof_files; n++)
        pFunc(handle, FileNames[n]);
    return FTPD_OK;
}
```

Parameters

<i>current_directory</i>	The current value of the session directory
<i>pSession</i>	The void * object returned from the <code>FTPBSessionStart()</code> function call
<i>pFunc</i>	The pointer to the callback function to be called for each file name. This is a callback function provided and used by the NetBurner internal FTP code.
<i>handle</i>	The handle value to be passed back into the <code>pFunc</code> . This is a handle provided and used by the NetBurner internal FTP code.

Return values

<i>FTPD_OK</i>	The requested files were listed
<i>FTPD_FAIL</i>	The requested file was not listed

See also

[FTPD_FileExists](#), [FTPD_SendFileToClient](#), [FTPD_AbleToCreateFile](#), [FTPD_GetFileFromClient](#), [FTPD_DeleteFile](#)

14.19.2.3.10 FTPD_ListSubDirectories()

```
int FTPD_ListSubDirectories (
    const char * current_directory,
    void * pSession,
    FTPDCallBackReportFunct * pFunc,
    int handle )
```

```
#include <ftpd.h>
```

Called by the FTP Server to list all subdirectories under the current directory Called by the FTP Server as the result of a client's attempt to list the contents of a directory. This function must be implemented by the programmer.

Example:

Everything inside the callback function stub must be supplied by the programmer. The FTP server will automatically call this function and provide values for the function variables. It is the programmer's responsibility to execute `pFunc()` with the provided handle and a pointer to the string representing the subdirectory name. `pFunc()` must be executed once for each subdirectory name. In this example, the variables `number_of_directories` and `DirectoryName[]` must be declared and initialized elsewhere in the application program.

```
int FTPD_ListSubDirectories(const char * current_directory, void * pSession, FTPDCallBackReportFunct * pFunc, int handle);
{
    for (int n = 0; n < number_of_dir; n++)
        pFunc(handle, DirectoryName[n]);
    return FTPD_OK;
}
```

Parameters

<i>current_directory</i>	The current value of the session current directory
--------------------------	--

Parameters

<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call
<i>pFunc</i>	The pointer to the callback function to be called for each subdirectory
<i>handle</i>	The handle value to be passed back into the pFunc

Return values

<i>FTPD_OK</i>	The requested listing was successfully delivered
<i>FTPD_FAIL</i>	The requested directory could not be listed

See also

[FTPD_DirectoryExists](#), [FTPD_DeleteSubDirectory](#), [FTPD_CreateSubDirectory](#)

14.19.2.3.11 FTPD_Rename()

```
int FTPD_Rename (
    const char * current_directory,
    const char * cur_file_name,
    const char * new_file_name,
    void * pSession )
```

```
#include <ftpd.h>
```

Rename a file Rename a file. This function must be implemented by the programmer.

Parameters

<i>current_directory</i>	The current value of the session directory
<i>cur_file_name</i>	The name of the file to rename
<i>new_file_name</i>	
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

Return values

<i>FTPD_OK</i>	The requested file was deleted
<i>FTPD_FAIL</i>	The requested file could not be renamed

See also

[FTPD_FileExists](#), [FTPD_SendFileToClient](#), [FTPD_AbleToCreateFile](#), [FTPD_GetFileFromClient](#), [FTPD_ListFile](#)

14.19.2.3.12 FTPD_SendFileToClient()

```
int FTPD_SendFileToClient (
    const char * full_directory,
    const char * file_name,
    void * pSession,
    int fd )
```

```
#include <ftpd.h>
```

Send the contents of a file to a file descriptor Send a file to a FTP client. This function must be implemented by the programmer.

Parameters

<i>full_directory</i>	The current value of the session directory
<i>file_name</i>	The name of the file to send
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call
<i>fd</i>	The file descriptor to send to

Return values

<i>FTPD_OK</i>	The requested file was sent.
<i>FTPD_FAIL</i>	The requested file was not sent.

See also

[FTPD_FileExists](#), [FTPD_AbleToCreateFile](#), [FTPD_GetFileFromClient](#), [FTPD_DeleteFile](#), [FTPD_ListFile](#)

14.19.2.3.13 FTPDSessionEnd()

```
void FTPDSessionEnd (
    void * pSession )
#include <ftpd.h>
```

Indicate an FTP user session will be terminated. This callback function gives the user program the opportunity to clean up any storage associated with the void pointer returned from the FTPBSessionStart() call.

Parameters

<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call
-----------------	---

See also

[FTPBSessionStart](#)

14.19.2.3.14 FTPDSessionStart()

```
void * FTPDSessionStart (
    const char * user,
    const char * passwd,
    const IPADDR4 hi_ip )
#include <ftpd.h>
```

Start an FTP user session (User) This function is called following the creation of a new FTP session. The function needs to determine the validity of the user/password pair. The returned void pointer will be passed to all access functions, which will be asked to determine the validity of the operation based on the permissions associated with the return value.

Parameters

<i>user</i>	The name of the user attempting to establish an FTP session
<i>passwd</i>	The password of the user attempting to establish an FTP session
<i>hi_ip</i>	The IP address of the server trying to establish this connection

Return values

<i>NULL</i>	The user name/password set is invalid
-------------	---------------------------------------

Return values

<i>(obj)</i>	A non-null void pointer to an object that will be associated with this login session
--------------	--

See also

[FTPDSessionEnd](#)

14.19.2.3.15 FTPDStart()

```
int FTPDStart (
    uint16_t port,
    uint8_t server_priority )
```

```
#include <ftpd.h>
```

Starts the FTP Server task (non-SSL/TLS) Listens for incoming connections. Only one instance of the FTPD is allowed. If FTPD SSL support exists, [FTPDStartSSL\(\)](#) may be used instead.

Parameters

<i>port</i>	The TCP port to listen to for incoming FTP requests
<i>server_priority</i>	The RTOS task priority for the FTP Server

Return values

<i>FTPD_RUNNING</i>	- The FTPD is already running
<i>FTPD_LISTEN_ERR</i>	- The listen socket was not able to be opened
<i>FTPD_OK</i>	- The FTPD was successfully started
<i>FTPD_FAIL</i>	- The FTPD task could not be created

See also

[FTPDStartSSL](#), [FTPDSopReq](#)

14.19.2.3.16 FTPDStartSSL()

```
int FTPDStartSSL (
    uint16_t port,
    uint8_t server_priority,
    bool enableFTPS = false,
    bool encryptData = false )
```

```
#include <ftpd.h>
```

Starts the FTP Server task (SSL) Listens for incoming connections. Only one instance of the FTPD is allowed.

Parameters

<i>port</i>	The TCP port to listen to for incoming FTP requests
<i>server_priority</i>	The RTOS task priority for the FTP Server
<i>enableFTPS</i>	
<i>encryptData</i>	

Return values

<i>FTPD_RUNNING</i>	- The FTPD is already running
---------------------	-------------------------------

Return values

<code>FTPD_LISTEN_ERR</code>	- The listen socket was not able to be opened
<code>FTPD_OK</code>	- The FTPD was successfully started
<code>FTPD_FAIL</code>	- The FTPD task could not be created

See also

[FTPStart](#), [FTPStopReq](#)

14.19.2.3.17 FTPDStopReq()

```
int FTPDStopReq ( )
#include <ftpd.h>
```

Stops the FTP Server task Sends a stop request to the currently running FTPD.

Return values

<code>FTPD_RUNNING</code>	- The FTPD is still running
<code>FTPD_NOT_RUNNING</code>	- The FTPD is no longer running

See also

[FTPStart](#), [FTPStartSSL](#)

14.19.2.4 FTP Server Core Return Codes**Macros**

- #define **FTPD_FAIL** (0)
Operation failed.
- #define **FTPD_OK** (1)
Operation succeeded.
- #define **FTPD_RUNNING** (2)
FTP Server running.
- #define **FTPD_NOT_RUNNING** (3)
FTP Server not running.
- #define **FTPD_LISTEN_ERR** (4)
FTP listen socket could not be opened, or is not open.

14.19.2.4.1 Detailed Description**14.19.2.5 FTP Server File Return Codes****Macros**

- #define **FTPD_FILE_SIZE_NOSUCH_FILE** (-1)
No such file.
- #define **FTPD_FILE_SIZE_UNKNOWN** (0)
File size unknown.

14.19.2.5.1 Detailed Description**14.19.3 FTP Server with EDFS-FAT**

```
#include< ftpd_effsfat.h >
```

FTP Server with EFFS-FAT file system implementation. For use with flash cards such as SD and microSD flash cards.

Note

Please refer to the FTP and HTTP examples in "\nburn\examples\EFFS\Fat".

14.19.4 FTP Server with EFFS-STD

```
#include < ftpd_effsstd.h >
```

FTP Server with EFFS-STD file system implementation. Implements a flash file system in the flash chips of your NetBurner device.

Note

Please refer to the HTTP example in "\nburn\examples\EFFS\Std".

14.20 File Descriptor Printf - fdprintf

Functions

- int [fdprintf](#) (int *fc*, const char **format*,...)
 - printf to a file descriptor*
- int [fdiprintf](#) (int *fc*, const char **format*,...)
 - printf to a file descriptor with integer (no floating point) support*
- int [vfdprintf](#) (int *fc*, const char **format*, va_list *arg*)
 - printf to a file descriptor using va_list arguments*
- int [vfdiprintf](#) (int *fc*, const char **format*, va_list *arg*)
 - printf to a file descriptor with integer (no floating point) support using va_list arguments*

14.20.1 Detailed Description

```
#include < fdprintf.h >
```

The `printf()` function is a valuable tool for messages at runtime, status, and debugging. The `fdprintf()` uses the same parameters, but is used to `printf` to any file descriptor, such as serial ports, network interfaces, and custom file descriptors.

Note

Please refer to the `fdprintf()` example in the "\nburn\examples\Filedescriptor" folder. There are also examples on how to create a custom file descriptor.

14.20.2 Function Documentation

14.20.2.1 fdiprintf()

```
int fdiprintf (
    int fc,
    const char * format,
    ... )
```

```
#include <fdprintf.h>
```

`printf` to a file descriptor with integer (no floating point) support

Parameters

<i>fc</i>	File descriptor to print to.
<i>format</i>	Format string, same format as standard <code>printf()</code> .
...	Arguments specified by format string.

Returns

Number of bytes written.

14.20.2.2 fdprintf()

```
int fdprintf (
    int fc,
    const char * format,
    ... )
```

#include <fdprintf.h>
printf to a file descriptor

Parameters

<i>fc</i>	File descriptor to print to.
<i>format</i>	Format string, same format as standard printf().
...	Arguments specified by format string.

Returns

Number of bytes written.

14.20.2.3 vfdprintf()

```
int vfdprintf (
    int fc,
    const char * format,
    va_list arg )
```

#include <fdprintf.h>
printf to a file descriptor with integer (no floating point) support using va_list arguments

Parameters

<i>fc</i>	File descriptor to print to.
<i>format</i>	Format string, same format as standard printf().
<i>arg</i>	Arguments specified by format string of type va_list (Variable Arguments)

Returns

Number of bytes written.

14.20.2.4 vfdprintf()

```
int vfdprintf (
    int fc,
    const char * format,
    va_list arg )
```

#include <fdprintf.h>
printf to a file descriptor using va_list arguments

Parameters

<i>fc</i>	File descriptor to print to.
<i>format</i>	Format string, same format as standard printf().
<i>arg</i>	Arguments specified by format string of type va_list (Variable Arguments)

Returns

Number of bytes written.

14.21 GDB Stub (Remote Debugging)

GDB Stub functions.

Stub Initialization functions

- void [InitGDBStub](#) (int port, int baudrate)

Start the GDB stub and then immediately stop at a break point This function will start the GDB stub, and will stop immediately at a breakpoint. This function is best used during development to stop the system from executing questionable code at startup. It is also useful to control the system execution to debug startup and initialization code.

- void [InitGDBStubNoBreak](#) (int port, int baudrate)

Start the GDB stub and continue without stopping This function will start the GDB stub, and continue with normal program execution. This function is best used to debug a program that is operating correctly and has intermitant bugs or anomallies. The program will run as normal until you connect the debugger. Thus you can operate the program until one needs to debug it.

14.21.1 Detailed Description

GDB Stub functions.

```
#include <gdbstub.h >
```

This module provides code for operating a serial GDB stub. This is used to debug programs running on a NetBurner system. More information can be found in ../nburn/docs/gdb/GDB-Gettingstarted

14.21.2 Function Documentation

14.21.2.1 InitGDBStub()

```
void InitGDBStub (
    int port,
    int baudrate )
```

```
#include <gdbstub.h>
```

Start the GDB stub and then immediately stop at a break point This function will start the GDB stub, and will stop immediately at a breakpoint. This function is best used during development to stop the system from executing questionable code at startup. It is also useful to control the system execution to debug startup and initialization code.

Parameters

<i>port</i>	The serial port to use this can be 0 or 1 coresponding to uart 0 or uart 1
<i>baudrate</i>	The baud rate to use on the port.

See also

[InitGDBStubNoBreak](#)

14.21.2.2 InitGDBStubNoBreak()

```
void InitGDBStubNoBreak (
    int port,
    int baudrate )
#include <gdbstub.h>
```

Start the GDB stub and continue without stopping This function will start the GDB stub, and continue with normal program execution. This function is best used to debug a program that is operating correctly and has intermittent bugs or anomalies. The program will run as normal until you connect the debugger. Thus you can operate the program until one needs to debug it.

Parameters

<i>port</i>	The serial port to use this can be 0 or 1 corresponding to uart 0 or uart 1
<i>baudrate</i>	The baud rate to use on the port.

See also

[InitGDBStub](#)

14.22 HAL - Hardware Abstraction Layer

Functions

- void **HardwareSetup** ()
Initializes the system hardware such as the timer, cache and clock speed.
- void **PostConfigHardwareInit** ()
Initializes the system hardware that depend on config variables such as the watchdog.
- void **ForceReboot** (bool bFromException=false)
Forces the system hardware to perform a soft reset.
- int **HalStorage_Save** (uint8_t area, void *pData, int len, int offset=0)
Save a blob to a specific persistent storage area as defined by the platform. This routine will perform all storage maintenance routines necessary to ensure a valid write.
- int **HalStorage_SavePartial** (uint8_t area, void *pData, int len, int offset)
Save a blob to a specific persistent storage area as defined by the platform. This routine requires that any maintenance required for a valid write be explicitly performed prior to being called.
- int **HalStorage_Prepare** (uint8_t area, int len, int offset=0)
Prepare a storage area for writing new data. For platforms with direct flash mapping this function is an alias for HalStorage_Erase.
- int **HalStorage_Finalize** (uint8_t area)
Finalize a storage area after writing new data. This will perform any final completion or cleanup routines required to persist the previously saved data from HalStorage_SavePartial calls.
- int **HalStorage_Erase** (uint8_t area, int len=-1, int offset=0)
Erase all or part of a storage area. Note: due to physical storage granularities, the total area erased may extend beyond the requested area.
- int **HalStorage_GetAllocated** (uint8_t area)
Obtain the total size allocated to the given persistent storage area.
- int **HalStorage_GetMaxAllocation** (uint8_t area)
Obtain the maximum size that may be allocated to the given persistent storage area. For direct flash mapped platforms, this is aliased to HalStorage_GetAllocated.
- int **HalStorage_RemainingSpace** (uint8_t area)
Obtain the number of remaining bytes available to be written in the given persistent storage area.
- int **HalStorage_WriteOffset** (uint8_t area)
Get the offset of the next byte that can be written in the given persistent storage area.
- int **HalStorage_AddressOffset** (uint8_t area, void *pWhere)
Get the offset within a persistent storage area of an address. A platform may map any address to any offset of its choosing for a given storage area, and may modify its behavior on an area by area basis.
- void **FlashErase** (void *pWhere, int len)
Erases the flash memory.
- void **FlashProgram** (void *pWhere, void *pWhat, int len)

- Program flash memory.*

 - void [FlashProgramApplmage](#) (void *pWhere, void *pWhat, int len)
 - Write an application image to flash memory.*
 - void **DisableCache** ()
 - Disable the instruction and data cache.*
 - void **EnableCache** ()
 - Enable the instruction and data cache.*
 - uint32_t [spaceleft](#) ()
 - Report how much free unallocated space is left in dynamic memory.*
 - uint16_t [HalGetTickFraction](#) (void)
 - Returns the fraction of the current system time tick.*
 - void [StdioCheckIntc](#) (void)
 - Check STDIO interrupt sources.*
 - void [SysLogCheckIntc](#) (void)
 - This is just like the [StdioCheckIntc\(\)](#) function, except that the results are displayed via UDP.*
 - bool [HalDeviceCertValid](#) ()
 - Determine if the stored certificate is valid.*
 - uint8_t * [HalGetDeviceCert](#) ()
 - Get a pointer to the stored certificate.*
 - uint16_t [HalGetDeviceCertLen](#) ()
 - Get the length of the stored certificate.*
 - uint8_t * [HalGetDeviceKey](#) ()
 - Get a pointer to the stored certificate.*
 - uint16_t [HalGetDeviceKeyLen](#) ()
 - Get the length of the stored key.*
 - bool [HalSaveNewDeviceCert](#) (const uint8_t *cert, uint16_t certlen, uint8_t format=SSL_FILETYPE_PEM)
 - Save a device certificate in persistent storage.*
 - bool [HalSaveNewDeviceKey](#) (const uint8_t *key, uint16_t keylen, uint8_t format=SSL_FILETYPE_PEM)
 - Save a device key in persistent storage.*
 - void [HalEraseDeviceCertAndKey](#) ()
 - Clear the device certificate and key from persistent storage.*

Variables

- void(* [watchdog_service_function](#))(void)
 - Watchdog callback service function.*
- uint32_t [HalTickMaxCount](#)
 - Rollover value for the system hardware tick timer.*

14.22.1 Detailed Description

```
#include < hal.h >
```

The HAL provides a common function name interface to the various NetBurner hardware platforms. Other than the [ForceReboot\(\)](#) and [spaceleft\(\)](#) functions, these are advanced functions that should only be used by developers experienced with NetBurner hardware, firmware and memory maps.

14.22.2 Function Documentation

14.22.2.1 FlashErase()

```
void FlashErase (  
    void * pWhere,  
    int len )
```

```
#include <hal.h>
```

Erases the flash memory.

Parameters

<i>pWhere</i>	The starting location in flash memory to begin the erasure
<i>len</i>	Specified the number of bytes to erase

14.22.2.2 FlashProgram()

```
void FlashProgram (
    void * pWhere,
    void * pWhat,
    int len )
```

```
#include <hal.h>
```

Program flash memory.

Parameters

<i>pWhere</i>	Pointer to the starting location in flash to begin programming
<i>pWhat</i>	Pointer to the content that will be programmed into flash
<i>len</i>	Number of bytes to program

14.22.2.3 FlashProgramAppImage()

```
void FlashProgramAppImage (
    void * pWhere,
    void * pWhat,
    int len )
```

```
#include <hal.h>
```

Write an application image to flash memory.

On some platforms writing the application image may require calling ProgramImage even though it may only call FlashErase and FlashProgram. As a result, ProgramImage should always be used when updating the application image.

Parameters

<i>pWhere</i>	Pointer to the starting location in flash to begin the programming
<i>pWhat</i>	Pointer to the content that will be programmed into flash
<i>len</i>	Number of bytes to write

14.22.2.4 HalDeviceCertValid()

```
bool HalDeviceCertValid ( )
```

```
#include <hal.h>
```

Determine if the stored certificate is valid.

This is the only function recommended to be used to determine the validity of the stored certificate. It is not recommended to use [HalGetDeviceCert\(\)](#) nor [HalGetDeviceCertLen\(\)](#) to determine validity. For safest use of the cert/key getter functions, use [HalDeviceCertValid\(\)](#) prior.

Return values

<i>true</i>	if the certificate is valid false otherwise
-------------	---

14.22.2.5 HalEraseDeviceCertAndKey()

```
void HalEraseDeviceCertAndKey ( )  
#include <hal.h>
```

Clear the device certificate and key from persistent storage.

[HalEraseDeviceCertAndKey\(\)](#) is recommended instead of [HalStorage_Erase\(\)](#) to clear the stored certificate and key.

14.22.2.6 HalGetDeviceCert()

```
uint8_t * HalGetDeviceCert ( )  
#include <hal.h>
```

Get a pointer to the stored certificate.

It is recommended to use [HalDeviceCertValid\(\)](#) prior to calling this function.

Return values

<i>pointer</i>	to the certificate storage location in memory.
----------------	--

14.22.2.7 HalGetDeviceCertLen()

```
uint16_t HalGetDeviceCertLen ( )  
#include <hal.h>
```

Get the length of the stored certificate.

It is recommended to use [HalDeviceCertValid\(\)](#) prior to calling this function.

Return values

<i>length</i>	of the stored certificate. 0 or 65535 if no certificates is stored.
---------------	---

14.22.2.8 HalGetDeviceKey()

```
uint8_t * HalGetDeviceKey ( )  
#include <hal.h>
```

Get a pointer to the stored certificate.

It is recommended to use [HalDeviceCertValid\(\)](#) prior to calling this function.

Return values

<i>pointer</i>	to the certificate storage location in memory.
----------------	--

14.22.2.9 HalGetDeviceKeyLen()

```
uint16_t HalGetDeviceKeyLen ( )  
#include <hal.h>
```

Get the length of the stored key.

It is recommended to use [HalDeviceCertValid\(\)](#) prior to calling this function.

Return values

<i>length</i>	of the stored key. 0 or 65535 if no key is stored.
---------------	--

14.22.2.10 HalGetTickFraction()

```
uint16_t HalGetTickFraction (
    void ) [extern]
```

```
#include <hal.h>
```

Returns the fraction of the current system time tick.

return - The current counter value used to generate tick count

14.22.2.11 HalSaveNewDeviceCert()

```
bool HalSaveNewDeviceCert (
    const uint8_t * cert,
    uint16_t certlen,
    uint8_t format = SSL_FILETYPE_PEM )
```

```
#include <hal.h>
```

Save a device certificate in persistent storage.

Parameters

<i>cert</i>	Pointer to the buffer containing the certificate
<i>certlen</i>	length of the certificate
<i>format</i>	filetype (SSL_FILETYPE_PEM, or SSL_FILETYPE_ASN1)

Return values

<i>true</i>	if the certificate was successfully stored
<i>false</i>	otherwise

14.22.2.12 HalSaveNewDeviceKey()

```
bool HalSaveNewDeviceKey (
    const uint8_t * key,
    uint16_t keylen,
    uint8_t format = SSL_FILETYPE_PEM )
```

```
#include <hal.h>
```

Save a device key in persistent storage.

Parameters

<i>key</i>	Pointer to the buffer containing the key
<i>keylen</i>	length of the key
<i>format</i>	filetype (SSL_FILETYPE_PEM, or SSL_FILETYPE_ASN1)

Return values

<i>true</i>	if the key was successfully stored
<i>false</i>	otherwise

14.22.2.13 HalStorage_AddressOffset()

```
int HalStorage_AddressOffset (
    uint8_t area,
    void * pWhere )
```

```
#include <hal.h>
```

Get the offset within a persistent storage area of an address. A platform may map any address to any offset of its choosing for a given storage area, and may modify its behavior on an area by area basis.

Parameters

<i>area</i>	The storage area being queried
<i>pWhere</i>	An address value to be translated

Returns

Offset of the requested address within the storage area. Returns negative on error.

14.22.2.14 HalStorage_Erase()

```
int HalStorage_Erase (
    uint8_t area,
    int len = -1,
    int offset = 0 )
```

```
#include <hal.h>
```

Erase all or part of a storage area. Note: due to physical storage granularities, the total area erased may extend beyond the requested area.

Parameters

<i>area</i>	The storage area to be erased
<i>len</i>	Number of bytes to be erased (a negative length will erase the entire area)
<i>offset</i>	The location within the area that the erasure should begin

Returns

Number of bytes erased. Returns negative on error.

See also

[HalEraseDeviceCertAndKey\(\)](#)

14.22.2.15 HalStorage_Finalize()

```
int HalStorage_Finalize (
    uint8_t area )
```

```
#include <hal.h>
```

Finalize a storage area after writing new data. This will perform any final completion or cleanup routines required to persist the previously saved data from HalStorage_SavePartial calls.

Parameters

<i>area</i>	The storage area to finalize
-------------	------------------------------

Returns

Returns negative on error.

14.22.2.16 HalStorage_GetAllocated()

```
int HalStorage_GetAllocated (
    uint8_t area )
#include <hal.h>
```

Obtain the total size allocated to the given persistent storage area.

Parameters

<i>area</i>	The storage area being queried
-------------	--------------------------------

Returns

Number of bytes allocated. Returns negative on error.

14.22.2.17 HalStorage_GetMaxAllocation()

```
int HalStorage_GetMaxAllocation (
    uint8_t area )
#include <hal.h>
```

Obtain the maximum size that may be allocated to the given persistent storage area. For direct flash mapped platforms, this is aliased to HalStorage_GetAllocated.

Parameters

<i>area</i>	The storage area being queried
-------------	--------------------------------

Returns

Number of bytes allocated. Returns negative on error.

14.22.2.18 HalStorage_Prepere()

```
int HalStorage_Prepere (
    uint8_t area,
    int len,
    int offset = 0 )
#include <hal.h>
```

Prepare a storage area for writing new data. For platforms with direct flash mapping this function is an alias for HalStorage_Erase.

Parameters

<i>area</i>	The storage area to be readied
<i>len</i>	Number of bytes to be written by later HalStorage_SavePartial calls
<i>offset</i>	The location within the area that the readying should begin

Returns

Number of bytes readied. Returns negative on error.

14.22.2.19 HalStorage_RemainingSpace()

```
int HalStorage_RemainingSpace (
    uint8_t area )
```

```
#include <hal.h>
```

Obtain the number of remaining bytes available to be written in the given persistent storage area.

Parameters

<i>area</i>	The storage area being queried
-------------	--------------------------------

Returns

Number of bytes available. Returns negative on error.

14.22.2.20 HalStorage_Save()

```
int HalStorage_Save (
    uint8_t area,
    void * pData,
    int len,
    int offset = 0 )
```

```
#include <hal.h>
```

Save a blob to a specific persistent storage area as defined by the platform. This routine will perform all storage maintenance routines necessary to ensure a valid write.

Parameters

<i>area</i>	The storage area to be used. A platform is only <i>required</i> to support the areas as defined by HalStorage_t, however it may define additional areas as needed
<i>pData</i>	Pointer to the data to be written
<i>len</i>	Number of bytes to be written to the storage area
<i>offset</i>	Where in the storage area the first byte should be written. Default is 0.

Returns

Number of bytes written. Returns negative on error.

14.22.2.21 HalStorage_SavePartial()

```
int HalStorage_SavePartial (
    uint8_t area,
    void * pData,
    int len,
    int offset )
```

```
#include <hal.h>
```

Save a blob to a specific persistent storage area as defined by the platform. This routine requires that any maintenance required for a valid write be explicitly performed prior to being called.

Parameters

<i>area</i>	The storage area to be used. A platform is only <i>required</i> to support the areas as defined by HalStorage_t, however it may define additional areas as needed.
<i>pData</i>	Pointer to the data to be written
<i>len</i>	Number of bytes to be written to the storage area
<i>offset</i>	Where in the storage area the first byte should be written.

Returns

Number of bytes written. Returns negative on error.

14.22.2.22 HalStorage_WriteOffset()

```
int HalStorage_WriteOffset (
    uint8_t area )
```

```
#include <hal.h>
```

Get the offset of the next byte that can be written in the given persistent storage area.

Parameters

<i>area</i>	The storage area being queried
-------------	--------------------------------

Returns

Offset of the next byte that can be written. Returns negative on error.

14.22.2.23 spaceleft()

```
uint32_t spaceleft ( )
```

```
#include <hal.h>
```

Report how much free unallocated space is left in dynamic memory.

Returns

Number of bytes unallocated in dynamic memory

14.22.2.24 StdioCheckIntc()

```
void StdioCheckIntc (
    void )
```

```
#include <hal.h>
```

Check STDIO interrupt sources.

Checks the interrupt sources used in the system along with their associated interrupt level and priority, and also checks for any conflicts in using the same level and priority between different sources. These results are sent to stdout.

See also

[SysLogCheckIntc\(\)](#)

14.22.2.25 SysLogCheckIntc()

```
void SysLogCheckIntc (
    void )
```

```
#include <hal.h>
```

This is just like the [StdioCheckIntc\(\)](#) function, except that the results are displayed via UDP.

See also

[StdioCheckIntc\(\)](#)

14.22.3 Variable Documentation**14.22.3.1 HalTickMaxCount**

```
uint32_t HalTickMaxCount [extern]
```

```
#include <hal.h>
```

Rollover value for the system hardware tick timer.

Returns

The max/rollover counter value used to generate the tick count

14.22.3.2 watchdog_service_function

```
void(* watchdog_service_function) (void) (
    void ) [extern]
```

```
#include <hal.h>
```

Watchdog callback service function.

If the following function pointer is set to point at a function of the form:

```
void YourFunc( void );
```

Then the system will call this function throughout the AutoUpdate/TCPUpdate process to make sure that the watchdog timer is serviced.

14.23 HTTP and HTML Functions**Classes**

- struct [HTTP_Request](#)
HTTP Request Structure.
- class [HtmlPageHandler](#)
Base class for all GET handlers. To handle GET requests for a specific URL in your application, build a GET handler object for that specific URL. A NULL name will be a catch all for all GET requests.
- class [CallBackFunctionPageHandler](#)
Implements the [HtmlPageHandler](#) class as a function pointer callback for GET requests.
- class [CallBackFunctionPostHandler](#)
Implements the [HtmlPostHandler](#) class as a function pointer callback for POST requests.
- class [HtmlPostVariableListCallback](#)
Implements the [HtmlPostVariableListHandler](#) class as a function pointer callback for HTTP POST submissions.

Typedefs

- typedef int [http_gethandlerfunc](#)(int sock, [HTTP_Request](#) &pd)
Implements the [HtmlPageHandler](#) class as a function pointer callback for GET requests.
- typedef int [http_posthandler](#)(int sock, [HTTP_Request](#) &httpReqInfo)
Type definition of the [HtmlPostHandler](#) callback for POST requests.

Enumerations

- enum [HTTP_RequestTypes](#) { [tUnknown](#) , [tGet](#) , [tPost](#) , [tHead](#) }
HTTP request types for HTTP page handler callback functions.
- enum [HTTP_ACCESS](#)
HTTP page access return values.

Functions

- int [SendEmailResponse](#) (int sock, const char *name, const char *attachment)
Send an email with HTML formatting.
- int [SendFullResponse](#) (char const *name, int fd)
Send a file with the proper HTTP header, file specified by file name.
- int [SendFullResponse](#) (HTML_FILE_RECORD *fr, int fd, const char *pUrl)
Send a file with the proper HTTP header, file specified by HTML_FILE_RECORD.
- int [SendHeaderResponse](#) (char const *name, int fd)
Send a HTTP header response for the specified file type.

- int [SendHeaderResponse](#) (HTML_FILE_RECORD *fr, int fd)
Send a HTTP header response for the specified HTML_FILE_RECORD type.
- int32_t [SendFileFragment](#) (char const *name, int32_t fd, PCSTR url=NULL)
Send a file fragment without a header.
- HTML_FILE_RECORD * [GetRecordFromName](#) (char const *name)
Returns a pointer to a HTML_FILE_RECORD for the specified file name.
- CONFIG_RENDER_OBJ [ConfigRenderFunc](#) (int mode, const char *pobj, int len=20, const char *extra=0)
Render a configuration object as HTML for the specified configuration object.
- CONFIG_RENDER_OBJ [ConfigRenderFunc](#) (int mode, config_leaf &cl, int len=20, const char *extra=0)
Render a configuration object as HTML for the specified configuration leaf object.
- void [WriteHtmlVariable](#) (int fd, CONFIG_RENDER_OBJ co)
Send a CONFIG_RENDER_OBJ to the client.
- HTTP_Request * [GetActiveHttpRequest](#) ()
Get the current active running http request. Only valid from within http get or post handling. Also valid during page fill in operations.
- HTTP_ACCESS [CheckHttpAccess](#) (int sock, int access_level, HTTP_Request &Req)
All HTTP requests go through this function.
- void [StartHttp](#) (uint16_t port, bool RunConfigMirror)
Start the HTTP web server. Further documentation in the Initialization section [Initialization - System Initialization Functions](#).
- void [StopHttp](#) ()
Stop the HTTP web server.
- void [SendHTMLHeader](#) (int sock)
Send a HTML response header.
- void [SendHTMLHeaderWCookie](#) (int sock, char *cookie)
Send a HTML response header and cookie.
- void [SendTextHeader](#) (int sock)
Send a HTML plain text header.
- void [SendGifHeader](#) (int sock)
Send a HTML GIF header.
- void [EmptyResponse](#) (int sock)
Send an empty response back.
- void [NoContentResponse](#) (int sock)
Send a no content response back.
- void [RedirectResponse](#) (int sock, PCSTR new_page)
Redirect a HTTP request to a different page.
- void [NotFoundResponse](#) (int sock, PCSTR new_page)
Send a page not found response.
- void [ForbiddenResponse](#) (int sock, PCSTR new_page)
Send a page is forbidden response.
- void [NotAvailableResponse](#) (int sock, PCSTR new_page)
Send a response indicating that the requested resource is not available at this time.
- void [BadRequestResponse](#) (int sock, PCSTR url, PCSTR data)
Send a response indicating that the client request itself is faulty in some manner.
- int [writeallsafestring](#) (int fd, PCSTR str)
Send a string and escape all special characters.
- int [writesafestring](#) (int fd, PCSTR str, size_t strLength)
Send a string with a specified length and escape all special characters.
- int [httpstricmp](#) (PCSTR str1, PCSTR str1sUpper2)
Special string compare. Returns 1 if the strings match until one string ends with a null (0).
- void [StartHttps](#) (uint16_t ssl_port, uint16_t http_port)
Start the HTTPS secure web server.

14.23.1 Detailed Description

```
#include< htmlfiles.h >
```

API to process and delivery files from the web server to clients. In particular, processing of files in a project's html folder.

For the majority of applications these functions will not be necessary; the web server system will automatically handle both static and dynamic content. This API is available if more advances processing is required, such as sending custom response headers or very large amounts of data.

```
#include< http.h >
```

In addition to the functions to start a web server, [StartHttp\(\)](#), this module provides functions used to create a custom web interface. Please refer to the Programmers Guide for additional details on web interface programming and dynamic content.

See also

[StartHttps\(\)](#)

```
#include< httpost.h >
```

```
#include< https.h >
```

14.23.2 Typedef Documentation

14.23.2.1 [http_gethandlerfunc](#)

```
typedef int http\_gethandlerfunc(int sock, HTTP\_Request &pd)
#include <http.h>
```

Implements the [HtmlPageHandler](#) class as a function pointer callback for GET requests.

Return values

0	Not handled, no changes are made
1	Handled
2	TCP socket will be kept. Socket will get closed by some other method. For example, a large file could be sent from a different task. Any return value other than 2 means the page was processed normally.

14.23.2.2 [http_posthandler](#)

```
typedef int http\_posthandler(int sock, HTTP\_Request &httpReqInfo)
#include <httpost.h>
```

Type definition of the [HtmlPostHandler](#) callback for POST requests.

This should only be used if the specific variable callback implementations will not work in your application. This is mostly an internal use function.

Parameters

<i>sock</i>	The socket the request came in on.
<i>httpReqInfo</i>	Information about the request HTTP_Request .

Return values

0	Not handled, no changes are made
1	Handled

Return values

2	TCP socket will be kept. Socket will get closed by some other method. For example, a large file could be sent from a different task. Any return value other than 2 means the page was processed normally.
---	---

See also

[HtmlPostVariableListCallback](#)

[HtmlPostVariableListHandler](#)

14.23.3 Enumeration Type Documentation

14.23.3.1 HTTP_RequestTypes

```
enum HTTP_RequestTypes
```

```
#include <http.h>
```

HTTP request types for HTTP page handler callback functions.

Enumerator

tUnknown	The type of request is not yet known.
tGet	GET request.
tPost	POST request.
tHead	Header request, does not include content.

14.23.4 Function Documentation

14.23.4.1 BadRequestResponse()

```
void BadRequestResponse (
    int sock,
    PCSTR url,
    PCSTR data )
```

```
#include <http.h>
```

Send a response indicating that the client request itself is faulty in some manner.

Parameters

<i>sock</i>	Socket to send response
<i>url</i>	The URL of the page to display
<i>data</i>	An explanation or segment of data to display indicating the fault

See also

[RedirectResponse\(\)](#), [NotFoundResponse\(\)](#), [ForbiddenResponse\(\)](#)

[NotAvailableResponse\(\)](#)

14.23.4.2 CheckHttpAccess()

```
HTTP_ACCESS CheckHttpAccess (
    int sock,
    int access_level,
    HTTP_Request & Req )
```

```
#include <http.h>
```

All HTTP requests go through this function.

By default the library provides a weak reference implementation that approves all transactions. To provide your own just add an implementation of this function to your code.

Parameters

<i>sock</i>	The socket the request came in on.
<i>access_level</i>	The user defined access level for this request. See HtmlPageHandler
<i>Req</i>	The HTTP request where one can extract the URL , access type, password, etc

Returns

The desired response.

14.23.4.3 ConfigRenderFunc() [1/2]

```
CONFIG_RENDER_OBJ ConfigRenderFunc (
    int mode,
    config_leaf & cl,
    int len = 20,
    const char * extra = 0 )
```

```
#include <htmlfiles.h>
```

Render a configuration object as HTML for the specified configuration leaf object.

Parameters

<i>mode</i>	CONFIG_RENDER_OBJ eMode value
<i>cl</i>	Reference to the config_leaf object to render
<i>len</i>	Optional length parameter for text input elements
<i>extra</i>	Pointer to any additional information to be added to the HTML input element. Will be added to the end of the <input> tag.

Returns

A CONFIG_RENDER_OBJ that can be sent to the client using WriteHtmlVariable()

14.23.4.4 ConfigRenderFunc() [2/2]

```
CONFIG_RENDER_OBJ ConfigRenderFunc (
    int mode,
    const char * pobj,
    int len = 20,
    const char * extra = 0 )
```

```
#include <htmlfiles.h>
```

Render a configuration object as HTML for the specified configuration object.

Parameters

<i>mode</i>	CONFIG_RENDER_OBJ eMode value
<i>pobj</i>	Pointer to a configuration object. Can be specified as the JSON configuration path. For example, "Config/Sys/NetIf/Ethernet0/StaticAddr".
<i>len</i>	Optional length parameter for text input elements
<i>extra</i>	Pointer to any additional information to be added to the HTML input element. Will be added to the end of the <input> tag.

Returns

A CONFIG_RENDER_OBJ that can be sent to the client using WriteHtmlVariable()

14.23.4.5 EmptyResponse()

```
void EmptyResponse (
    int sock )
#include <http.h>
Send an empty response back.
```

Parameters

<i>sock</i>	Socket to send response
-------------	-------------------------

See also

[ForbiddenResponse\(\)](#), [ForbiddenResponse\(\)](#), [SendHTMLHeaderWCookie\(\)](#)
[NotAvailableResponse\(\)](#), [BadRequestResponse\(\)](#), [RedirectResponse\(\)](#)

14.23.4.6 ForbiddenResponse()

```
void ForbiddenResponse (
    int sock,
    PCSTR new_page )
#include <http.h>
Send a page is forbidden response.
```

Parameters

<i>sock</i>	Socket to send response
<i>new_page</i>	The URL of the page to display

See also

[RedirectResponse\(\)](#), [NotFoundResponse\(\)](#)
[NotAvailableResponse\(\)](#), [BadRequestResponse\(\)](#)

14.23.4.7 GetRecordFromName()

```
HTML_FILE_RECORD * GetRecordFromName (
    char const * name )
#include <htmlfiles.h>
Returns a pointer to a HTML_FILE_RECORD for the specified file name.
```

Parameters

<i>name</i>	Name of file in htmldata.cpp to search for
-------------	--

Return values

<i>A</i>	pointer to a HTML_FILE_RECORD if found
<i>NULL</i>	if file name not found

14.23.4.8 httpstricmp()

```
int httpstricmp (
    PCSTR str1,
    PCSTR strIsUpper2 )
```

```
#include <http.h>
```

Special string compare. Returns 1 if the strings match until one string ends with a null (0).

strIsUpper2 must be specified in upper case

Used to match URL with stored file prefixes.

Parameters

<i>str1</i>	The string to search
<i>strIsUpper2</i>	The string to search for, must be specified in upper case

Return values

<i>0</i>	if the prefixes do not match
<i>1</i>	if the prefixes match

Example: `httpstricmp(str1, "LED.HTML");`

str1	Return Value
LED	1
led.HTML	1
led.html	1
LED.HTM?	0

14.23.4.9 NoContentResponse()

```
void NoContentResponse (
    int sock )
```

```
#include <http.h>
```

Send a no content response back.

Parameters

<i>sock</i>	Socket to send response
-------------	-------------------------

See also

[ForbiddenResponse\(\)](#), [ForbiddenResponse\(\)](#), [SendHTMLHeaderWCookie\(\)](#)

[NotAvailableResponse\(\)](#), [BadRequestResponse\(\)](#), [RedirectResponse\(\)](#)

14.23.4.10 NotAvailableResponse()

```
void NotAvailableResponse (
    int sock,
    PCSTR new_page )
```

```
#include <http.h>
```

Send a response indicating that the requested resource is not available at this time.

Parameters

<i>sock</i>	Socket to send response
<i>new_page</i>	The URL of the page to display

See also

[RedirectResponse\(\)](#), [NotFoundResponse\(\)](#), [ForbiddenResponse\(\)](#)
[BadRequestResponse\(\)](#)

14.23.4.11 NotFoundResponse()

```
void NotFoundResponse (
    int sock,
    PCSTR new_page )
#include <http.h>
```

Send a page not found response.

Parameters

<i>sock</i>	Socket to send response
<i>new_page</i>	The URL of the page to display

See also

[ForbiddenResponse\(\)](#), [RedirectResponse\(\)](#)
[NotAvailableResponse\(\)](#), [BadRequestResponse\(\)](#)

14.23.4.12 RedirectResponse()

```
void RedirectResponse (
    int sock,
    PCSTR new_page )
#include <http.h>
```

Redirect a HTTP request to a different page.

Parameters

<i>sock</i>	Socket to send response
<i>new_page</i>	The URL of the new page

See also

[ForbiddenResponse\(\)](#), [ForbiddenResponse\(\)](#), [SendHTMLHeaderWCookie\(\)](#)
[NotAvailableResponse\(\)](#), [BadRequestResponse\(\)](#), [EmptyResponse\(\)](#)

14.23.4.13 SendEmailResponse()

```
int SendEmailResponse (
    int sock,
    const char * name,
    const char * attachment )
#include <htmlfiles.h>
```

Send an email with HTML formatting.

Parameters

<i>sock</i>	Network socket in which to send the data
<i>name</i>	Name of file from project's html folder, this is the email body
<i>attachment</i>	

Return values

1	Success, the file specified the name parameter was found
0	File does not exist

14.23.4.14 SendFileFragment()

```
int32_t SendFileFragment (
    char const * name,
    int32_t fd,
    PCSTR url = NULL )
```

```
#include <htmlfiles.h>
```

Send a file fragment without a header.

Search through the files stored in the system by `comhtml` in the project's `html` folder for the specified file name. If found, the file content is sent as a file fragment. A `SendHeaderResponse` function must be sent prior to sending file fragments.

This function is useful when building HTML responses with large amounts of data. If the file has embedded dynamic HTML function tags and/or variable tags, such as `CPPCALL` and `VARIABLE`, they will be processed as the content is delivered.

Parameters

<i>name</i>	Name of the file
<i>fd</i>	File descriptor used to send the file fragment
<i>url</i>	Optional URL string in fragment header

Return values

1	if the file was found
0	otherwise

14.23.4.15 SendFullResponse() [1/2]

```
int SendFullResponse (
    char const * name,
    int fd )
```

```
#include <htmlfiles.h>
```

Send a file with the proper HTTP header, file specified by file name.

This function searches through the files stored in the system by `comhtml` in the project's `html` folder for the specified file name. If found, it sends the proper HTTP header and file to the client. If the file has embedded dynamic HTML function tags and/or variable tags, such as `CPPCALL` and `VARIABLE`, they will be processed as the content is delivered.

Parameters

<i>name</i>	Name of the file
<i>fd</i>	File descriptor used to send the file

Return values

1	Success, file was found
0	File does not exist

See also

[SendFullResponse\(HTML_FILE_RECORD *fr, int fd, const char *pUrl\)](#)

14.23.4.16 SendFullResponse() [2/2]

```
int SendFullResponse (
    HTML_FILE_RECORD * fr,
    int fd,
    const char * pUrl )
```

```
#include <htmlfiles.h>
```

Send a file with the proper HTTP header, file specified by HTML_FILE_RECORD.

While the [SendFullResponse\(char const *name, int fd\)](#) function will resolve the file name, this lower level function requires knowledge of the file pointer to the HTML_FILE_RECORD in htmldata.cpp.

Parameters

<i>fr</i>	Pointer to the HTML_FILE_RECORD in htmldata.cpp
<i>fd</i>	File descriptor used to send the file
<i>pUrl</i>	Pointer to a URL string used by response functions such a CPPCALL and VARIABLE callbacks. In default web server processing the URL is automatically set to what the client requested. When processing web requests manually you must specify the URL string. If you are not using dynamic content that relies on the URL, this can be set to NULL.

Return values

1	if the file was found
0	otherwise

See also

[SendFullResponse\(char const *name, int fd\)](#)

14.23.4.17 SendGifHeader()

```
void SendGifHeader (
    int sock )
```

```
#include <http.h>
```

Send a HTML GIF header.

Sends a GIF response header. Can be useful when dynamically creating your own GIF images.

Parameters

<i>sock</i>	Socket to send response
-------------	-------------------------

See also

[SendHTMLHeader\(\)](#), [SendTextHeader\(\)](#), [SendHTMLHeaderWCookie\(\)](#)

14.23.4.18 SendHeaderResponse() [1/2]

```
int SendHeaderResponse (
    char const * name,
    int fd )
```

```
#include <htmlfiles.h>
```

Send a HTTP header response for the specified file type.

This function searches through the files stored in the system by `comhtml` in the project's `html` folder for the specified file name. If found, it sends the proper HTTP header only to the client. Unlike a full response, only the header is sent.

Parameters

<i>name</i>	Name of the file
<i>fd</i>	File descriptor used to send the file

Return values

1	Success, file was found
0	File does not exist

See also

[SendHeaderResponse\(HTML_FILE_RECORD *fr, int fd\)](#)

14.23.4.19 SendHeaderResponse() [2/2]

```
int SendHeaderResponse (
    HTML_FILE_RECORD * fr,
    int fd )
```

```
#include <htmlfiles.h>
```

Send a HTTP header response for the specified `HTML_FILE_RECORD` type.

While the [SendFullResponse\(HTML_FILE_RECORD *fr, int fd, const char *pUrl\)](#); function will resolve the file name, this lower level function requires knowledge of the file pointer to the `HTML_FILE_RECORD` array in `htmldata.cpp`.

Parameters

<i>fr</i>	Pointer to the <code>HTML_FILE_RECORD</code> in <code>htmldata.cpp</code>
<i>fd</i>	File descriptor used to send the file

Return values

1	Success, file was found
0	File does not exist

See also

[SendHeaderResponse\(char const *name, int fd\)](#)

14.23.4.20 SendHTMLHeader()

```
void SendHTMLHeader (
    int sock )
```

```
#include <http.h>
```

Send a HTML response header.

Used to build your own HTML response

Parameters

<i>sock</i>	Socket to send response
-------------	-------------------------

See also

[SendHTMLHeaderWCookie\(\)](#), [SendTextHeader\(\)](#), [SendGifHeader\(\)](#)

14.23.4.21 SendHTMLHeaderWCookie()

```
void SendHTMLHeaderWCookie (
    int sock,
    char * cookie )
```

```
#include <http.h>
```

Send a HTML response header and cookie.

Sends a header as well as a cookie to be stored by the client browser.

Parameters

<i>sock</i>	Socket to send response
<i>cookie</i>	Pointer to the cookie

See also

[SendHTMLHeader\(\)](#), [SendGifHeader\(\)](#), [SendTextHeader\(\)](#)

14.23.4.22 SendTextHeader()

```
void SendTextHeader (
    int sock )
```

```
#include <http.h>
```

Send a HTML plain text header.

Use as the first part of building your own plain text response.

Parameters

<i>sock</i>	Socket to send response
-------------	-------------------------

See also

[SendHTMLHeader\(\)](#), [SendGifHeader\(\)](#), [SendHTMLHeaderWCookie\(\)](#)

14.23.4.23 StartHttp()

```
void StartHttp (
    uint16_t port,
    bool RunConfigMirror )
```

```
#include <http.h>
```

Start the HTTP web server. Further documentation in the Initialization section [Initialization - System Initialization Functions](#).

If no parameters are specified it will listen on port 80, and enable the configuration mirror feature so an application can create its own custom configuration web page.

Parameters

<i>port</i>	Listen port, defaults to port 80
<i>RunConfigMirror</i>	Enable configuration mirror, default is true

See also

[StopHttp\(\)](#), [StartHttps\(\)](#)

14.23.4.24 StartHttps()

```
void StartHttps (
    uint16_t ssl_port,
    uint16_t http_port )
```

```
#include <https.h>
```

Start the HTTPS secure web server.

If no parameters are specified, the web server will listen on ports 443 and 80, and enable the configuration mirror feature so an application can create its own custom configuration web page. If no user certificate/key is installed, the default system key will be used.

Default parameter values defined in [init.h](#)

Parameters

<i>ssl_port</i>	Secure listen port, defaults to port 443
<i>http_port</i>	Non-secure listen port, defaults to port 80

See also

[StartHttp\(\)](#), [StopHttp\(\)](#)

14.23.4.25 StopHttp()

```
void StopHttp ( )
#include <http.h>
Stop the HTTP web server.
```

See also

[StartHttp\(\)](#)

14.23.4.26 writeallsafestring()

```
int writeallsafestring (
    int fd,
    PCSTR str )
```

```
#include <http.h>
```

Send a string and escape all special characters.

When sending a HTML text response, certain characters (e.g. '<') are interpreted by the browser as formatting. This function properly escapes the text so it will appear as intended.

Parameters

<i>fd</i>	File descriptor used to send response
<i>str</i>	String to send

Returns

The number of characters sent

14.23.4.27 WriteHtmlVariable()

```
void WriteHtmlVariable (
```

```

        int fd,
        CONFIG_RENDER_OBJ co )
#include <htmlfiles.h>

```

Send a CONFIG_RENDER_OBJ to the client.

The CONFIG_RENDER_OBJ must have been previously created with a [ConfigRenderFunc\(\)](#) function.

Parameters

<i>fd</i>	File descriptor to send data to
<i>co</i>	CONFIG_RENDER_OBJ to send

14.23.4.28 writesafestring()

```

int writesafestring (
    int fd,
    PCSTR str,
    size_t strLength )
#include <http.h>

```

Send a string with a specified length and escape all special characters.

When sending a HTML text response, certain characters (e.g. '<') are interpreted by the browser as formatting. This function properly escapes the text so it will appear as intended.

Parameters

<i>fd</i>	File descriptor used to send response
<i>str</i>	String to send
<i>strLength</i>	number of characters from str to send

Returns

The number of characters sent

14.24 I2C

[I2C APIs](#).

Topics

- [MCF5441x I2C](#)
- [SAME70 I2C](#)

Classes

- class [BBI2C](#)
I2C Peripheral Class.

14.24.1 Detailed Description

[I2C APIs](#).

[I2C API for NetBurner Platforms](#)

```
#include <bb_i2c.h >
```

[BBI2C](#) is specifically for platforms without native hardware [I2C](#) support. See other sub-modules for device-specific [I2C](#) details.

Provides access to the all the I2C peripherals on the processor. The I2C peripherals available will vary by platform. For example, `Wire.read()`; will execute a read operation on I2C module 0.

14.24.2 MCF5441x I2C

Functions

- void `MultiChannel_I2CInit` (int moduleNum=DEFAULT_I2C_MODULE, uint8_t slave_Addr=0x08, uint8_t freqdiv=0x3C)
Initialize the I2C peripheral module.
- uint8_t `MultiChannel_I2CSendBuf` (int moduleNum, uint8_t addr, uint8_t buf, int num, bool stop=true)
Send a buffer of bytes to an I2C device.
- uint8_t `MultiChannel_I2CReadBuf` (int moduleNum, uint8_t addr, uint8_t buf, int num, bool stop=true)
Read a number of bytes from an I2C device and store in the specified buffer.
- void `I2CMultiChannelResetPeripheral` (int moduleNum)
Reset the specified I2C peripheral module.
- uint8_t `MultiChannel_I2CRestart` (int moduleNum, uint8_t addr, bool Read_Not_Write, uint32_t ticks_to_wait=I2C_RX_TX_TIMEOUT)
Restart communication with a I2C device.
- uint8_t `MultiChannel_I2CStart` (int moduleNum, uint8_t addr, bool Read_Not_Write, uint32_t ticks_to_wait=I2C_START_TIMEOUT)
Send an I2C start to an I2C device to begin communication.
- uint8_t `MultiChannel_I2CStop` (int moduleNum=DEFAULT_I2C_MODULE, uint32_t ticks_to_wait=I2C_RX_TX_TIMEOUT)
Issue an I2C stop terminate communication with an I2C device and release the bus.
- uint8_t `MultiChannel_I2CSend` (int moduleNum, uint8_t val, uint32_t ticks_to_wait=I2C_RX_TX_TIMEOUT)
Send a single byte on the I2C bus.
- uint8_t `MultiChannel_I2CRead` (int moduleNum, uint8_t val, uint32_t ticks_to_wait=I2C_RX_TX_TIMEOUT)
Read a single byte from the I2C bus.

Multichannel I2C Return Values

Function return values

- #define `I2C_OK` (0)
Last instruction terminated correctly.
- #define `I2C_NEXT_WRITE_OK` (1)
I2C bus is OK for a write.
- #define `I2C_NEXT_READ_OK` (2)
I2C bus is OK for a read.
- #define `I2C_MASTER_OK` (3)
I2C finished transmission but still owns but (need to stop or restart)
- #define `I2C_TIMEOUT` (4)
A timeout occurred while trying communicate on I2C bus.
- #define `I2C_BUS_NOT_AVAIL` (5)
A timeout occurred while trying gain I2C bus control.
- #define `I2C_NOT_READY` (6)
A read or write was attempted before I2C ready or during a slave transmission.
- #define `I2C_LOST_ARB` (7)
Lost arbitration during start.
- #define `I2C_LOST_ARB_ADD` (8)
Lost arbitration and then winner addressed our slave address.
- #define `I2C_NO_LINK_RX_ACK` (9)
We are in Master TX mode and received no ACK from slave device, possibly during start.

Multichannel I2C Macros

I2C Macros

- #define **I2C_SR_BUSY** (((0x20 & I2C_SR) == 0x20))
Bus is busy (bit 5 of I2SR)
- #define **I2C_CR_SLAVE** (((0x20 & I2C_CR) == 0x00))
Bus set as slave (bit 5 of I2CR)
- #define **I2C_SR_ARB_LOST** (((0x10 & I2C_SR) == 0x10))
Bus arbitration was lost (bit 4 of I2SR)
- #define **I2C_SR_ADRES_AS_SLAVE** (((0x40 & I2C_SR) == 0x40))
Addressed as a slave (bit 6 of I2SR)
- #define **I2C_SR_SLAVE_TX** (((0x04 & I2C_SR) == 0x04))
State of read/write bit of the received address command (bit 2 of I2SR)
- #define **I2C_CR_TX** (((0x10 & I2C_CR) == 0x10))
Configured for transmit (bit 4 of I2CR)
- #define **I2C_SR_RX_ACK** (((0x01 & I2C_SR) == 0x00))
Received a RX ACK after last transmit (bit 0 of I2SR)
- #define **I2C_CR_RX_ACK** (((0x08 & I2C_CR) == 0x00))
Configured to RX Ack.
- #define **I2C_SET_NO_ACK** ((I2C_CR |= 0x08))
Configure I2C module not to send a RX ACK (bit 3 of I2CR)
- #define **I2C_SET_ACK** ((I2C_CR &= 0xF7))
Configure I2C module to send a RX ACK (bit 3 of I2CR)
- #define **I2C_SET_TX** ((I2C_CR |= 0x10))
Configure I2C module to be in TX mode (bit 4 of I2CR)
- #define **I2C_SET_RX** ((I2C_CR &= 0xEF))
Configure I2C module to be in RX mode (bit 4 of I2CR)
- #define **I2C_SET_REPEAT_START** ((I2C_CR |= 0x04))
Configure I2C to send a repeated start signal.
- #define **I2C_CLR_ARB_LOST** ((I2C_SR &= 0xEF))
Clear Arbitration lost error condition.

14.24.2.1 Detailed Description

Supported platforms:

- MOD54415
- MOD54417
- NANO54415
- SB800EX

The platforms have multiple I2C interfaces called "modules". The available I2C modules available on a particular platform are determined by the connector configuration of that platform. Available I2C module numbers are defined below. Since the processor pins are multiplexed with many other functions, the modules chosen are not sequential. The default module number is 0.

I2C MODULE NUMBERS BY PLATFORM:

- MOD5441x: 0, 1, 2, 4, 5.
- NANO54415: 0, 1, 4, 5.

The most common I2C functions used are listed below. They automatically handle I2C start and stop conditions, as well as checking for I2C bus errors and recovery:

- [MultiChannel_I2CInit \(\)](#)
- [MultiChannel_I2CSendBuf \(\)](#)
- [MultiChannel_I2CReadBuf \(\)](#)
- [I2CMultiChannelResetPeripheral\(\)](#)

14.24.2.2 Function Documentation

14.24.2.2.1 I2CMultiChannelResetPeripheral()

```
void I2CMultiChannelResetPeripheral (
    int moduleNum )
#include <multichanneli2c.h>
Reset the specified I2C peripheral module.
Clears all interrupts, I2C conditions, and releases the bus.
```

Parameters

<i>moduleNum</i>	I2C peripheral module number.
------------------	-------------------------------

14.24.2.2.2 MultiChannel_I2CInit()

```
void MultiChannel_I2CInit (
    int moduleNum = DEFAULT_I2C_MODULE,
    uint8_t slave_Addr = 0x08,
    uint8_t freqdiv = 0x3C )
#include <multichanneli2c.h>
Initialize the I2C peripheral module.
The frequency is based on the internal bus clock of the processor. The formula is: Freq = (250MHZ (sys clock)/2) /
freqdiv to give max baud rate of the master mode I2C bus clock. Values for freqdiv are found in the i2fdr section of
the NXP MCF5441x User Manual.
```

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>slave_Addr</i>	I2C address of the module. If not specified, default value is 0x08.
<i>freqdiv</i>	I2C module frequency divider. If not specified, default value is 0x3C, which is the maximum value of 100KHz.

14.24.2.2.3 MultiChannel_I2CRead()

```
uint8_t MultiChannel_I2CRead (
    int moduleNum,
    uint8_t val,
    uint32_t ticks_to_wait = I2C_RX_TX_TIMEOUT )
#include <multichanneli2c.h>
Read a single byte from the I2C bus.
Reads a single byte from the I2C bus and stores it in val. A start or restart must have been previously issued to
become the bus master, and a stop must be issued to release the bus when you are finished reading the desired
number of bytes.
Does not handle no Ack of last byte, which needs to have a I2C_SET_NO_ACK called before the last read.
```

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>val</i>	Location to store the byte read.

Parameters

<i>ticks_to_wait</i>	Amount of time to wait for a start transmission to complete, specified as system time ticks. The TICKS_PER_SECOND macro can be used with a multiplier or divisor. Includes the time to receive an ack from the I2C device. If not specified, the default time of I2C_RX_TX_TIMEOUT will be used.
----------------------	--

Returns

The state of the I2C bus: [I2C Return Values](#)

14.24.2.2.4 MultiChannel_I2CReadBuf()

```
uint8_t MultiChannel_I2CReadBuf (
    int moduleNum,
    uint8_t addr,
    uint8_t buf,
    int num,
    bool stop = true )
```

```
#include <multichanneli2c.h>
```

Read a number of bytes from an I2C device and store in the specified buffer.

Sends an I2C start, reads the specified number of bytes into buf, and finishes with or without an I2C stop (default is stop). If a stop is not issued, for purposes such as a restart, a stop must be called manually.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>addr</i>	I2C device address.
<i>buf</i>	The buffer to store the data.
<i>num</i>	The number of bytes to read.
<i>stop</i>	Send a stop signal at the end of the transaction. If not specified, the default value is true.

Returns

The state of the I2C bus: [I2C Return Values](#)

14.24.2.2.5 MultiChannel_I2CRestart()

```
uint8_t MultiChannel_I2CRestart (
    int moduleNum,
    uint8_t addr,
    bool Read_Not_Write,
    uint32_t ticks_to_wait = I2C_RX_TX_TIMEOUT )
```

```
#include <multichanneli2c.h>
```

Restart communication with a I2C device.

Restarts communication with an I2C device after completion of a read or write command in which a stop was not issued. Enables communicate on bus again without giving up control as the I2C bus master.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>addr</i>	I2C device address.
<i>Read_Not_Write</i>	Specifies the next bus operation: true = read, false = write.
<i>ticks_to_wait</i>	Amount of time to wait for a start transmission to complete, specified as system time ticks. The TICKS_PER_SECOND macro can be used with a multiplier or divisor. Includes the time to receive an ack from the I2C device. If not specified, the default time of I2C_RX_TX_TIMEOUT will be used.

Returns

The state of the I2C bus: [I2C Return Values](#)

14.24.2.2.6 MultiChannel_I2CSend()

```
uint8_t MultiChannel_I2CSend (
    int moduleNum,
    uint8_t val,
    uint32_t ticks_to_wait = I2C_RX_TX_TIMEOUT )
```

```
#include <multichanneli2c.h>
```

Send a single byte on the I2C bus.

Sends a single byte on the I2C bus. A start or restart must have been previously issued to become the bus master, and a stop must be issued to release the bus when you are finished with writing the desired number of bytes.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>val</i>	Byte to send
<i>ticks_to_wait</i>	Amount of time to wait for a start transmission to complete, specified as system time ticks. The TICKS_PER_SECOND macro can be used with a multiplier or divisor. Includes the time to receive an ack from the I2C device. If not specified, the default time of I2C_RX_TX_TIMEOUT will be used.

Returns

The state of the I2C bus: [I2C Return Values](#)

14.24.2.2.7 MultiChannel_I2CSendBuf()

```
uint8_t MultiChannel_I2CSendBuf (
    int moduleNum,
    uint8_t addr,
    puint8_t buf,
    int num,
    bool stop = true )
```

```
#include <multichanneli2c.h>
```

Send a buffer of bytes to an I2C device.

Sends an I2C start, the bytes in buf, and finishes with or without an I2C stop (default is stop). If a stop is not issued, for purposes such as a restart, a stop must be called manually.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>addr</i>	I2C device address.
<i>buf</i>	The buffer to send.
<i>num</i>	The number of bytes in the buffer.
<i>stop</i>	Send a stop signal at the end of transmission. If not specified, the default value is true.

Returns

The state of the I2C bus: [I2C Return Values](#)

14.24.2.2.8 MultiChannel_I2CStart()

```
uint8_t MultiChannel_I2CStart (
    int moduleNum,
```

```

    uint8_t addr,
    bool Read_Not_Write,
    uint32_t ticks_to_wait = I2C_START_TIMEOUT )
#include <multichanneli2c.h>

```

Send an I2C start to an I2C device to begin communication.

Restarts communication with an I2C device after completion of a read or write command in which a stop was not issued. Enables communicate on bus again without giving up control as the I2C bus master.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>addr</i>	I2C device address.
<i>Read_Not_Write</i>	Specifies the next bus operation: true = read, false = write.
<i>ticks_to_wait</i>	Amount of time to wait for a start transmission to complete, specified as system time ticks. The TICKS_PER_SECOND macro can be used with a multiplier or divisor. Includes the time to receive an ack from the I2C device. If not specified, the default time of I2C_START_TIMEOUT will be used.

Returns

The state of the I2C bus: [I2C Return Values](#)

14.24.2.2.9 MultiChannel_I2CStop()

```

uint8_t MultiChannel_I2CStop (
    int moduleNum = DEFAULT_I2C_MODULE,
    uint32_t ticks_to_wait = I2C_RX_TX_TIMEOUT )
#include <multichanneli2c.h>

```

Issue an I2C stop terminate communication with an I2C device and release the bus.

Terminate any communication and release the I2C bus.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>ticks_to_wait</i>	Amount of time to wait for a start transmission to complete, specified as system time ticks. The TICKS_PER_SECOND macro can be used with a multiplier or divisor. Includes the time to receive an ack from the I2C device. If not specified, the default time of I2C_RX_TX_TIMEOUT will be used.

Returns

The state of the I2C bus: [I2C Return Values](#)

14.24.3 SAME70 I2C

Classes

- class [WireIntf](#)
Wire Interface Class for I2C.
- class [I2C](#)

- class [I2CDevice](#)
I2C Device Class (recommended)

14.24.3.1 Detailed Description

Supported Platforms:

- MODM7AE70
- SBE70LC

The I2C peripheral interfaces can be controlled three ways:

- The I2C Device class (recommended): [I2CDevice](#)
- The I2C Class, which offers additional low level control [I2C](#)
- The Wire Interface Class, which offers a Two Wire Interface API [WireIntf](#)

14.25 IOSYS - I/O System

Typedefs

- typedef void [FDCallback](#)(int fd, [FDChangeType](#) change, void *pData)
Define the function signature for file descriptor notification callbacks.

Functions

- int [close](#) (int fd)
Close the specified file descriptor and free the associated resources.
- int [read](#) (int fd, char *buf, int nbytes)
Read data from a file descriptor (fd).
- int [peek](#) (int fd, char *c)
Peek at the data for the specified file descriptor (fd). Will block forever until at least one byte is available to be read. The byte returned is not removed from the fd buffer, it will be the first byte of data returned on any subsequent read operation.
- int [write](#) (int fd, const char *buf, int nbytes)
Write data to the stream associated with a file descriptor (fd). Can be used to write data to stdio, a TCP socket, or a Serial port.
- int [writestring](#) (int fd, const char *str)
Write a null terminated ascii string to the stream associated with a file descriptor (fd). Can be used to write data to stdio, a TCP socket, or a Serial port.
- int [writeall](#) (int fd, const char *buf, int nbytes=0)
Write the specified number of bytes to a file descriptor. Will block until all bytes are sent, or a file descriptor error occurs (such as a TCP socket error). Can be used to write data to stdio, a TCP socket, or a Serial port.
- int [ReadWithTimeout](#) (int fd, char *buf, int nbytes, unsigned long timeout)
Read data from a file descriptor(fd), or return if at least one byte is not read within the specified timeout. Can be used instead of the [read\(\)](#) function, which will block forever until at least one byte is read. File descriptors include such things as stdio, TCP sockets, TLS sockets, and Serial ports.
- int [ReadWithTickTimeout](#) (int fd, char *buf, int nbytes, [TickTimeout](#) &timeout)
Same as [ReadWithTimeout\(\)](#), except the timeout value parameter is of type [TickTimeout](#) instead of an unsigned long. The [TickTimeout](#) object is more robust in terms of sequential timeout calls and rollover protection.
- int [ReadAllWithTimeout](#) (int fd, char *buf, int nbytes, unsigned long timeout)
Attempt to read the specified number of bytes from a file descriptor, or return with the number of bytes read if the timeout value has expired.
- int [ReadAllWithTickTimeout](#) (int fd, char *buf, int nbytes, [TickTimeout](#) &timeout)
Same as [ReadWithTimeout\(\)](#), except the timeout value parameter is of type [TickTimeout](#) instead of an unsigned long. The [TickTimeout](#) object is more robust in terms of sequential timeout calls and rollover protection.
- int [readall](#) (int fd, char *buf, int nbytes)
Read the specified number of bytes from a file descriptor (fd). This function will block until either the requested number of bytes have been read, or a file descriptor error occurs. It can be used to read from stdio, TCP sockets, or Serial ports.
- int [PeekWithTimeout](#) (int fd, char *c, unsigned long timeout)
This function peeks at data from a file descriptor (fd), with a specified timeout value (as opposed to the peek function which will block forever until at least one byte is available to be read). This function can be used to peek from stdio, TCP sockets, or Serial ports.

- int [getchar](#) ()

Get a character from stdin. Will block if no character is available, from stdio library. The default stdin is the debug serial port.
- int [dataavail](#) (int fd)

Check the specified file descriptor to determine if data is available to be read.
- int [writeavail](#) (int fd)

Check the specified file descriptor to determine data can be written.
- int [haserror](#) (int fd)

Check if a file descriptor has an error.
- int [charavail](#) ()

Checks to see if data is available for read on stdin. By default, stdin is the boot/debug serial port.
- void [RegisterFDCallback](#) (int fd, [FDCallback](#) *fp, void *pData)

Register a callback function to receive notification when an FD state changes. Register a NULL fp to remove the notification.
- void [FD_ZERO](#) (fd_set *pfd)

Clear (set to 0) a fd_set (file descriptor set) so no file descriptors (fds) are selected.
- void [FD_CLR](#) (int fd, fd_set *pfd)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function clears or removes a specific file descriptor in an fd_set.
- void [FD_SET](#) (int fd, fd_set *pfd)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function sets or adds a specific file descriptor to an fd_set.
- int [FD_ISSET](#) (int fd, fd_set *pfd)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function checks whether or not a particular fd is set in the specified fd_set.
- int [FD_OVERLAP](#) (const fd_set *f1, const fd_set *f2)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function determines whether there exists a common file descriptor between the two sets.
- void [FD_COPY](#) (const fd_set *from, fd_set *to)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function copies one file descriptor set to another.
- void [FD_SETFROMSET](#) (const fd_set *from, fd_set *to)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function adds the file descriptors from one set to another.
- void [FD_CLRFROMSET](#) (const fd_set *from, fd_set *to)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function remove the file descriptors in one set from another.
- int [select](#) (int nfds, fd_set *readfds, fd_set *writefds, fd_set *errorfds, unsigned long timeout)

Wait for events to occur on one or more I/O resources associated with a set of file descriptors (fds), such as data available to be read, a resource is available to write data, or an error has occurred.
- int [ZeroWaitSelect](#) (int nfds, fd_set *readfds, fd_set *writefds, fd_set *errorfds)

Returns whether events have occurred on one or more I/O resources associated with a set of file descriptors (fds), and returns immediately.
- int [ioctl](#) (int fd, int cmd)

This function controls the selection of input/output control options for stdio: stdin = 0, stdout = 1 and stderr = 2.
- int [ReplaceStdio](#) (int stdio_fd, int new_fd)

Maps stdio to any file descriptor (fd).
- int [CurrentStdioFD](#) (int stdio_fd)

Returns the current file descriptor mapped to the stdio file descriptor.
- void [IrqStdio](#) ()

Open the system default serial port in interrupt mode using the system default baud rate, and assign this serial port to stdin, stdout and stderr.

FD Change Type

The notifications that a registered FD monitor can receive.

- enum `FDChangeType` { `eReadSet` , `eWriteSet` , `eErrorSet` , `eClosingNow` }

The notifications that a registered FD monitor can receive.

I/O Control Options

The legal options for use with `ioctl()` and in conjunction with `ioctlCmdFlags`

- #define `IOCTL_TX_CHANGE_CRLF` (1)
When set, transmitted char \n gets converted to \r\n
- #define `IOCTL_RX_CHANGE_CRLF` (2)
When set, received \r\n get turned into \n
- #define `IOCTL_RX_PROCESS_EDITS` (4)
When set, process backspace and do simple line editing.
- #define `IOCTL_RX_ECHO` (8)
When set, echo chars received to tx.
- #define `IOCTL_TX_NO_BLOCK` (32)
When set, stdout and stderr will drop output instead of blocking.
- #define `IOCTL_ALL_OPTIONS` (15)
When set, turns on all options.

I/O Control Command Flags

The command flags to use in contuction with `ioctl()` and `ioctlOptions`

- #define `IOCTL_SET` (0x4000)
Set an option.
- #define `IOCTL_CLR` (0x2000)
Clear an option.

14.25.1 Detailed Description

```
#include <iosys.h >
```

I/O system functions use file descriptors for communication and status of network interfaces, serial interfaces, and any custom file descriptors created by an application.

14.25.2 Typedef Documentation

14.25.2.1 FDCallBack

```
typedef void FDCallBack(int fd, FDChangeType change, void *pData)
```

```
#include <iosys.h>
```

Define the function signature for file descriptor notification callbacks.

Parameters

<i>fd</i>	The file descriptor number
<i>change</i>	The reason for the call back, <code>FDChangeType</code>
<i>*pData</i>	A void pointer passed into the register function. Can be used to reference objects or other data

See also

[FDChangeType](#), [RegisterFDCallBack](#)

14.25.3 Enumeration Type Documentation

14.25.3.1 FDChangeType

```
enum FDChangeType
```

```
#include <iosys.h>
```

The notifications that a registered FD monitor can receive.

Enumerator

eReadSet	When read data changes from not available to available.
eWriteSet	When an FD changes from not writable to writeable.
eErrorSet	When an FD goes from no error to having an error.
eClosingNow	when the underlying protocol closes the fd

14.25.4 Function Documentation

14.25.4.1 charavail()

```
int charavail ( )
```

```
#include <iosys.h>
```

Checks to see if data is available for read on stdin. By default, stdin is the boot/debug serial port.

Return values

1	Data available
0	No data available

See also

[dataavail\(\)](#), [getchar\(\)](#), [writeavail\(\)](#), [read\(\)](#)

14.25.4.2 close()

```
int close (
    int fd )
```

```
#include <iosys.h>
```

Close the specified file descriptor and free the associated resources.

Parameters

<i>fd</i>	The file descriptor number
-----------	----------------------------

Returns

0 on success, or a resource specific error on failure.

See also

[peek\(\)](#)

[PeekWithTimeout\(\)](#)

[read\(\)](#)

[ReadWithTimeout\(\)](#)
[write\(\)](#)

14.25.4.3 CurrentStdioFD()

```
int CurrentStdioFD (
    int stdio_fd )
#include <iosys.h>
```

Returns the current file descriptor mapped to the stdio file descriptor.

Parameters

<i>stdio</i> ↔ <i>_fd</i>	The stdio file descriptor to check. Options are stdin (0), stdout (1), and stderr (2).
------------------------------	--

Returns

The current file descriptor mapped to *stdio_fd*

14.25.4.4 dataavail()

```
int dataavail (
    int fd )
#include <iosys.h>
```

Check the specified file descriptor to determine if data is available to be read.

Parameters

<i>fd</i>	The file descriptor number
-----------	----------------------------

Return values

1	Data available
0	No data available

See also

[charavail\(\)](#), [getchar\(\)](#), [peek\(\)](#), [read\(\)](#), [ReadWithTimeout\(\)](#)

14.25.4.5 FD_CLR()

```
void FD_CLR (
    int fd,
    fd_set * pfds )
#include <iosys.h>
```

A *fd_set* (file descriptor set) holds a set of file descriptors (fds). This function clears or removes a specific file descriptor in an *fd_set*.

Parameters

<i>fd</i>	The file descriptor number
* <i>pfds</i>	Pointer to the <i>fd_set</i> to modify

See also

[FD_ZERO\(\)](#), [FD_SET\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.6 FD_CLRFROMSET()

```
void FD_CLRFROMSET (
    const fd_set * from,
    fd_set * to )
```

```
#include <iosys.h>
```

A `fd_set` (file descriptor set) holds a set of file descriptors (fds). This function remove the file descriptors in one set from another.

Parameters

<i>*from</i>	Pointer to the <code>fd_set</code> defining which file descriptors to remove.
<i>*to</i>	Pointer to the <code>fd_set</code> containing file descriptprs to remove.

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.7 FD_COPY()

```
void FD_COPY (
    const fd_set * from,
    fd_set * to )
```

```
#include <iosys.h>
```

A `fd_set` (file descriptor set) holds a set of file descriptors (fds). This function copies one file descriptor set to another.

Parameters

<i>*from</i>	Pointer to the file descriptor set being copied from.
<i>*to</i>	Pointer to the <code>fd_set</code> to copy to.

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.8 FD_ISSET()

```
int FD_ISSET (
    int fd,
    fd_set * pfdset )
```

```
#include <iosys.h>
```

A `fd_set` (file descriptor set) holds a set of file descriptors (fds). This function checks whether or not a particular fd is set in the specified `fd_set`.

For example:

```
if ( FD_ISSET( fdListen, &readFds ) )
{
    // do processing for fdListen
}
```

Parameters

<i>fd</i>	The file descriptor number
<i>*pfdset</i>	A pointer to the <code>fd_set</code> to test

Return values

0	File descriptor is not set in the file descriptor set
>0	File descriptor is set in the file descriptor set

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_SET\(\)](#), [FD_OVERLAP\(\)](#), [select\(\)](#)

14.25.4.9 FD_OVERLAP()

```
int FD_OVERLAP (
    const fd_set * f1,
    const fd_set * f2 )
#include <iosys.h>
```

A `fd_set` (file descriptor set) holds a set of file descriptors (fds). This function determines whether there exists a common file descriptor between the two sets.

Parameters

<i>*f1</i>	Pointer to the first file descriptor set.
<i>*f2</i>	Pointer to the second file descriptor set.

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.10 FD_SET()

```
void FD_SET (
    int fd,
    fd_set * pfdset )
#include <iosys.h>
```

A `fd_set` (file descriptor set) holds a set of file descriptors (fds). This function sets or adds a specific file descriptor to an `fd_set`.

Parameters

<i>fd</i>	The file descriptor number
<i>*pfdset</i>	Pointer to the <code>fd_set</code> to modify

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.11 FD_SETFROMSET()

```
void FD_SETFROMSET (
    const fd_set * from,
    fd_set * to )
#include <iosys.h>
```

A `fd_set` (file descriptor set) holds a set of file descriptors (fds). This function adds the file descriptors from one set to another.

Parameters

<i>*from</i>	Pointer to the file descriptor set being copied from.
<i>*to</i>	Pointer to the fd_set to add to.

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.12 FD_ZERO()

```
void FD_ZERO (
    fd_set * pfdset )
#include <iosys.h>
```

Clear (set to 0) a fd_set (file descriptor set) so no file descriptors (fds) are selected.

Parameters

<i>*pfdset</i>	Pointer to the file descriptor set
----------------	------------------------------------

See also

[FD_CLR\(\)](#), [FD_SET\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.13 getchar()

```
int getchar ( )
#include <iosys.h>
```

Get a character from stdin. Will block if no character is available, from stdio library. The default stdin is the debug serial port.

Returns

Character value (int) from stdin.

See also

[charavail\(\)](#), [dataavail\(\)](#), [peek\(\)](#), [read\(\)](#), [ReadWithTimeout\(\)](#)

14.25.4.14 haserror()

```
int haserror (
    int fd )
#include <iosys.h>
```

Check if a file descriptor has an error.

Parameters

<i>fd</i>	File descriptor number
-----------	------------------------

Return values

1	The file descriptor has an error
0	The file descriptor does not have an error

See also

[dataavail\(\)](#), [writeavail\(\)](#), [charavail\(\)](#)

14.25.4.15 ioctl()

```
int ioctl (
    int fd,
    int cmd )
#include <iosys.h>
```

This function controls the selection of input/output control options for stdio: stdin = 0, stdout = 1 and stderr = 2. The legal options are listed in [ioctlOptions](#).

Parameters

<i>fd</i>	The file descriptor number. The three options are stdin (0), stdout (1), and stderr (2).
<i>cmd</i>	The ioctl command options are ioctlCmdFlags and the bit of the associated options as defined by ioctlOptions .

Returns

The old option value.

```
ioctl(0,IOCTL_SET|IOCTL_ALL_OPTIONS); // Sets all options
ioctl(1,IOCTL_CLR|IOCTL_ALL_OPTIONS); // Clears all options
ioctl(1,IOCTL_SET|IOCTL_RX_CHANGE_CRLF|IOCTL_RX_PROCESS_EDITS); // Sets some options
ioctl(2,IOCTL_CLR|IOCTL_RX_CHANGE_CRLF|IOCTL_RX_PROCESS_EDITS); // Clears some options
```

See also

[ReplaceStdio\(\)](#)

14.25.4.16 peek()

```
int peek (
    int fd,
    char * c )
#include <iosys.h>
```

Peek at the data for the specified file descriptor (fd). Will block forever until at least one byte is available to be read. The byte returned is not removed from the fd buffer, it will be the first byte of data returned on any subsequent read operation.

Parameters

<i>fd</i>	File descriptor
<i>*c</i>	Pointer to the read destination character string

Returns

- 1 on success
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[TCP Socket Status](#), [close\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [write\(\)](#)

14.25.4.17 PeekWithTimeout()

```
int PeekWithTimeout (
    int fd,
    char * c,
    unsigned long timeout )
```

```
#include <iosys.h>
```

This function peeks at data from a file descriptor (fd), with a specified timeout value (as opposed to the peek function which will block forever until at least one byte is available to be read). This function can be used to peek from stdio, TCP sockets, or Serial ports.

The byte returned is *not* removed from the fd. The byte returned will be the first byte of data returned on the first subsequent [read\(\)](#).

Parameters

<i>fd</i>	The file descriptor number
<i>*c</i>	A pointer to the read destination
<i>timeout</i>	The number of time ticks to wait for at least 1 byte of data

Returns

- 1 on success.
- 0 on timeout.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[TCP Socket Status](#), [close\(\)](#), [peek\(\)](#), [read\(\)](#), [ReadWithTimeout\(\)](#), [write\(\)](#)

14.25.4.18 read()

```
int read (
    int fd,
    char * buf,
    int nbytes )
```

```
#include <iosys.h>
```

Read data from a file descriptor (fd).

This function will block forever until at least one byte is available to be read from the input buffer of the specified file descriptor. To wait for a period of time if no data is immediately available in the buffer, please see [ReadWithTimeout\(\)](#). File descriptors include: TCP, UDP, Serial and Extra File Descriptors (EFD). EFDs can be used for custom purposes, such as reading/writing to buffers, or any peripheral custom to your application.

The function will return the number of bytes read, or a negative number if there is an error condition. The error value depends on the type of file descriptor, such as TCP or Serial:

- TCP Status Codes: [TCP Socket Status](#)
- Serial Status Codes: [Serial Port Error Codes](#)

Parameters

<i>fd</i>	The file descriptor number.
<i>*buf</i>	Pointer to the read data destination.
<i>nbytes</i>	Maximum number of bytes to read.

Returns

- Number of bytes read
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[TCP Socket Status](#), [close\(\)](#), [peek\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [ReadAllWithTimeout\(\)](#), [readall\(\)](#), [write\(\)](#)

14.25.4.19 readall()

```
int readall (
    int fd,
    char * buf,
    int nbytes )
```

```
#include <iosys.h>
```

Read the specified number of bytes from a file descriptor (fd). This function will block until either the requested number of bytes have been read, or a file descriptor error occurs. It can be used to read from stdio, TCP sockets, or Serial ports.

Parameters

<i>fd</i>	File descriptor
<i>*buf</i>	Pointer to the read destination buffer
<i>nbytes</i>	Number of bytes to read

Returns

- Number of bytes read.
- 0 on timeout.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [ReadAllWithTimeout\(\)](#), [write\(\)](#)

14.25.4.20 ReadAllWithTickTimeout()

```
int ReadAllWithTickTimeout (
    int fd,
    char * buf,
    int nbytes,
    TickTimeout & timeout )
```

```
#include <iosys.h>
```

Same as [ReadWithTimeout\(\)](#), except the timeout value parameter is of type [TickTimeout](#) instead of an unsigned long. The [TickTimeout](#) object is more robust in terms of sequential timeout calls and rollover protection.

This function can be used to read from stdio, TCP sockets, or Serial ports. This function will block until on of the following conditions occurs:

- The requested number of bytes have been read.
- The timeout expires. The number of bytes read are returned, and buf contains the data.
- An error occurs on the file descriptor, such as a TCP socket error.

Note

The return value must be checked to verify the number of bytes read and that a timeout or error did not occur.

Parameters

<i>fd</i>	The file descriptor number
<i>*buf</i>	A pointer to the read destination
<i>nbytes</i>	Number of bytes to read
<i>timeout</i>	A reference to the timeout value of type TickTimeout .

Returns

- Number of bytes read.
- 0 on timeout.
- Negative value on error. Error value is determined by the type of *fd*, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [ReadAllWithTimeout\(\)](#), [readall\(\)](#), [write\(\)](#)

14.25.4.21 ReadAllWithTimeout()

```
int ReadAllWithTimeout (
    int fd,
    char * buf,
    int nbytes,
    unsigned long timeout )
#include <iosys.h>
```

Attempt to read the specified number of bytes from a file descriptor, or return with the number of bytes read if the timeout value has expired.

This function can be used to read from stdio, TCP sockets, or Serial ports. This function will block until on of the following conditions occurs:

- The requested number of bytes have been read.
- The timeout expires. The number of bytes read are returned, and *buf* contains the data.
- An error occurs on the file descriptor, such as a TCP socket error.

Note

The return value must be checked to verify the number of bytes read and that a timeout or error did not occur.

Parameters

<i>fd</i>	The file descriptor number
<i>*buf</i>	A pointer to the read destination
<i>nbytes</i>	Number of bytes to read
<i>timeout</i>	The number of timer ticks to wait for data

Returns

- Number of bytes read.
- 0 on timeout.

- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [ReadAllWithTickTimeout\(\)](#), [ReadWithTickTimeout\(\)](#), [readall\(\)](#), [write\(\)](#)

14.25.4.22 ReadWithTickTimeout()

```
int ReadWithTickTimeout (
    int fd,
    char * buf,
    int nbytes,
    TickTimeout & timeout )
#include <iosys.h>
```

Same as [ReadWithTimeout\(\)](#), except the timeout value parameter is of type [TickTimeout](#) instead of an unsigned long. The [TickTimeout](#) object is more robust in terms of sequential timeout calls and rollover protection.

Note

This function operates like the [read](#) function in that it reads all available bytes up to the maximum and returns. The addition of a timeout does not cause the function to block until the specified maximum number of bytes are available. As with [read](#), the application must use the return value of the [ReadWithTimeout](#) function to determine how many bytes were read, and call the function again if necessary.

When using with a TCP socket, you may want to use the [SockReadWithTimeout\(\)](#) function, which returns additional values related to network connections.

Parameters

<i>fd</i>	The file descriptor number.
<i>*buf</i>	A pointer to the read destination.
<i>nbytes</i>	Maximum number of bytes to read.
<i>timeout</i>	A reference to the timeout value of type TickTimeout .

Returns

- Number of bytes read.
- 0 on timeout.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [ReadAllWithTimeout\(\)](#), [readall\(\)](#), [SockReadWithTimeout\(\)](#), [write\(\)](#)

14.25.4.23 ReadWithTimeout()

```
int ReadWithTimeout (
    int fd,
    char * buf,
    int nbytes,
    unsigned long timeout )
#include <iosys.h>
```

Read data from a file descriptor(fd), or return if at least one byte is not read within the specified timeout. Can be used instead of the [read\(\)](#) function, which will block forever until at least one byte is read. File descriptors include such things as stdio, TCP sockets, TLS sockets, and Serial ports.

Note

This function operates like the read function in that it reads all available bytes up to the maximum and returns. The addition of a timeout does not cause the function to block until the specified maximum number of bytes are available. As with read, the application must use the return value of the ReadWithTimeout function to determine how many bytes were read, and call the function again if necessary.

When using with a TCP socket, you may want to use the [SockReadWithTimeout\(\)](#) function, which returns additional values related to network connections.

Parameters

<i>fd</i>	The file descriptor number.
<i>*buf</i>	A pointer to the read destination.
<i>nbytes</i>	Maximum number of bytes to read.
<i>timeout</i>	The number of timer ticks to wait for data.

Returns

- Number of bytes read.
- 0 on timeout.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTickTimeout\(\)](#), [ReadAllWithTimeout\(\)](#), [readall\(\)](#), [SockReadWithTimeout\(\)](#), [write\(\)](#)

14.25.4.24 RegisterFDCallback()

```
void RegisterFDCallback (
    int fd,
    FDCallback * fp,
    void * pData )
#include <iosys.h>
```

Register a callback function to receive notification when an FD state changes. Register a NULL fp to remove the notification.

Parameters

<i>fd</i>	The file descriptor number
<i>*fp</i>	The function pointer to call back
<i>*pData</i>	A void * passed to the callback function, can be used for any purpose, such as object references

See also

[FDChangeType](#), [FDCCallback](#)

14.25.4.25 ReplaceStdio()

```
int ReplaceStdio (
    int stdio_fd,
    int new_fd )
#include <iosys.h>
```

Maps stdio to any file descriptor (fd).

If the file descriptor generates an error (such as a closed TCP connection), then `stdio` will be remapped to a negative `fd` (this will cause `stdio` to generate errors). When this function is used to remap a `stdio` channel that has errored, then the error will be cleared.

Parameters

<code>stdio↔ _fd</code>	The <code>stdio</code> file descriptor to map to. Options are <code>stdin</code> (0), <code>stdout</code> (1), and <code>stderr</code> (2).
<code>new_fd</code>	The file descriptor to replace <code>stdio</code> with. A value of 0 returns <code>stdio</code> to the default debug monitor based traps.

Return values

0	If <code>stdio</code> had not been previously mapped
>0	The value of the <code>fd</code> for the previous <code>stdio</code> override

See also

[ioctl\(\)](#)

14.25.4.26 select()

```
int select (
    int nfds,
    fd_set * readfds,
    fd_set * writefds,
    fd_set * errorfds,
    unsigned long timeout )
#include <iosys.h>
```

Wait for events to occur on one or more I/O resources associated with a set of file descriptors (`fds`), such as data available to be read, a resource is available to write data, or an error has occurred.

The most common use for this function is to monitor multiple serial and/or TCP file descriptors at one time to read incoming data. For example, an application could use a single RTOS task and a `select()` to process incoming data on multiple TCP sockets at one time, instead of using multiple tasks or looping through each `fd` sequentially.

The file descriptors of interest are specified with file descriptor sets (`fds`) for read, write and error conditions. `select()` will block until one of the `fd` conditions are true, or the specified timeout occurs (a value of 0 blocks forever). For example, if the `readfds` is used for multiple TCP sockets, `select()` will return if data is available to read on one or more of them. The application would then use macros such as `FD_ISSET()` to handle reading the data.

Note

A timeout value can be used to cause `select()` to return periodically for any type of processing an application would like to do in the event no activity is occurring on the `fd` sets.

Parameters

<code>nfds</code>	The number of file descriptors to examine (This parameter is currently ignored)
<code>*readfds</code>	Pointer to the <code>fd_set</code> to select for read events, or null if no read events are to be monitored. It is modified on exit to reflect the read availability of the selected <code>fds</code> in the set.
<code>*writefds</code>	Pointer to the <code>fd_set</code> to select for write availability events, or null if no events are to be monitored. If non-null, it is modified on exit to reflect the write availability of the selected <code>fds</code> in the set.
<code>*errorfds</code>	Pointer to the <code>fd_set</code> to select for error events, or null if no error events are to be monitored. It is modified on exit to reflect the error state of the selected <code>fds</code> in the set.
<code>timeout</code>	The number of system time ticks to wait before timing out if no events occurred in the selected <code>fd</code> sets. Note: The <code>TICKS_PER_SECOND</code> multiplier should be used to specify the timeout in seconds. For example, <code>TICKS_PER_SECOND * 5</code> to specify a timeout of 5 seconds.

Return values

0	Timeout occurred
>0	The number of fds in all of the non-null fd_sets

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_SET\(\)](#), [FD_ISSET\(\)](#)

14.25.4.27 write()

```
int write (
    int fd,
    const char * buf,
    int nbytes )
```

```
#include <iosys.h>
```

Write data to the stream associated with a file descriptor (fd). Can be used to write data to stdio, a TCP socket, or a Serial port.

Note

The function will block until at least 1 byte is written, but will not write all requested bytes if there is not enough space in the write buffer. The return value must always be checked to verify the number of bytes written.

Parameters

<i>fd</i>	File descriptor
<i>*buf</i>	Pointer to the buffer to write
<i>nbytes</i>	Maximum number of bytes to write

Returns

- The number of bytes written to write buffer.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [writestring\(\)](#), [writeall\(\)](#)

14.25.4.28 writeall()

```
int writeall (
    int fd,
    const char * buf,
    int nbytes = 0 )
```

```
#include <iosys.h>
```

Write the specified number of bytes to a file descriptor. Will block until all bytes are sent, or a file descriptor error occurs (such as a TCP socket error). Can be used to write data to stdio, a TCP socket, or a Serial port.

Note

The function will block until at least 1 byte is written, but will not write all requested bytes if there is not enough space in the write buffer. The return value must always be checked to verify the number of bytes written.

Parameters

<i>fd</i>	File descriptor
<i>*buf</i>	Pointer to the buffer to write
<i>nbytes</i>	Maximum number of bytes to write

Returns

- The number of bytes written to write buffer.
- Negative value on error. Error value is determined by the type of *fd*, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [write\(\)](#), [writestring\(\)](#)

14.25.4.29 writeavail()

```
int writeavail (
    int fd )
#include <iosys.h>
```

Check the specified file descriptor to determine data can be written.

Parameters

<i>fd</i>	File descriptor number
-----------	------------------------

Return values

1	Data can be written
0	Data cannot be written, such as when an output buffer is full

See also

[dataavail\(\)](#), [charavail\(\)](#), [haserror\(\)](#)

14.25.4.30 writestring()

```
int writestring (
    int fd,
    const char * str )
#include <iosys.h>
```

Write a null terminated ascii string to the stream associated with a file descriptor (*fd*). Can be used to write data to *stdio*, a TCP socket, or a Serial port.

Note

The function will block until at least 1 byte is written, but will not write all requested bytes if there is not enough space in the write buffer. The return value must always be checked to verify the number of bytes written.

Parameters

<i>fd</i>	File descriptor
<i>*str</i>	Pointer to the null terminated string to write

Returns

- The number of bytes written to write buffer.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [write\(\)](#), [writeall\(\)](#)

14.25.4.31 ZeroWaitSelect()

```
int ZeroWaitSelect (
    int nfds,
    fd_set * readfds,
    fd_set * writefds,
    fd_set * errorfds )
```

```
#include <iosys.h>
```

Returns whether events have occurred on one or more I/O resources associated with a set of file descriptors (fds), and returns immediately.

Parameters

<i>nfds</i>	The number of file descriptors to examine. Note: This parameter is currently ignored.
<i>*readfds</i>	A pointer to the fd_set to select for read events. Note: This parameter can be NULL. It is modified on exit to reflect the read availability of the selected fds in the set.
<i>*writefds</i>	A pointer to the fd_set to select for write availability events. Note: This parameter can be NULL. It is modified on exit to reflect the write availability of the selected fds in the set.
<i>*errorfds</i>	A pointer to the fd_set to select for error events. Note: This parameter can be NULL. It is modified on exit to reflect the error state of the selected fds in the set.

Return values

0	If there is no valid fds
>0	The number of fds in all of the non null fd_sets

14.26 IP

Definitions for various IP definitions and structures.

Topics

- [IPADDR4 Class](#)
- [IPADDR6 Class](#)

Classes

- struct [_IpHeaderIPv4](#)
IP Header (IPv4)
- struct [IPPKT](#)
Internal IPv4 Header.

- struct [UDPPKT](#)
Internal UDP Header.
- struct [PsudeoHeader](#)
UDP IPv4 Pseudo-header segment (bits 0 through 95)

Macros

- #define **ICMP_PING_DATA_SIZE** (32)
size for ICMP echo request and replay ("ping")

Typedefs

- typedef struct [_IpHeaderIPv4](#) [IpHeaderIPv4](#)
IP Header (IPv4)

Functions

- void **IpProcessEthernetPacket** (PoolPtr poolPtr, uint16_t packetSizeInBytes)
IP packet insertion for processing.
- uint16_t **GetSum** (puint16_t addr, uint16_t count)
Checksum.
- uint16_t **GetSum20** (puint32_t addr)
Checksum.
- uint16_t **GetSumHdr** ([PsudeoHeader](#) &hdr, puint16_t addr, uint16_t count)
Checksum using pseudo-header.
- BOOL **IsMyIp4** ([IPADDR4](#) ip, int ifc=-1)
Is this my IP address?
- [IPADDR4](#) **GetSrcIp4** ([IPADDR4](#) dst)
Get source IP address for this destination.
- [IPADDR4](#) **GetSrcIpwlf4** (int ifn, const [IPADDR4](#) dst)
- BOOL **IsMyIp** (const [IPADDR](#) &ip, int ifc=-1)
Is this my IP address?
- [IPADDR](#) **GetSrcIp** (const [IPADDR](#) &dst)
Get source IP address for this destination.
- [IPADDR](#) **GetSrcIpwlf** (int ifn, const [IPADDR](#) &dst)
Get source IP address for an interface.
- void **SendICMPError** (PoolPtr pBadPacket, uint8_t type, uint8_t code)
Send ICMP error.
- void **FixHeaderAndSend** (PoolPtr p, [PIPPKT](#) plp)
Complete header and send on primary network interface.
- void **FixHeaderAndSendViaInterface** (PoolPtr p, [PIPPKT](#) plp, int Interface)
Complete header and send on an interface.
- void **InitializeStack** ()
Initializes the IP stack.
- int **AddInterface** ([IPADDR4](#) addr, [IPADDR4](#) mask, [IPADDR4](#) gateway, int root_if)
Add an interface with an interface number.

Global Data

- uint8_t **bTTL_Default**
Default number of hops (time to live)
- uint16_t **wArpLifetime**
ARP lifetime in seconds.
- BOOL **bQuietStart**
Quiet start.

Get Packet Functions

WARNING:

If you use these functions on an uninitialized buffer you will get bogus values for the pointer as the header length field in the IP packet is not yet set up!

- **PIPPKT GetIpPkt** (PoolPtr p)
Get IP Packet pointer from network buffer pool buffer.
- **PIPPKT GetIpPkt** (PEFRAME pFrame)
Get IP packet pointer from pointer to frame.
- **PIPPKT GetIpPkt** (PVLEFRAME pFrame)
Get IP Packet pointer from network buffer pool buffer.
- **PUDPPKT GetUdpPkt** (PIPPKT plp)
Get UDP packet pointer from IP packet pointer.

IP Version

Uncomment for debugging

- #define **IP_VERSION_MASK** (0xF0)
Version Mask.
- #define **IP_VERSION_IPv4** (0x40)
IPv4.
- #define **IP_VERSION_IPv6** (0x60)
IPv6.

Header Length

- #define **IP_HEADER_LENGTH_MASK** (0x0F)
- #define **IP_HEADER_LENGTH_NO_OPTIONS** (0x05)

Flags and Fragment Offset

- #define **IP_FLAGS_MASK** (0xE000)
- #define **IP_FRAGMENT_OFFSET_MASK** (0x1FFF)

IP protocol numbers

- #define **IP_PROTOCOL_ICMP** (0x01)
- #define **IP_PROTOCOL_IGMP** (0x02)
- #define **IP_PROTOCOL_INTERNET** (0x04)
- #define **IP_PROTOCOL_TCP** (0x06)
- #define **IP_PROTOCOL_UDP** (0x11)

control message type(s) and code(s)

- #define **ICMP_TYPE_ECHO_REPLY** (0)
- #define **ICMP_CODE_ECHO_REPLY** (0)
- #define **ICMP_TYPE_DEST_UNREACHABLE** (3)
- #define **ICMP_CODE_PORT_UNREACHABLE** (3)
- #define **ICMP_TYPE_SOURCE_QUENCH** (4)
- #define **ICMP_CODE_SOURCE_QUENCH** (0)
- #define **ICMP_TYPE_REDIRECT_MESSAGE** (5)
- #define **ICMP_TYPE_ECHO_REQUEST** (8)
- #define **ICMP_CODE_ECHO_REQUEST** (0)

Well Known Ports

- #define [IANA_ECHO_PORT](#) (7)
- #define [IANA_DISCARD_PORT](#) (9)
- #define [IANA_SSH_PORT](#) (22)
- #define [IANA_TELNET_PORT](#) (23)
- #define [IANA_NETBIOS_NAME_SERVICE_PORT](#) (137)

14.26.1 Detailed Description

Definitions for various IP definitions and structures.

```

#include <ip.h>
```

14.26.2.23 IP_PROTOCOL_UDP

```
#define IP_PROTOCOL_UDP (0x11)
#include <ip.h>
```

14.26.3 Typedef Documentation**14.26.3.1 IpHeaderIPv4**

```
typedef struct _IpHeaderIPv4 IpHeaderIPv4
#include <ip.h>
```

IP Header (IPv4)

Can contain options, determined by header length. No options header length is 5 for 5 32 bit words (20 bytes)
IETF RFC 791 September 1981, MIL-STD-1777

14.26.4 Function Documentation**14.26.4.1 AddInterface()**

```
int AddInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
    int root_if = 0 ) [inline]
```

```
#include <ip.h>
```

Add an interface with an interface number.

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>root_if</i>	Optional root physical interface number. If not specified the default is 0, for Ethernet 0.

returns Interface number of newly created interface

14.26.4.2 GetIpPkt()

```
PIPPKT GetIpPkt (
    PVLEFRAME pFrame ) [inline]
```

```
#include <ip.h>
```

Get IP Packet pointer from network buffer pool buffer.

14.26.4.3 GetSrcIpwIf4()

```
IPADDR4 GetSrcIpwIf4 (
    int ifn,
    const IPADDR4 dst )
```

```
#include <ip.h>
```

14.26.4.4 InitializeStack()

```
void InitializeStack ( )
```

```
#include <ip.h>
```

Initializes the IP stack.

Should be called once and only once before UserMain resets its priority. The default settings cause the configuration record settings to be used. This provides the network infrastructure for additional network interfaces.

14.26.5 IPADDR4 Class

Classes

- class [MACADR](#)
Used to store and manipulate MAC addresses.
- class [IPADDR4](#)
Used to store and manipulate IPv4 addresses in dual stack mode.

Typedefs

- typedef class [MACADR](#) **MACADR**
Used to store and manipulate MAC addresses.
- typedef [IPADDR6](#) **IPADDR**
IPADDR Object Type (either v4 or v6)

Functions

- bool **operator==** (const [MACADR](#) &i, const [MACADR](#) &j)
Check MAC equality.
- bool **operator!=** (const [MACADR](#) &i, const [MACADR](#) &j)
Check MAC inequality.
- bool **operator>** (const [MACADR](#) &i, const [MACADR](#) &j)
Check MAC greater than.

14.26.5.1 Detailed Description

```
#include< nettypes.h >
```

The IPADDR C++ objects were created to provide a portable and easy implementation to support IPv4 and IPv6 IP addresses. There are 3 types of IPADDR objects:

- [IPADDR4](#): Used exclusively for IPv4 addresses
- [IPADDR](#): Used for either an IPv6 or IPv4 address
- **IPADDR**: The typedef [IPADDR](#) is defines a type IPADDR. Its purpose is to provide clarity that an IPADDR object can be used for both IPv4 and IPv6 addresses. Any functions called with a parameter of type IPADDR will automatically execute the correct IPv4 or IPv6 underling function.

14.26.6 IPADDR6 Class

Classes

- class [IPADDR6](#)
Used to hold and manipulate IPv4 and IPv6 addresses in dual stack mode.

14.26.6.1 Detailed Description

```
#include< ipv6_addr.h >
```

The IPADDR C++ objects were created to provide a portable and easy implementation to support IPv4 and IPv6 IP addresses. There are 3 types of IPADDR objects:

- [IPADDR4](#): Used exclusively for IPv4 addresses

- **IPADDR6**: Used for either an IPv6 or IPv4 address
- **IPADDR**: The typedef **IPADDR** defines a type **IPADDR6**. Its purpose is to provide clarity that an **IPADDR** object can be used for both IPv4 and IPv6 addresses. Any functions called with a parameter of type **IPADDR** will automatically execute the correct IPv4 or IPv6 underlying function.

14.27 Initialization - System Initialization Functions

Functions

- void **init** ()
System initialization. Ideally called at the beginning of all applications, since the easiest Recovery procedures pause execution inside of `init`, which is impossible if there is a crash before `init`.
- void **StartHttp** (uint16_t port=80)
Start the HTTP web server.
- void **StartHttps** (uint16_t ssl_port=443, uint16_t http_port=80)
Start the HTTPS secure web server.
- bool **WaitForActiveNetwork** (uint32_t ticks_to_wait=120 ***TICKS_PER_SECOND**, int interface=-1)
Wait for an active network connection on at least one interface.
- void **EnableSystemDiagnostics** ()
Turn on the diagnostic reports from the config page.
- void **EnableSecureConfigServer** (bool bSec_Only)
Enable the minimal http config server to operate over TLS.

14.27.1 Detailed Description

#include <init.h >

14.27.2 Function Documentation

14.27.2.1 EnableSecureConfigServer()

```
void EnableSecureConfigServer (
    bool bSec_Only )
```

```
#include <init.h>
```

Enable the minimal http config server to operate over TLS.

Due to the nature of the server operating on a non-standard HTTP port, a client (such as a webbrowser) cannot infer whether to utilize TLS unless explicitly told to do so. Therefore, the secure configuration server has two modes it can operate in: a less secure, more compliant manner that allows both plaintext and TLS secured transactions and a HSTS (Http Strict Transport Security) mode that will only respond to plaintext requests with a redirect indicating the TLS requirement.

Parameters

<code>bSec_Only</code>	Whether the SecureConfigServer should disallow non-secure requests
------------------------	--

14.27.2.2 EnableSystemDiagnostics()

```
void EnableSystemDiagnostics ( )
```

```
#include <init.h>
```

Turn on the diagnostic reports from the config page.

This should be used under development. In production it has no performance impact, but could leak possibly sensitive information.

14.27.2.3 `init()`

```
void init ( )
#include <init.h>
```

System initialization. Ideally called at the beginning of all applications, since the easiest Recovery procedures pause execution inside of `init`, which is impossible if there is a crash before `init`.

Initialize the system including the following:

- Enable interrupt driven stdio
- Read the configuration record and set parameters accordingly. If the configuration specifies `DHCP`, start the `DHCP` Client. All interfaces will be checked.
- Initialize the network stack
- Start the configuration server for both web and serial
- Assign the `UserMain()` task priority to `MAIN_PRIOR`
- Enable the Task Monitor diagnostic tool
- Initialize the GDB stub if in debug mode

14.27.2.4 `StartHttp()`

```
void StartHttp (
    uint16_t port = 80 )
#include <init.h>
```

Start the HTTP web server.

If no parameters are specified it will listen on port 80, and enable the configuration mirror feature so an application can create its own custom configuration web page.

Parameters

<code>port</code>	Listen port, defaults to port 80
-------------------	----------------------------------

See also

[StartHttps\(\)](#), [StopHttp\(\)](#)

14.27.2.5 `StartHttps()`

```
void StartHttps (
    uint16_t ssl_port = 443,
    uint16_t http_port = 80 )
#include <init.h>
```

Start the HTTPS secure web server.

If no parameters are specified the web server will listen on ports 443 and 80, and enable the configuration mirror feature so an application can create its own custom configuration web page. If no user key is installed the default system key will be used.

Parameters

<code>ssl_port</code>	Secure listen port, defaults to port 443
<code>http_port</code>	Non-secure listen port, defaults to port 80

See also

[StartHttp\(\)](#), [StopHttp\(\)](#)

14.27.2.6 WaitForActiveNetwork()

```
bool WaitForActiveNetwork (
    uint32_t ticks_to_wait = 120 *TICKS_PER_SECOND,
    int interface = -1 )
#include <init.h>
```

Wait for an active network connection on at least one interface.

If [DHCP](#) is enabled it will wait for a lease. If static IP parameters are configured it will wait for link.

Parameters

<i>ticks_to_wait</i>	Number of system time ticks to wait. Default is 120 seconds.
<i>interface</i>	Interface number to check. Default is -1, which checks all interfaces.

14.28 Interrupt Macro - ColdFire

Macro for ColdFire platforms to set up an interrupt function handler including entry and exit code.

14.28.1 Detailed Description

Macro for ColdFire platforms to set up an interrupt function handler including entry and exit code.

Parameters

<i>x</i>	need to add
<i>y</i>	need to add

Example Usage:

```
INTERRUPT(timetick) { // Interrupt handler code goes here.. }
```

The example exposes the symbol `timetick` that can be used as a function pointer to put in the vector base register array.

14.29 JSON Lexer

NetBurner's JSON library. See more details and examples below.

Classes

- struct [JsonAllocString](#)
A list of large strings that are created with malloc.
- class [JsonRef](#)
Represents a positional reference (pointer) of a location inside a [ParsedJsonDataSet](#) object
- class [ParsedJsonDataSet](#)
A class to create, read, and modify a JSON object.
- class [JsonLexerFDAdapter](#)
Get the type name of the JSON primitive type passed in.

Typedefs

- typedef void [CharOutputFn](#)(const char *chars, int len, void *blob)

Helper function typedef for print functions.

Enumerations

- enum [json_primitive_type](#) {
[UNDEFINED](#) , [BEGIN_ARRAY](#) , [BEGIN_OBJECT](#) , [END_ARRAY](#) ,
[END_OBJECT](#) , [NAME](#) , [STRING](#) , [VALUE_SEPERATOR](#) ,
[NUMBER](#) , [FALSE_EL](#) , [TRUE_EL](#) , [NULL_EL](#) ,
[STRING_TOO_BIG](#) , [ALLOC_STRING](#) , [NOTFOUND](#) , [EOF_EL](#) }

The following types define the basic building blocks that make up a JSON data set. These are the values that will be returned from the functions used to parse the data set. Member functions include operators to return specific data type, as well as type validity checks.

14.29.1 Detailed Description

NetBurner's JSON library. See more details and examples below.

```
#include <json\_lexer.h>
```

The library enables rapid, performant parsing, traversal, and querying of JSON data. It also works seamlessly as a `buffer_object` for the [Web Client's DoGet\(\)](#) function.

[ParsedJsonDataSet](#) is the root object that holds the document, and [JsonRef](#) is the result of each query function, serving as a pointer to a location in the document but also as a chainable query and inspection interface.

See also the [JSON Lexer Example Applications](#).

Example

```
ParsedJsonDataSet pjd;
bool result = DoGet("https://www.example.com/users.json", pjd);
// pjd.PrintObject(true);
// pjd("users").PrintChildren(true);
if (!result ||
    !pjd("users")[0].IsObject() ||
    !pjd("users")[0]("id").IsNumber() ||
    !pjd("users")[0]("name").IsString()
) {
    return false;
}
printf("Got user %d name %s",
       (int)pjd("users")[0]("id"),
       (const char *)pjd("users")[0]("name")
);
```

14.29.2 Typedef Documentation

14.29.2.1 CharOutputFn

```
typedef void CharOutputFn(const char *chars, int len, void *blob)
```

```
#include <json\_lexer.h>
```

Helper function typedef for print functions.

Parameters

<i>chars</i>	The characters to print.
<i>len</i>	The length of the characters to print.
<i>blob</i>	A pointer to where they should be printed.

14.29.3 Enumeration Type Documentation

14.29.3.1 json_primitive_type

```
enum json_primitive_type
#include <json_lexer.h>
```

The following types define the basic building blocks that make up a JSON data set. These are the values that will be returned from the functions used to parse the data set. Member functions include operators to return specific data type, as well as type validity checks.

Enumerator

UNDEFINED	Not a defined primitive type. This indicates an error somewhere.
BEGIN_ARRAY	[- Signals the start of an array.
BEGIN_OBJECT	{ - Signals the start of an object.
END_ARRAY] - Signals the end of an array.
END_OBJECT	} - Signals the end of an object.
NAME	"xxx": - Signals the name of a name/value pair.
STRING	"xxx" - An element with a string value.
VALUE_SEPERATOR	, - Signals the separation between to arrays, objects, or values.
NUMBER	An element with a number value.
FALSE_EL	An element with the value false.
TRUE_EL	An element with the value true.
NULL_EL	An element with the null value.
STRING_TOO_BIG	Error, we got a sting but it was too big to fit in the storage scheme (1500 bytes).
ALLOC_STRING	We allocated a large string.
NOTFOUND	Return value when we don't find what we are looking for.
EOF_EL	Last token in the data set.

14.30 Multicast

Functions

- void [RegisterMulticastFifo4](#) (IPADDR4 group, uint16_t dest_port, OS_FIFO *pfifo, int interface=0)
Register to join a Multicast group.
- void [UnregisterMulticastFifo4](#) (IPADDR4 group, uint16_t destination_port, int interface=0)
Unregister from a Multicast group.
- void [RegisterMulticastFifo6](#) (IPADDR group, uint16_t dest_port, OS_FIFO *pfifo, int interface=0)
Register to join a Multicast group.
- void [UnregisterMulticastFifo6](#) (IPADDR group, uint16_t destination_port, int interface=0)
Unregister from a Multicast group.

14.30.1 Detailed Description

```
#include< multicast.h >
```

The NetBurner Multicast API

14.30.2 Function Documentation

14.30.2.1 RegisterMulticastFifo4()

```
void RegisterMulticastFifo4 (
    IPADDR4 group,
```

```

uint16_t dest_port,
OS_FIFO * pfifo,
int interface = 0 )

```

```
#include <multicast.h>
```

Register to join a Multicast group.

Calling RegisterMulticastFifo() in dual stack mode will automatically select the correct IPv4/IPv6 function.

IGMP Multicast is a method for distributing UDP packets within a group of hosts and servers. The NetBurner Multicast functions extend the NetBurner UDP interface. Instead of [RegisterUDPFifo\(\)](#), the RegisterMulticastFifo() function is used to listen for Multicast UDP packets. To transmit Multicast packets, use the UDP Send function with a multicast IP address.

Parameters

<i>group</i>	The IP address of the group to join
<i>dest_port</i>	The port number of the group to join
<i>pfifo</i>	Pointer to the FIFO to store incoming packets
<i>interface</i>	Optional interface number. If not specified or 0, the first system interface will be used.

See also

[UnregisterMulticastFifo4\(\)](#)

14.30.2.2 RegisterMulticastFifo6()

```

void RegisterMulticastFifo6 (
    IPADDR group,
    uint16_t dest_port,
    OS_FIFO * pfifo,
    int interface = 0 )

```

```
#include <multicast.h>
```

Register to join a Multicast group.

Calling RegisterMulticastFifo() in dual stack mode will automatically select the correct IPv4/IPv6 function.

IGMP Multicast is a method for distributing UDP packets within a group of hosts and servers. The NetBurner Multicast functions extend the NetBurner UDP interface. Instead of [RegisterUDPFifo\(\)](#), the RegisterMulticastFifo() function is used to listen for Multicast UDP packets. To transmit Multicast packets, use the UDP Send function with a multicast IP address.

Parameters

<i>group</i>	The IP address of the group to join
<i>dest_port</i>	The port number of the group to join
<i>pfifo</i>	Pointer to the FIFO to store incoming packets
<i>interface</i>	Optional interface number. If not specified or 0, the first system interface will be used.

See also

[UnregisterMulticastFifo4\(\)](#)

14.30.2.3 UnregisterMulticastFifo4()

```

void UnregisterMulticastFifo4 (
    IPADDR4 group,
    uint16_t destination_port,
    int interface = 0 )

```

```
#include <multicast.h>
```

Unregister from a Multicast group.

Calling `UnregisterMulticastFifo()` in dual stack mode will automatically select the correct IPv4/IPv6 function.

Parameters

<code>group</code>	The IP address of the group to leave
<code>destination_port</code>	The port number of the group to leave
<code>interface</code>	Specifies the interface number, the default is 0

See also

[RegisterMulticastFifo4\(\)](#)

14.30.2.4 UnregisterMulticastFifo6()

```
void UnregisterMulticastFifo6 (
    IPADDR group,
    uint16_t destination_port,
    int interface = 0 )
```

```
#include <multicast.h>
```

Unregister from a Multicast group.

Calling `UnregisterMulticastFifo()` in dual stack mode will automatically select the correct IPv4/IPv6 function.

Parameters

<code>group</code>	The IP address of the group to leave
<code>destination_port</code>	The port number of the group to leave
<code>interface</code>	Optional interface number. If not specified or 0, the first system interface will be used.

[RegisterMulticastFifo4\(\)](#)

14.31 Multihome and VLAN

Functions

- int [AddVlanInterface](#) (IPADDR4 addr, IPADDR4 mask, IPADDR4 gateway, uint16_t vlan_tag, const char *ParentName)
Add a VLAN interface with a Parent Name.
- int [AddVlanInterface](#) (IPADDR4 addr, IPADDR4 mask, IPADDR4 gateway, uint16_t vlan_tag, [InterfaceBlock](#) &parent)
Add a VLAN interface with a Parent [InterfaceBlock](#) reference.
- int [AddVlanInterface](#) (IPADDR4 addr, IPADDR4 mask, IPADDR4 gateway, uint16_t vlan_tag, int root_if=0)
Add a VLAN interface with an interface number.
- int [AddInterface](#) (IPADDR4 addr, IPADDR4 mask, IPADDR4 gateway, const char *ParentName)
Add an interface with a Parent Name.
- int [AddInterface](#) (IPADDR4 addr, IPADDR4 mask, IPADDR4 gateway, [InterfaceBlock](#) &parent)
Add an interface with a Parent [InterfaceBlock](#) reference.
- int [AddInterface](#) (IPADDR4 addr, IPADDR4 mask, IPADDR4 gateway, int root_if=0)
Add an interface with an interface number.

14.31.1 Detailed Description

```
#include < multihome.h >
```

Create Multihome and VLAN Interfaces

14.31.2 Function Documentation

14.31.2.1 AddInterface() [1/3]

```
int AddInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
    const char * ParentName ) [inline]
```

```
#include <multihome.h>
```

Add an interface with a Parent Name.

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>ParentName</i>	Name of parent physical interface, such as Ethernet0.

returns Interface number of newly created interface

14.31.2.2 AddInterface() [2/3]

```
int AddInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
    int root_if = 0 ) [inline]
```

```
#include <multihome.h>
```

Add an interface with an interface number.

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>root_if</i>	Optional root physical interface number. If not specified the default is 0, for Ethernt 0.

returns Interface number of newly created interface

14.31.2.3 AddInterface() [3/3]

```
int AddInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
    InterfaceBlock & parent ) [inline]
```

```
#include <multihome.h>
```

Add an interface with a Partent [InterfaceBlock](#) reference.

Parameters

<i>addr</i>	IP address of new interface
-------------	-----------------------------

Parameters

<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>parent</i>	Reference to parent physical interface of type InterfaceBlock .

returns Interface number of newly created interface

14.31.2.4 AddVlanInterface() [1/3]

```
int AddVlanInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
    uint16_t vlan_tag,
    const char * ParentName )
```

```
#include <multihome.h>
```

Add a VLAN interface with a Parent Name.

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>vlan_tag</i>	VLAN tag/id for interface
<i>ParentName</i>	Name of parent physical interface, such as Ethernet0.

returns Interface number of newly created VLAN interface

14.31.2.5 AddVlanInterface() [2/3]

```
int AddVlanInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
    uint16_t vlan_tag,
    int root_if = 0 )
```

```
#include <multihome.h>
```

Add a VLAN interface with an interface number.

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>vlan_tag</i>	VLAN tag/id for interface
<i>root_if</i>	Optional root physical interface number. If not specified the default is 0 for Ethernet 0.

returns Interface number of newly created VLAN interface

14.31.2.6 AddVlanInterface() [3/3]

```
int AddVlanInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
```

```

        uint16_t vlan_tag,
        InterfaceBlock & parent )
#include <multihome.h>

```

Add a VLAN interface with a Parent [InterfaceBlock](#) reference.

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>vlan_tag</i>	VLAN tag/id for interface
<i>parent</i>	Reference to parent physical interface of type InterfaceBlock

returns Interface number of newly created VLAN interface

14.32 NBRTOS Real Time Operating System

Topics

- [NBRTOS Error Codes](#)
- [NBRTOS Task Status](#)

Classes

- class [TickTimeout](#)
TickTimeout objects are used to facilitate sequential function calls with timeout parameters that need to be indexed from an initial start time, and to prevent TimeTick rollover errors.
- struct [OS_SEM](#)
Semaphores are used to control access to shared resources or to communicate between tasks in a multithreaded system or with interrupt service routines. Semaphores can be 0 or 1, or they can be counting semaphores that increment and decrement based on calls to [Pend\(\)](#) and [Post\(\)](#) functions.
- struct [OS_MBOX](#)
Mailboxes are single value storage locations used to communicate between tasks.
- struct [OS_Q](#)
A message queue is an object that enables tasks and interrupt service routines to send and receive pointer sized messages. The pointer values typically point to some type of object or structure that contains the actual message or data. A queue functions as a fixed size First In First Out (FIFO) storage for 32-bit void pointers that can be used for communication between tasks.
- struct [TEMPL_Q< T >](#)
A convenience wrapper around [OS_Q](#).
- struct [os_fifo_el](#)
OS_FIFO element definition.
- struct [OS_FIFO](#)
- struct [OS_CRIT](#)
An [OS_CRIT](#) object is used to establish critical sections of code that can only be run by one task at a time. Tasks that try to claim a critical section which is currently claimed by another task will stop and wait for that task to release the critical section before continuing execution.
- struct [OS_FLAGS](#)
OSFlags enables a function or task to pend on multiple flags or events.
- class [OSLockObj](#)
A simple wrapper class that helps use OS locks effectively.
- class [OSCriticalSectionObj](#)
A simple wrapper class that helps utilize [OS_CRIT](#) objects more effectively.
- class [OSLockAndCritObj](#)

- A simple wrapper class that helps utilize `OS_CRIT` objects to lock tasks and enter critical sections more effectively.*

 - class `OSSpinCrit`

A simple wrapper class that uses an `OS_CRIT` object to try and claim a critical section, and will continue the attempt until it is able to do so.
 - class `USERCritObj`

User critical section object class.
 - class `NBRtosInitObj`

A simple class to derive from if you are creating tasks that are constructed at global scope and need to do RTOS initialization.

Macros

- #define `WAIT_FOREVER` 0

Parameter macro used for timeout parameters that have a 0 value and wait forever.
- #define `OSSimpleTaskCreatwName(x, p, n)`

Simpler form of creating a new task. Will automatically allocate the default task stack size.
- #define `OSSimpleTaskCreatwNameSRAM(x, p, n)`
- #define `OSSimpleTaskCreateLambda(p, n, f) LambdaTask2(p,n,[(void *)f, __COUNTER__])`

This macro functions the same as `OSTaskCreatwName()`.

Typedefs

- typedef struct `os_fifo_el` `OS_FIFO_EL`

`OS_FIFO` element definition.

Functions

- void `OSFlagSet (OS_FLAGS *flags, uint32_t bits_to_set)`

*This function sets the corresponding bits asserted in `bits_to_set` of an `OS_FLAGS` object pointed to by `*flags`.*
- void `OSFlagClear (OS_FLAGS *flags, uint32_t bits_to_clr)`

*This function clears the bits asserted in `bits_to_clr` of an `OS_FLAGS` object pointed to by `*flags`.*
- uint8_t `OSFlagPendAny (OS_FLAGS *flags, uint32_t bit_mask, uint16_t timeout)`

This function waits a number of time ticks specified by `timeout` until any of the flags indicated by `bit_mask` are set.
- uint8_t `OSFlagPendAnyNoWait (OS_FLAGS *flags, uint32_t bit_mask)`

This function immediately checks to see if any of the flag bits indicated by `bit_mask` are set; it does not wait.
- uint8_t `OSFlagPendAll (OS_FLAGS *flags, uint32_t bit_mask, uint16_t timeout)`

*This function waits a number of time ticks specified by `timeout` until **all** the flags indicated by `bit_mask` are set.*
- uint8_t `OSFlagPendAllNoWait (OS_FLAGS *flags, uint32_t bit_mask)`

*This function immediately checks to see if **all** the flag bits indicated by `bit_mask` are set; it does not wait.*
- uint32_t `OSFlagState (OS_FLAGS *flags)`

This function returns the current values of the flags stored in the `OS_FLAGS` object structure.
- uint8_t `OSTaskCreatwName (void(*task)(void *dptr), void *data, void *pstkbot, void *pstkbot, uint8_t prio, const char *name)`

Create a new task.
- void `OSTimeWaitUntil (uint32_t systemTickValue)`

Delay the task until the specified value of the system timer tick. The number of system ticks per second is defined by the constant: `TICKS_PER_SECOND` in `<nburn_install>/nbrtos/include/constants.h`. The default value is 20 ticks per second.
- void `OSTimeDly (uint32_t to_count)`

Delay the task until the specified value of the system timer ticks. The number of system ticks per second is defined by the constant: `TICKS_PER_SECOND` in `<nburn_install>/nbrtos/include/constants.h`. The default value is 20 ticks per second.
- void `OSTaskDelete (void)`

This function deletes the current calling task, but we do not recommend the use of this function because it can cause memory leaks.

- `uint8_t OSChangePrio (uint32_t newp)`
Set the priority of the calling task.
- `void OSSetName (const char *cp)`
Set the name of the calling task.
- `void OSLock (void)`
Calling the OSLock function will prevent the OS from changing tasks.
- `void OSUnlock (void)`
This function unlocks the OS.
- `uint8_t OSSemInit (OS_SEM *psem, long value)`
Initializes a semaphore.
- `uint8_t OSSemPost (OS_SEM *psem)`
*Increases the value of the semaphore by one. **Note:** If any higher priority tasks were waiting on the semaphore - it releases them.*
- `uint8_t OSSemPend (OS_SEM *psem, uint16_t timeout)`
*Wait timeout ticks for the value of the semaphore to be non zero. **Note:** A timeout value of 0 (zero) waits forever.*
- `uint8_t OSSemPendNoWait (OS_SEM *psem)`
OSSemPendNoWait() is identical to OSSemPend(), but it does not wait.
- `uint8_t OSMboxInit (OS_MBOX *pmbox, void *msg)`
This function is used to initialize an OS_MBOX structure.
- `uint8_t OSMboxPost (OS_MBOX *pmbox, void *msg)`
This function posts a message to a Mail box.
- `void * OSMboxPend (OS_MBOX *pmbox, uint16_t timeout, uint8_t *err)`
Wait timeout ticks for some other task to post to the Mailbox.
- `void * OSMboxPendNoWait (OS_MBOX *pmbox, uint8_t *err)`
*OSMboxPendNoWait() is identical to OSMboxPend(), but it does **not** wait.*
- `uint8_t OSQInit (OS_Q *pq, void **start, uint8_t size)`
A queue functions as a fixed size FIFO for communication between tasks. This function initializes an OS_Q structure.
- `uint8_t OSQPost (OS_Q *pq, void *msg)`
This function posts a message to a Queue.
- `uint8_t OSQPostFirst (OS_Q *pq, void *msg)`
This function posts a message like OSQPost, but posts the message at the head of the queue.
- `uint8_t OSQPostUnique (OS_Q *pq, void *msg)`
This function posts a message like OSQPost, but only if the message isn't already in the queue The function performs a brute force check to see if the message is already in the queue.
- `uint8_t OSQPostUniqueFirst (OS_Q *pq, void *msg)`
This function posts a message like OSQPostFirst, but only if the message isn't already in the queue The function performs a brute force check to see if the message is already in the queue.
- `void * OSQPend (OS_Q *pq, uint16_t timeout, uint8_t *err)`
Wait timeout ticks for another task to post to the queue.
- `void * OSQPendNoWait (OS_Q *pq, uint8_t *err)`
OSQPendNoWait() is identical to the OSQPend() function but it does not wait.
- `uint8_t OSFifoInit (OS_FIFO *pFifo)`
Initialize a FIFO, which is used to pass structures from one task to another.
- `uint8_t OSFifoPost (OS_FIFO *pFifo, OS_FIFO_EL *pToPost)`
This function posts to a FIFO.
- `uint8_t OSFifoPostFirst (OS_FIFO *pFifo, OS_FIFO_EL *pToPost)`
This function is identical to OSFifoPost(), but the element posted is put at the beginning of the FIFO list.
- `OS_FIFO_EL * OSFifoPend (OS_FIFO *pFifo, uint16_t timeout)`
This function pends on a FIFO.

- [OS_FIFO_EL](#) * [OSFifoPendNoWait](#) ([OS_FIFO](#) *pFifo)
*This function is identical to the [OSFifoPen\(\)](#) function, but it does **not** wait.*
- [uint8_t](#) [OSCritInit](#) ([OS_CRIT](#) *pCrit)
This function initializes the critical section.
- [uint8_t](#) [OSCritEnter](#) ([OS_CRIT](#) *pCrit, [uint16_t](#) timeout)
This function tries to enter or claim the critical section.
- [uint8_t](#) [OSCritEnterNoWait](#) ([OS_CRIT](#) *pCrit)
This function tries to enter or claim the critical section.
- [uint8_t](#) [OSCritLeave](#) ([OS_CRIT](#) *pCrit)
This function releases the critical section.
- [uint8_t](#) [OSTaskID](#) (void)
Returns the current task's priority.
- const char * [OSTaskName](#) ()
Returns the current task's name.
- void [OSChangeTaskDly](#) ([uint16_t](#) task_prio, [uint32_t](#) to_count)
This function allows the User to modify the timeout delay for a task that is waiting.
- void [OSDumpStack](#) (void)
Dump the task stack to the stdout.
- void [OSDumpTCBStacks](#) (void)
This function dumps information about the UCOS stacks and tasks to stdout. This function is useful for debugging.
- void [OSDumpTasks](#) (void)
Dump the state and call stack for every task to stdout. This function is useful for debugging.
- void [OSStartTaskDumper](#) ([uint8_t](#) prio, [uint32_t](#) reportInterval)
This function creates a task that calls [OSDumpTasks\(\)](#) at the specified system time tick interval. The task is intended for use when debugging run status of multiple tasks.
- void [ShowTaskList](#) (void)
This functions dumps the current RTOS task states to stdio.
- bool [OS_CRIT::OwnedByCurTask](#) ()
Check if critical section owned by the current task.

14.32.1 Detailed Description

```
#include< nbrtos.h >
```

The NetBurner Real-Time OS

14.32.2 Macro Definition Documentation

14.32.2.1 OSSimpleTaskCreateLambda

```
#define OSSimpleTaskCreateLambda(  
    p,  
    n,  
    f ) LambdaTask2(p,n,[( void * pv)f, __COUNTER__])
```

```
#include <nbrtos.h>
```

This macro functions the same as [OSTaskCreatewName\(\)](#).

Parameters

<i>p</i>	The priority for this new task (OS_MAX_PRIOS is lowest priority and 1 is highest). Look in <code><nbrtos_install>/nbrtos/include/constants.h</code> to see which priorities are used by the OS.
<i>n</i>	The optional name of the task.
<i>f</i>	The function to run as the task.

Example:

```
OSSimpleTaskCreateLambda(MAIN_PRIO-1, "MyLambdaTask", { Code to run goes here });
```

See also

[OSTaskCreatewName\(\)](#), [OSSimpleTaskCreatewName\(\)](#)

14.32.2.2 OSSimpleTaskCreatewName

```
#define OSSimpleTaskCreatewName(
    x,
    p,
    n )
#include <nbrtos.h>
```

Value:

```
{
    static uint32_t func_##x_Stk[USER_TASK_STK_SIZE] __attribute__((aligned(4)));
    OSTaskCreatewName(x, NULL, (void *)&func_##x_Stk[USER_TASK_STK_SIZE], (void *)func_##x_Stk, p, n);
}
```

Simpler form of creating a new task. Will automatically allocate the default task stack size.

Parameters

<i>x</i>	The address of the function where this task will start executing.
<i>p</i>	The priority for this new task (OS_MAX_PRIOS is lowest priority and 1 is highest). Look in <nburn_install>/nbrtos/include/constants.h to see which priorities are used by the OS.
<i>n</i>	The optional name of the task.

See also

[OSTaskCreatewName\(\)](#), [OSTaskDelete\(\)](#), [OSChangePrio\(\)](#)

14.32.2.3 OSSimpleTaskCreatewNameSRAM

```
#define OSSimpleTaskCreatewNameSRAM(
    x,
    p,
    n )
#include <nbrtos.h>
```

Value:

```
{
    static uint32_t func_##x_Stk[USER_TASK_STK_SIZE] __attribute__((aligned(4))) FAST_USER_STK;
    OSTaskCreatewName(x, NULL, (void *)&func_##x_Stk[USER_TASK_STK_SIZE], (void *)func_##x_Stk, p, n);
}
```

14.32.3 Typedef Documentation

14.32.3.1 OS_FIFO_EL

```
typedef struct os_fifo_el OS_FIFO_EL
#include <nbrtos.h>
```

[OS_FIFO](#) element definition.

This structure is a union of a pointer to the next [OS_FIFO](#) and a byte pointer to the same data.

14.32.4 Function Documentation

14.32.4.1 OSChangePrio()

```
uint8_t OSChangePrio (
    uint32_t newp )
```

```
#include <nbrtos.h>
```

Set the priority of the calling task.

Note

There can only be one task at each priority level. Task priorities can range from 1 to OS_MAX_PRIOS, where OS_MAX_PRIOS is the lowest priority level and 1 is highest priority level. Priorities 1-4 and the NetBurner system priority levels are reserved as described below. The recommended user priority levels for your application are in the range of 46 to OS_MAX_PRIOS-1. This avoids any conflicts with network communications.

System priorities are defined in `<nburn_install>/nrtos/include/constants.h` for all platforms.

Parameters

<i>newp</i>	The new priority of the calling task
-------------	--------------------------------------

Return values

<i>OS_NO_ERR</i>	If successful
<i>OS_PRIO_EXIST</i>	If the requested priority already exists

See also

[NRTOS Error Codes](#), [OSTaskCreateName\(\)](#)

14.32.4.2 OSChangeTaskDly()

```
void OSChangeTaskDly (
    uint16_t task_prio,
    uint32_t to_count ) [inline]
#include <nrtos.h>
```

This function allows the User to modify the timeout delay for a task that is waiting.

Warning

Use of this function is discouraged.

Parameters

<i>task_prio</i>	The task's priority
<i>to_count</i>	The new number of ticks to delay

See also

[OSTimeDly\(\)](#)

14.32.4.3 OSCritEnter()

```
uint8_t OSCritEnter (
    OS_CRIT * pCrit,
    uint16_t timeout ) [inline]
#include <nrtos.h>
```

This function tries to enter or claim the critical section.

Parameters

<i>pCrit</i>	A pointer to the critical section.
<i>timeout</i>	How many time ticks do we want to wait for this critical section? Note: A timeout of 0 (zero) waits forever.

Returns

OS_NO_ERR - If we were successful in claiming the critical section, or if our task owns it
OS_TIMEOUT - If we were unable to claim the section

See also

[NRTOS Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_CRIT](#) for current usage.

14.32.4.4 OSCritEnterNoWait()

```
uint8_t OSCritEnterNoWait (
    OS_CRIT * pCrit ) [inline]
#include <nrtos.h>
```

This function tries to enter or claim the critical section.

Parameters

<i>pCrit</i>	A pointer to the critical section.
--------------	------------------------------------

Returns

OS_NO_ERR - If we were successful in claiming the critical section, or if our task owns it
OS_TIMEOUT - If we were unable to claim the section

See also

[NRTOS Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_CRIT](#) for current usage.

14.32.4.5 OSCritInit()

```
uint8_t OSCritInit (
    OS_CRIT * pCrit ) [inline]
#include <nrtos.h>
```

This function initializes the critical section.

Parameters

<i>pCrit</i>	A pointer to the critical section.
--------------	------------------------------------

Returns

OS_NO_ERR - If successful

See also

[NRTOS Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_CRIT](#) for current usage.

14.32.4.6 OSCritLeave()

```
uint8_t OSCritLeave (
    OS_CRIT * pCrit ) [inline]
```

```
#include <nbrtos.h>
```

This function releases the critical section.

Parameters

<i>pCrit</i>	A pointer to the critical section we want to leave/release.
--------------	---

Returns

OS_NO_ERR - If we were successful in releasing the critical section

OS_CRIT_ERR - If we are trying to release a critical section that we do not own

See also

[NBRRTOS Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_CRIT](#) for current usage.

14.32.4.7 OSDumpTasks()

```
void OSDumpTasks (  
    void )
```

```
#include <nbrtos.h>
```

Dump the state and call stack for every task to stdout. This function is useful for debugging.

Note

This function can only be called if `NBRRTOS_STACKCHECK` is defined in [predef.h](#).

See also

[OSDumpTCBStacks\(\)](#)

14.32.4.8 OSDumpTCBStacks()

```
void OSDumpTCBStacks (  
    void )
```

```
#include <nbrtos.h>
```

This function dumps information about the UCOS stacks and tasks to stdout. This function is useful for debugging.

Note

This function can only be called if `NBRRTOS_STACKCHECK` is defined in [predef.h](#).

See also

[OSDumpTasks\(\)](#)

14.32.4.9 OSFifoInit()

```
uint8_t OSFifoInit (  
    OS_FIFO * pFifo ) [inline]
```

```
#include <nbrtos.h>
```

Initialize a FIFO, which is used to pass structures from one task to another.

Parameters

<i>pFifo</i>	A pointer to an OS_FIFO structure.
--------------	--

Returns

OS_NO_ERR - If successful
 OS_CRIT_ERR - If pFifo is NULL

See also

[NBRtos Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_FIFO](#) for current usage.

14.32.4.10 OSFifoPend()

```
OS_FIFO_EL * OSFifoPend (
    OS_FIFO * pFifo,
    uint16_t timeout ) [inline]
#include <nbrtos.h>
```

This function pends on a FIFO.

Parameters

<i>pFifo</i>	A pointer to an OS_FIFO structure.
<i>timeout</i>	The number of ticks to wait on the FIFO.

Returns

A pointer to the posted structure if successful, or NULL if it timed out.

Deprecated This function is now deprecated. Please see [OS_FIFO](#) for current usage.

14.32.4.11 OSFifoPendNoWait()

```
OS_FIFO_EL * OSFifoPendNoWait (
    OS_FIFO * pFifo ) [inline]
#include <nbrtos.h>
```

This function is identical to the OSFifoPen() function, but it does **not** wait.

Parameters

<i>pFifo</i>	A pointer to an OS_FIFO structure.
--------------	--

Returns

A pointer to the posted structure if successful, or NULL if it timed out.

14.32.4.12 OSFifoPost()

```
uint8_t OSFifoPost (
    OS_FIFO * pFifo,
    OS_FIFO_EL * pToPost ) [inline]
#include <nbrtos.h>
```

This function posts to a FIFO.

Parameters

<i>pFifo</i>	A pointer to an OS_FIFO structure.
<i>pToPost</i>	A pointer to the user's structure cast as an OS_FIFO_EL to be posted to the FIFO.

Returns

OS_NO_ERR - If successful

See also

[NRTOS Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_FIFO](#) for current usage.

14.32.4.13 OSFifoPostFirst()

```
uint8_t OSFifoPostFirst (
    OS_FIFO * pFifo,
    OS_FIFO_EL * pToPost ) [inline]
```

```
#include <nrtos.h>
```

This function is identical to [OSFifoPost\(\)](#), but the element posted is put at the beginning of the FIFO list.

Parameters

<i>pFifo</i>	A pointer to an OS_FIFO structure.
<i>pToPost</i>	A pointer to the user's structure cast as an OS_FIFO_EL to be posted to the FIFO.

Returns

OS_NO_ERR - If successful

See also

[NRTOS Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_FIFO](#) for current usage.

14.32.4.14 OSFlagClear()

```
void OSFlagClear (
    OS_FLAGS * flags,
    uint32_t bits_to_clr ) [inline]
```

```
#include <nrtos.h>
```

This function clears the bits asserted in *bits_to_clr* of an [OS_FLAGS](#) object pointed to by **flags*.

Parameters

<i>flags</i>	A pointer to the OS_FLAGS object to be configured.
<i>bits_to_clr</i>	A bit or set of bits to be cleared.

Deprecated This function is now deprecated. Please see [OS_FLAGS](#) for current usage.

14.32.4.15 OSFlagPendAll()

```
uint8_t OSFlagPendAll (
    OS_FLAGS * flags,
    uint32_t bit_mask,
    uint16_t timeout ) [inline]
```

```
#include <nrtos.h>
```

This function waits a number of time ticks specified by *timeout* until **all** the flags indicated by *bit_mask* are set.

Parameters

<i>flags</i>	A pointer to the OS_FLAGS object with the desired flag bits.
<i>bit_mask</i>	A bit or set of bits to wait on.
<i>timeout</i>	Number of time ticks to wait for all specified flag bits to be set.

Return values

<i>OS_NO_ERR</i>	If the flags condition is satisfied
<i>OS_TIMEOUT</i>	If the timeout expired

Deprecated This function is now deprecated. Please see [OS_FLAGS](#) for current usage.

14.32.4.16 OSFlagPendAllNoWait()

```
uint8_t OSFlagPendAllNoWait (
    OS_FLAGS * flags,
    uint32_t bit_mask ) [inline]
```

```
#include <nbrtos.h>
```

This function immediately checks to see if **all** the flag bits indicated by *bit_mask* are set; it does not wait.

Parameters

<i>flags</i>	A pointer to the OS_FLAGS object with the desired flag bits.
<i>bit_mask</i>	A bit or set of bits to wait on.

Return values

<i>OS_NO_ERR</i>	All flags indicated by <i>bit_mask</i> are set.
<i>OS_TIMEOUT</i>	Not all of the flags indicated by <i>bit_mask</i> are set.

Deprecated This function is now deprecated. Please see [OS_FLAGS](#) for current usage.

14.32.4.17 OSFlagPendAny()

```
uint8_t OSFlagPendAny (
    OS_FLAGS * flags,
    uint32_t bit_mask,
    uint16_t timeout ) [inline]
```

```
#include <nbrtos.h>
```

This function waits a number of time ticks specified by *timeout* until any of the flags indicated by *bit_mask* are set.

Parameters

<i>flags</i>	A pointer to the OS_FLAGS object with the desired flag bits.
<i>bit_mask</i>	A bit or set of bits to wait on.
<i>timeout</i>	Number of time ticks to wait for all specified flag bits to be set.

Return values

<code>OS_NO_ERR</code>	At least one of the flag bits are set before <code>timeout</code> expires.
<code>OS_TIMEOUT</code>	None of the flag bits are set before <code>timeout</code> expires.

Deprecated This function is now deprecated. Please see [OS_FLAGS](#) for current usage.

14.32.4.18 OSFlagPendAnyNoWait()

```
uint8_t OSFlagPendAnyNoWait (
    OS_FLAGS * flags,
    uint32_t bit_mask ) [inline]
```

```
#include <nbrtos.h>
```

This function immediately checks to see if any of the flag bits indicated by `bit_mask` are set; it does not wait.

Parameters

<code>flags</code>	A pointer to the OS_FLAGS object with the desired flag bits.
<code>bit_mask</code>	A bit or set of bits to wait on.

Return values

<code>OS_NO_ERR</code>	At least one of the flags indicated by <code>bit_mask</code> are set.
<code>OS_TIMEOUT</code>	None of the flags indicated by <code>bit_mask</code> are set.

Deprecated This function is now deprecated. Please see [OS_FLAGS](#) for current usage.

14.32.4.19 OSFlagSet()

```
void OSFlagSet (
    OS_FLAGS * flags,
    uint32_t bits_to_set ) [inline]
```

```
#include <nbrtos.h>
```

This function sets the corresponding bits asserted in `bits_to_set` of an [OS_FLAGS](#) object pointed to by `*flags`.

Parameters

<code>flags</code>	A pointer to the OS_FLAGS object to be configured.
<code>bits_to_set</code>	A bit or set of bits to be set.

Deprecated This function is now deprecated. Please see [OS_FLAGS](#) for current usage.

14.32.4.20 OSFlagState()

```
uint32_t OSFlagState (
    OS_FLAGS * flags ) [inline]
```

```
#include <nbrtos.h>
```

This function returns the current values of the flags stored in the [OS_FLAGS](#) object structure.

Parameters

<i>flags</i>	A pointer to the OS_FLAGS object whose flag states are to be returned.
--------------	--

Returns

The state of the [OS_FLAGS](#) object.

Deprecated This function is now deprecated. Please see [OS_FLAGS](#) for current usage.

14.32.4.21 OSLock()

```
void OSLock (
    void )
```

```
#include <nbrtos.h>
```

Calling the OSLock function will prevent the OS from changing tasks.

This is used to protect critical variables that must be accessed one task at a time. Use the OSUnlock function to release your lock. **Important:** You must call [OSUnlock\(\)](#) once for each call to OSLock.

Warning: Do not keep a task locked for a long period of time, or the performance of the network subsystem will degrade, and eventually loose packets. For example, use of I/O is not recommended inside an OSLock protected block.

See also

[OSUnlock\(\)](#), [OSLockObj\(\)](#)

14.32.4.22 OSMboxInit()

```
uint8_t OSMboxInit (
    OS_MBOX * pmbox,
    void * msg ) [inline]
```

```
#include <nbrtos.h>
```

This function is used to initialize an [OS_MBOX](#) structure.

Parameters

<i>pmbox</i>	A pointer to the OS_MBOX structure to initialize.
<i>msg</i>	The initial mail box message (NULL) for none.

Returns

OS_NO_ERR - If successful

OS_CRIT_ERR - If pmbox is NULL

See also

[NBRtos Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_MBOX](#) for current usage.

14.32.4.23 OSMboxPend()

```
void * OSMboxPend (
    OS_MBOX * pmbox,
    uint16_t timeout,
    uint8_t * err ) [inline]
```

```
#include <nbrtos.h>
```

Wait timeout ticks for some other task to post to the Mailbox.

Parameters

	<i>pmbbox</i>	A pointer to the OS_MBOX structure.
	<i>timeout</i>	The number of time ticks to wait.
out	<i>err</i>	A variable to receive the result code (OS_NO_ERR if successful or OS_TIMEOUT if it fails).

Returns

The posted message if successful, or NULL if timed out.

Deprecated This function is now deprecated. Please see [OS_MBOX](#) for current usage.

14.32.4.24 OSMboxPendNoWait()

```
void * OSMboxPendNoWait (
    OS_MBOX * pmbbox,
    uint8_t * err ) [inline]
```

```
#include <nbrtos.h>
```

[OSMboxPendNoWait\(\)](#) is identical to [OSMboxPend\(\)](#), but it does **not** wait.

Parameters

<i>pmbbox</i>	A pointer to the OS_MBOX structure.
<i>err</i>	A variable to receive the result code (OS_NO_ERR if successful or OS_TIMEOUT if it fails).

Returns

The posted message if successful, or NULL if it fails.

Deprecated This function is now deprecated. Please see [OS_MBOX](#) for current usage.

14.32.4.25 OSMboxPost()

```
uint8_t OSMboxPost (
    OS_MBOX * pmbbox,
    void * msg ) [inline]
```

```
#include <nbrtos.h>
```

This function posts a message to a Mail box.

Parameters

<i>pmbbox</i>	A pointer to the OS_MBOX structure.
<i>msg</i>	The message to post.

Returns

[OS_NO_ERR](#) - If successful

[OS_MBOX_FULL](#) - If the mailbox is full

See also

[NRTOS Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_MBOX](#) for current usage.

14.32.4.26 OSQInit()

```
uint8_t OSQInit (
    OS_Q * pq,
    void ** start,
    uint8_t size ) [inline]
#include <nbrtos.h>
```

A queue functions as a fixed size FIFO for communication between tasks. This function initializes an [OS_Q](#) structure.

Parameters

<i>pq</i>	A pointer to the OS_Q structure.
<i>start</i>	A pointer to an array of (void *) pointers to hold queue messages.
<i>size</i>	The number of pointers in the Q data storage area.

Returns

OS_NO_ERR - If Successful

OS_CRIT_ERR - If start or pq is NULL

See also

[NBRtos Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_Q](#) for current usage.

14.32.4.27 OSQPend()

```
void * OSQPend (
    OS_Q * pq,
    uint16_t timeout,
    uint8_t * err ) [inline]
#include <nbrtos.h>
```

Wait timeout ticks for another task to post to the queue.

Parameters

	<i>pq</i>	A pointer to the OS_Q structure.
	<i>timeout</i>	The number of ticks to wait.
out	<i>err</i>	A variable to receive the result code, either OS_NO_ERR on receiving a posted message, or OS_TIMEOUT on a timeout.

Returns

The posted message, or NULL if the function failed

Deprecated This function is now deprecated. Please see [OS_Q](#) for current usage.

14.32.4.28 OSQPendNoWait()

```
void * OSQPendNoWait (
    OS_Q * pq,
    uint8_t * err ) [inline]
#include <nbrtos.h>
```

[OSQPendNoWait\(\)](#) is identical to the [OSQPend\(\)](#) function but it does not wait.

Parameters

	<i>pq</i>	A pointer to the OS_Q structure.
out	<i>err</i>	A variable to receive the result code, either <code>OS_NO_ERR</code> on receiving a posted message, or <code>OS_TIMEOUT</code> on a timeout.

Returns

The posted message, or `NULL` if the function failed

Deprecated This function is now deprecated. Please see [OS_Q](#) for current usage.

14.32.4.29 OSQPost()

```
uint8_t OSQPost (
    OS_Q * pq,
    void * msg ) [inline]
```

```
#include <nbrtos.h>
```

This function posts a message to a Queue.

Parameters

<i>pq</i>	A pointer to the OS_Q structure.
<i>msg</i>	The message to be posted to the queue.

Returns

`OS_NO_ERR` - If Successful

`OS_Q_FULL` - If the queue is full and has no more room

See also

[NRTOS Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_Q](#) for current usage.

14.32.4.30 OSQPostFirst()

```
uint8_t OSQPostFirst (
    OS_Q * pq,
    void * msg ) [inline]
```

```
#include <nbrtos.h>
```

This function posts a message like `OSQPost`, but posts the message at the head of the queue.

Parameters

<i>pq</i>	A pointer to the OS_Q structure.
<i>msg</i>	The message to post at the head of the queue.

Returns

`OS_NO_ERR` - If Successful

`OS_Q_FULL` - If the queue is full and has no more room

See also

[NBRtos Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_Q](#) for current usage.

14.32.4.31 OSQPostUnique()

```
uint8_t OSQPostUnique (
    OS_Q * pq,
    void * msg ) [inline]
#include <nbrtos.h>
```

This function posts a message like `OSQPost`, but only if the message isn't already in the queue. The function performs a brute force check to see if the message is already in the queue.

Parameters

<i>pq</i>	A pointer to the OS_Q structure.
<i>msg</i>	The message to post at the head of the queue.

Returns

- OS_NO_ERR - If Successful
- OS_Q_FULL - If the queue is full and has no more room
- OS_Q_EXISTS - If the message already exists in the queue

See also

[NBRtos Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_Q](#) for current usage.

14.32.4.32 OSQPostUniqueFirst()

```
uint8_t OSQPostUniqueFirst (
    OS_Q * pq,
    void * msg ) [inline]
#include <nbrtos.h>
```

This function posts a message like `OSQPostFirst`, but only if the message isn't already in the queue. The function performs a brute force check to see if the message is already in the queue.

Parameters

<i>pq</i>	A pointer to the OS_Q structure.
<i>msg</i>	The message to post at the head of the queue.

Returns

- OS_NO_ERR - If Successful
- OS_Q_FULL - If the queue is full and has no more room
- OS_Q_EXISTS - If the message already exists in the queue

See also

[NBRtos Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_Q](#) for current usage.

14.32.4.33 OSemInit()

```
uint8_t OSemInit (
    OS_SEM * psem,
    long value ) [inline]
#include <nbrtos.h>
```

Initializes a semaphore.

Parameters

<i>psem</i>	A pointer to the OS_SEM structure to initialize.
<i>value</i>	The initial count value for the semaphore.

Returns

OS_NO_ERR - If successful
 OS_SEM_ERR - If value is < 0 (zero), it cannot initialize
 OS_CRIT_ERR - If psem is NULL

See also

[NRTOS Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_SEM](#) for current usage.

14.32.4.34 OSemPend()

```
uint8_t OSemPend (
    OS_SEM * psem,
    uint16_t timeout ) [inline]
#include <nbrtos.h>
```

Wait timeout ticks for the value of the semaphore to be non zero. **Note:** A timeout value of 0 (zero) waits forever.

Parameters

<i>psem</i>	A pointer to the OS_SEM structure.
<i>timeout</i>	The number of time ticks to wait

Returns

OS_NO_ERR - If successful
 OS_TIMEOUT - If the function timed out or if the NoWait function failed

See also

[NRTOS Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_SEM](#) for current usage.

14.32.4.35 OSemPendNoWait()

```
uint8_t OSemPendNoWait (
    OS_SEM * psem ) [inline]
#include <nbrtos.h>
```

[OSemPendNoWait\(\)](#) is identical to [OSemPend\(\)](#), but it does not wait.

Parameters

<i>psem</i>	A pointer to the OS_SEM structure
-------------	---

Returns

OS_NO_ERR - If successful

OS_TIMEOUT - If it fails

See also

[NBRtos Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_SEM](#) for current usage.

14.32.4.36 OSemPost()

```
uint8_t OSemPost (
    OS_SEM * psem ) [inline]
#include <nbrtos.h>
```

Increases the value of the semaphore by one. **Note:** If any higher priority tasks were waiting on the semaphore - it releases them.

Parameters

<i>psem</i>	A pointer to the OS_SEM structure.
-------------	--

Returns

OS_NO_ERR - If successful

OS_SEM_OVF - If the value of the semaphore overflows

See also

[NBRtos Error Codes](#)

Deprecated This function is now deprecated. Please see [OS_SEM](#) for current usage.

14.32.4.37 OSSetName()

```
void OSSetName (
    const char * cp )
#include <nbrtos.h>
```

Set the name of the calling task.

Parameters

<i>cp</i>	Character pointer to new task name
-----------	------------------------------------

14.32.4.38 OSStartTaskDumper()

```
void OSStartTaskDumper (
    uint8_t prio,
    uint32_t reportInterval )
#include <nbrtos.h>
```

This function creates a task that calls [OSDumpTasks\(\)](#) at the specified system time tick interval. The task is intended for use when debugging run status of multiple tasks.

Note

This function can only be called if `NRTOS_STACKCHECK` is defined in [predef.h](#).

See also

[OSDumpTasks\(\)](#)

14.32.4.39 OSTaskCreatewName()

```
uint8_t OSTaskCreatewName (
    void(*) (void *dptr) task,
    void * data,
    void * pstktop,
    void * pstkbot,
    uint8_t prio,
    const char * name )
```

```
#include <nbrtos.h>
```

Create a new task.

You must allocate storage for the task stack that this new task will use, and it must be 4 byte aligned.

Task priorities can range from 1 to `OS_MAX_PRIOS`, where `OS_MAX_PRIOS` is the lowest priority level and 1 is highest priority level. The recommended user priority levels for your application are in the range of 46 to `OS_MAX_PRIOS-1`. This avoids any conflicts with network communications. The maximum number of tasks your application can run is defined by `OS_MAX_TASKS`. Both `OS_MAX_PRIOS` and `OS_MAX_TASKS` are defined in "`\nburn\nbrtos\include\constants.h`".

Note

The system can have only one task at each priority

It is good practice to check the function return value to ensure the task was created successfully.

Parameters

<i>task</i>	The address of the function where this task will start executing.
<i>data</i>	The data to pass to the task function.
<i>pstktop</i>	The highest address of the stack space.
<i>pstkbot</i>	The lowest address of the stack space.
<i>prio</i>	The priority for this new task (<code>OS_MAX_PRIOS</code> is lowest priority and 1 is highest). Look in <code><nburn_install>/nbrtos/include/constants.h</code> to see which priorities are used by the OS.
<i>name</i>	The name of the task

Return values

<code>OS_NO_ERR</code>	If successful
<code>OS_PRIO_EXIST</code>	If the requested priority already exists, NRTOS Error Codes

See also

[OSTaskDelete\(\)](#), [OSChangePrio\(\)](#), [NBRRTOS Error Codes](#)

14.32.4.40 OSTaskDelete()

```
void OSTaskDelete (
    void )
```

```
#include <nbrtos.h>
```

This function deletes the current calling task, but we do not recommend the use of this function because it can cause memory leaks.

The preferred method for terminating a task is to set a flag or semaphore that the task is listening for. The flag can then be set by an outside task, which enables the task to be deleted to free any resources and terminate gracefully by simply returning.

See also

[OSTaskCreateName\(\)](#), [OSChangePrio\(\)](#)

14.32.4.41 OSTimeDly()

```
void OSTimeDly (
    uint32_t to_count ) [inline]
```

```
#include <nbrtos.h>
```

Delay the task until the specified value of the system timer ticks. The number of system ticks per second is defined by the constant: `TICKS_PER_SECOND` in `<nburn_install>/nbrtos/include/constants.h`. The default value is 20 ticks per second.

Note

The `TICKS_PER_SECOND` macro is a great way to make code more readable, and will also adjust if the default of 20 ticks/second is changed.

Parameters

<i>to_count</i>	The number of system ticks to delay.
-----------------	--------------------------------------

See also

[OSChangeTaskDly\(\)](#), [OSTimeWaitUntil\(\)](#)

14.32.4.42 OSTimeWaitUntil()

```
void OSTimeWaitUntil (
    uint32_t systemTickValue )
```

```
#include <nbrtos.h>
```

Delay the task until the specified value of the system timer tick. The number of system ticks per second is defined by the constant: `TICKS_PER_SECOND` in `<nburn_install>/nbrtos/include/constants.h`. The default value is 20 ticks per second.

Parameters

<i>systemTickValue</i>	The system time tick value to wait for
------------------------	--

```
uint32_t Now = TimeTick;
while(1)
{
    Now += 60 * TICKS_PER_SECOND;
    OSTimeWaitUntil(Now);
}
```

```
// Do whatever every 60 seconds, no mater how long this takes to run the interval will have a consistant
    spacing
}
```

See also

[OSChangeTaskDly\(\)](#), [OSTimeDly\(\)](#)

14.32.4.43 OSUnlock()

```
void OSUnlock (
    void )
#include <nbrtos.h>
```

This function unlocks the OS.

Important: You must call [OSUnlock\(\)](#) once for each call to [OSLock\(\)](#).

See also

[OSLock\(\)](#), [OSLockObj\(\)](#)

14.32.4.44 OwnedByCurTask()

```
bool OS_CRIT::OwnedByCurTask ( ) [inline]
#include <nbrtos.h>
```

Check if critical section owned by the current task.

Check if current task owns the critical section.

Return values

<i>true</i>	if owned
<i>false</i>	if not owned

14.32.4.45 ShowTaskList()

```
void ShowTaskList (
    void )
#include <nbrtos.h>
```

This functions dumps the current RTOS task states to stdio.

The output takes on multiple lines of the following format for each logged state:

```
at t= [T] [Message]
```

Followed by a tally of the number of task states logged since system start:

```
Total messages: [N]
```

[T] represents the number of ticks in hexadecimal since system start; [N] represents the number of task state messages in decimal logged since system start; [Message] represents one of the output messages listed in the below table.

Message	Description
Wait for Semaphore	Task is asleep and pending for semaphore
Wake from Semaphore	Task gets a semaphore and wakes up
Task locked	Task becomes locked

Message	Description
Task lock++	Task gets an added nested lock
Task lock-	Task get a nested lock unlocked
Task unlocked	Task becomes completely unlocked
Task priority changed	The task's priority level is changed
Unknown flag [F]	The flag value defining the task's state is undefined
Switched to Task [P]	Task priority [P] (in decimal) gets control
Switched to Task [P] PC=[X]	Task priority [P] gets control with the program counter containing the address [X] (in hexadecimal) of the instruction being executed

Note: Usage of this function is valid only when defining `NBRTOS_TASKLIST` in debug mode. In order to enable this macro definition, it must be uncommented in `\Nburn\include\predef.h`, followed by rebuilding the system files to incorporate the modification. Attempting to load a compiled non-debug application image with the macro defined will cause a trap error.

14.32.5 NBRTOS Error Codes

Macros

- `#define OS_NO_ERR 0`
No error.
- `#define OS_TIMEOUT 10`
Timeout.
- `#define OS_MBOX_FULL 20`
Mailbox full.
- `#define OS_Q_FULL 30`
Queue full.
- `#define OS_Q_EXISTS 31`
Queue already exists.
- `#define OS_PRIO_EXIST 40`
Task priority number already exists.
- `#define OS_PRIO_INVALID 41`
Invalid task priority number.
- `#define OS_SEM_ERR 50`
Semaphore error.
- `#define OS_SEM_OVF 51`
Semaphore count overflow.
- `#define OS_CRIT_ERR 60`
Critical section error.
- `#define OS_NO_MORE_TCB 70`
No Task Control Blocks (TCB) available to create task.

14.32.5.1 Detailed Description

```
#include <nbrtos.h >
```

NBRTOS function return codes

14.32.6 NBRtos Task Status

Macros

- #define **OS_STAT_RDY** 0x00
Ready to run.
- #define **OS_STAT_MBOX** 0x01
Pending on mailbox.
- #define **OS_STAT_SEM** 0x02
Pending on semaphore.
- #define **OS_STAT_Q** 0x04
Pending on queue.
- #define **OS_STAT_FIFO** 0x08
Pending on FIFO.
- #define **OS_STAT_CRIT** 0x10
Pending on Critical Section.
- #define **OS_STAT_DELAY** 0x20
Reserved.
- #define **OS_STAT_RES4** 0x40
Reserved.
- #define **OS_STAT_RES5** 0x80
Reserved.

14.32.6.1 Detailed Description

#include< [nbrtos.h](#) >

Values for the current state of a running task

14.33 NBString - NetBurner String Class

Classes

- class [NBString](#)
Lightweight alternative to C++ CString class.

14.33.1 Detailed Description

#include< [nbstring.h](#) >

The NetBurner lightweight String Class alternative to CString.

14.34 Network Interfaces

Network Interface Functions.

Topics

- [IPADDR4 Functions](#)
Network Interface functions with [IPADDR4](#) return types.
- [Low Level Processing \(NetDoRx\)](#)
Callback functions to add custom Ethernet handlers and pass Ethernet frames in the bottom of the TCP/IP stack.

Classes

- class [InterfaceBlock](#)
Network interface configuration block class for interface control and configuration.

Functions

- int [Removeinterface](#) (int interface)
Remove a network interface from the system.
- void [EnableMulticast](#) (MACADR macAddress, int interface=0)
Enable Multicast on an existing interface.
- void [DisableMulticast](#) (MACADR macAddress, int interface=0)
Disable Multicast on an existing interface.
- [InterfaceBlock](#) * [GetInterfaceBlock](#) (int interface=0)
Get an [InterfaceBlock](#) control and configuration object.
- int32_t [GetFirstInterface](#) (void)
Returns the Interface Number of the first registered network interface.
- int32_t [GetNextInterface](#) (int lastInterface)
Returns the Interface Number of the next registered network interface.
- int32_t [GetInterfaceNumber](#) ([InterfaceBlock](#) *pifb)
Returns the Interface Number of the specified network interface [InterfaceBlock](#).
- int32_t [GetInterfaceForMyAddress4](#) (IPADDR4 ip)
Returns the Interface Number of the specified network interface IPv4 address.
- bool [GetInterfaceLink](#) (int ifn)
Returns the network interface link status.
- MACADR [InterfaceMAC](#) (int interface)
Returns the MAC address of the specified network interface.
- bool [InterfaceLinkActive](#) (int interface)
Returns the link status of the specified network interface.
- int [InterfaceLinkSpeed](#) (int interface)
Returns the 10/100 link speed of the specified network interface.
- bool [InterfaceLinkDuplex](#) (int interface)
Returns the full or half link duplex of the specified network interface.
- const char * [InterfaceName](#) (int interface)
Returns the interface name of the specified network interface.

14.34.1 Detailed Description

Network Interface Functions.

Callback functions to add custom Ethernet handlers and pass Ethernet.

```
#include< netinterface.h >
```

Network Interfaces are configured and controlled C++ [InterfaceBlock](#) objects. The [InterfaceBlock](#) contains variables and member functions for things such as:

- The Configuration Server interface
- IP settings for both IPv4 and IPv6 types
- Configuration to static or [DHCP](#), and [DHCP](#) status (both v4 and v6)
- Multihome
- Routing
- AutoIP

Note

While the recommended method for getting and setting network interface parameters is to obtain a pointer to an [InterfaceBlock](#), there are also non-member functions of the object that can be used for situations that are best served by a single function call, such as just getting a single IP address of an interface. When using those functions pay special attention to the return value type. While `IPADDR` should be used because it supports both `IPADDR4` and `IPADDR6` types automatically, some of these helper functions may specifically return an `IPADDR4` type.

```
#include < netrx.h >
```

14.34.2 Function Documentation**14.34.2.1 DisableMulticast()**

```
void DisableMulticast (
    MACADR macAddress,
    int interface = 0 )
```

```
#include <netinterface.h>
```

Disable Multicast on an existing interface.

Calls registered interface multicast routine.

Parameters

<i>macAddress</i>	Multicast MAC address.
<i>interface</i>	Interface number. If not specified or 0, operates on the first registered interface.

See also

[EnableMulticast\(MACADR macAddress, int interface\)](#), [InterfaceBlock::EnableMulticast\(\)](#)

14.34.2.2 EnableMulticast()

```
void EnableMulticast (
    MACADR macAddress,
    int interface = 0 )
```

```
#include <netinterface.h>
```

Enable Multicast on an existing interface.

Calls registered interface multicast routine.

Parameters

<i>macAddress</i>	Multicast MAC address.
<i>interface</i>	Interface number. If not specified, default is 0.

See also

[DisableMulticast\(\)](#), [InterfaceBlock::EnableMulticast\(\)](#)

14.34.2.3 GetFirstInterface()

```
int32_t GetFirstInterface (
    void )
```

```
#include <netinterface.h>
```

Returns the Interface Number of the first registered network interface.

If called on a device with wired Ethernet, this will be the first Ethernet interface typical interface number 1.

Returns

Interface number of the first network interface, or 0 if none exist.

14.34.2.4 GetInterfaceBlock()

```
InterfaceBlock * GetInterfaceBlock (
    int interface = 0 )
```

```
#include <netinterface.h>
```

Get an [InterfaceBlock](#) control and configuration object.

Parameters

<i>interface</i>	Interface number. If not specified or 0, operates on the first registered interface.
------------------	--

Returns

Pointer to an [InterfaceBlock](#) on success, Null if requested interface is invalid.

14.34.2.5 GetInterfaceForMyAddress4()

```
int32_t GetInterfaceForMyAddress4 (
    IPADDR4 ip )
```

```
#include <netinterface.h>
```

Returns the Interface Number of the specified network interface IPv4 address.

Parameters

<i>ip</i>	IPv4 network interface address.
-----------	---------------------------------

Returns

Interface number of the specified IPv4 address

14.34.2.6 GetInterfaceLink()

```
bool GetInterfaceLink (
    int ifn )
```

```
#include <netinterface.h>
```

Returns the network interface link status.

Parameters

<i>ifn</i>	Network interface number
------------	--------------------------

Returns

True if link, otherwise false

See also

[InterfaceBlock::LinkActive\(\)](#), [InterfaceLinkActive\(\)](#)

14.34.2.7 GetInterfaceNumber()

```
int32_t GetInterfaceNumber (
    InterfaceBlock * pifb )
```

```
#include <netinterface.h>
```

Returns the Interface Number of the specified network interface [InterfaceBlock](#).

Parameters

<i>pifb</i>	Pointer to the InterfaceBlock
--------------------	---

Returns

Interface number of the [InterfaceBlock](#).

See also

[InterfaceBlock::GetInterfaceNumber\(\)](#)

14.34.2.8 GetNextInterface()

```
int32_t GetNextInterface (  
    int lastInterface )
```

```
#include <netinterface.h>
```

Returns the Interface Number of the next registered network interface.

Parameters

<i>lastInterface</i>	Specifies the interface number starting point to begin search.
----------------------	--

Returns

Interface number of the next network interface, or 0 if none exist.

14.34.2.9 InterfaceLinkActive()

```
bool InterfaceLinkActive (  
    int interface )
```

```
#include <netinterface.h>
```

Returns the link status of the specified network interface.

Parameters

<i>interface</i>	Interface number
------------------	------------------

Returns

True if link is active, otherwise false

See also

[InterfaceBlock::LinkActive\(\)](#), [GetInterfaceLink\(\)](#)

14.34.2.10 InterfaceLinkDuplex()

```
bool InterfaceLinkDuplex (  
    int interface )
```

```
#include <netinterface.h>
```

Returns the full or half link duplex of the specified network interface.

Parameters

<i>interface</i>	Interface number
------------------	------------------

Returns

True if full duplex, false if half duplex

See also

[InterfaceBlock::LinkDuplex\(\)](#)

14.34.2.11 InterfaceLinkSpeed()

```
int InterfaceLinkSpeed (  
    int interface )  
#include <netinterface.h>
```

Returns the 10/100 link speed of the specified network interface.

Parameters

<i>interface</i>	Interface number
------------------	------------------

Returns

10 or 100 representing the Mbps speed

See also

[InterfaceBlock::LinkSpeed\(\)](#)

14.34.2.12 InterfaceMAC()

```
MACADR InterfaceMAC (  
    int interface )  
#include <netinterface.h>
```

Returns the MAC address of the specified network interface.

Parameters

<i>interface</i>	Interface number
------------------	------------------

Returns

MAC address of type [MACADR](#)

14.34.2.13 InterfaceName()

```
const char * InterfaceName (  
    int interface )  
#include <netinterface.h>
```

Returns the interface name of the specified network interface.

Parameters

<i>interface</i>	Interface number
------------------	------------------

Returns

Pointer to a character string containing the name of the network interface

See also

[InterfaceBlock::GetInterfaceName\(\)](#)

14.34.2.14 Removeinterface()

```
int Removeinterface (
    int interface )
#include <netinterface.h>
Remove a network interface from the system.
```

Parameters

<i>interface</i>	Interface number
------------------	------------------

Returns

1 if successful, 0 if invalid interface number

See also

[InterfaceBlock::RegisterInterface\(\)](#)

14.34.3 IPADDR4 Functions

Network Interface functions with [IPADDR4](#) return types.

Functions

- [IPADDR4 InterfaceIP](#) (int interface)
Returns the IPv4 IP address of the specified network interface.
- [IPADDR4 InterfaceAutoIP](#) (int interface)
Returns the IPv4 IP AutoIP address of the specified network interface.
- [IPADDR4 InterfaceDNS](#) (int interface)
Returns the IPv4 DNS address of the specified network interface.
- [IPADDR4 InterfaceDNS2](#) (int interface)
Returns the second IPv4 DNS address of the specified network interface.
- [IPADDR4 InterfaceMASK](#) (int interface)
Returns the IPv4 network mask of the specified network interface.
- [IPADDR4 InterfaceGate](#) (int interface)
Returns the IPv4 gateway address of the specified network interface.

14.34.3.1 Detailed Description

Network Interface functions with [IPADDR4](#) return types.

```
#include< netinterface.h >
```

Note

While the recommended method for getting and setting network interface parameters is to obtain a pointer to an [InterfaceBlock](#), there are also non-member functions of the object that can be used for situations that are best served by a single function call, such as just getting a single IP address of an interface. When using those functions pay special attention to the return value type. While IPADDR should be used because it supports both [IPADDR4](#) and [IPADDR6](#) types automatically, some of these helper functions may specifically return an [IPADDR4](#) type.

14.34.3.2 Function Documentation

14.34.3.2.1 InterfaceAutoIP()

```
IPADDR4 InterfaceAutoIP (  
    int interface )  
#include <netinterface.h>
```

Returns the IPv4 IP AutoIP address of the specified network interface.

Parameters

<i>interface</i>	Interface number
------------------	------------------

Returns

IPv4 IP address of type [IPADDR4](#)

14.34.3.2.2 InterfaceDNS()

```
IPADDR4 InterfaceDNS (  
    int interface )  
#include <netinterface.h>
```

Returns the IPv4 DNS address of the specified network interface.

Parameters

<i>interface</i>	Interface number
------------------	------------------

Returns

IPv4 IP address of type [IPADDR4](#)

14.34.3.2.3 InterfaceDNS2()

```
IPADDR4 InterfaceDNS2 (  
    int interface )  
#include <netinterface.h>
```

Returns the second IPv4 DNS address of the specified network interface.

Parameters

<i>interface</i>	Interface number
------------------	------------------

Returns

IPv4 IP address of type [IPADDR4](#)

14.34.3.2.4 InterfaceGate()

```
IPADDR4 InterfaceGate (  
    int interface )  
#include <netinterface.h>
```

Returns the IPv4 gateway address of the specified network interface.

Parameters

<i>interface</i>	Interface number
------------------	------------------

Returns

IPv4 IP address of type [IPADDR4](#)

14.34.3.2.5 InterfaceIP()

```
IPADDR4 InterfaceIP (
    int interface )
#include <netinterface.h>
```

Returns the IPv4 IP address of the specified network interface.

Parameters

<i>interface</i>	Interface number
------------------	------------------

Returns

IPv4 IP address of type [IPADDR4](#)

14.34.3.2.6 InterfaceMASK()

```
IPADDR4 InterfaceMASK (
    int interface )
#include <netinterface.h>
```

Returns the IPv4 network mask of the specified network interface.

Parameters

<i>interface</i>	Interface number
------------------	------------------

Returns

IPv4 network mask of type [IPADDR4](#)

14.34.4 Low Level Processing (NetDoRx)

Callback functions to add custom Ethernet handlers and pass Ethernet frames in the bottom of the TCP/IP stack.

Typedefs

- typedef int(* [netDoRXFunc](#)) (PoolPtr, uint16_t, int)
Typedef interface for all network rx processing functions.

Functions

- [netDoRXFunc SetCustomNetDoRX](#) ([netDoRXFunc](#) customFunc)
Registers a new custom ethernet handler to run prior to the primary handler.
- [netDoRXFunc ClearCustomNetDoRX](#) ()
Clears the custom ethernet handler, resetting the handler to NULL.
- int [NetDoRX](#) (PoolPtr pp, uint16_t ocount, int if_num)
Entry function for Ethernet frames into the system TCP/IP stack.

14.34.4.1 Detailed Description

Callback functions to add custom Ethernet handlers and pass Ethernet frames in the bottom of the TCP/IP stack.

```
#include< netrx.h >
```

Note

Custom handlers require that the system is(re)compiled with the ALLOW_CUSTOM_NET_DO_RX macro defined.

Warning

These functions are for advanced developers only! Code written can affect all receive network processing.

14.34.4.2 Typedef Documentation**14.34.4.2.1 netDoRXFunc**

```
typedef int(* netDoRXFunc) (PoolPtr, uint16_t, int)
#include <netrx.h>
```

Typedef interface for all network rx processing functions.

Parameter Types:

```
PoolPtr    The buffer structure containing the received network data
uint16_t   The total number of receive bytes of network data
int        The network interface number of the interface that the frame was received from
```

Returns

Boolean integer value declaring whether the frame was handled or if it should continue to be processed 1 = processed and should be released 0 = not processed and should continue being handled

14.34.4.3 Function Documentation**14.34.4.3.1 ClearCustomNetDoRX()**

```
netDoRXFunc ClearCustomNetDoRX ( ) [inline]
#include <netrx.h>
```

Clears the custom ethernet handler, resetting the handler to NULL.

Returns

Previously registered custom handler (NULL if there was none)

14.34.4.3.2 NetDoRX()

```
int NetDoRX (
    PoolPtr pp,
    uint16_t ocount,
    int if_num )
#include <netrx.h>
```

Entry function for Ethernet frames into the system TCP/IP stack.

Parameters

<i>pp</i>	PoolPtr to PoolBuffer containing the ethernet frame
<i>ocount</i>	A count of the number of octets (bytes) of ethernet payload
<i>if_num</i>	The interface number that the frame came in on.

Returns

The number of system time ticks to wait before calling again, call with null if timeout.

14.34.4.3.3 SetCustomNetDoRX()

```
netDoRXFunc SetCustomNetDoRX (
    netDoRXFunc customFunc ) [inline]
#include <netrx.h>
```

Registers a new custom ethernet handler to run prior to the primary handler.

Parameters

<i>customFunc</i>	The netDoRXFunc to call when processing an ethernet frame
-------------------	---

Returns

Previously registered custom handler (NULL if there was none)

14.35 PEM Conversion**Macros**

- #define **CONVERT_BUFFER_LENGTH_MAX** ((4 * 1024) - 1)
Minimum data buffer length in bytes.

Functions

- int [ConvertPEMFormattedData](#) (uint8_t dataPtr, const char *pemEncodedData, uint32_t dataSize, uint32_t convertedDataLength, char **nextPtr=NULL)
Convert data from Privacy-enhanced Electronic Mail (PEM) format to binary.
- uint16_t [convertLittleEndianWord](#) (uint16_t hData)
Convert multibyte host format data to/from little endian.
- uint32_t [convertLittleEndianDword](#) (uint32_t hData)
Convert multibyte host format data to/from little endian.

14.35.1 Detailed Description

```
#include< convert.h >
```

14.35.2 Function Documentation**14.35.2.1 convertLittleEndianDword()**

```
uint32_t convertLittleEndianDword (
    uint32_t hData )
#include <convert.h>
```

Convert multibyte host format data to/from little endian.

Parameters

<i>hData</i>	Multibyte data to convert
--------------	---------------------------

Returns

data in little-endian format

14.35.2.2 convertLittleEndianWord()

```
uint16_t convertLittleEndianWord (
    uint16_t hData )
#include <convert.h>
Convert multibyte host format data to/from little endian.
```

Parameters

<i>hData</i>	Multibyte data to convert
--------------	---------------------------

Returns

data in little-endian format

14.35.2.3 ConvertPEMFormattedData()

```
int ConvertPEMFormattedData (
    uint8_t dataPtr,
    const char * pemEncodedData,
    uint32_t dataSize,
    uint32_t convertedDataLength,
    char ** nextPtr = NULL )
#include <convert.h>
```

Convert data from Privacy-enhanced Electronic Mail (PEM) format to binary. *dataSize* should be at least `CONVERT_BUFFER_LENGTH_MAX` and NULL terminated. Limited to file formats used for RSA & DSA keys and X.509 certificates.

Parameters

<i>dataPtr</i>	Buffer for converted data
<i>pemEncodedData</i>	PEM encoded data
<i>dataSize</i>	Buffer size in bytes
<i>convertedDataLength</i>	Set to length of converted data
<i>nextPtr</i>	

Return values

<code>CONVERT_NONE</code>	Malformed data or calling parameters
<code>CONVERT_CERTIFICATE</code>	
<code>CONVERT_RSA_PRIVATE_KEY</code>	
<code>CONVERT_DSA_PRIVATE_KEY</code>	

14.36 POP3 - Post Office Protocol**Topics**

- [POP3 Return Codes](#)

Functions

- int [POPGetResultCode](#) (int fd, uint32_t timeout)
Returns the result code of the previous POP3 operation.
- int [POP3_InitializeSession](#) (IPADDR server_address, uint16_t port, PCSTR UserName, PCSTR Password, uint32_t timeout)
Create a connection to the POP3 server and log in.
- int [POP3_CloseSession](#) (int session)
Close a POP3 session.
- int [POP3_StatCmd](#) (int session, uint32_t *num_messages, uint32_t *total_bytes, uint32_t timeout)
Returns the status of the mailstore on the POP3 server.
- int [POP3_ListCmd](#) (int session, uint32_t message_number, uint32_t *total_bytes, uint32_t timeout)
Get the size of a message on the server.
- int [POP3_DeleteCmd](#) (int session, uint32_t message_number, uint32_t timeout)
Delete a pending message on the server.
- int [POP3_RetrieveMessage](#) (int session, uint32_t message_number, char *buffer, char **subject_ptr, char **body_ptr, int max_bufferlen, uint32_t timeout)
Retrieve a message from the server.
- PCSTR [GetPOPErrorString](#) (int err)
Returns the error text for an error code.
- int [SSL_POP3_InitializeSession](#) (IPADDR server_address, uint16_t port, PCSTR UserName, PCSTR Password, uint32_t timeout)
Initialize Post Office Protocol Version 3 (POP3) on a SSL socket.

14.36.1 Detailed Description

```
#include <pop3.h >
```

14.36.2 Function Documentation

14.36.2.1 GetPOPErrorString()

```
PCSTR GetPOPErrorString (
    int err )
```

```
#include <pop3.h>
```

Returns the error text for an error code.

Parameters

<i>err</i>	Error number to decode
------------	------------------------

Returns

Pointer to a string containing the error code text

14.36.2.2 POP3_CloseSession()

```
int POP3_CloseSession (
    int session )
```

```
#include <pop3.h>
```

Close a POP3 session.

Parameters

<i>session</i>	The session number returned by POP3_InitializeSession()
----------------	---

Returns

[POP3 Return Codes](#)

14.36.2.3 POP3_DeleteCmd()

```
int POP3_DeleteCmd (
    int session,
    uint32_t message_number,
    uint32_t timeout )
```

```
#include <pop3.h>
```

Delete a pending message on the server.

Note: the server will not actually delete the message until the session is closed.

Parameters

<i>session</i>	The session number returned by POP3_InitializeSession() .
<i>message_number</i>	The message number to delete. The message number can be obtained by POP3_StatCmd() .
<i>timeout</i>	Timeout in system Time Ticks.

Returns

Return code [POP3 Return Codes](#)

14.36.2.4 POP3_InitializeSession()

```
int POP3_InitializeSession (
    IPADDR server_address,
    uint16_t port,
    PCSTR UserName,
    PCSTR Password,
    uint32_t timeout )
```

```
#include <pop3.h>
```

Create a connection to the POP3 server and log in.

Parameters

<i>server_address</i>	Server IP address
<i>port</i>	Server port number
<i>UserName</i>	Account username
<i>Password</i>	Account password
<i>timeout</i>	Timeout in system Time Ticks

Returns

The POP3 session number if greater than 0, otherwise error code [POP3 Return Codes](#)

See also

[SSL_POP3_InitializeSession](#)

14.36.2.5 POP3_ListCmd()

```
int POP3_ListCmd (
    int session,
    uint32_t message_number,
    uint32_t * total_bytes,
    uint32_t timeout )
```

```
#include <pop3.h>
```

Get the size of a message on the server.

Parameters

<i>session</i>	The session number returned by POP3_InitializeSession() .
<i>message_number</i>	The message number to query. The message number can be obtained by POP3_StatCmd() .
<i>total_bytes</i>	Pointer to the variable in which to store the total number of bytes of the pending message.
<i>timeout</i>	Timeout in system Time Ticks.

Returns

Return code [POP3 Return Codes](#)

14.36.2.6 POP3_RetrieveMessage()

```
int POP3_RetrieveMessage (
    int session,
    uint32_t message_number,
    char * buffer,
    char ** subject_ptr,
    char ** body_ptr,
    int max_bufferlen,
    uint32_t timeout )
```

```
#include <pop3.h>
```

Retrieve a message from the server.

The message is retrieved as a block of bytes including the header, subject, etc. The headers will appear first. Note that the message is left on the server and will not be deleted until the [POP3_DeleteCmd\(\)](#) function is called for the message number.

Parameters

<i>session</i>	The session number returned by POP3_InitializeSession() .
<i>message_number</i>	The message number to retrieve. The message number can be obtained by POP3_StatCmd() .
<i>buffer</i>	Pointer to the buffer to store the entire message, including headers
<i>subject_ptr</i>	If not NULL, a pointer to the start of the subject in the message buffer
<i>body_ptr</i>	If not NULL, a pointer to the start of the body in the message buffer
<i>max_bufferlen</i>	Maximum length of the buffer
<i>timeout</i>	Timeout in system Time Ticks.

Returns

Return code [POP3 Return Codes](#)

14.36.2.7 POP3_StatCmd()

```
int POP3_StatCmd (
    int session,
```

```

uint32_t * num_messages,
uint32_t * total_bytes,
uint32_t timeout )

```

```
#include <pop3.h>
```

Returns the status of the mailstore on the POP3 server.

Parameters

<i>session</i>	The session number returned by POP3_InitializeSession()
<i>num_messages</i>	Pointer to the variable in which to store the number of pending messages
<i>total_bytes</i>	Pointer to the variable in which to store the total number of bytes of the pending messages
<i>timeout</i>	Timeout in system Time Ticks

Returns

Return code [POP3 Return Codes](#)

14.36.2.8 POPGetResultCode()

```

int POPGetResultCode (
    int fd,
    uint32_t timeout )

```

```
#include <pop3.h>
```

Returns the result code of the previous POP3 operation.

Parameters

<i>fd</i>	TCP socket file descriptor for the active session
<i>timeout</i>	Timeout in system Time Ticks

Returns

[POP3 Return Codes](#)

14.36.2.9 SSL_POP3_InitializeSession()

```

int SSL_POP3_InitializeSession (
    IPADDR server_address,
    uint16_t port,
    PCSTR UserName,
    PCSTR PassWord,
    uint32_t time_out )

```

```
#include <ssl_pop3.h>
```

Initialize Post Office Protocol Version 3 (POP3) on a SSL socket.

Note: Routine makes the connection to the POP server and logs in with the provided UserName and PassWord. Session is release with [POP3_CloseSession](#) in [pop3.h](#).

Post Office Protocol, Version 3 (POP3) is defined in RFC1939.

Parameters

<i>server_address</i>	IP address of the server.
<i>port</i>	Port to connect to the server.
<i>UserName</i>	Account user name string.
<i>PassWord</i>	Account password string.
<i>time_out</i>	Number of ticks to wait.

Return values

≥ 0	The session handle
< 0	Error code from POP3 Return Codes

See also

[POP3_InitializeSession](#)

14.36.3 POP3 Return Codes**Macros**

- #define **POP_OK** (0)
No errors occurred.
- #define **POP_TIMEOUT** (-1)
Time out.
- #define **POP_PASSWORDERROR** (-2)
Password error.
- #define **POP_CONNECTFAIL** (-3)
Connection failed.
- #define **POP_COMMANDFAIL** (-4)
Command failed.
- #define **POP_BADSESSION** (-5)
Session error.
- #define **POP_NETWORKERROR** (-6)
Network error.
- #define **POP_BUFFER_FULL** (-7)
Receive buffer full.

14.36.3.1 Detailed Description

```
#include <pop3.h >
```

14.37 PPP - Point to Point Protocol**Topics**

- [PPP Connection State](#)
- [PPP Return Codes](#)

14.37.1 Detailed Description

```
#include <ppp.h >
```

Like Ethernet, Point to Point Protocol (PPP) is a data link layer which transfers data between nodes on a network. The main difference is that PPP is used between two end points, whereas Ethernet is a multidrop configuration. PPP can be used over many types of physical networks, including: fiber, phone line, serial cable and cellular telephone. Once you have created a PPP connection to or from your NetBurner device you can use it with all the standard network applications such as the web server, tcp, udp, ftp, email, etc.

Internet Service Providers (ISP) can implement PPP with many different options that vary from ISP to ISP. The PPP example program included in the development kit examples directory specifies the most common ISP options and can be used as a code example to specify any specific options you may need in your application.

14.37.2 PPP Connection State

Enumerations

- enum `enum_PPPState` {
`eClosed` , `eInitializingModem` , `eDialing` , `eWait4Ring` ,
`eAnswering` , `eWaitForTrain` , `eLCPNegotiate` , `ePAPAuthenticate` ,
`eCHAPAuthenticate` , `eNCPNegotiate` , `eOpen` , `eClosing` }

PPP States.

14.37.2.1 Detailed Description

```
#include < ppp.h >
```

14.37.2.2 Enumeration Type Documentation

14.37.2.2.1 enum_PPPState

```
enum enum_PPPState  

#include < ppp.h >  

PPP States.
```

Enumerator

<code>eClosed</code>	Connection closed.
<code>eInitializingModem</code>	Initializing modem.
<code>eDialing</code>	Dialing.
<code>eWait4Ring</code>	Waiting for ring indicator.
<code>eAnswering</code>	Answering incoming connection.
<code>eWaitForTrain</code>	Waiting for train.
<code>eLCPNegotiate</code>	LCP negotiation.
<code>ePAPAuthenticate</code>	PAP authentication.
<code>eCHAPAuthenticate</code>	CHAP authentication.
<code>eNCPNegotiate</code>	NCP negotiation.
<code>eOpen</code>	Connection open.
<code>eClosing</code>	Connection closing.

14.37.3 PPP Return Codes

Macros

- #define `ERR_PPP_SUCCESS` (0)
Success.
- #define `ERR_PPP_ALREADY_OPEN` (-1)
A session is already open.
- #define `ERR_PPP_NO_DIALTONE` (-2)
No dial tone.
- #define `ERR_PPP_NO_ANSWER` (-3)
The remote client did not answer.
- #define `ERR_PPP_BUSY` (-4)
The remote client is sending a busy signal.
- #define `ERR_PPP_FAIL` (-5)
The attempted action has failed.

- #define **ERR_PPP_PASSFAIL** (-6)
Pass/Fail.
- #define **ERR_PPP_LOSTCARRIER** (-7)
Lost connection carrier signal.
- #define **ERR_PPP_NO_MODEM** (-8)
No modem detected.
- #define **ERR_PPP_LCP_FAILED** (-9)
LCP negotiation has failed.
- #define **ERR_PPP_CHAPFAIL** (-10)
CHAP negotiation has failed.

14.37.3.1 Detailed Description

#include < ppp.h >

14.38 SAM Control Area Network (MCAN) Low Level Driver

Module Setting

- enum **mcan_timeout_mode** { **MCAN_TIMEOUT_CONTINUOUS** = **MCAN_TOCC_TOS_CONTINUOUS** , **MCAN_TIMEOUT_TX_EVEN_FIFO** = **MCAN_TOCC_TOS_TX_EV_TIMEOUT** , **MCAN_TIMEOUT_RX_FIFO_0** = **MCAN_TOCC_TOS_RX0_EV_TIMEOUT** , **MCAN_TIMEOUT_RX_FIFO_1** = **MCAN_TOCC_TOS_RX1_EV_TIMEOUT** }
- Can time out modes.*
- enum **mcan_nonmatching_frames_action** { **MCAN_NONMATCHING_FRAMES_FIFO_0** , **MCAN_NONMATCHING_FRAMES_FIFO_1** , **MCAN_NONMATCHING_FRAMES_REJECT** }
- Can non-matching frames action.*
- enum **mcan_interrupt_source** { **MCAN_RX_FIFO_0_NEW_MESSAGE** = **MCAN_IE_RF0NE** , **MCAN_RX_FIFO_0_WATERMARK** = **MCAN_IE_RF0WE** , **MCAN_RX_FIFO_0_FULL** = **MCAN_IE_RF0FE** , **MCAN_RX_FIFO_0_LOST_MESSAGE** = **MCAN_IE_RF0LE** , **MCAN_RX_FIFO_1_NEW_MESSAGE** = **MCAN_IE_RF1NE** , **MCAN_RX_FIFO_1_WATERMARK** = **MCAN_IE_RF1WE** , **MCAN_RX_FIFO_1_FULL** = **MCAN_IE_RF1FE** , **MCAN_RX_FIFO_1_MESSAGE_LOST** = **MCAN_IE_RF1LE** , **MCAN_RX_HIGH_PRIORITY_MESSAGE** = **MCAN_IE_HPME** , **MCAN_TIMESTAMP_COMPLETE** = **MCAN_IE_TCE** , **MCAN_TX_CANCELLATION_FINISH** = **MCAN_IE_TCFE** , **MCAN_TX_FIFO_EMPTY** = **MCAN_IE_TFEE** , **MCAN_TX_EVENT_FIFO_NEW_ENTRY** = **MCAN_IE_TEFNE** , **MCAN_TX_EVENT_FIFO_WATERMARK** = **MCAN_IE_TEFWE** , **MCAN_TX_EVENT_FIFO_FULL** = **MCAN_IE_TEFWE** , **MCAN_TX_EVENT_FIFO_ELEMENT_LOST** = **MCAN_IE_TEFLE** , **MCAN_TIMESTAMP_WRAPAROUND** = **MCAN_IE_TSWE** , **MCAN_MESSAGE_RAM_ACCESS_FAILURE** = **MCAN_IE_MRAFE** , **MCAN_TIMEOUT_OCCURRED** = **MCAN_IE_TOOE** , **MCAN_RX_BUFFER_NEW_MESSAGE** = **MCAN_IE_DRXE** , **MCAN_ERROR_LOGGING_OVERFLOW** = **MCAN_IE_ELOE** , **MCAN_ERROR_PASSIVE** = **MCAN_IE_EPE** , **MCAN_WARNING_STATUS** = **MCAN_IE_EWE** , **MCAN_BUS_OFF** = **MCAN_IE_BOE** , **MCAN_WATCHDOG** = **MCAN_IE_WDIE** , **MCAN_CRC_ERROR** = **MCAN_IE_CRCEE** , **MCAN_BIT_ERROR** = **MCAN_IE_BEE** , **MCAN_ACKNOWLEDGE_ERROR** = **MCAN_IE_ACKEE** , **MCAN_FORMAT_ERROR** = **MCAN_IE_FOEE** , **MCAN_STUFF_ERROR** = **MCAN_IE_STEE** }
- Can module interrupt source.*

14.38.1 Detailed Description

This driver for Atmel® | SMART SAM devices provides an low level interface for the configuration and management of the device's Control Area Network functionality.

Note

Since "The Control Area Network (CAN) performs communication according to ISO 11898-1 (Bosch CAN specification 2.0 part A,B) and to Bosch CAN FD specification V1.0", the driver is focus on the MAC layer and try to offer the APIs which can be used by upper application layer.

For storage of Rx/Tx messages and for storage of the filter configuration, a message RAM is needed to the CAN module. In this driver, the message RAM is static allocated, the related setting is defined and can be changed in the module configuration file "conf_mcan.h".

The following peripherals are used by this module:

- CAN (Control Area Network)

The following devices can use this module:

- SAMV71

The outline of this documentation is as follows:

- [Prerequisites](#)
- [Module Overview](#)
- [Special Considerations](#)
- [Extra Information](#)
- [Examples](#)
- [API Overview](#)

14.38.2 Prerequisites

There are no prerequisites for this module.

14.38.3 Module Overview

This driver provides an interface for the Control Area Network Controller functions on the device.

14.38.4 Special Considerations

There are no special considerations for this module.

14.38.5 Extra Information

For extra information see asfdoc_sam_mcan_extra. This includes:

- asfdoc_sam_mcan_extra_acronyms
- asfdoc_sam_mcan_extra_dependencies
- asfdoc_sam_mcan_extra_errata
- asfdoc_sam_mcan_extra_history

14.38.6 Examples

For a list of examples related to this driver, see asfdoc_sam_mcan_exqsg.

14.38.7 API Overview

14.38.8 Enumeration Type Documentation

14.38.8.1 mcan_interrupt_source

```
enum mcan_interrupt_source  
#include <mcan_internal.h>  
Can module interrupt source.  
Enum for the interrupt source.
```

Enumerator

MCAN_RX_FIFO_0_NEW_MESSAGE	Rx FIFO 0 New Message Interrupt Enable.
MCAN_RX_FIFO_0_WATERMARK	Rx FIFO 0 Watermark Reached Interrupt Enable.
MCAN_RX_FIFO_0_FULL	Rx FIFO 0 Full Interrupt Enable.
MCAN_RX_FIFO_0_LOST_MESSAGE	Rx FIFO 0 Message Lost Interrupt Enable.
MCAN_RX_FIFO_1_NEW_MESSAGE	Rx FIFO 1 New Message Interrupt Enable.
MCAN_RX_FIFO_1_WATERMARK	Rx FIFO 1 Watermark Reached Interrupt Enable.
MCAN_RX_FIFO_1_FULL	Rx FIFO 1 Full Interrupt Enable.
MCAN_RX_FIFO_1_MESSAGE_LOST	Rx FIFO 1 Message Lost Interrupt Enable.
MCAN_RX_HIGH_PRIORITY_MESSAGE	High Priority Message Interrupt Enable.
MCAN_TIMESTAMP_COMPLETE	Transmission Completed Interrupt Enable.
MCAN_TX_CANCELLATION_FINISH	Transmission Cancellation Finished Interrupt Enable.
MCAN_TX_FIFO_EMPTY	Tx FIFO Empty Interrupt Enable.
MCAN_TX_EVENT_FIFO_NEW_ENTRY	Tx Event FIFO New Entry Interrupt Enable.
MCAN_TX_EVENT_FIFO_WATERMARK	Tx Event FIFO Watermark Reached Interrupt Enable.
MCAN_TX_EVENT_FIFO_FULL	Tx Event FIFO Full Interrupt Enable.
MCAN_TX_EVENT_FIFO_ELEMENT_LOST	Tx Event FIFO Element Lost Interrupt Enable.
MCAN_TIMESTAMP_WRAPAROUND	Timestamp Wraparound Interrupt Enable.
MCAN_MESSAGE_RAM_ACCESS_FAILURE	Message RAM Access Failure Interrupt Enable.
MCAN_TIMEOUT_OCCURRED	Timeout Occurred Interrupt Enable.
MCAN_RX_BUFFER_NEW_MESSAGE	Message stored to Dedicated Rx Buffer Interrupt Enable.
MCAN_ERROR_LOGGING_OVERFLOW	Error Logging Overflow Interrupt Enable.
MCAN_ERROR_PASSIVE	Error Passive Interrupt Enable.
MCAN_WARNING_STATUS	Warning Status Interrupt Enable.
MCAN_BUS_OFF	Bus_Off Status Interrupt Enable.
MCAN_WATCHDOG	Watchdog Interrupt Enable.
MCAN_CRC_ERROR	CRC Error Interrupt Enable
MCAN_BIT_ERROR	Bit Error Interrupt Enable.
MCAN_ACKNOWLEDGE_ERROR	Acknowledge Error Interrupt Enable .
MCAN_FORMAT_ERROR	Format Error Interrupt Enable
MCAN_STUFF_ERROR	Stuff Error Interrupt Enable

14.38.8.2 mcan_nonmatching_frames_action

```
enum mcan_nonmatching_frames_action
#include <mcan_internal.h>
Can non-matching frames action.
```

Enumerator

MCAN_NONMATCHING_FRAMES_FIFO_0	Accept in Rx FIFO 0.
MCAN_NONMATCHING_FRAMES_FIFO_1	Accept in Rx FIFO 1.
MCAN_NONMATCHING_FRAMES_REJECT	Reject.

14.38.8.3 mcan_timeout_mode

```
enum mcan_timeout_mode
#include <mcan_internal.h>
```

Can time out modes.

Enumerator

MCAN_TIMEOUT_CONTINUES	Continuous operation.
MCAN_TIMEOUT_TX_EVEN_FIFO	Timeout controlled by TX Event FIFO.
MCAN_TIMEOUT_RX_FIFO_0	Timeout controlled by Rx FIFO 0.
MCAN_TIMEOUT_RX_FIFO_1	Timeout controlled by Rx FIFO 1.

14.39 SAME70 GPIO (MODM7AE70)

Classes

- class [PinIO](#)
GPIO Pin Class.
- class [_PinVector](#)
GPIO Pin Vector Base Class.
- class [PinVector< n >](#)
GPIO Pin Vector Class [PinVector](#) is a template instantiation of the [_PinVector](#) class, allowing for minimal storage requirements for potentially large vectors, without heavy code duplication due to template copies.

Variables

- volatile Pio & [PinIO::pio](#)
- uint32_t [PinIO::mask](#)

14.39.1 Detailed Description

The Netburner ARM SAME70 GPIO Pins class driver.

14.39.2 Variable Documentation

14.39.2.1 mask

`PinIO::mask`

Bit mask setting which pins in the given Pio hardware module the [PinIO](#) object will manage.

14.39.2.2 pio

`PinIO::pio`

Reference to the Pio hardware module that this [PinIO](#) will manage. Combines with the mask to manage a single pin or multiple within the module.

14.40 SMTP - Send Email

Topics

- [MIME Content Types](#)
- [SMTP Error Codes](#)
- [SSL SMTP Functions](#)

Functions

- int [SendMail](#) (IPADDR smtp_server, PCSTR userid, PCSTR from_addr, PCSTR to_addr, PCSTR subject, PCSTR textbody)

Send an email message. The function will open a TCP connection to the specified SMTP server, create a message based on the parameters, and send the message.
- int [SendMailAuth](#) (IPADDR smtp_server, PCSTR userid, PCSTR pass, PCSTR from_addr, PCSTR to_addr, PCSTR subject, PCSTR textbody)

Send an email message with plain text authentication. The function will open a TCP connection to the specified SMTP server, create a message based on the parameters, and send the message.
- int [SendMailEx](#) (IPADDR smtp_server, PCSTR userid, PCSTR from_addr_rev_path, PCSTR from_addr_rev_memo_hdr, PCSTR to_addr, PCSTR subject, PCSTR textbody)

Send an email message function, extended version.
- int [IsMailError](#) ()

Returns the error status of the last send mail transaction.
- void [PrintNBError](#) (int fd=0)

If an error occurred, prints the error information received from the SMTP server.
- void [PrintServerLog](#) (int fd=0)

Prints the server log of the last send mail transaction.
- int [SendMailAuthStartMIME](#) (IPADDR smtp_server, PCSTR userid, PCSTR pass, PCSTR from_addr, PCSTR to_addr, PCSTR subject, int &fd)

Start a Multi-purpose Internet Mail Extension (MIME) session.
- int [SendMailAuthAddMIME](#) (int fd, int ContentType, const char *pContent, const char *FileName)

Add a MIME part or attachment to an open MIME Session.
- int [SendMailAuthEndMIME](#) (int fd, PCSTR userid)

Send a MIME email message and close the SMTP session.
- enum [CONTENT_TYPE_ENUM](#) {
 - [CONTENT_TYPE_PLAIN_TEXT](#) , [CONTENT_TYPE_PLAIN_TEXT_ATTACH](#) , [CONTENT_TYPE_BINARY_ATTACH](#) ,
 - [CONTENT_TYPE_HTML_DECOMP](#) ,
 - [CONTENT_TYPE_END](#) }

SMTP MIME Conetnet Types.

14.40.1 Detailed Description

```
#include <mailto.h >
```

Send emails using the SMTP specification. The Send Mail functions provide a variety of sending options for simple sending an email, or sending with authentication. The IsMailError function is used to check for errors after an email is sent.

14.40.2 Enumeration Type Documentation

14.40.2.1 CONTENT_TYPE_ENUM

```
enum CONTENT\_TYPE\_ENUM
#include <mailto.h>
SMTP MIME Conetnet Types.
```

Enumerator

CONTENT_TYPE_PLAIN_TEXT	Plain text.
CONTENT_TYPE_PLAIN_TEXT_ATTACH	Plain text attachment.
CONTENT_TYPE_BINARY_ATTACH	Binary attachment.
CONTENT_TYPE_HTML_DECOMP	HTML.
CONTENT_TYPE_END	Additional content types can be added above this line.

14.40.3 Function Documentation

14.40.3.1 IsMailError()

```
int IsMailError ( )
```

```
#include <mailto.h>
```

Returns the error status of the last send mail transaction.

Returns

0 if no error occurred, [SMTP Error Codes](#).

See also

[PrintNError\(\)](#), [PrintServerLog\(\)](#)

14.40.3.2 PrintNError()

```
void PrintNError (
```

```
    int fd = 0 )
```

```
#include <mailto.h>
```

If an error occurred, prints the error information received from the SMTP server.

If an error occurs when sending an email, the system will record the error information received from the SMTP server. The information is only valid for the last transaction.

Parameters

<i>fd</i>	If no parameter is specified information will be sent to stdout. Otherwise it will be sent to the specified file descriptor.
-----------	--

See also

[IsMailError\(\)](#), [PrintServerLog\(\)](#)

14.40.3.3 PrintServerLog()

```
void PrintServerLog (
```

```
    int fd = 0 )
```

```
#include <mailto.h>
```

Prints the server log of the last send mail transaction.

The results of each send mail transaction are logged to a buffer. This function will send the results of the last transaction to stdout, or the specified file descriptor. The information is only valid for the last transaction.

Parameters

<i>fd</i>	If no parameter is specified information will be sent to stdout. Otherwise it will be sent to the specified file descriptor.
-----------	--

See also

[IsMailError\(\)](#), [PrintNError\(\)](#)

14.40.3.4 SendMail()

```
int SendMail (
```

```
    IPADDR smtp_server,
```

```
    PCSTR userid,
```

```
    PCSTR from_addr,
```

```

        PCSTR to_addr,
        PCSTR subject,
        PCSTR textbody )
#include <mailto.h>

```

Send an email message. The function will open a TCP connection to the specified SMTP server, create a message based on the parameters, and send the message.

Parameters

<i>smtp_server</i>	IP address of the destination SMTP server.
<i>userid</i>	ASCII string representing the RFC 931 identification.
<i>from_addr</i>	"From" email address
<i>to_addr</i>	Destination email address
<i>subject</i>	Email subject
<i>textbody</i>	Body of email message

Returns

0 on failure, 1 on success.

See also

[SendMailAuth\(\)](#)

14.40.3.5 SendMailAuth()

```

int SendMailAuth (
    IPADDR smtp_server,
    PCSTR userid,
    PCSTR pass,
    PCSTR from_addr,
    PCSTR to_addr,
    PCSTR subject,
    PCSTR textbody )
#include <mailto.h>

```

Send an email message with plain text authentication. The function will open a TCP connection to the specified SMTP server, create a message based on the parameters, and send the message.

Send an email message with SMTP plain text authentication per RFC 931. The function will open a TCP connection to the specified SMTP server, authenticate the connection with the specified username and password, create a message based on the parameters, and send the message.

Parameters

<i>smtp_server</i>	IP address of the destination SMTP server.
<i>userid</i>	ASCII string representing the RFC 931 identification.
<i>pass</i>	ASCII string to provide for AUTH identification.
<i>from_addr</i>	"From" email address
<i>to_addr</i>	Destination email address
<i>subject</i>	Email subject
<i>textbody</i>	Body of email message

Returns

0 on failure, 1 on success.

See also

[SendMail\(\)](#)

14.40.3.6 SendMailAuthAddMIME()

```
int SendMailAuthAddMIME (
    int fd,
    int ContentType,
    const char * pContent,
    const char * FileName )
```

```
#include <mailto.h>
```

Add a MIME part or attachment to an open MIME Session.

Must only be called for an open session started with [SendMailAuthStartMIME\(\)](#). It can be called as many times as needed to add each MIME part or attachment to the message.

Parameters

<i>fd</i>	The file descriptor of the open MIME session.
<i>ContentType</i>	The MIME content type, such as: CONTENT_TYPE_PLAIN_TEXT, CONTENT_TYPE_PLAIN_TEXT_ATTACH, CONTENT_TYPE_BINARY_ATTACH.
<i>*pContent</i>	Pointer to the content to add.
<i>*FileName</i>	File name for the attachment.

Returns

0 on failure, 1 on success.

See also

[SendMailAuthStartMIME\(\)](#), [SendMailAuthEndMIME\(\)](#)

14.40.3.7 SendMailAuthEndMIME()

```
int SendMailAuthEndMIME (
    int fd,
    PCSTR userid )
```

```
#include <mailto.h>
```

Send a MIME email message and close the SMTP session.

Must only be called for an open session started with [SendMailAuthStartMIME\(\)](#).

Parameters

<i>fd</i>	The file descriptor of the open MIME session.
<i>*userid</i>	The user ID that was used by SendMailAuthStartMIME() to open the session.

Returns

0 on failure, 1 on success.

See also

[SendMailAuthStartMIME\(\)](#), [SendMailAuthAddMIME\(\)](#)

14.40.3.8 SendMailAuthStartMIME()

```
int SendMailAuthStartMIME (
    IPADDR smtp_server,
```

```

PCSTR userid,
PCSTR pass,
PCSTR from_addr,
PCSTR to_addr,
PCSTR subject,
int & fd )

```

```
#include <mailto.h>
```

Start a Multi-purpose Internet Mail Extension (MIME) session.

Start a MIME session with plain text password authentication. This function will open a TCP connection to the SMTP server, authenticate, then return while leaving the TCP connection open. The Session file descriptor is returned in the "int &fd" reference variable. This function must be called before any other SendMail MIME function.

Sending an E-Mail message with Multipurpose Internet Mail Extensions (MIME) is a multi step process:

- Call [SendMailAuthStartMIME\(\)](#) to begin a Session with the SMTP server, connection will remain open.
- Call [SendMailAuthAddMIME\(\)](#) for each MIME attachment you want to add.
- Call [SendMailAuthEndMIME\(\)](#) to send the email message and close the Session.

The following MIME types are supported by default. The binary attachment should cover most types such as jpg, gif, etc. The types are defined in `\nburn\nbrtos\include\mailto.h`, and the functions are implemented in `\nburn\system\mailto.cpp`.

MIME Content Types defined by [MIME Content Types](#).

Parameters

<i>smtp_server</i>	IP address of the destination SMTP server.
<i>userid</i>	ASCII string representing the RFC 931 identification.
<i>pass</i>	Password.
<i>from_addr</i>	Reverse path per RFC 821, reverse source route.
<i>to_addr</i>	Destination email address.
<i>subject</i>	Email subject.
<i>fd</i>	A \diamond reference \diamond (or pointer) to an integer value of the calling function. The value of fd is modified by this function and will contain the file descriptor for the open SMTP Session. This value must always be checked to be greater than 0 for a valid Session. The fd is passed to other MIME functions to identify the open Session.

Returns

0 on failure, 1 on success.

See also

[SendMailAuthAddMIME\(\)](#), [SendMailAuthEndMIME\(\)](#)

14.40.3.9 SendMailEx()

```

int SendMailEx (
    IPADDR smtp_server,
    PCSTR userid,
    PCSTR from_addr_rev_path,
    PCSTR from_addr_memo_hdr,
    PCSTR to_addr,
    PCSTR subject,
    PCSTR textbody )

```

```
#include <mailto.h>
```

Send an email message function, extended version.

Send an email message with extended parameters. The function will open a TCP connection to the specified SMTP server, create a message based on the parameters, and send the message. This function is identical to [SendMail\(\)](#), with the addition of the `from_addr_rev_path` and `from_addr_memo_hdr` parameters.

Parameters

<code>smtp_server</code>	IP address of the destination SMTP server.
<code>userid</code>	ASCII string representing the RFC 931 identification.
<code>from_addr_rev_path</code>	Reverse path per RFC 821, reverse source route.
<code>from_addr_memo_hdr</code>	From address memo header per RFC 821. Contains items such as date, subject, to:, CC: and from:.
<code>to_addr</code>	Destination email address
<code>subject</code>	Email subject
<code>textbody</code>	Body of email message

Returns

0 on failure, 1 on success.

See also

[SendMail\(\)](#)

14.40.4 MIME Content Types

```
#include <mailto.h >
```

14.40.5 SMTP Error Codes

Macros

- `#define STATUS_OK (0)`
OK, no errors.
- `#define CONNECT_TO_SMTP_SERVER_FAILED (-1)`
Could not connect to SMTP server.
- `#define INITIAL_SERVER_REPLY_FAILED (-2)`
Initial server reply failed.
- `#define HELO_SERVER_REPLY_FAILED (-3)`
Server HELO reply failed.
- `#define MAIL_FROM_SERVER_REPLY_FAILED (-4)`
Mail From server reply failed.
- `#define RCPT_TO_SERVER_REPLY_FAILED (-5)`
Receipt To server reply failed.
- `#define DATA_SERVER_REPLY_FAILED (-6)`
Data server reply failed.
- `#define DATA_END_SERVER_REPLY_FAILED (-7)`
Date end server reply failed.
- `#define AUTH_LOGIN_SERVER_REPLY_FAILED (-8)`
AUTH login server reply failed.
- `#define USER_ID_SERVER_REPLY_FAILED (-9)`
User ID server reply failed.
- `#define PASSWORD_SERVER_REPLY_FAILED (-10)`
Password server reply failed.
- `#define CONNECT931_SMTP_SERVER_FAILED (-11)`
SMTP connection failed.

14.40.5.1 Detailed Description

```
#include <mailto.h >
```

14.40.6 SSL SMTP Functions

Functions

- int [SSL_SendMail](#) (IPADDR smtp_server, PCSTR userid, PCSTR pass, PCSTR from_addr, PCSTR to_addr, PCSTR subject, PCSTR textbody, BOOL STARTTLS=false, int remotePort=-1, const char *serverName=nullptr, bool verifyPeer=false, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Send an email message using SSL encryption.
- int [SSL_SendMailHTML](#) (IPADDR smtp_server, PCSTR userid, PCSTR pass, PCSTR from_addr, PCSTR to_addr, PCSTR subject, const char *filename, BOOL STARTTLS=false, int remotePort=-1, const char *serverName=nullptr, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Send an HTML email message from a file using SSL encryption.
- int [SSL_SendMailStartMIME](#) (IPADDR smtp_server, PCSTR userid, PCSTR pass, PCSTR from_addr, PCSTR to_addr, PCSTR subject, BOOL STARTTLS=false, int remotePort=-1, const char *serverName=nullptr, bool verifyPeer=false, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Start a Multi-purpose Internet Mail Extension (MIME) session using SSL encryption.

14.40.6.1 Detailed Description

The following functions is very similar to the unencrypted [SendMail\(\)](#) function. The initial connection of the SMTP server can happen in one of two ways:

1) An SSL connection is negotiated immediately. 2) A TCP connection is opened first, and a SSL connection is negotiated when the SMTP server sends a STARTTLS command to the NetBurner device.

Setting STARTTLS = TRUE enables the second mode of operation.

14.40.6.2 Function Documentation

14.40.6.2.1 SSL_SendMail()

```
int SSL_SendMail (
    IPADDR smtp_server,
    PCSTR userid,
    PCSTR pass,
    PCSTR from_addr,
    PCSTR to_addr,
    PCSTR subject,
    PCSTR textbody,
    BOOL STARTTLS = false,
    int remotePort = -1,
    const char * serverName = nullptr,
    bool verifyPeer = false,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
```

```
#include <ssl_mailto.h>
```

Send an email message using SSL encryption.

Parameters

<code>smtp_server</code>	IP address of the SMTP server.
--------------------------	--------------------------------

Parameters

<i>userid</i>	Ascll String to provide for RFC931 IDentification.
<i>pass</i>	Ascll String to provide for AUTH IDentification.
<i>from_addr</i>	From email address.
<i>to_addr</i>	To email address.
<i>subject</i>	The email subject.
<i>textbody</i>	The email body.
<i>STARTTLS</i>	Enable/disable STARTTLS functionality. Default is disabled.
<i>remotePort</i>	Port number to connect to on the SMTP server.
<i>serverName</i>	Server common name to use for certificate name verification and when sending SNI extensions.
<i>verifyPeer</i>	Set true to verify the server's certificate against a Certificate Authority list. Default if false.
<i>certBuff</i>	Buffer containing the certificate data.Default is null.
<i>certBuffSize</i>	Size of the buffer containing the certificate data.
<i>certBuffFormat</i>	The format of the certificate buffer. Default is SSL_FILETYPE_PEM.

Return values

0	Send failed
1	Send was successful

[SendMail\(\)](#)

14.40.6.2.2 SSL_SendMailHTML()

```
int SSL_SendMailHTML (
    IPADDR smtp_server,
    PCSTR userid,
    PCSTR pass,
    PCSTR from_addr,
    PCSTR to_addr,
    PCSTR subject,
    const char * filename,
    BOOL STARTTLS = false,
    int remotePort = -1,
    const char * serverName = nullptr,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
```

```
#include <ssl_mailto.h>
```

Send an HTML email message from a file using SSL encryption.

Parameters

<i>smtp_server</i>	IP address of the SMTP server.
<i>userid</i>	Ascii string to provide for RFC931 IDentification.
<i>pass</i>	Ascii string to provide for AUTH IDentification.
<i>from_addr</i>	From email address.
<i>to_addr</i>	To email address.

Parameters

<i>subject</i>	The email subject.
<i>filename</i>	HTTP server filename to send.
<i>STARTTLS</i>	Enable/disable STARTTLS functionality. Default is disabled.
<i>remotePort</i>	Port number to connect to on the SMTP server.
<i>serverName</i>	Server name to use for certificate name verification and when sending SNI extensions.
<i>certBuff</i>	Buffer containing the certificate data. Default is null.
<i>certBuffSize</i>	Size of the buffer containing the certificate data.
<i>certBuffFormat</i>	The format of the certificate buffer. Default is SSL_FILETYPE_PEM.

Return values

0	Send failed
1	Send was successful

[SSL_SendMail\(\)](#)

[SSL_SendMailStartMIME\(\)](#)

[SendMail\(\)](#)

14.40.6.2.3 SSL_SendMailStartMIME()

```
int SSL_SendMailStartMIME (
    IPADDR smtp_server,
    PCSTR userid,
    PCSTR pass,
    PCSTR from_addr,
    PCSTR to_addr,
    PCSTR subject,
    BOOL STARTTLS = false,
    int remotePort = -1,
    const char * serverName = nullptr,
    bool verifyPeer = false,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
```

```
#include <ssl_mailto.h>
```

Start a Multi-purpose Internet Mail Extension (MIME)session using SSL encryption.

Sending an E-Mail message with Multipurpose Internet Mail Extensions (MIME) is a multi step process:

- Call [SSL_SendMailStartMIME\(\)](#) to begin a Session with the SMTP server, connection will remain open.
- Call [SendMailAuthAddMIME\(\)](#) for each MIME attachment you want to add.
- Call [SendMailAuthEndMIME\(\)](#) to send the email message and close the Session.

The following MIME types are supported by default. The binary attachment should cover most types such as jpg, gif, etc. The types are defined by [MIME Content Types](#).

Parameters

<i>smtp_server</i>	IP address of the SMTP server.
<i>userid</i>	Ascii string to provide for RFC931 IDentification.
<i>pass</i>	Ascii string to provide for AUTH IDentification.

Parameters

<i>from_addr</i>	From email address.
<i>to_addr</i>	To email address.
<i>subject</i>	The email subject.
<i>STARTTLS</i>	Enable/disable STARTTLS functionality. Default is disabled.
<i>remotePort</i>	Port number to connect to on the SMTP server.
<i>serverName</i>	Server name to use for certificate name verification and when sending SNI extensions.
<i>verifyPeer</i>	Set true to verify the server's certificate against a Certificate Authority list. Default if false.
<i>certBuff</i>	Buffer containing the certificate data. Default is null.
<i>certBuffSize</i>	Size of the buffer containing the certificate data.
<i>certBuffFormat</i>	The format of the certificate buffer.

Return values

0	Send failed
1	Send was successful

14.41 SOCKS

Topics

- [SOCKS Error Codes](#)

Macros

- #define **SOCKS_MAX_UNAME_SIZE** 255
Max character length for usernames. Defined in RFC 1929.
- #define **SOCKS_MAX_PASSWD_SIZE** 255
Max character length for passwords. Defined in RFC 1929.

Enumerations

- enum **SocksAuthType** : unsigned char { **eSocksAuthTypeGssApi** = 0x01 , **eSocksAuthTypeUnPw** = 0x02 , **eSocksAuthTypeNoAuth** = 0x04 }
- SOCKS Authorization Types.*
- enum **SocksClientCmd** : unsigned char { **eSocksClientCmdConnect** = 1 , **eSocksClientCmdBind** = 2 , **eSocksClientCmdUdpAssoc** = 3 }
- SOCKS Client Commands.*
- enum **SocksAdrType** : unsigned char { **eSocksAdrTypeNone** = 0x00 , **eSocksAdrTypeIpv4** = 0x01 , **eSocksAdrTypeDomain** = 0x03 , **eSocksAdrTypeIpv6** = 0x04 }
- SOCKS Address Types.*

Functions

- bool **AuthWithGssApi** ()
A weak function that should be overridden by the developer in order to support GSSAPI authorization.

- void [SetSocksProxySettings](#) (SocksProxy *socksProxy)

Set the system level SOCKS proxy settings object to the one that is passed in. If this object is set and is marked as enabled, calls to [CoreConnect\(\)](#) (made from [connect\(\)](#), [DoGet\(\)](#), etc), will all initially connect to the proxy server using the SOCKS5 protocol.

- SocksProxy * [GetSocksProxySettings](#) ()

Get a pointer to the currently set Socks proxy settings object.

14.41.1 Detailed Description

#include< [Socks.h](#) >

The NetBurner SOCKS Library

14.41.2 Enumeration Type Documentation

14.41.2.1 SocksAdrType

enum [SocksAdrType](#) : unsigned char

#include <[Socks.h](#)>

SOCKS Address Types.

Enumerator

eSocksAdrTypeNone	None.
eSocksAdrTypeIpv4	IPv4.
eSocksAdrTypeDomain	Domain.
eSocksAdrTypeIpv6	IPv6.

14.41.2.2 SocksAuthType

enum [SocksAuthType](#) : unsigned char

#include <[Socks.h](#)>

SOCKS Authorization Types.

Enumerator

eSocksAuthTypeGssApi	GSS API.
eSocksAuthTypeUnPw	User name and password.
eSocksAuthTypeNoAuth	Not as defined in RFC so that it could be properly tested against when being set by user.

14.41.2.3 SocksClientCmd

enum [SocksClientCmd](#) : unsigned char

#include <[Socks.h](#)>

SOCKS Client Commands.

Enumerator

eSocksClientCmdConnect	Connect.
eSocksClientCmdBind	Not currently supported, see RFC 1928.
eSocksClientCmdUdpAssoc	Not currently supported, see RFC 1928.

14.41.3 Function Documentation

14.41.3.1 AuthWithGssApi()

```
bool AuthWithGssApi ( )
#include <Socks.h>
```

A weak function that should be overridden by the developer in order to support GSSAPI authorization.

Return values

<i>true</i>	The GSSAPI authorization succeeded.
<i>false</i>	The GSSAPI authorization failed.

14.41.3.2 GetSocksProxySettings()

```
SocksProxy * GetSocksProxySettings ( )
#include <Socks.h>
```

Get a pointer to the currently set Socks proxy settings object.

Returns

SocksProxy*

14.41.3.3 SetSocksProxySettings()

```
void SetSocksProxySettings (
    SocksProxy * socksProxy )
#include <Socks.h>
```

Set the system level SOCKS proxy settings object to the one that is passed in. If this object is set and is marked as enabled, calls to CoreConnect() (made from [connect\(\)](#), [DoGet\(\)](#), etc), will all initially connect to the proxy server using the SOCKS5 protocol.

Parameters

<i>socksProxy</i>	The proxy object that the system should reference.
-------------------	--

14.41.4 SOCKS Error Codes

Macros

- #define **SOCKS_SUCCESS** (0)
The connection was successful.
- #define **SOCKS_ERR_TIMEOUT** (-500)
The connection timed out.
- #define **SOCKS_BAD_ADR_TYPE** (-501)
Address type specified does not match the address provided.
- #define **SOCKS_CONN_ABORTED** (-502)
The other side aborted the connection.
- #define **SOCKS_BAD_AUTH_TYPE** (-503)
The server doesn't support the requested authorization types.
- #define **SOCKS_BAD_UN_PW** (-504)
The server did not approve the username and password provided.
- #define **SOCKS_UN_TOO_LONG** (-505)
The specified username is too long.
- #define **SOCKS_PW_TOO_LONG** (-506)

- The specified password is too long.*

 - #define **SOCKS_BAD_REPLY** (-507)
- The server reply was not successful.*

 - #define **SOCKS_BAD_DOMAIN** (-508)
- Unable to resolve domain name passed.*

 - #define **SOCKS_CMD_NOT_SUPPORTED** (-509)
- The requested command aren't supported.*

 - #define **SOCKS_BAD_PARAM** (-510)
- The passed in parameters are not valid.*

14.41.4.1 Detailed Description

#include< [Socks.h](#) >

Error codes that can be returned by SOCKS related functions.

14.42 SPI

Topics

- [SAME70 \(DSPI\)](#)
- [SAME70 \(QSPI\)](#)
- [SAME70 \(USART\)](#)

14.42.1 Detailed Description

Serial Peripheral Interface (SPI) is an interface bus commonly used to send data between microcontrollers and small peripherals over a short distance, such as port expanders, FPGAs, CPLDs, shift registers, sensors, and flash SD cards. Unlike an asynchronous UART that does not use a separate clock, the SPI operates in a synchronous mode using a single clock for both sender and receiver that determines the data rate as well as when each bit of data is valid. This API uses the "native" SPI mode with the following signals:

- Clock (CLK). Synchronous clock signal.
- Master out, Slave in (MOSI). Data signal from master to slave device.
- Master in, Slave out (MISO). Data signal from slave to master.
- Chip select (CS). Chip selects can be part of the SPI peripheral, or can be general purpose I/O.

An advantage of SPI is that the receiving hardware can be a simple shift register. This is a much simpler and less expensive than a UART implementation.

14.42.2 MCF5441x (DSPI)

Classes

- struct [dspidMAStruct](#)
- struct [dspidDriverStruct](#)
 - Major variables/configurations used for a DSPI transfer.*
- class [DSPIModule](#)
 - [DSPIModule](#) is a SPI communications driver. It is an object based driver, which allows for low overhead multiplexing between peripherals with different bus configurations.*

Macros

- #define `DEFAULT_DSPI_MODULE` 1
- #define `DSPI_MODULE_COUNT` 4

Enumerations

- enum `csReturnType` { `DEASSERT_NEVER` = 0 , `DEASSERT_AFTER_LAST` = 1 , `DEASSERT_EVERY_TRANSFER` = 2 }

14.42.2.1 Detailed Description

Supported platforms:

- MOD54415
- MOD54417
- NANO54415
- SB800EX

The DMA serial peripheral interface (DSPI) interfaces (up to 3 depending on your platform) provide a synchronous serial bus for communication between the processor and an external peripheral device. DSPI interface modules are numbered from 0 to 3. DSPI 0 is reserved for system use. The DSPI supports up to 32 queued SPI transfers (16 receive and 16 transmit) in the DSPI resident FIFOs eliminating CPU intervention between transfers.

The DSPI specification allows for sharing the SPI bus with multiple devices. However, when designing your system, you must consider what devices are connected and the desired throughput. For example, if you are using the Embedded Flash File System (EFlash) with external Flash cards, or the WiFi module, they will require exclusive use of the DSPI interface.

The DSPI uses the following hardware signals:

- SCLK Serial clock output from master.
- MOSI Master data output (transmit), slave data input (receive).
- MISO Master data input (receive), slave data output (transmit).
- QSPI_CS_n Optional QSPI chip selects. Note that you can also use GPIO signals and control them manually for the chip select functionality. In some cases, there are advantages to doing it this way.

DSPI Configuration and Initialization

Use of the DSPI requires:

1. Identify which pins on your NetBurner device provide primary or secondary QSPI functionality. Use the NetBurner Pins class functions to configure these pins for QSPI operation.
2. Single task applications: you can choose to call the [DSPIDone\(\)](#) function to determine when the DSPI transfer is complete, or use a semaphore and pend for completion.
3. Multi-task applications: If your application has more than one task that will access the same DSPI, you must create a semaphore to control access to the DSPI resource, just as you would with any shared resource.
4. Initialize the DSPI with the [DSPIInit\(\)](#) function.
5. When you have data to send, or want to read data from the DSPI slave device, call the [QSPIStart\(\)](#) function to initiate the data transfer.
6. The semaphore will post when the data transfer is complete.

14.42.2.3 Enumeration Type Documentation**14.42.2.3.1 csReturnType**

```
enum csReturnType
#include <dspi.h>
```

Chip select return types.

Chip select deassertion modes. Used to determine when the driver should deassert chip selects during SPI transfer.

Enumerator

DEASSERT_NEVER	The chip select used for the transaction should remain asserted, even after the transaction is complete.
DEASSERT_AFTER_LAST	The chip select should remain asserted for the full duration of the transaction, and only be deasserted after the final transfer.
DEASSERT_EVERY_TRANSFER	The chip select should be deasserted between every transfer within the transaction.

14.42.2.3.2 spiChipSelect

```
enum spiChipSelect
#include <dspi.h>
```

Chip select number.

If supported by the SPI peripheral, these values can be used to configure the chip select to be used during a SPI transfer.

Enumerator

CHIP_SELECT_0	Configure bit mask for SPI chip select 0.
CHIP_SELECT_1	Configure bit mask for SPI chip select 1.
CHIP_SELECT_2	Configure bit mask for SPI chip select 2.
CHIP_SELECT_3	Configure bit mask for SPI chip select 3.
CHIP_SELECT_DISABLED	Configure bit mask to disable chip select.

14.42.2.3.3 spiChipSelectPolarity

```
enum spiChipSelectPolarity
#include <dspi.h>
```

Chip select polarity.

These values can be used to configure the chip select's asserted/deasserted logic level. These values will configure all chip selects to the same configuration. If you intend on using an SPI peripheral with multiple chip selects with different polarities, these values cannot not be used.

Enumerator

CS_ASSERT_LOW	Bit mask configures all active chip selects as active low, inactive high.
CS_ASSERT_HIGH	Bit mask configures all active chip selects as inactive low, active high.

14.42.2.4 Function Documentation

14.42.2.4.1 DSPIDone()

```
BOOL DSPIDone (
    uint8_t SPIModule = DEFAULT_DSPI_MODULE )
```

```
#include <dspi.h>
```

Check current DSPI Data Transfer.

Parameters: None

Return: Progress of transfer - TRUE is finished, FALSE is active

Notes: None

14.42.2.4.2 DSPIInit()

```
uint8_t DSPIInit (
    uint8_t SPIModule = DEFAULT_DSPI_MODULE,
    uint32_t Baudrate = 2000000,
    uint8_t QueueBitSize = 8,
    uint8_t CS = 0x00,
    uint8_t CSPol = 0x0F,
    uint8_t ClkPolarity = 0,
    uint8_t ClkPhase = 1,
    BOOL DoutHiz = TRUE,
    uint8_t QCD = 0,
    uint8_t DTL = 0 )
```

```
#include <dspi.h>
```

Initialize a DSPI module.

Notes:

- The maximum baud rate is CPU_CLOCK / 3
- Will initialize to the highest available baud rate that does not exceed the maximum
- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for greater than 8 bits per transfer then the data must be uint16_t aligned
- If configured for greater than 16 bits per transfer then the data must be uint32_t aligned
- Chip select is based on chipSelectPolarity
- 0 data captured leading edge of DSPI_CLK, changed following edge.
- 1 data changed leading edge of DSPI_CLK, captured following edge.
- 0 default is as close to 1/2 DSPI_CLK without going under, keeping with the interface to SPI
- 0 default is 17/(system clock / 2), in keeping with interface to QSPI

Parameters

<i>SPIModule</i>	SPI module number, 0 - 1
<i>Baudrate</i>	Maximum baud rate requested
<i>QueueBitSize</i>	Number of bits per transfer: 8, 16 or 32
<i>CS</i>	SPI chip selects to use for transfer
<i>CSPol</i>	0 = inactive logic level low, 1 = high
<i>ClkPolarity</i>	0 = inactive logic level low, 1 = high
<i>ClkPhase</i>	0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge.
<i>DoutHiz</i>	Data output high impedance between transfers
<i>QCD</i>	Delay from chip select to valid clock (default is 0). QCD is a value in the QDLYR register and will change the delay between the assertion of the chip select and the start of the DSPI clock. Default setting of one half DSPI clk will be used if parameter is specified as 0x0 or not included.
<i>DTL</i>	DTL is a value in the QDLYR register and will change the delay following a transfer of a single uint16_t in the DSPI queue. Default reset value of 17/(fsys/2) will be used if parameter is specified 0 or not included.

Returns

Current stat of DSPI bus [MOD5441xDspiStates](#)

14.42.2.4.3 DSPIStart()

```
uint8_t DSPIStart (
    uint8_t SPIModule,
    uint8_t transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    OS_SEM * finishedSem = NULL,
    uint8_t enableDMA = TRUE,
    int csReturnToInactive = DEASSERT_AFTER_LAST )
```

#include <dspi.h>

Start DSPI Data Transfer.

Parameters:

transmitBufferPtr - Buffer with data to send, NULL for receiving
 receiveBufferPtr - Buffer to receive data, NULL for sending
 byteCount - Count of bytes to send or receive
 SPIModule - Selects the dspi module to use
 finishedSem - Optional semaphore to set when completed

Return:

Current DSPI state - DSPI_OK success or DSPI_BUSY busy

Notes:

None

14.42.2.4.4 QSPIdone()

```
BOOL QSPIdone (
    void ) [inline]
```

#include <dspi.h>

Can be called after [QSPIStart\(\)](#). Returns TRUE when transfer is complete. This is an alternative to using a semaphore.

Return values

<i>TRUE</i>	When transfer is complete
<i>FALSE</i>	On error

See also

[QSPInit\(\)](#)

[QSPStart\(\)](#)

14.42.2.4.5 QSPInit()

```
uint8_t QSPInit (
    uint32_t baudRateInBps = 2000000,
    uint8_t transferSizeInBits = 8,
    uint8_t peripheralChipSelects = 0x0F,
    uint8_t chipSelectPolarity = 1,
    uint8_t clockPolarity = 0,
    uint8_t clockPhase = 1,
    BOOL doutHiz = TRUE,
    uint8_t csToClockDelay = 0,
    uint8_t delayAfterTransfer = 0 ) [inline]
#include <dspl.h>
```

Initialize Queued Serial Peripheral Interface (QSPI)

Notes: (3) Transfers > 8 must be word aligned (4) Select based on chipSelectPolarity (5) 0 data captured leading edge of QSPI_CLK, changed following edge. (6) 1 data changed leading edge of QSPI_CLK, captured following edge. (7) 0 default is 1/2 QSPI_CLK or see MFCXXXX reference manual (8) 0 default is 8192/(system clock / 2) see MFCXXXX reference manual

Parameters

<i>baudRateInBps</i>	Maximum requested baud rate in bits per second. The maximum possible baud rate is determined by the system clock. The function will select the highest possible baud rate if the specified value cannot be achieved.
<i>transferSizeInBits</i>	Size of data values to be transferred. Values can be 8, 16 or 32 bits. Note that 16 and 32 bit size values must be word (16-bit) aligned (16-bit).
<i>peripheralChipSelects</i>	Peripheral chip select drive level. Used to select an external device for serial data transfer. More than one chip select may be active at once, and more than one device can be connected to each chip select. Bits 3-0 map directly to QSPI_CS[3:0], respectively. For each bit: <ul style="list-style-type: none"> • 0 = Chip select is 0 during a transfer. • 1 = Chip select is 1 during a transfer.
<i>chipSelectPolarity</i>	Peripheral chip select inactive level (no transfer in progress). Applies to all chip selects. <ul style="list-style-type: none"> • 0 = 0 when inactive • 1 = 1 when inactive
<i>clockPolarity</i>	Clock polarity: <ul style="list-style-type: none"> • 0 = The inactive state value of QSPI_CLK is logic level 0. • 1 = The inactive state value of QSPI_CLK is logic level 1.

Parameters

<i>clockPhase</i>	<p>Clock phase:</p> <ul style="list-style-type: none"> • 0 = Data captured on the leading edge of QSPI_CLK and changed on the following edge of QSPI_CLK. • 1 = Data changed on the leading edge of QSPI_CLK and captured on the following edge of QSPI_CLK.
<i>doutHiz</i>	<p>Data output high impedance enable. Selects QSPI_DOUT mode of operation.</p> <ul style="list-style-type: none"> • 0 = Default value after reset. QSPI_DOUT is actively driven between transfers. • 1 = QSPI_DOUT is high impedance between transfers.
<i>csToClockDelay</i>	<p>QCD, QSPICLK delay. When the DSCK bit in the command RAM is set this field determines the length of the delay from assertion of the chip selects to valid QSPI_CLK transition.</p>
<i>delayAfterTransfer</i>	<p>Delay after transfer. When the DT bit in the command RAM is set this field determines the length of delay after the serial transfer.</p>

Returns

groupQspiState

[QSPIInit\(\)](#)

[QSPIStart\(\)](#)

14.42.2.4.6 QSPIStart()

```
uint8_t QSPIStart (
    uint8_t transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    OS_SEM * finishedSem = NULL ) [inline]
```

#include <dspi.h>

Start QSPI Data Transfer.

Parameters

<i>transmitBufferPtr</i>	Pointer to the buffer to use in the transfer. Specify NULL for receive only.
<i>receiveBufferPtr</i>	Pointer to buffer to store received data. NULL for transmit only.
<i>byteCount</i>	Number of bytes to send or receive. If the data size is greater than 8-bit, you must provide the total number of bytes.
<i>finishedSem</i>	Pointer to preinitialized semaphore to post to when transfer is complete. A value of NULL disables the semaphore function.

Can be called after [QSPIStart\(\)](#). Returns TRUE when transfer is complete. This is an alternative to using a semaphore.

14.42.3.1 Detailed Description

```
#include < qspi.h >
```

Supported platforms:

- MOD54415
- MOD54417
- NANO54415
- SB800EX

Note

The SPI interface modules (up to 4 depending on the platform) on the MCF5441x processor are termed DMA SPI (DSPI). Earlier ColdFire processors had a single SPI with a queue, and were termed QSPI. This header file is here as a guide for customers using earlier ColdFire processors to make porting code easier. However, we highly recommend using the DSPI driver instead. The calls are nearly identical.

Introduction

The Queued Serial Peripheral Interface (QSPI) is a full duplex synchronous serial data link that operates in master/slave mode. The QSPI is similar to SPI, but also provided a hardware queue for transmit data, receive data, and commands. Up to 16 transfers can be queued at one time, eliminating CPU intervention between transfers. The NetBurner QSPI driver and API provide interrupt driven QSPI communication.

The QSPI specification allows for sharing the QSPI bus with multiple devices. However, when designing your system you must consider what devices are connected and the desired throughput. For example, if you are using the Embedded Flash File System (EPPS) with external SD flash cards, or the WiFi module, they will require exclusive use of the QSPI.

The QSPI uses the following hardware signals:

- SCLK Serial clock output from master
- MOSI Master data output (transmit), slave data input (receive)
- MISO Master data input (receive), slave data output (transmit)

- `QSPI_CS` Optional QSPI chip selects

Programming tip: If you are new to QSPI and require a chip select for your device, we recommend using a GPIO signal during initial development to simplify your application code. Once proper operation has been achieved, modify the code to use the QSPI chip selects.

QSPI Configuration and Initialization

Use of the QSPI requires:

1. Identify which pins on your NetBurner device provide primary or secondary QSPI functionality. Use the NetBurner Pins class functions to configure these pins for QSPI operation.
2. Single task applications: you can choose to call the `QSPIdone()` function to determine when the QSPI transfer is complete, or use a semaphore and pend for completion.
3. Multi-task applications: If your application has more than one task that will access the QSPI, you must create a semaphore to control access to the QSPI resource.
4. Initialize the QSPI with the `QSPIInit()` function.
5. When you have data to send, or want to read data from the QSPI slave device, call the `QSPIStart()` function to initiate the data transfer.
6. The semaphore will post when the data transfer is complete.

14.42.3.2 Function Documentation

14.42.3.2.1 QSPIdone()

```

BOOL QSPIdone (
    void ) [inline]
#include <qspi.h>

```

Can be called after `QSPIStart()`. Returns TRUE when transfer is complete. This is an alternative to using a semaphore.

Return values

<code>TRUE</code>	When transfer is complete
<code>FALSE</code>	On error

See also

[QSPIInit\(\)](#)

[QSPIStart\(\)](#)

Can be called after `QSPIStart()`. Returns TRUE when transfer is complete. This is an alternative to using a semaphore.

Note that the 'Q' stands for Queued SPI

Returns

true if DSPI is finished, false if active

14.42.3.2.2 QSPIInit()

```

uint8_t QSPIInit (
    uint32_t baudRateInBps = 2000000,
    uint8_t transferSizeInBits = 8,
    uint8_t peripheralChipSelects = 0x0F,
    uint8_t chipSelectPolarity = 1,
    uint8_t clockPolarity = 0,
    uint8_t clockPhase = 1,

```

```

    BOOL doutHiz = TRUE,
    uint8_t csToClockDelay = 0,
    uint8_t delayAfterTransfer = 0 ) [inline]

```

```
#include <qspi.h>
```

Initialize Queued Serial Peripheral Interface (QSPI)

Notes: (3) Transfers > 8 must be word aligned (4) Select based on chipSelectPolarity (5) 0 data captured leading edge of QSPI_CLK, changed following edge. (6) 1 data changed leading edge of QSPI_CLK, captured following edge. (7) 0 default is 1/2 QSPI_CLK or see MFCXXXX reference manual (8) 0 default is 8192/(system clock / 2) see MFCXXXX reference manual

Parameters

<i>baudRateInBps</i>	Maximum requested baud rate in bits per second. The maximum possible baud rate is determined by the system clock. The function will select the highest possible baud rate if the specified value cannot be achieved.
<i>transferSizeInBits</i>	Size of data values to be transferred. Values can be 8, 16 or 32 bits. Note that 16 and 32 bit size values must be word (16-bit) aligned (16-bit).
<i>peripheralChipSelects</i>	Peripheral chip select drive level. Used to select an external device for serial data transfer. More than one chip select may be active at once, and more than one device can be connected to each chip select. Bits 3-0 map directly to QSPI_CS[3:0], respectively. For each bit: <ul style="list-style-type: none"> • 0 = Chip select is 0 during a transfer. • 1 = Chip select is 1 during a transfer.
<i>chipSelectPolarity</i>	Peripheral chip select inactive level (no transfer in progress). Applies to all chip selects. <ul style="list-style-type: none"> • 0 = 0 when inactive • 1 = 1 when inactive
<i>clockPolarity</i>	Clock polarity: <ul style="list-style-type: none"> • 0 = The inactive state value of QSPI_CLK is logic level 0. • 1 = The inactive state value of QSPI_CLK is logic level 1.
<i>clockPhase</i>	Clock phase: <ul style="list-style-type: none"> • 0 = Data captured on the leading edge of QSPI_CLK and changed on the following edge of QSPI_CLK. • 1 = Data changed on the leading edge of QSPI_CLK and captured on the following edge of QSPI_CLK.
<i>doutHiz</i>	Data output high impedance enable. Selects QSPI_DOUT mode of operation. <ul style="list-style-type: none"> • 0 = Default value after reset. QSPI_DOUT is actively driven between transfers. • 1 = QSPI_DOUT is high impedance between transfers.
<i>csToClockDelay</i>	QCD, QSPICLK delay. When the DSCK bit in the command RAM is set this field determines the length of the delay from assertion of the chip selects to valid QSPI_CLK transition.
<i>delayAfterTransfer</i>	Delay after transfer. When the DT bit in the command RAM is set this field determines the length of delay after the serial transfer.

Returns

groupQspiState

See also

[QSPIInit\(\)](#)

[QSPIStart\(\)](#)

Initialize Queued Serial Peripheral Interface (QSPI)

Note that the 'Q' stands for Queued SPI

Will use the default SPI module, 0.

- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for > than 8 bits per transfer then the data must be uint16_t aligned
- If configured for > than 16 bits per transfer then the data must be uint32_t aligned
- If either RX or TX pointer is assigned 'null' then that communication direction will not occur.
- If DSPI_Finished points to a semaphore, then the DSPI will POST to it when the transfer is complete.
- The semaphore is optional, but it can increase efficiency.

Parameters

<i>baudRateInBps</i>	Maximum baud rate requested
<i>transferSizeInBits</i>	Number of bits per transfer: 8, 16 or 32
<i>peripheralChipSelects</i>	SPI chip selects to use for transfer
<i>chipSelectPolarity</i>	0 = inactive logic level low, 1 = high
<i>clockPolarity</i>	0 = inactive logic level low, 1 = high
<i>clockPhase</i>	0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge.
<i>doutHiz</i>	Data output high impedance between transfers
<i>csToClockDelay</i>	Delay from chip select to valid clock (default is 0)
<i>delayAfterTransfer</i>	Chip select mode spiChipSelect

Returns

The current state of the SPI bus [dspState](#)

14.42.3.2.3 QSPIStart()

```
uint8_t QSPIStart (
    uint8_t transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    OS_SEM * finishedSem = NULL ) [inline]
```

#include <qspi.h>

Start QSPI Data Transfer.

Parameters

<i>transmitBufferPtr</i>	Pointer to the buffer to use in the transfer. Specify NULL for receive only.
<i>receiveBufferPtr</i>	Pointer to buffer to store received data. NULL for transmit only.
<i>byteCount</i>	Number of bytes to send or receive. If the data size is greater than 8-bit, you must provide the total number of bytes.

Parameters

<i>finishedSem</i>	Pointer to preinitialized semaphore to post to when transfer is complete. A value of NULL disables the semaphore function.
--------------------	--

Returns

groupQspiState

14.42.4.1 Detailed Description

Supported Platforms:

- MODM7AE70
- SBE70LC

The NetBurner ARM SAME70 DSPI Group. Note that for the ARM SAME70 there are 3 types of SPI peripherals:

- SPI using the SPI peripheral: Provides the most configuration options. Used in single data channel mode: SCLK, MISO, MOSI, Chip Selects.
- SPI using the QSPI peripheral: Single data channel as with SPI, but fewer configuration options.
- SPI using the USART peripheral: Single data channel as with SPI, but fewer configuration options.

14.42.4.2 Enumeration Type Documentation

14.42.4.2.1 csReturnType

```
enum csReturnType
#include <dspi.h>
```

Chip select deassertion modes. Used to determine when the driver should deassert chip selects during SPI transfer.

Enumerator

DEASSERT_NEVER	The chip select used for the transaction should remain asserted, even after the transaction is complete.
DEASSERT_AFTER_LAST	The chip select should remain asserted for the full duration of the transaction, and only be deasserted after the final transfer.
DEASSERT_EVERY_TRANSFER	The chip select should be deasserted between every transfer within the transaction. Deassert chip select After every transfer.

14.42.4.2.2 spiChipSelect

```
enum spiChipSelect
#include <dspi.h>
```

Chip select number.

If supported by the SPI peripheral, these values can be used to configure the chip select to be used during a SPI transfer.

Enumerator

CHIP_SELECT_0	Configure the SPI peripheral to use chip select 0.
CHIP_SELECT_1	Configure the SPI peripheral to use chip select 1.
CHIP_SELECT_2	Configure the SPI peripheral to use chip select 2.
CHIP_SELECT_3	Configure the SPI peripheral to use chip select 3.
CHIP_SELECT_DISABLED	Configure the SPI peripheral to disable chip select.

14.42.4.2.3 spiChipSelectPolarity

```
enum spiChipSelectPolarity
#include <dspi.h>
```

Chip select polarity.

This enum exists for API compatibility between platforms. The SAME70's SPI peripheral does not support modifying chip select polarity. The SPI peripheral only supports asserting chip select to logic level LOW during a transaction. If you need to assert the chip select to logic level HIGH during a transaction, your alternative is to use a GPIO for

chip select.

Enumerator

CS_ASSERT_LOW	Assert all chip selects to logic level LOW during a SPI transaction.
CS_ASSERT_HIGH	Assert all chip selects to logic level HIGH during a SPI transaction.

14.42.4.3 Function Documentation

14.42.4.3.1 DSPIdone()

```

BOOL DSPIdone (
    uint8_t SPIModule = DEFAULT_DSPI_MODULE )
#include <dspi.h>
Check SPI status.

```

Returns

true if DSPI is finished, false if active

14.42.4.3.2 DSPIInit()

```

uint8_t DSPIInit (
    uint8_t SPIModule = DEFAULT_DSPI_MODULE,
    uint32_t Baudrate = 2000000,
    uint8_t QueueBitSize = 8,
    uint8_t CS = 0x00,
    uint8_t CSPol = 0x0F,
    uint8_t ClkPolarity = 0,
    uint8_t ClkPhase = 1,
    BOOL DoutHiz = TRUE,
    uint8_t QCD = 0,
    uint8_t DTL = 0 )
#include <dspi.h>

```

Initialize a DSPI module.

Notes:

- The maximum baud rate is CPU_CLOCK / 3
- Will initialize to the highest available baud rate that does not exceed the maximum
- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for greater than 8 bits per transfer then the data must be uint16_t aligned
- If configured for greater than 16 bits per transfer then the data must be uint32_t aligned
- Chip select is based on chipSelectPolarity
- 0 data captured leading edge of DSPI_CLK, changed following edge.
- 1 data changed leading edge of DSPI_CLK, captured following edge.
- 0 default is as close to 1/2 DSPI_CLK without going under, keeping with the interface to SPI
- 0 default is 17/(system clock / 2), in keeping with interface to QSPI

Parameters

<i>SPIModule</i>	SPI module number, 0 - 1
<i>Baudrate</i>	Maximum baud rate requested

Parameters

<i>QueueBitSize</i>	Number of bits per transfer: 8, 16 or 32
<i>CS</i>	SPI chip selects to use for transfer
<i>CSPol</i>	0 = inactive logic level low, 1 = high
<i>ClkPolarity</i>	0 = inactive logic level low, 1 = high
<i>ClkPhase</i>	0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge.
<i>DoutHiz</i>	Data output high impedance between transfers
<i>QCD</i>	Delay from chip select to valid clock (default is 0)
<i>DTL</i>	Chip select mode dspIChipSelectMode

Returns

Current stat of DSPI bus [dspIState](#)

14.42.4.3.3 DSPIStart()

```
uint8_t DSPIStart (
    uint8_t SPIModule,
    uint8_t transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    OS_SEM * finishedSem = NULL,
    uint8_t enableDMA = TRUE,
    int csReturnToInactive = DEASSERT_AFTER_LAST )
```

```
#include <dspI.h>
```

Start a DSPI transfer.

- If configured for 8 bits per transfer then the data must be `uint8_t` aligned
- If configured for > than 8 bits per transfer then the data must be `uint16_t` aligned
- If configured for > than 16 bits per transfer then the data must be `uint32_t` aligned
- If either RX or TX pointer is assigned 'null' then that communication direction will not occur.
- If `DSPIS_Finished` points to a semaphore, then the DSPI will POST to it when the transfer is complete.
- The semaphore is optional, but it can increase efficiency.

Parameters

<i>SPIModule</i>	DSPI module to use, 0 - 1
<i>transmitBufferPtr</i>	Pointer to the buffer containing the data to transmit
<i>receiveBufferPtr</i>	Pointer to the buffer to store the received data
<i>byteCount</i>	Number of bytes to transmit
<i>finishedSem</i>	Optional semaphore to post to when finished
<i>enableDMA</i>	Enable DMA transfers
<i>csReturnToInactive</i>	Chip select state

Returns

The current state of the SPI bus [dspIState](#)

14.42.4.3.4 QSPIdone()

```
BOOL QSPIdone (
    void ) [inline]
```

```
#include <dspi.h>
```

Compatibility function for previous drivers. Check SPI status.

Can be called after [QSPIStart\(\)](#). Returns TRUE when transfer is complete. This is an alternative to using a semaphore.

Note that the 'Q' stands for Queued SPI

Returns

true if DSPI is finished, false if active

14.42.4.3.5 QSPIInit()

```
uint8_t QSPIInit (
    uint32_t baudRateInBps = 2000000,
    uint8_t transferSizeInBits = 8,
    uint8_t peripheralChipSelects = 0x0F,
    uint8_t chipSelectPolarity = 1,
    uint8_t clockPolarity = 0,
    uint8_t clockPhase = 1,
    BOOL doutHiz = TRUE,
    uint8_t csToClockDelay = 0,
    uint8_t delayAfterTransfer = 0 ) [inline]
```

```
#include <dspi.h>
```

Compatibility function for previous drivers. Initialize SPI module.

Initialize Queued Serial Peripheral Interface (QSPI)

Note that the 'Q' stands for Queued SPI

Will use the default SPI module, 0.

- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for > than 8 bits per transfer then the data must be uint16_t aligned
- If configured for > than 16 bits per transfer then the data must be uint32_t aligned
- If either RX or TX pointer is assigned 'null' then that communication direction will not occur.
- If DSPI_Finished points to a semaphore, then the DSPI will POST to it when the transfer is complete.
- The semaphore is optional, but it can increase efficiency.

Parameters

<i>baudRateInBps</i>	Maximum baud rate requested
<i>transferSizeInBits</i>	Number of bits per transfer: 8, 16 or 32
<i>peripheralChipSelects</i>	SPI chip selects to use for transfer
<i>chipSelectPolarity</i>	0 = inactive logic level low, 1 = high
<i>clockPolarity</i>	0 = inactive logic level low, 1 = high
<i>clockPhase</i>	0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge.
<i>doutHiz</i>	Data output high impedance between transfers
<i>csToClockDelay</i>	Delay from chip select to valid clock (default is 0)
<i>delayAfterTransfer</i>	Chip select mode spiChipSelect

Returns

The current state of the SPI bus [dspState](#)

14.42.4.3.6 QSPIStart()

```
uint8_t QSPIStart (
    uint8_t * transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    OS_SEM * finishedSem = NULL ) [inline]
```

```
#include <dsp.h>
```

Compatibility function for previous drivers. Start a SPI transfer.

Start QSPI Data Transfer.

Note that the 'Q' stands for Queued SPI

- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for > than 8 bits per transfer then the data must be uint16_t aligned
- If configured for > than 16 bits per transfer then the data must be uint32_t aligned
- If either RX or TX pointer is assigned 'null' then that communication direction will not occur.
- If DSPI_Finished points to a semaphore, then the DSPI will POST to it when the transfer is complete.
- The semaphore is optional, but it can increase efficiency.

Parameters

<i>transmitBufferPtr</i>	Pointer to the buffer containing the data to transmit
<i>receiveBufferPtr</i>	Pointer to the buffer to store the received data
<i>byteCount</i>	Number of bytes to transmit
<i>finishedSem</i>	Optional semaphore to post to when finished

Returns

The current state of the SPI bus [dspState](#)

14.42.5 SAME70 (QSPI)**Classes**

- class [SPI_QSPI](#)
The Single-Bit SPI mode QSPI Peripheral Class.

QuadSPI Peripheral Module Definitions

- #define **DEFAULT_QUADSPI_MODULE** 0
Default QUADSPI module.
- #define **QUADSPI_MODULE_COUNT** 1
Number of modules: 0, 1.

14.42.5.1 Detailed Description

Supported Platforms:

- MODM7AE70
- SBE70LC

The NetBurner ARM SAME70 Quad SPI (QSPI) API. Note that there are 3 types of SPI peripherals:

- SPI using the SPI peripheral: Provides the most configuration options. Used in single data channel mode: SCLK, MISO, MOSI, Chip Selects.
- SPI using the QuadSPI peripheral: Single data channel as with SPI, but fewer configuration options.
- SPI using the USART peripheral: Single data channel as with SPI, but fewer configuration options.

14.42.6 SAME70 (USART)

Topics

- [UsartModuleNumber](#)
USART Peripheral Module .

Classes

- class [SPI_USART](#)
USART in SPI mode Peripheral Module Class.

14.42.6.1 Detailed Description

Supported Platforms:

- MODM7AE70
- SBE70LC

Note that for the ARM SAME70 there are 3 types of SPI peripherals:

- SPI using the SPI peripheral: Provides the most configuration options. Used in single data channel mode: SCLK, MISO, MOSI, Chip Selects.
- SPI using the QSPI peripheral: Single data channel as with SPI, but fewer configuration options.
- SPI using the USART peripheral: Single data channel as with SPI, but fewer configuration options.

14.42.6.2 UsartModuleNumber

USART Peripheral Module .

Macros

- #define **DEFAULT_USART_SPI_MODULE** 0
Default QUADSPI module.
- #define **USART_SPI_MODULE_COUNT** 2
Number of modules: 0, 1.

14.42.6.2.1 Detailed Description

USART Peripheral Module .

14.43 SSH

Topics

- [SSH Error Codes](#)

Typedefs

- typedef int(* [sshUserAuthenticateFn](#)) (const char *usernamePtr, const char *passwordPtr)
[DEPRECATED] User provided SSH username and password authenticate routine for a server. Please consider [sshUserAuthenticateWithTypeFn](#).
- typedef int(* [sshUserAuthenticateWithTypeFn](#)) (const char *usernamePtr, const char *authValPtr, [AuthType](#) authType)
User provided SSH user authenticate routine for a server.
- typedef int(* [sshGetUserPwFn](#)) (const [NBString](#) &usernamePtr, [NBString](#) &passwordPtr)
User provided SSH user password authentication routine for clients.
- typedef int(* [sshGetUserKeyFn](#)) (const [NBString](#) &usernamePtr, [NBString](#) &publicKey, [NBString](#) &privateKey, [NBString](#) &keyType)
User provided SSH user key authenticate routine for clients.
- typedef int(* [sshUserGetKeyFn](#)) (int keyRequested, const unsigned char **keyBufferPtr, int *keyLengthPtr)
The user defined callback to get the server key used during the initial SSH negotiation.

Functions

- void [SshSetUserAuthenticate](#) ([sshUserAuthenticateFn](#) sshUserAuthenticateFnPtr)
[DEPRECATED] Sets the user defined server authentication function. Please consider [sshUserAuthenticateWithTypeFn](#).
- [sshUserAuthenticateFn](#) [SshGetUserAuthenticate](#) (void)
[DEPRECATED] Gets the user defined server authentication function. Please consider [SshGetUserAuthenticateWithType](#).
- void [SshSetUserAuthenticateWithType](#) ([sshUserAuthenticateWithTypeFn](#) sshUserAuthenticateFnPtr)
Sets the user defined server authentication function.
- [sshUserAuthenticateWithTypeFn](#) [SshGetUserAuthenticateWithType](#) (void)
Gets the user defined server authentication function..
- void [SshClientSetGetUserPaswordFn](#) ([sshGetUserPwFn](#) sshGetUserPwFnPtr)
Sets the user defined client authentication function for getting user passwords during SSH authentication.
- [sshGetUserPwFn](#) [SshClientGetUserPaswordFn](#) (void)
Gets the user defined client authentication function for getting a user password during authentication.
- void [SshClientSetGetUserKeyFn](#) ([sshGetUserKeyFn](#) sshGetUserKeyFnPtr)
Sets the user defined client authentication function for getting user keys during SSH authentication.
- [sshGetUserKeyFn](#) [SshClientGetUserKeyFn](#) (void)
Gets the user defined client authentication function for getting a user key during authentication.
- void [SshSetUserGetKey](#) ([sshUserGetKeyFn](#) sshUserGetKeyFnPtr)
Sets the user defined callback method to provide the server key.
- [sshUserGetKeyFn](#) [SshGetUserGetKey](#) (void)
Gets the user defined callback method to provide the server key.
- bool [SshValidateKey](#) (const char *candidateKey, int candidateKeySize, int *keyTypePtr, int keyFormat=WOLFSSH_FORMAT_ASN1)
Takes a key and returns if it's valid or not.
- bool [SshWritePublicKey](#) (int publicKeyFd, unsigned char *candidateKey, int candidateKeySize)
Write public key to file descriptor. Takes both PEM and ANS1 formats.
- int [NbSshInit](#) ()
Initializes the underlying SSH framework. This will start a background task used to handle negotiations and SSH traffic. This is automatically called by [SshAccept](#) and [SshConnect](#), and doesn't need to be called directly except in special circumstances.
- int [SshAccept](#) (int listenFd, [IPADDR](#) *clientAddress, uint16_t *securePort, uint16_t timeout)
Accepts and negotiates SSH session. Automatically calls [NbSshInit\(\)](#) if required.
- int [SshConnect](#) ([IPADDR](#) clientAddress, uint16_t securePort, uint16_t localPort, uint16_t timeout, const char *username)

- Issues a connect request to negotiates an SSH session. Automatically calls [NbSshInit\(\)](#) if required.*
- SshSocket * [SshNegotiateSession](#) (int fd)
Negotiates an SSH server session on an open file descriptor.
 - SshSocket * [SshNegotiateSessionClient](#) (int secureFd, const char *username)
Negotiates an SSH client session on an open file descriptor.
 - void [SshPrintStatistics](#) (int secureFd)
Negotiates an SSH client session on an open file descriptor.
 - int [SshGetKeySize](#) ()
Determines and returns SSH's installed key size.
 - int [SshSetBannerText](#) (const char *banner)
Sets the banner text displayed by the SSH server on connection.
 - int [SshSetSockOption](#) (int fd, int option)
Set SSH TCP socket options.
 - int [SshClrSockOption](#) (int fd, int option)
Clear SSH TCP socket options.
 - int [SshGetSockOption](#) (int fd)
Returns the options for the specified SSH TCP socket.

14.43.1 Detailed Description

The NetBurner SSH Library

14.43.2 Typedef Documentation

14.43.2.1 sshGetUserKeyFn

```
typedef int(* sshGetUserKeyFn) (const NBString &usernamePtr, NBString &publicKey, NBString
&privateKey, NBString &keyType)
#include <NbWolfSsh.h>
```

User provided SSH user key authenticate routine for clients.

Parameters

	<i>usernamePtr</i>	Username in plain text
out	<i>publicKey</i>	Used to return the corresponding public key for the user
out	<i>privateKey</i>	Used to return the corresponding private key for the user
out	<i>keyType</i>	Used to return the corresponding key type (ECC or RSA) for the user

Return values

>0	Password available for the user
<=0	Authentication failed

14.43.2.2 sshGetUserPwFn

```
typedef int(* sshGetUserPwFn) (const NBString &usernamePtr, NBString &passwordPtr)
#include <NbWolfSsh.h>
```

User provided SSH user password authentication routine for clients.

Parameters

	<i>usernamePtr</i>	Username in plain text
out	<i>passwordPtr</i>	Used to return the corresponding password for the user

Return values

>0	Password available for the user
<=0	Authentication failed

14.43.2.3 sshUserAuthenticateFn

```
typedef int(* sshUserAuthenticateFn) (const char *usernamePtr, const char *passwordPtr)
#include <NbWolfSsh.h>
```

[DEPRECATED] User provided SSH username and password authenticate routine for a server. Please consider `sshUserAuthenticateWithTypeFn`.

Parameters

<i>usernamePtr</i>	Username in plain text
<i>passwordPtr</i>	Password in plain text

Return values

1	Authentication passed
!1	Authentication failed

14.43.2.4 sshUserAuthenticateWithTypeFn

```
typedef int(* sshUserAuthenticateWithTypeFn) (const char *usernamePtr, const char *authValPtr,
AuthType authType)
#include <NbWolfSsh.h>
```

User provided SSH user authenticate routine for a server.

Parameters

<i>usernamePtr</i>	Username in plain text
<i>authValPtr</i>	The value that is being passed in for authentication
<i>authType</i>	Either a password or a key

Return values

1	Authentication passed
!1	Authentication failed

14.43.2.5 sshUserGetKeyFn

```
typedef int(* sshUserGetKeyFn) (int keyRequested, const unsigned char **keyBufferPtr, int *key↔
LengthPtr)
#include <NbWolfSsh.h>
```

The user defined callback to get the server key used during the initial SSH negotiation.

Parameters

<i>keyRequested</i>	Type key requested (ECC or RSA)
<i>keyBufferPtr</i>	Buffer containing the key (ASN1 or PEM format supported)
<i>keyLengthPtr</i>	Size of the key in 8 bit bytes

Return values

0	Key and length are valid
-1	Key requested is not available

14.43.3 Function Documentation

14.43.3.1 NbSshInit()

```
int NbSshInit ( )
#include <NbWolfSsh.h>
```

Initializes the underlying SSH framework. This will start a background task used to handle negotiations and SSH traffic. This is automatically called by `SshAccept` and `SshConnect`, and doesn't need to be called directly except in special circumstances.

Return values

<code>SSH_SUCCESS</code>	if SSH system has been correctly initialized.
<i>Other</i>	SSH error code if initialization was unsuccessful.

See also

[SshAccept\(\)](#)

[SshConnect\(\)](#)

14.43.3.2 SshAccept()

```
int SshAccept (
    int listenFd,
    IPADDR * clientAddress,
    uint16_t * securePort,
    uint16_t timeout )
#include <NbWolfSsh.h>
```

Accepts and negotiates SSH session. Automatically calls [NbSshInit\(\)](#) if required.

Parameters

<i>listenFd</i>	File descriptor of listening socket
<i>clientAddress</i>	Address of client
<i>securePort</i>	Secure port of negotiated socket
<i>timeout</i>	Ticks to wait for connection, 0 is infinite

Return values

>0	The secure file descriptor if successful.
<i>Other</i>	A TCP or SSH error code, depending on the error..

See also

[NbSshInit\(\)](#)

[SshConnect\(\)](#)

14.43.3.3 SshClientGetUserKeyFn()

```
sshGetUserKeyFn SshClientGetUserKeyFn (
    void )
#include <NbWolfSsh.h>
```

Gets the user defined client authentication function for getting a user key during authentication.

Return values

<code>sshGetUserPwFnPtr</code>	Sets the user defined server authentication function.
--------------------------------	---

See also

[SshClientSetGetUserPaswordFn\(\)](#)

[SshClientGetUserPaswordFn\(\)](#)

[SshClientSetGetUserKeyFn\(\)](#)

14.43.3.4 SshClientGetUserPaswordFn()

```
sshGetUserPwFn SshClientGetUserPaswordFn (
    void )
#include <NbWolfSsh.h>
```

Gets the user defined client authentication function for getting a user password during authentication.

Return values

A	pointer to the fuction that is currently set for passing in a user's password during authentication.
---	--

See also

[SshClientSetGetUserPaswordFn\(\)](#)

[SshClientSetGetUserKeyFn\(\)](#)

[SshClientGetUserKeyFn\(\)](#)

14.43.3.5 SshClientSetGetUserKeyFn()

```
void SshClientSetGetUserKeyFn (
    sshGetUserKeyFn sshGetUserKeyFnPtr )
#include <NbWolfSsh.h>
```

Sets the user defined client authentication function for getting user keys during SSH authentication.

Parameters

<code>sshGetUserKeyFnPtr</code>	Sets the user defined server authentication function.
---------------------------------	---

See also

[SshClientSetGetUserPaswordFn\(\)](#)

[SshClientGetUserPaswordFn\(\)](#)

[SshClientGetUserKeyFn\(\)](#)**14.43.3.6 SshClientSetGetUserPaswordFn()**

```
void SshClientSetGetUserPaswordFn (
    sshGetUserPwFn sshGetUserPwFnPtr )
#include <NbWolfSsh.h>
```

Sets the user defined client authentication function for getting user passwords during SSH authentication.

Parameters

<i>sshGetUserPwFnPtr</i>	Sets the user defined client authentication function.
--------------------------	---

See also[SshClientGetUserPaswordFn\(\)](#)[SshClientSetGetUserKeyFn\(\)](#)[SshClientGetUserKeyFn\(\)](#)**14.43.3.7 SshClrSockOption()**

```
int SshClrSockOption (
    int fd,
    int option )
#include <NbWolfSsh.h>
```

Clear SSH TCP socket options.

Parameters

<i>fd</i>	Socket file descriptor.
<i>option</i>	Socket option to clear: TCP Socket Options .

Returns

A bitmask of the options for the specified socket

See also[SshSetSockOption\(\)](#)[SshGetSockOption\(\)](#)**14.43.3.8 SshConnect()**

```
int SshConnect (
    IPADDR clientAddress,
    uint16_t securePort,
    uint16_t localPort,
    uint16_t timeout,
    const char * username )
#include <NbWolfSsh.h>
```

Issues a connect request to negotiates an SSH session. Automatically calls [NbSshInit\(\)](#) if required.

Parameters

<i>clientAddress</i>	Address of client
----------------------	-------------------

Parameters

<i>securePort</i>	Secure port of negotiated socket
<i>localPort</i>	Optional parameter to specify a Local port number. Recommend this always be set to a value of 0 so a random local port number is used.
<i>timeout</i>	Ticks to wait for connection, 0 is infinite
<i>username</i>	Username to use in negotiation process of secure connection

Return values

>0	The secure file descriptor if successful.
0	Request timed out.
<0	A TCP or SSH error code, depending on the error..

See also

[SshAccept\(\)](#)

[NbSshInit\(\)](#)

14.43.3.9 SshGetKeySize()

```
int SshGetKeySize (
#include <NbWolfSsh.h>
Determins and returns SSH's installed key size.
```

Returns

The installed key's size

14.43.3.10 SshGetSockOption()

```
int SshGetSockOption (
    int fd )
#include <NbWolfSsh.h>
Returns the options for the specified SSH TCP socket.
```

Parameters

<i>fd</i>	Socket file descriptor.
-----------	-------------------------

Returns

A bitmask of the options for the specified socket

See also

[SshSetSockOption\(\)](#)

[SshClrSockOption\(\)](#)

14.43.3.11 SshGetUserAuthenticate()

```
sshUserAuthenticateFn SshGetUserAuthenticate (
    void )
#include <NbWolfSsh.h>
```

[DEPRECATED] Gets the user defined server authentication function. Please consider [SshGetUserAuthenticate↔](#)
[WithType](#).

Return values

<i>Returns</i>	a pointer to the function fuction that is currently set for server user authentication.
----------------	---

See also

[SshGetUserAuthenticateWithType](#)

14.43.3.12 SshGetUserAuthenticateWithType()

```
sshUserAuthenticateWithTypeFn SshGetUserAuthenticateWithType (
    void )
```

```
#include <NbWolfSsh.h>
```

Gets the user defined server authentication function..

Return values

<i>A</i>	pointer to the fuction that is currently set for server user authentication.
----------	--

See also

[SshGetUserAuthenticateWithType\(\)](#)

14.43.3.13 SshGetUserGetKey()

```
sshUserGetKeyFn SshGetUserGetKey (
    void )
```

```
#include <NbWolfSsh.h>
```

Gets the user defined callback method to provide the server key.

Return values

<i>sshUserGetKeyFn</i>	The user defined callback
------------------------	---------------------------

See also

[sshUserGetKeyFn\(\)](#)

[SshSetUserGetKey\(\)](#)

14.43.3.14 SshNegotiateSession()

```
SshSocket * SshNegotiateSession (
    int fd )
```

```
#include <NbWolfSsh.h>
```

Negotiates an SSH server session on an open file descriptor.

Parameters

<i>fd</i>	File descriptor to use in the SSN negotiation, usually obtained with a call to accept()
-----------	---

Returns

A pointer to the SSH socket created on a successfull connection, or a nullptr if not successful.

14.43.3.15 SshNegotiateSessionClient()

```
SshSocket * SshNegotiateSessionClient (
    int secureFd,
    const char * username )
```

```
#include <NbWolfSsh.h>
```

Negotiates an SSH client session on an open file descriptor.

Parameters

<i>secureFd</i>	File descriptor to use in the SSN negotiation
<i>username</i>	Username to use in negotiation process of secure connection

Returns

A pointer to the SSH socket created on a successful connection, or a nullptr if not successful.

14.43.3.16 SshPrintStatistics()

```
void SshPrintStatistics (
    int secureFd )
```

```
#include <NbWolfSsh.h>
```

Negotiates an SSH client session on an open file descriptor.

Parameters

<i>secureFd</i>	Secure file descriptor
-----------------	------------------------

14.43.3.17 SshSetBannerText()

```
int SshSetBannerText (
    const char * banner )
```

```
#include <NbWolfSsh.h>
```

Sets the banner text displayed by the SSH server on connection.

Parameters

<i>banner</i>	The text to display to any connected clients
---------------	--

Return values

<i>SSH_SUCCESS</i>	If successful
<0	Error code on failure

14.43.3.18 SshSetSockOption()

```
int SshSetSockOption (
    int fd,
    int option )
```

```
#include <NbWolfSsh.h>
```

Set SSH TCP socket options.

Parameters

<i>fd</i>	Socket file descriptor.
-----------	-------------------------

Parameters

<i>option</i>	Socket option to set: TCP Socket Options .
---------------	--

Returns

A bitmask of the options for the specified socket

See also

[SshClrSockOption\(\)](#)

[SshGetSockOption\(\)](#)

14.43.3.19 SshSetUserAuthenticate()

```
void SshSetUserAuthenticate (
    sshUserAuthenticateFn sshUserAuthenticateFnPtr )
```

```
#include <NbWolfSsh.h>
```

[DEPRECATED] Sets the user defined server authentication function. Please consider [sshUserAuthenticateWithTypeFn](#).

Parameters

<i>sshUserAuthenticateFnPtr</i>	Fuction to set
---------------------------------	----------------

See also

[SshSetUserAuthenticateWithType\(\)](#)

14.43.3.20 SshSetUserAuthenticateWithType()

```
void SshSetUserAuthenticateWithType (
    sshUserAuthenticateWithTypeFn sshUserAuthenticateFnPtr )
```

```
#include <NbWolfSsh.h>
```

Sets the user defined server authentication function.

Parameters

<i>sshUserAuthenticateFnPtr</i>	Fuction to set
---------------------------------	----------------

See also

[SshSetUserAuthenticateWithType\(\)](#)

14.43.3.21 SshSetUserGetKey()

```
void SshSetUserGetKey (
    sshUserGetKeyFn sshUserGetKeyFnPtr )
```

```
#include <NbWolfSsh.h>
```

Sets the user defined callback method to provide the server key.

Parameters

<i>sshUserGetKeyFnPtr</i>	The user defined callback
---------------------------	---------------------------

See also

[sshUserGetKeyFn\(\)](#)

[SshGetUserGetKey\(\)](#)

14.43.3.22 SshValidateKey()

```
bool SshValidateKey (
    const char * candidateKey,
    int candidateKeySize,
    int * keyTypePtr,
    int keyFormat = WOLFSSH_FORMAT_ASN1 )
#include <NbWolfSsh.h>
```

Takes a key and returns if it's valid or not.

Parameters

	<i>candidateKey</i>	A pointer to a buffer containing the key
	<i>candidateKeySize</i>	The size of the key in bytes
out	<i>keyTypePtr</i>	Is set to what kind of key is passed it (ECC and RSA are valid)
	<i>keyFormat</i>	The key format (ASN1 or PEM)

Return values

<i>true</i>	The key is valid
<i>false</i>	The key is not valid

14.43.3.23 SshWritePublicKey()

```
bool SshWritePublicKey (
    int publicKeyFd,
    unsigned char * candidateKey,
    int candidateKeySize )
#include <NbWolfSsh.h>
```

Write public key to file descriptor. Takes both PEM and ANS1 formats.

Parameters

<i>publicKeyFd</i>	Open target file descriptor
<i>candidateKey</i>	key in buffer
<i>candidateKeySize</i>	Size of key in bytes

Return values

<i>true</i>	A valid key was written to the file descriptor
<i>false</i>	An error occurred

14.43.4 SSH Error Codes

Macros

- #define **SSH_SUCCESS** (0)

- The function completed successfully.*

 - #define **SSH_ERROR_FAILED_SESSION_FAILED** (-300)
Not currently used, kept for backward compatibility.
 - #define **SSH_ERROR_FAILED_NEGOTIATION** (-301)
The connection failed the SSH negotiation.
 - #define **SSH_ERROR_FAILED_INITIALIZATION** (-302)
The SSH system failed to initialize.
 - #define **SSH_ERROR_FAILED_CONTEXT_INIT** (-303)
Unable to instantiate SSH client/server context.
 - #define **SSH_ERROR_BAD_KEY** (-304)
The key provided was invalid.
 - #define **SSH_ERROR_BAD_ARGUMENT** (-305)
A bad argument was provided to the function.
 - #define **SSH_FAILED_KEY_CHECK** (-306)
There were no keys designated to use for the SSH library, .

14.43.4.1 Detailed Description

Error codes that can be returned by the NetBurner SSH functions.

14.44 SSL/TLS

The NetBurner SSL/TLS Library. See [SSL/TLS Programming Guide](#) and examples in the examples/SSL folder.

Topics

- [ACME Certificate Generation](#)
Request valid public certificates from an ACME certificate authority for devices with a public IP and DNS.
- [Onboard Self-Signed Certificate Generation](#)
See [On-board Cert Generation - Simple](#) and other examples in the examples/SSL folder.
- [SSL Error Codes](#)

Enumerations

- enum class [ExpireRetCodes](#) : unsigned char { [ExpireRetCodes::E_CERT_VALID](#) = 0 , [ExpireRetCodes::E_CERT_EXPIRED](#) = 1 , [ExpireRetCodes::E_BAD_EXPIRATION_VALUE](#) = 2 , [ExpireRetCodes::E_NO_SYSTEM_TIME](#) = 3 }
- Return values for [SSL_IsCertExpired\(\)](#).*

Functions

- int [SSL_connect](#) (IPADDR ip, uint16_t remotePort, uint32_t timeout, const char *commonName, bool verify↔ Peer=false, bool waitForNegotiation=true, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM, int intf=-1)
SSL mirror of the TCP::connect() call.
- int [SSL_connect](#) (IPADDR ip, uint16_t localPort, uint16_t remotePort, uint32_t timeout, const char *commonName, bool verifyPeer=false, bool waitForNegotiation=true, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM, int intf=-1)
Old version of [SSL_Connect](#) with local port.
- int [SSL_makeSecure](#) (int tcpFd, const char *commonName, bool verifyPeer=false, bool waitFor↔ Negotiation=true, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuff↔ Format=SSL_FILETYPE_PEM, bool blsClient=true, uint32_t timeout=[WAIT_FOREVER](#))
SSL mirror of the TCP::connect() call, but uses an existing TCP file descriptor.
- int [SSL_negotiate](#) (int tcpFd, const char *common_name, bool reuseSessionPort=true, bool verifyPeer=false, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_↔ PEM, bool blsClient=true)

- Executes the TLS negotiation over a given socket, to establish a secure communication channel through that socket.*
- int [SSLReadWithTimeout](#) (int fd, char *cp, int size, uint32_t timeout)
SSL mirror of the ReadWithTimeout() function.
 - uint32_t [SetMaxSessionReuseTime](#) (uint32_t newLifetimeTicks)
Allows one to specify at runtime what the longest duration that an established session can be used for before new connections must be fully renegotiated.
 - bool [IsSSL_CertNKeyValid](#) (const char *keyPEM, ssize_t keylen, const char *certPEM, ssize_t certlen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Validate candidate certificate and private key.
 - bool [SSL_AddCertToClientCaList](#) (const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Attempts to add a cert to the Certificate Authority List to the client SSL context.
 - bool [SSL_AddCertToServerCaList](#) (const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Attempts to add a cert to the Certificate Authority List to the client SSL context.
 - bool [SSL_ClearClientCaList](#) ()
Clears certs that have been added to the client's Certificate Authority list.
 - bool [SSL_ClearServerCaList](#) ()
Clears certs that have been added to the server's Certificate Authority list.
 - uint16_t [SSLGetRxBufferSizeUsed](#) (int fd)
Returns the amount of data buffered to be read from the socket.
 - uint16_t [SSLGetTxBufferAvailSpace](#) (int fd)
Returns the amount of data buffered to be read from the socket.
 - void [SslInit](#) ()
This function initializes the SSL library.
 - void [SSL_DumpSSL.Sockets](#) ()
Prints the current state of all used sockets to stdout.
 - void [SSL_ClientReadyCert](#) (const unsigned char *cert, const unsigned char *key, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Add a key and certificate to the client.
 - void [SSL_ServerReadyCert](#) (const unsigned char *cert, const unsigned char *key, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Add a key and certificate to the server.
 - [ExpireRetCodes SSL_IsCertExpired](#) (unsigned char *certBuff, int certLen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Returns whether the given certificate has expired or not.
 - bool [SSL_GetIssuerFromCert](#) (unsigned char *certBuff, int certLen, unsigned char *issBuf, int issBufLen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Returns the issuer from a certificate blob in the PEM format.
 - bool [SSL_GetSubjectNameFromCert](#) (unsigned char *certBuff, int certLen, unsigned char *subNamBuf, int subNamBufLen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Returns the subject name from a certificate blob in the PEM format.
 - bool [SSL_GetAltNameFromCert](#) (unsigned char *certBuff, int certLen, unsigned char *altNamBuf, int altNamBufLen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Returns an alternate name from a certificate blob in the PEM format.
 - bool [SSL_GetExpirationDate](#) (unsigned char *certBuff, int certLen, unsigned char *expBuf, int expBufLen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Returns the expiration data of the certificate in question.
 - bool [SSL_GetTimeToExpire](#) (unsigned char *certBuff, int certLen, uint16_t certBuffFormat, time_t &timeToExp)
Returns whether the given certificate has expired or not.
 - bool [SSL_GetCnFromCert](#) (unsigned char *certBuff, int certLen, unsigned char *comNamBuf, int comNamBufLen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)

- Returns the common name from a certificate blob in the PEM format.*

 - const char * [GetCertificatePEM](#) ()
 - Function that returns a pointer to the compiled in server certificate.*
 - int [GetCertificateLen](#) ()
 - Function that returns the length of the compiled in server certificate.*
 - const char * [GetPrivateKeyPEM](#) ()
 - Function that returns a pointer to the compiled in server key.*
 - int [GetPrivateKeyLen](#) ()
 - Function that the length of the compiled in server key.*
 - void [SslSetVerifyPeerClient](#) (bool verifyPeer)
 - Sets whether or not verify peer should be enabled on the global SSL client context.*
 - void [SslSetVerifyPeerServer](#) (bool verifyPeer)
 - Sets whether or not verify peer should be enabled on the global SSL server context.*
 - bool [SSL_IsCertAddedToClientCaList](#) ()
 - Checks to see if any certificates have been added to the global SSL client context.*
 - bool [SSL_IsCertAddedToServerCaList](#) ()
 - Checks to see if any certificates have been added to the global SSL server context.*

SSL Server Functions

- BOOL(* [IsSSLfd](#))(int fd)
- Returns whether or not a file descriptor is an SSL file descriptor.*
- int(* [SSL_GetRawSocket](#))(int sslSocketFd)
- Returns the TCP file descriptor associated with an SSL socket file descriptor.*
- int(* [SSL_setsockopt](#))(int fd, int option)
- Set SSL TCP socket options.*
- int(* [SSL_clrsockopt](#))(int fd, int option)
- Clear SSL TCP socket options.*
- int(* [SSL_getsockopt](#))(int fd)
- Returns the options for the specified SSL TCP socket.*
- int [SSL_accept](#) (int fdListen, IPADDR *address, uint16_t *port, uint16_t timeout, bool waitFor↔ Negotiation=true, bool verifyPeer=false, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM, const char *commonName=nullptr)
- This call is a mirror of the TCP::accept() call.*
- IPADDR [SSL_GetSocketRemoteAddr](#) (int fd)
- Returns the remote address of this connected socket.*
- uint16_t [SSL_GetSocketRemotePort](#) (int fd)
- Returns the remote port of this connected socket.*
- IPADDR [SSL_GetSocketLocalAddr](#) (int fd)
- Returns the local address of this connected socket.*
- uint16_t [SSL_GetSocketLocalPort](#) (int fd)
- Returns the local port of this connected socket.*
- int [SSL_GetSocketInterface](#) (int fd)
- Return the network interface associated with an SSL TCP socket.*
- uint16_t [SSL_GetTcpRtxCount](#) (int fd)
- Return the current state of a SSL TCP socket.*
- uint32_t [SSL_TcpGetLastRxTime](#) (int fd)
- SSL mirror of [TcpGetLastRxTime\(\)](#).*
- uint32_t [SSL_TcpGetLastRxInterval](#) (int fd)
- SSL mirror of [TcpGetLastRxInterval\(\)](#).*
- void [SSL_TcpSendKeepAlive](#) (int fd)

SSL mirror of [TcpSendKeepAlive\(\)](#).

- bool [SSLSocketsAvail](#) ()
Returns whether or not there are any sockets available.
- int [FreeSSLSockets](#) ()
Returns the number of currently free SSL sockets.

SSL socket option functions

- int [SSL_getsocketerror](#) (int fd)
Returns the socket error state for the specified SSL socket.

14.44.1 Detailed Description

The NetBurner SSL/TLS Library. See [SSL/TLS Programming Guide](#) and examples in the examples/SSL folder.
#include <[ssl.h](#)>

14.44.2 Enumeration Type Documentation

14.44.2.1 ExpireRetCodes

```
enum class ExpireRetCodes : unsigned char [strong]
#include <ssl.h>
Return values for SSL\_IsCertExpired\(\).
```

Enumerator

E_CERT_VALID	Certificate not expired.
E_CERT_EXPIRED	Certificate expired.
E_BAD_EXPIRATION_VALUE	Unable to read the expiration information from the certificate.
E_NO_SYSTEM_TIME	The system time has not been set.

14.44.3 Function Documentation

14.44.3.1 FreeSSLSockets()

```
int FreeSSLSockets ( )
#include <ssl.h>
Returns the number of currently free SSL sockets.
```

Returns

The number of free SSL sockets.

14.44.3.2 GetCertificateLen()

```
int GetCertificateLen ( )
#include <ssl.h>
Function that returns the length of the compiled in server certificate.
```

See the SSL documentation and examples for information on generating a self signed certificate and key. This function can be overridden to provide the ability to install uploaded certificates.

Returns

The length of the compiled in certificate.

See also

[GetCertificatePEM\(\)](#)

[GetPrivateKeyLen\(\)](#)

14.44.3.3 GetCertificatePEM()

```
const char * GetCertificatePEM ( )  
#include <ssl.h>
```

Function that returns a pointer to the compiled in server certificate.

See the SSL documentation and examples for information on generating a self signed certificate and key.

Returns

A pointer to the compiled in certificate.

See also

[GetPrivateKeyPEM\(\)](#)

[GetCertificateLen\(\)](#)

14.44.3.4 GetPrivateKeyLen()

```
int GetPrivateKeyLen ( )  
#include <ssl.h>
```

Function that the length of the compiled in server key.

See the SSL documentation and examples for information on generating a self signed certificate and key. This function can be overridden to provide the ability to install uploaded keys.

Returns

The length of the compiled in key.

See also

[GetPrivateKeyPEM\(\)](#)

[GetCertificateLen\(\)](#)

14.44.3.5 GetPrivateKeyPEM()

```
const char * GetPrivateKeyPEM ( )  
#include <ssl.h>
```

Function that returns a pointer to the compiled in server key.

See the SSL documentation and examples for information on generating a self signed certificate and key.

Returns

A pointer to the compiled in server key.

See also

[GetCertificatePEM\(\)](#)

[GetPrivateKeyLen\(\)](#)

14.44.3.6 IsSSL_CertNKeyValid()

```
bool IsSSL_CertNKeyValid (
    const char * keyPEM,
    ssize_t keylen,
    const char * certPEM,
    ssize_t certlen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
```

```
#include <ssl.h>
```

Validate candidate certificate and private key.

Determines if the passed in certificate and private key are valid or note.

Parameters

<i>keyPEM</i>	A buffer containing the private key
<i>keylen</i>	The length of the buffer containing the private key
<i>certPEM</i>	A buffer containing the certificate
<i>certlen</i>	The length of the buffer containing the certificate
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>>true</code></code>	Certificate and key passed in are valid
<code><code>>false</code></code>	Certificate and/or key passed in are not valid

14.44.3.7 SetMaxSessionReuseTime()

```
uint32_t SetMaxSessionReuseTime (
    uint32_t newLifetimeTicks )
```

```
#include <ssl.h>
```

Allows one to specify at runtime what the longest duration that an established session can be used for before new connections must be fully renegotiated.

This is a security trade-off feature. It will negatively impact performance to decrease this value. To disable maximum reuse lifetime, pass the argument as 0. This will force a new negotiation on every connection. Calling this function will not affect sessions that are currently stored until they have been used to establish a new connection.

The default value used for this purpose on startup is defined in [predef.h](#) as the macro `SSL_DEFAULT_MAX_SESSION_AGE_TICKS` and is set to one hour.

Parameters

<i>newLifetimeTicks</i>	How long (in ticks) to allow an established session to be used.
-------------------------	---

Returns

Returns previously assigned reuse maximum.

14.44.3.8 SSL_accept()

```
int SSL_accept (
    int fdListen,
    IPADDR * address,
    uint16_t * port,
    uint16_t timeout,
    bool waitForNegotiation = true,
```

```

bool verifyPeer = false,
const unsigned char * certBuff = nullptr,
uint32_t certBuffSize = 0,
uint16_t certBuffFormat = SSL_FILETYPE_PEM,
const char * commonName = nullptr )

```

```
#include <ssl.h>
```

This call is a mirror of the TCP::accept() call.

Parameters

<i>fdListen</i>	File descriptor of the TCP listening socket.
<i>*address</i>	IPADDR variable to hold the address of the connecting computer.
<i>*port</i>	Variable to receive the remote port of this connection.
<i>timeout</i>	Number of system time ticks to wait for a connection (regular TCP::accept()).
<i>waitForNegotiation</i>	Wait for negotiation to complete. Default is true.
<i>verifyPeer</i>	Default is false. Set to true to verify the client certificate on connect.
<i>certBuff</i>	Buffer containing the certificate data. Default is null.
<i>certBuffSize</i>	Size of the buffer containing the certificate data. Default is 0.
<i>certBuffFormat</i>	Format of the certificate buffer. Default is SSL_FILETYPE_PEM.
<i>commonName</i>	Common name to use for checking certificate validity. Default is null, which will accept any connection.

Return values

>0	The file descriptor of the connected SSL socket
<0	The error code for the failure from SSL Error Codes or TCP Socket Status

[SSL_getsockopt\(\)](#)

14.44.3.9 SSL_AddCertToClientCaList()

```

bool SSL_AddCertToClientCaList (
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )

```

```
#include <ssl.h>
```

Attempts to add a cert to the Certificate Authority List to the client SSL context.

Parameters

<i>certBuff</i>	A buffer containing the certificate to add.
<i>certBuffSize</i>	The size of the cert being passed in.

Parameters

<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.
-----------------------	---

Return values

<code><code>>true</code></code>	Successfully add the certificate to the CA List
<code><code>>false</code></code>	Was not able to add the certificate to the CA List

14.44.3.10 SSL_AddCertToServerCaList()

```
bool SSL_AddCertToServerCaList (
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
```

```
#include <ssl.h>
```

Attempts to add a cert to the Certificate Authority List to the client SSL context.

Parameters

<i>certBuff</i>	A buffer containing the certificate to add.
<i>certBuffSize</i>	The size of the cert being passed in.
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>true</code></code>	Successfully add the certificate to the CA List
<code><code>>false</code></code>	Was not able to add the certificate to the CA List

14.44.3.11 SSL_ClearClientCaList()

```
bool SSL_ClearClientCaList ( )
```

```
#include <ssl.h>
```

Clears certs that have been added to the client's Certificate Authority list.

Return values

<code><code>true</code></code>	Successfully cleared the Certificate Authority list
<code><code>>false</code></code>	Failed to clear the Certificate Authority list

14.44.3.12 SSL_ClearServerCaList()

```
bool SSL_ClearServerCaList ( )
```

```
#include <ssl.h>
```

Clears certs that have been added to the server's Certificate Authority list.

Return values

<code><code>true</code></code>	Successfully cleared the Certificate Authority list
<code><code>>false</code></code>	Failed to clear the Certificate Authority list

14.44.3.13 SSL_ClientReadyCert()

```
void SSL_ClientReadyCert (
    const unsigned char * cert,
    const unsigned char * key,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
```

```
#include <ssl.h>
```

Add a key and certificate to the client.

Parameters

<i>cert</i>	Pointer to the buffer holding the PEM certificate data
<i>key</i>	Pointer to the buffer holding the PEM key data
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

14.44.3.14 SSL_connect() [1/2]

```
int SSL_connect (
    IPADDR ip,
    uint16_t localPort,
    uint16_t remotePort,
    uint32_t timeout,
    const char * commonName,
    bool verifyPeer = false,
    bool waitForNegotiation = true,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM,
    int intf = -1 )
```

```
#include <ssl.h>
```

Old version of SSL_Connect with local port.

Parameters

<i>ip</i>	The address to connect to.
<i>localPort</i>	The local port to use. 0 will pick one
<i>remotePort</i>	The remote port to connect to.
<i>timeout</i>	The number of ticks to wait for a connection.
<i>*commonName</i>	The common name to use for checking certificate validity passing in NULL will accept any connection.
<i>verifyPeer</i>	Should the client verify the server's certificate against a Certificate Authority list?
<i>waitForNegotiation</i>	Should the function wait until the negotiation is complete before returning?
<i>certBuff</i>	Buffer containing the certificate data
<i>certBuffSize</i>	Size of the buffer containing the certificate data
<i>certBuffFormat</i>	The format of the certificate buffer
<i>intf</i>	Optional local interface number to use for connection

Return values

>0	The file descriptor of the connected SSL socket
<0	The error code for the failure from SSL Error Codes or TCP Socket Status

14.44.3.15 SSL_connect() [2/2]

```

int SSL_connect (
    IPADDR ip,
    uint16_t remotePort,
    uint32_t timeout,
    const char * commonName,
    bool verifyPeer = false,
    bool waitForNegotiation = true,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM,
    int intf = -1 )

```

#include <ssl.h>

SSL mirror of the TCP::connect() call.

Parameters

<i>ip</i>	The address to connect to.
<i>remotePort</i>	The remote port to connect to.
<i>timeout</i>	The number of ticks to wait for a connection.
<i>*commonName</i>	The common name to use for checking certificate validity passing in NULL will accept any connection.
<i>verifyPeer</i>	Should the client verify the server's certificate against a Certificate Authority list?
<i>waitForNegotiation</i>	Should the function wait until the negotiation is complete before returning?
<i>certBuff</i>	Buffer containing the certificate data
<i>certBuffSize</i>	Size of the buffer containing the certificate data
<i>certBuffFormat</i>	The format of the certificate buffer
<i>intf</i>	Optional local interface number to use for connection

Return values

>0	The file descriptor of the connected SSL socket
<0	The error code for the failure from SSL Error Codes or TCP Socket Status

14.44.3.16 SSL_GetAltNameFromCert()

```

bool SSL_GetAltNameFromCert (
    unsigned char * certBuff,
    int certLen,
    unsigned char * altNamBuf,
    int altNamBufLen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
#include <ssl.h>

```

Returns an alternate name from a certificate blob in the PEM format.

Parameters

<i>certBuff</i>	The buffer containing the certificate data
<i>certLen</i>	The length of the certificate
<i>altNamBuf</i>	The buffer to store the alternate name in
<i>altNamBufLen</i>	The length of the buffer where the alternate name will be placed
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>>true</code></code>	If successfully retrieved the alternate name from the cert
<code><code>>false</code></code>	If unable to retrieved the alternate name from the cert

14.44.3.17 SSL_GetCnFromCert()

```

bool SSL_GetCnFromCert (
    unsigned char * certBuff,
    int certLen,
    unsigned char * comNamBuf,
    int comNamBufLen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
#include <ssl.h>

```

Returns the common name from a certificate blob in the PEM format.

Parameters

<i>certBuff</i>	The buffer containing the certificate data
<i>certLen</i>	The length of the certificate
<i>comNamBuf</i>	The buffer to store the common name in
<i>comNamBufLen</i>	The length of the buffer where the common name will be placed
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>>true</code></code>	If successfully retrieved the common name from the cert
<code><code>>false</code></code>	If unable to retrieved the common name from the cert

14.44.3.18 SSL_GetExpirationDate()

```
bool SSL_GetExpirationDate (
    unsigned char * certBuff,
    int certLen,
    unsigned char * expBuf,
    int expBufLen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
```

```
#include <ssl.h>
```

Returns the expiration data of the certificate in question.

Parameters

<i>certBuff</i>	The buffer containing the certificate data
<i>certLen</i>	The length of the certificate
<i>expBuf</i>	The buffer to store the expiration date in
<i>expBufLen</i>	The length of the buffer where the expiration date will be placed
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>>true</code></code>	If successfully retrieved the alternate name from the cert
<code><code>>false</code></code>	If unable to retrieved the alternate name from the cert

14.44.3.19 SSL_GetIssuerFromCert()

```
bool SSL_GetIssuerFromCert (
    unsigned char * certBuff,
    int certLen,
    unsigned char * issBuf,
    int issBufLen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
```

```
#include <ssl.h>
```

Returns the issuer from a certificate blob in the PEM format.

Parameters

<i>certBuff</i>	The buffer containing the certificate data
<i>certLen</i>	The length of the certificate
<i>issBuf</i>	The buffer to store the issuer in
<i>issBufLen</i>	The length of the buffer where the issuer will be placed
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

Return values

<code><code>>true</code></code>	If successfully retrieved the issuer from the cert
<code><code>>false</code></code>	If unable to retrieved the issuer from the cert

14.44.3.20 SSL_getsocketerror()

```
int SSL_getsocketerror (
    int fd )
```

```
#include <ssl.h>
```

Returns the socket error state for the specified SSL socket.

Parameters

<i>fd</i>	Socket file descriptor.
-----------	-------------------------

Returns

The error state for the specified socket

14.44.3.21 SSL_GetSocketInterface()

```
int SSL_GetSocketInterface (
    int fd ) [inline]
```

```
#include <ssl.h>
```

Return the network interface associated with an SSL TCP socket.

Parameters

<i>fd</i>	The socket file descriptor.
-----------	-----------------------------

Returns

The network interface number (undefined for listening sockets)

See also

[TcpGetSocketInterface\(\)](#)

14.44.3.22 SSL_GetSocketLocalAddr()

```
IPADDR SSL_GetSocketLocalAddr (
    int fd ) [inline]
```

```
#include <ssl.h>
```

Returns the local address of this connected socket.

This function is used to retrieve the local address of an SSL fd. This function will also work correctly if you pass in an fd that is a TCP connection. This allows you to use one set of code for both normal TCP and SSL connections.

Parameters

<i>fd</i>	The file descriptor to test.
-----------	------------------------------

Returns

The local IP address of the TCP or SSL connection, or 0 otherwise.

See also

[IsSSLfd\(\)](#)

[SSL_GetSocketRemotePort\(\)](#)

[SSL_GetSocketRemoteAddr\(\)](#)

[SSL_GetSocketLocalPort\(\)](#)

14.44.3.23 SSL_GetSocketLocalPort()

```
uint16_t SSL_GetSocketLocalPort (
    int fd ) [inline]
#include <ssl.h>
```

Returns the local port of this connected socket.

This function is used to retrieve the local port of an SSL fd. This function will also work correctly if you pass in an fd that is a TCP connection. This allows you to use one set of code for both normal TCP and SSL connections.

Parameters

<i>fd</i>	The file descriptor to test.
-----------	------------------------------

Returns

The local port number of TCP or SSL connection, or 0 otherwise.

See also

[IsSSLfd\(\)](#)

[SSL_GetSocketRemoteAddr\(\)](#)

[SSL_GetSocketRemotePort\(\)](#)

[SSL_GetSocketLocalPort\(\)](#)

14.44.3.24 SSL_GetSocketRemoteAddr()

```
IPADDR SSL_GetSocketRemoteAddr (
    int fd ) [inline]
#include <ssl.h>
```

Returns the remote address of this connected socket.

This function is used to retrieve the remote address of an SSL fd. This function will also work correctly if you pass in an fd that is a TCP connection. This allows you to use one set of code for both normal TCP and SSL connections.

Parameters

<i>fd</i>	The file descriptor to test.
-----------	------------------------------

Returns

IP address of the TCP or SSL connection, or 0 otherwise.

See also

[IsSSLfd\(\)](#)
[SSL_GetSocketRemotePort\(\)](#)
[SSL_GetSocketLocalAddr\(\)](#)
[SSL_GetSocketLocalPort\(\)](#)

14.44.3.25 SSL_GetSocketRemotePort()

```
uint16_t SSL_GetSocketRemotePort (
    int fd ) [inline]
```

```
#include <ssl.h>
```

Returns the remote port of this connected socket.

This function is used to retrieve the remote port of an SSL fd. This function will also work correctly if you pass in an fd that is a TCP connection. This allows you to use one set of code for both normal TCP and SSL connections.

Parameters

<i>fd</i>	The file descriptor to test.
-----------	------------------------------

Returns

The remote port number of TCP or SSL connection, or 0 otherwise.

14.44.3.26 SSL_GetSubjectNameFromCert()

```
bool SSL_GetSubjectNameFromCert (
    unsigned char * certBuff,
    int certLen,
    unsigned char * subNamBuf,
    int subNamBufLen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
```

```
#include <ssl.h>
```

Returns the subject name from a certificate blob in the PEM format.

Parameters

<i>certBuff</i>	The buffer containing the certificate data
<i>certLen</i>	The length of the certificate
<i>subNamBuf</i>	The buffer to store the subject name in
<i>subNamBufLen</i>	The length of the buffer where the subject name will be placed
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>>true</code></code>	If successfully retrieved the subject name from the cert
--	--

Return values

<code><code>>false</code></code>	If unable to retrieved the subject name from the cert
---	---

14.44.3.27 SSL_GetTcpRtxCount()

```
uint16_t SSL_GetTcpRtxCount (
    int fd ) [inline]
#include <ssl.h>
```

Return the current state of a SSL TCP socket.

Parameters

<i>fd</i>	Socket file descriptor.
-----------	-------------------------

Returns

The current state of the socket: [TCP Socket State](#)

See also

[TcpGetSocketState\(\)](#)

Returns the number of re-transmits that have occurred on the specified SSL connection.

Parameters

<i>fd</i>	The socket file descriptor.
-----------	-----------------------------

Returns

The number of system time ticks since the last packet was received on the connection.

See also

[GetTcpRtxCount\(\);](#)

14.44.3.28 SSL_GetTimeToExpire()

```
bool SSL_GetTimeToExpire (
    unsigned char * certBuff,
    int certLen,
    uint16_t certBuffFormat,
    time_t & timeToExp )
#include <ssl.h>
```

Returns whether the given certificate has expired or not.

Parameters

	<i>certBuff</i>	The buffer containing the certificate data
	<i>certLen</i>	The length of the certificate
	<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.
out	<i>timeToExp</i>	The time the certificate is set to expire

Return values

<code><code>true</code></code>	If the certificate expiration was found
<code><code>false</code></code>	If the certificate expiration was not found

14.44.3.29 SSL_IsCertAddedToClientCaList()

```
bool SSL_IsCertAddedToClientCaList ( )
#include <ssl.h>
```

Checks to see if any certificates have been added to the global SSL client context. Certificate Authority certificates can be added to the client context during calls to [SSL_connect\(\)](#) or with calls to [SSL_AddCertToClientCaList\(\)](#).

Returns

- true If a certificate has been added to the certificate authority list.
- false If a certificate has not been added to the certificate authority list.

14.44.3.30 SSL_IsCertAddedToServerCaList()

```
bool SSL_IsCertAddedToServerCaList ( )
#include <ssl.h>
```

Checks to see if any certificates have been added to the global SSL server context. Certificate Authority certificates can be added to the server context during calls to [SSL_connect\(\)](#) or with calls to [SSL_AddCertToServerCaList\(\)](#).

Returns

- true If a certificate has been added to the certificate authority list.
- false If a certificate has not been added to the certificate authority list.

14.44.3.31 SSL_IsCertExpired()

```
ExpireRetCodes SSL_IsCertExpired (
    unsigned char * certBuff,
    int certLen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
#include <ssl.h>
```

Returns whether the given certificate has expired or not.

Parameters

<i>certBuff</i>	The buffer containing the certificate data
<i>certLen</i>	The length of the certificate
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>ExpireRetCodes::E_CERT_EXPIRED</code></code>	If the certificate has expired
<code><code>ExpireRetCodes::E_CERT_VALID</code></code>	If the certificate has not expired
<code><code>ExpireRetCodes::E_BAD_EXPIRATION_VALUE</code></code>	If unable to get the expiration data from the certificate

Return values

<code><code>ExpireRetCodes::E_NO_SYSTEM_↵ TIME</code></code>	If the system time has not been set
--	-------------------------------------

14.44.3.32 SSL_makeSecure()

```
int SSL_makeSecure (
    int tcpFd,
    const char * commonName,
    bool verifyPeer = false,
    bool waitForNegotiation = true,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM,
    bool bIsClient = true,
    uint32_t timeout = WAIT_FOREVER )
```

```
#include <ssl.h>
```

SSL mirror of the TCP::connect() call, but uses an existing TCP file descriptor.

Parameters

<i>tcpFd</i>	The file descriptor for the socket to be secured.
<i>*commonName</i>	The common name to use for checking certificate validity passing in NULL will accept any connection.
<i>verifyPeer</i>	Should the client verify the server's certificate against a Certificate Authority list?
<i>waitForNegotiation</i>	Should the function wait until the negotiation is complete before returning?
<i>certBuff</i>	Buffer containing the certificate data
<i>certBuffSize</i>	Size of the buffer containing the certificate data
<i>certBuffFormat</i>	The format of the certificate buffer
<i>bIsClient</i>	Perform the TLS negotiation as the Client and not the Server?
<i>timeout</i>	The number of timeticks to wait for completion

Return values

>0	The file descriptor of the connected SSL socket
<0	The error code for the failure from SSL Error Codes or TCP Socket Status

See also

14.44.3.33 SSL_negotiate()

```
int SSL_negotiate (
    int tcpFd,
    const char * common_name,
    bool reuseSessionPort = true,
    bool verifyPeer = false,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM,
    bool bIsClient = true )
```

```
#include <ssl.h>
```

Executes the TLS negotiation over a given socket, to establish a secure communication channel through that socket.

Parameters

<i>tcpFd</i>	The TCP file descriptor to associate the connection with.
<i>*common_name</i>	The common name to use for checking certificate validity passing in NULL will accept any connection.
<i>reuseSessionPort</i>	Should we look at the port for reuse lookup?
<i>verifyPeer</i>	Should the client verify the server's certificate against a Certificate Authority list?
<i>certBuff</i>	Buffer containing the certificate data
<i>certBuffSize</i>	Size of the buffer containing the certificate data
<i>certBuffFormat</i>	The format of the certificate buffer
<i>bIsClient</i>	Perform the TLS negotiation as the Client and not the Server?

Return values

>0	The file descriptor of the connected SSL socket
<0	The error code for the failure from SSL Error Codes or TCP Socket Status

14.44.3.34 SSL_ServerReadyCert()

```
void SSL_ServerReadyCert (
    const unsigned char * cert,
    const unsigned char * key,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM )
```

```
#include <ssl.h>
```

Add a key and certificate to the server.

Parameters

<i>cert</i>	Pointer to the buffer holding the PEM certificate data
<i>key</i>	Pointer to the buffer holding the PEM key data
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

14.44.3.35 SSL_TcpGetLastRxInterval()

```
uint32_t SSL_TcpGetLastRxInterval (
    int fd ) [inline]
#include <ssl.h>
SSL mirror of TcpGetLastRxInterval\(\).
```

Parameters

<i>fd</i>	The socket file descriptor.
-----------	-----------------------------

Returns

The number of system Time Ticks since the last packet was received on the connection.

See also

[SSL_TcpSendKeepAlive\(\)](#)
[TcpGetLastRxInterval\(\)](#)

14.44.3.36 SSL_TcpGetLastRxTime()

```
uint32_t SSL_TcpGetLastRxTime (
    int fd ) [inline]
#include <ssl.h>
SSL mirror of TcpGetLastRxTime\(\).
```

Parameters

<i>fd</i>	The socket file descriptor.
-----------	-----------------------------

Returns

The value of system Time Ticks when the last packet was received on the connection.

See also

[SSL_TcpSendKeepAlive\(\)](#)
[TcpGetLastRxTime\(\)](#)

14.44.3.37 SSL_TcpSendKeepAlive()

```
void SSL_TcpSendKeepAlive (
    int fd ) [inline]
#include <ssl.h>
SSL mirror of TcpSendKeepAlive\(\).
```

Parameters

<i>fd</i>	The socket file descriptor.
-----------	-----------------------------

See also

[SSL_TcpGetLastRxTime\(\)](#)

[TcpSendKeepAlive\(\)](#)

14.44.3.38 SSLGetRxBufferSpaceUsed()

```
uint16_t SSLGetRxBufferSpaceUsed (
    int fd )
```

```
#include <ssl.h>
```

Returns the amount of data buffered to be read from the socket.

Parameters

<i>fd</i>	The socket's file descriptor
-----------	------------------------------

Return values

≥ 0	The number of bytes available to be read
$<$	0 The requested socket does not exist

14.44.3.39 SSLGetTxBufferAvailSpace()

```
uint16_t SSLGetTxBufferAvailSpace (
    int fd )
```

```
#include <ssl.h>
```

Returns the amount of data buffered to be read from the socket.

Parameters

<i>fd</i>	The socket's file descriptor
-----------	------------------------------

Return values

≥ 0	The number of bytes available to be read
$<$	0 The requested socket does not exist

14.44.3.40 SslInit()

```
void SslInit ( )
#include <ssl.h>
```

This function initializes the SSL library.

Note: It should only be called in the case that you want to verify peer certificates as a client and need to add the certificates individually. Otherwise, calls to [SSL_connect\(\)](#) will automatically call this function for you.

14.44.3.41 SSLReadWithTimeout()

```
int SSLReadWithTimeout (
```

```

int fd,
char * cp,
int size,
uint32_t timeout )

```

```
#include <ssl.h>
```

SSL mirror of the ReadWithTimeout() function.

This function will block until either the time-out expires or at least one byte is available to be read. This function can be used to read from stdio, TCP sockets, or Serial ports.

Important: This function operates like a read function in that it reads all available bytes and returns. The addition of a time-out does not cause the function to block until the maximum number of bytes specified in the function call is available. The application must use the return value of the function to determine how many bytes were read, and call the function again if necessary.

Parameters

<i>fd</i>	The file descriptor number.
<i>*cp</i>	A pointer to the read destination.
<i>size</i>	Maximum number of bytes to read.
<i>timeout</i>	The number of timer ticks to wait for data.

Return values

<i>0</i>	Invalid buf or size parameters were passed
<i>>0</i>	The number of bytes read
<i>TCP_ERR_TIMEOUT</i>	No bytes were read before timeout
<i>TCP_ERR_CLOSING</i>	TCP connection is no longer valid, or the SSLSocket_Record no longer exists

See also

[ReadWithTimeout\(\)](#)

[SSL_negotiate\(\)](#)

14.44.3.42 SslSetVerifyPeerClient()

```

void SslSetVerifyPeerClient (
    bool verifyPeer )

```

```
#include <ssl.h>
```

Sets whether or not verify peer should be enabled on the global SSL client context.

Parameters

<i>verifyPeer</i>	True if verify should be enabled, or false otherwise.
-------------------	---

14.44.3.43 SslSetVerifyPeerServer()

```

void SslSetVerifyPeerServer (
    bool verifyPeer )

```

```
#include <ssl.h>
```

Sets whether or not verify peer should be enabled on the global SSL server context.

Parameters

<i>verifyPeer</i>	True if verify should be enabled, or false otherwise.
-------------------	---

14.44.3.44 SSLSocketsAvail()

```
bool SSLSocketsAvail ( )
#include <ssl.h>
```

Returns whether or not there are any sockets available.

Return values

<i>true</i>	If there are sockets available.
<i>false</i>	If there are not any sockets available

See also

[FreeSSLSockets\(\)](#)

14.44.4 Variable Documentation**14.44.4.1 IsSSLfd**

```
BOOL(* IsSSLfd) (int fd) (
    int fd ) [extern]
#include <ssl.h>
```

Returns whether or not a file descriptor is an SSL file descriptor.

This function is used to determine if the fd is an SSL connection. It can be used by things like the callback functions of the web server to determine how secure the fd is before sending sensitive information over it.

Parameters

<i>fd</i>	The file descriptor to test.
-----------	------------------------------

Return values

<i>TRUE</i>	If it is an SSL fd
<i>FALSE</i>	If it is not an SSL fd or if there was an error

See also

14.44.4.2 SSL_clrsocketoption

```
int(* SSL_clrsocketoption) (int fd, int option) (
    int fd,
    int option ) [extern]
#include <ssl.h>
```

Clear SSL TCP socket options.

Parameters

<i>fd</i>	Socket file descriptor.
<i>option</i>	Socket option to clear: TCP Socket Options .

Returns

A bitmask of the options for the specified socket

See also

[SSL_setsockopt\(\)](#)

[SSL_getsockopt\(\)](#)

14.44.4.3 SSL_GetRawSocket

```
int(* SSL_GetRawSocket) (int sslSocketFd) (
    int sslSocketFd ) [extern]
#include <ssl.h>
```

Returns the TCP file descriptor associated with an SSL socket file descriptor.

Parameters

<i>sslSocketFd</i>	The socket file descriptor.
--------------------	-----------------------------

Returns

The TCP file descriptor associated with the SSL socket.

See also

[SSL_GetSocketInterface\(\)](#)

14.44.4.4 SSL_getsockopt

```
int(* SSL_getsockopt) (int fd) (
    int fd ) [extern]
#include <ssl.h>
```

Returns the options for the specified SSL TCP socket.

Parameters

<i>fd</i>	Socket file descriptor.
-----------	-------------------------

Returns

A bitmask of the options for the specified socket

See also

[SSL_setsockopt\(\)](#)

[SSL_clrsockopt\(\)](#)

14.44.4.5 SSL_setsockopt

```
int(* SSL_setsockopt) (int fd, int option) (
    int fd,
    int option ) [extern]
#include <ssl.h>
```

Set SSL TCP socket options.

Parameters

<i>fd</i>	Socket file descriptor.
<i>option</i>	Socket option to set: TCP Socket Options .

Returns

A bitmask of the options for the specified socket

See also

[SSL_clrsockoption\(\)](#)

[SSL_getsockoption\(\)](#)

14.44.5 ACME Certificate Generation

Request valid public certificates from an ACME certificate authority for devices with a public IP and DNS.

Classes

- class [AcmeServletObject](#)
Main ACME Client Class.
- class [LetsEncryptAcmeServletObject](#)
ACME Client for Let's Encrypt.
- class [BuyPassAcmeServletObject](#)
ACME Client for BuyPass.

14.44.5.1 Detailed Description

Request valid public certificates from an ACME certificate authority for devices with a public IP and DNS.

To use, you can simply specify these constants, NTP, and the ACME Servlet in your program, editing as desired:

```
const char * DEFAULT_CERT_ALT_NAMES= "test.example.com,test2.example.com"; // alt name is required
const char * DEFAULT_CERT_COM_NAME= "test.example.com";
const char * DEFAULT_CERT_EMAIL= "changeme@example.com";
NtpClientServlet ntp_client;
```

You have a choice of supported providers or a custom provider. Just add to your code:

- Let's Encrypt: `LetsEncryptAcmeServletObject acme_client;`
 - Let's Encrypt Staging (for testing, no rate limits): `LetsEncryptAcmeServletObject acme_client(true);`
- BuyPass: `BuyPassAcmeServletObject acme_client;`
- Custom: `AcmeServletObject acme_client("https://192.168.10.90:14000/dir");`

Then for debugging you can add `acme_client.SetDiag(true);` to your `UserMain()`

If your device is accessible on the Internet at those DNS names, Let's Encrypt should automatically issue you a certificate within about a minute of boot.

The NetBurner Config system accepts changing the certificate data under "CertData". You can also provide it in the constructor:

```
AcmeServletObject acme_client("https://acme.example.com/dir");
```

EAB (External Account Binding) support is planned for the future, which paid providers like ZeroSSL, SSL.com and Google require.

See the [ACME Certificate Generation \(Easy Servlet\)](#) example for more details.

14.44.6 Onboard Self-Signed Certificate Generation

See [On-board Cert Generation - Simple](#) and other examples in the examples/SSL folder.

Classes

- struct [CertGenData](#)

Used to store the information that is passed in when enabling onboard generated certificates, as well as the information needed to determine when they need to be regenerated.

- class [CertData](#)

Enumerations

- enum [SslKeyType_t](#) {
[SSL_KEY_NONE](#) = 0 , [SSL_KEY_RSA_1024](#) = 1 , [SSL_KEY_RSA_2048](#) , [SSL_KEY_RSA_4096](#) ,
[SSL_KEY_ECC_SECP192R1](#) = [ECC_SECP192R1](#) , [SSL_KEY_ECC_SECP224R1](#) = [ECC_SECP224R1](#) ,
[SSL_KEY_ECC_SECP256R1](#) = [ECC_SECP256R1](#) , [SSL_KEY_ECC_SECP384R1](#) = [ECC_SECP384R1](#) ,
[SSL_KEY_ECC_SECP521R1](#) = [ECC_SECP521R1](#) }

Certificate Generation Key Types.

- enum [AltNameType_t](#) : char { [ALT_NAME_TYPE_NONE](#) = 0 , [ALT_NAME_TYPE_DNS](#) = (char)0x82 ,
[ALT_NAME_TYPE_IP](#) = (char)0x87 }

Certificate Generation Alternate Name Types.

- enum [CertGenReturnCode](#) : int {
[CERT_GEN_RETURN_SUCCESS](#) = 1 , [CERT_GEN_RETURN_NOT_REQUIRED](#) = 2 , [CERT_GEN_RETURN_INVALID_RANGE](#) = -1 ,
[CERT_GEN_RETURN_MALLOC_ERROR](#) = -2 ,
[CERT_GEN_RETURN_ECC_INIT_ERROR](#) = -3 , [CERT_GEN_RETURN_ECC_CREATE_ERROR](#) = -4 ,
[CERT_GEN_RETURN_RSA_INIT_ERROR](#) = -5 , [CERT_GEN_RETURN_RSA_CREATE_ERROR](#) = -6 ,
[CERT_GEN_RETURN_CERT_INIT_ERROR](#) = -7 , [CERT_GEN_RETURN_CERT_CREATE_ERROR](#) = -8 ,
[CERT_GEN_RETURN_CERT_SIGNING_ERROR](#) = -9 , [CERT_GEN_RETURN_CERT_SAVING_ERROR](#) = -10 ,
[CERT_GEN_RETURN_KEY_CONVERT_ERROR](#) = -11 , [CERT_GEN_RETURN_KEY_SAVING_ERROR](#) = -12 ,
[CERT_GEN_RETURN_SET_ISSUER_ERROR](#) = -13 }

Certificate Generation Function Return Codes.

Functions

- [CertGenReturnCode](#) [SSL_CreateNewSelfSignedCert](#) ([CertGenData](#) &pGenData)
Generates a new self-signed certificate that will be stored on the device.
- void [EnableOnboardCertificateCreation](#) ([CertGenReturnCode](#)(*createCertFunc)([CertGenData](#) &cGenData)=[SSL_CreateNewSelfSignedCert](#))
Enables the ability for the module to automatically generate self-signed certificates for use in SSL/TLS connections when acting as the server.
- void [FillInAltNamesASN1](#) (Cert &TheCert, [NBString](#) &altNameString)
Helper function used to build ASN1 representation of alt names.
- [CertGenReturnCode](#) [CheckAndCreateHalCertAndKey](#) ()
Check for a valid SSL certificate and generate one if not found.
- [CertGenData](#) * [GetDataForCertGen](#) ()
A function to be overridden to pass certificate details to the certificate generator.

14.44.6.1 Detailed Description

See [On-board Cert Generation - Simple](#) and other examples in the examples/SSL folder.

14.44.6.2 Enumeration Type Documentation

14.44.6.2.1 AltNameType_t

```
enum AltNameType_t : char
#include <certgen.h>
```

Certificate Generation Alternate Name Types.

Enumerator

ALT_NAME_TYPE_NONE	None.
ALT_NAME_TYPE_DNS	DNS Name.
ALT_NAME_TYPE_IP	IP Address.

14.44.6.2.2 CertGenReturnCode

```
enum CertGenReturnCode : int
#include <certgen.h>
```

Certificate Generation Function Return Codes.

Enumerator

CERT_GEN_RETURN_SUCCESS	Returned when the certificate was successfully generated.
CERT_GEN_RETURN_NOT_REQUIRED	Returned when the a new certificate was not required to be generated.
CERT_GEN_RETURN_INVALID_RANDOM	Returned when the device was unable to generate a valid random number.
CERT_GEN_RETURN_MALLOC_ERROR	Returned when the device is unable to malloc enough space to generate the certificate.
CERT_GEN_RETURN_ECC_INIT_ERROR	Returned when the device was unable to initialize the required ECC object.
CERT_GEN_RETURN_ECC_CREATE_ERROR	Returned when the device was unable to create the ECC key.
CERT_GEN_RETURN_RSA_INIT_ERROR	Returned when the device was unable to initialize the required RSA object.
CERT_GEN_RETURN_RSA_CREATE_ERROR	Returned when the device was unable to create the RSA key.
CERT_GEN_RETURN_CERT_INIT_ERROR	Returned when the device was unable to initialize the required certificate object.
CERT_GEN_RETURN_CERT_CREATE_ERROR	Returned when the device was unable to create the certificate.
CERT_GEN_RETURN_CERT_SIGNING_ERROR	Returned when the device was unable to sign the created certificate.
CERT_GEN_RETURN_CERT_SAVING_ERROR	Returned when the device was unable to properly save the certificate.
CERT_GEN_RETURN_KEY_CONVERT_ERROR	Returned when the device was unable to convert the certificate from PEM to DER format.
CERT_GEN_RETURN_KEY_SAVING_ERROR	Returned when the device was unable to save the key.
CERT_GEN_RETURN_SET_ISSUER_ERROR	Returned when the device was unable to set the issuer if a CA was used.

14.44.6.2.3 SslKeyType_t

```
enum SslKeyType_t
#include <certgen.h>
```

Certificate Generation Key Types.

Enumerator

SSL_KEY_NONE	None.
SSL_KEY_RSA_1024	RSA 1024.

Enumerator

SSL_KEY_RSA_2048	RSA 2048.
SSL_KEY_RSA_4096	RSA 4096.
SSL_KEY_ECC_SECP192R1	Defined in wolfssl/wolfcrypt/ecc.h.
SSL_KEY_ECC_SECP224R1	Defined in wolfssl/wolfcrypt/ecc.h.
SSL_KEY_ECC_SECP256R1	Defined in wolfssl/wolfcrypt/ecc.h.
SSL_KEY_ECC_SECP384R1	Defined in wolfssl/wolfcrypt/ecc.h.
SSL_KEY_ECC_SECP521R1	Defined in wolfssl/wolfcrypt/ecc.h.

14.44.6.3 Function Documentation**14.44.6.3.1 EnableOnboardCertificateCreation()**

```
void EnableOnboardCertificateCreation (
    CertGenReturnCode (*) (CertGenData &cGenData) createCertFunc = SSL_CreateNewSelfSignedCert
)
```

```
#include <certgen.h>
```

Enables the ability for the module to automatically generate self-signed certificates for use in SSL/TLS connections when acting as the server.

If a certificate is manually loaded on the module prior to the SSL server being initialized, that certificate will be used and nothing will be generated. If a certificate had been previously generated and a new certificate is manually loaded on the device, the newly loaded certificate will be used in place of the automatically generated one, though the automatically generated one will still be available on the module.

Parameters

<i>createCertFunc</i>	Optional parameter to specify a custom create certificate function.
-----------------------	---

14.44.6.3.2 FillInAltNamesASN1()

```
void FillInAltNamesASN1 (
    Cert & TheCert,
    NBString & altNameString )
```

```
#include <certgen.h>
```

Helper function used to build ASN1 representation of alt names.

Parameters

<i>TheCert</i>	The WolfSSL Cert structure to put the altnames in/onto.
<i>altNameString</i>	a NBString holding the comma separated list of alt names. A single string, with possibly multiple altnames separated by a comma. You can either include a tag telling the system what kind of AltName it is... So say you wanted : IP:192.168.1.36 and DNS:demo.netburner.com The following strings would both work: "IP:192.168.1.36,DNS:demo.netburner.com" "192.168.1.36,demo.netburner.com"

or dual interface IP's...

```
"192.168.1.36,10.1.1.35"
```

or both V4 and V6.... "IP:fe80::203:f4ff:fe0a:447f,192.168.1.36"

14.44.6.3.3 GetDataForCertGen()

```
CertGenData * GetDataForCertGen ( ) [extern]
#include <certgen.h>
```

A function to be overridden to pass certificate details to the certificate generator.

The library provides this function as a weak reference. The values returned by this weak reference are likely wrong for any real application and the user should provide their own function. Applicable for both self signed and ACME certificates generated onboard.

Returns

pointer to a [CertGenData](#) struct

14.44.6.3.4 SSL_CreateNewSelfSignedCert()

```
CertGenReturnCode SSL_CreateNewSelfSignedCert (
    CertGenData & pGenData )
#include <certgen.h>
```

Generates a new self-signed certificate that will be stored on the device.

The common name and alternative names used are taken from the parameters passed in.

By default, the certificate is generated using ECC with SECP384R1. This can be changed to an RSA key by undefining `ENABLE_ECCKEY_CREATE` in `<nndk_install>\libraries\crypto\platform\<module name>\user_settings.h`, and then rebuilding your application. To specify what curve or RSA key length is used in certificate generation, define `DEFAULT_KEY_TYPE` as one of the values defined by `SslKeyType_t`.

Parameters

<i>pGenData</i>	A pointer to structure used to hold data for certificate generation
-----------------	---

Returns

[CertGenReturnCode](#)

14.44.7 SSL Error Codes

Macros

- #define **SSL_ERROR_FAILED_NEGOTIATION** (-256)
The SSL system failed to successfully negotiate a connection.
- #define **SSL_ERROR_CERTIFICATE_UNKNOWN** (-258)
The received certificate could not be decoded.
- #define **SSL_ERROR_CERTIFICATE_NAME_FAILED** (-260)
The connected name did not match common_name.
- #define **SSL_ERROR_CERTIFICATE_VERIFY_FAILED** (-261)
The server returned a certificate that we did not trust.
- #define **SSL_ERROR_NO_BUFFER** (-262)
Unable to get a buffer from the pool.
- #define **SSL_ERROR_HANDSHAKE_INCOMPLETE** (-265)
The SSL handshake is not complete yet.
- #define **SSL_ERROR_NO_SERVER_CERTIFICATE** (-257)
The server wasn't able to load the certificate.
- #define **SSL_ERROR_NO_SERVER_KEY** (-258)
The server wasn't able to load the key.
- #define **SSL_ERROR_UNABLE_TO_LOAD_CIPHERS** (-259)
The client was unable to load the cipher list.
- #define **SSL_ERROR_CERTIFICATE_CHECK** (-260)
The server was unable to check the certificate.

14.44.7.1 Detailed Description

Error codes that can be returned by the NetBurner SSL functions.

14.45 Serial Interfaces

Topics

- [Serial Port Error Codes](#)

Macros

- #define **ADDR_ESCAPE_CHAR** (0xFF)
Address escape character.
- #define **SimpleOpenSerial**(p, b) **OpenSerial**(p, b, 1, 8, **eParityNone**)
Simple open a serial port.

Enumerations

- enum **parity_mode** {
eParityNone , **eParityOdd** , **eParityEven** , **eParityMulti** ,
eParityMultiOdd , **eParityMultiEven** }
Serial Parity Modes.

Functions

- int **OpenSerial** (int portnum, unsigned int baudrate, int stop_bits, int data_bits, **parity_mode** parity)
Open a serial port.
- int **OpenDefaultSerial** ()
Opens the Default serial port as defined by the Boot Config settings.
- void **SerialExpandRxBuffer** (int fd, int nb)
Expand the received serial buffer.
- int **SerialClose** (int portnum)
Close a serial port.
- void **SerialEnableTxFlow** (int port, int enab)
Enable transmit software flow control on the specified UART.
- void **SerialEnableRxFlow** (int port, int enab)
- void **SerialEnableHwTxFlow** (int port, int enab)
- void **SerialEnableHwRxFlow** (int port, int enab)
- void **Serial485HalfDupMode** (int port, int enab)
- void **SendBreak** (int port, uint32_t time)
- int **serwriteaddress** (int fd, const char c)
- int **GetUartErrorReg** (int fd)
- void **SetRTS** (int port, bool val)
- BOOL **SerialSendComplete** (int fd)

14.45.1 Detailed Description

```
#include < serial.h >
```

The NetBurner Serial

14.45.2 Macro Definition Documentation

14.45.2.1 SimpleOpenSerial

```
#define SimpleOpenSerial(  
    p,  
    b ) OpenSerial(p, b, 1, 8, eParityNone)
```

#include <serial.h>

Simple open a serial port.

Select the UART number and baud rate, default parameters will be 1 stop bit, no parity, 8 data bits.

Parameters

<i>p</i>	The UART to open. First port is 0. The maximum number is platform dependent
<i>b</i>	The speed of the serial port in bits per second

See also

[OpenSerial\(\)](#)

14.45.3 Enumeration Type Documentation

14.45.3.1 parity_mode

```
enum parity_mode
```

```
#include <serial.h>
```

Serial Parity Modes.

Enumerator

eParityNone	No parity.
eParityOdd	Odd parity.
eParityEven	Even parity.
eParityMulti	Multi parity.
eParityMultiOdd	Multi mode, Odd parity.
eParityMultiEven	Multi mode, Even parity.

14.45.4 Function Documentation

14.45.4.1 GetUartErrorReg()

```
int GetUartErrorReg (  
    int fd )
```

```
#include <serial.h>
```

Gets the UART error register. This is only applicable on select platforms. Any errors are added to this register in a logical OR operation. Calling this function to read the error status will clear the register.

Bit Description

3 Received break 2 Framing error 1 Parity error 0 Overrun error

fd - The file descriptor associated with the UART serial port whose error register is to be retrieved.

return - The value of the error register if successful (positive int - the bitwise values are represented by the UART_↔
ERR* definitions found near the top of this file); otherwise, one of the error codes is returned: SERIAL_ERR_↔
NOSUCH_PORT (-1) SERIAL_ERR_PORT_NOTOPEN (-2)

14.45.4.2 OpenDefaultSerial()

```
int OpenDefaultSerial ( )
```

```
#include <serial.h>
```

Opens the Default serial port as defined by the Boot Config settings.

This function opens the Default serial port as defined by the Boot Config settings. It is called automatically by the system as part of the system initialization process. Unlike `OpenSerial` and `SimpleOpenSerial`, `OpenDefaultSerial` will configure the Tx and Rx pins to the Boot Config settings.

Returns

The file descriptor of the default serial port (> 0), or [Serial Port Error Codes](#)

See also

[OpenSerial\(\)](#)

14.45.4.3 OpenSerial()

```
int OpenSerial (
    int portnum,
    unsigned int baudrate,
    int stop_bits,
    int data_bits,
    parity_mode parity )
```

```
#include <serial.h>
```

Open a serial port.

This function opens a serial port. Note that functions to open a serial port, such as [OpenSerial\(\)](#) and [SimpleOpenSerial\(\)](#), must be called before any functions or pin assignments that configure the operation of the serial port. You must also configure all pins that have the same UART capability. For example, if UART 1 TX can be configured to come out on more than one pin (as a second or third alternate function), you must set those pins to some function other than UART 1 TX. This is because the functions that open a serial port will configure all serial port functions to default operation and default pins. For example, hardware flow control will be off, and the default pin assignments will be used on those platform that have multiple outputs.

Parameters

<i>portnum</i>	The UART to open. First port is 0. The maximum number is platform dependent
<i>baudrate</i>	The speed of the serial port in bits per second
<i>stop_bits</i>	The number of stop bits, 1 or 2
<i>data_bits</i>	The number of data bits sent per character or frame: 5, 6, 7 or 8
<i>parity</i>	The type of parity checking to use: eParityNone, eParityEven, eParityOdd or eParityMulti

Returns

The file descriptor of the serial port (> 0), or [Serial Port Error Codes](#)

See also

[SimpleOpenSerial\(\)](#)

14.45.4.4 SendBreak()

```
void SendBreak (
    int port,
    uint32_t time )
```

```
#include <serial.h>
```

Sets a break in the UART transmission for a given period of time. The break starts when character transmission completes. The break is delayed until any character in the transmitter shift register is sent. Any character in the transmitter holding register is sent after the break.

Note: This feature may not be supported on all UART modules. Please refer to the processor's datasheet for details on supported features.

port - The UART whose transmitter will be forced low (start break). time - Specifies the amount of time in ticks that the break will hold; when time expires, the break will be stopped; 20 ticks equal 1 second by default.

return - Nothing to return.

14.45.4.5 Serial485HalfDupMode()

```
void Serial485HalfDupMode (
    int port,
    int enab )
```

```
#include <serial.h>
```

Enables or disables RS-485 half-duplex mode. Full-duplex mode is automatically enabled when half-duplex mode is disabled. This must be explicitly called before RS-485 functionality can be used. Jumpers may also be needed depending on the hardware device and/or development board used.

port - The UART port to use; the UART that can only be used for RS-485 depends on the platform (e.g., MOD52xx mounted on the MOD-DEV-100 development board use only UART 0 for RS-485, CB34-EX use only UART 1 for RS-485). enab - '0' disables half-duplex (enables full-duplex); '1' enables half-duplex (disables full-duplex)

return - Nothing to return.

14.45.4.6 SerialClose()

```
int SerialClose (
    int portnum )
```

```
#include <serial.h>
```

Close a serial port.

Parameters

<i>portnum</i>	The UART to close. First port is 0. The maximum number is platform dependent
----------------	--

Returns

0 if successful, otherwise [Serial Port Error Codes](#)

See also

[OpenSerial\(\)](#)

14.45.4.7 SerialEnableHwRxFlow()

```
void SerialEnableHwRxFlow (
    int port,
    int enab )
```

```
#include <serial.h>
```

Enables or disables request-to-send hardware flow control on receive (RxRTS). When enabled, receive throttles the transmitter on the other end. Jumpers may also be needed to enable the RxRTS line depending on the device and/or development board used.

(NB Device) Rx <--<--< Tx (Other Device) (NB Device) RxRTS >-->--> TxCTS (Other Device)

port - The UART whose flow control will be toggled. enab - '0' disables flow control; '1' (or any non-zero number) will enable it.

return - Nothing to return.

14.45.4.8 SerialEnableHwTxFlow()

```
void SerialEnableHwTxFlow (
    int port,
    int enab )
```

```
#include <serial.h>
```

Enables or disables clear-to-send hardware flow control on transmit (TxCTS). When enabled, transmit is throttled by the receiver on the other end. Jumpers may also be needed to enable the TxCTS line depending on the device and/or development board used.

(NB Device) Tx >-->--> Rx (Other Device) (NB Device) TxCTS <--<--< RxRTS (Other Device)

Note: Calling this function to disable Tx hardware flow control after enabling RS-485 full-duplex mode configures for RS-422 mode (Tx stays actively driven).

port - The UART whose flow control will be toggled. enab - '0' disables flow control; '1' (or any non-zero number) will enable it.

return - Nothing to return.

14.45.4.9 SerialEnableRxFlow()

```
void SerialEnableRxFlow (
    int port,
    int enab )
```

```
#include <serial.h>
```

Enables or disables software flow control (XON/XOFF) on receive. When enabled, the NetBurner device will send special XON and XOFF characters to another device in order to control the flow of incoming data.

port - The UART whose flow control will be toggled. enab - '0' disables flow control; '1' (or any non-zero number) will enable it.

return - Nothing to return.

14.45.4.10 SerialEnableTxFlow()

```
void SerialEnableTxFlow (
    int port,
    int enab )
```

```
#include <serial.h>
```

Enable transmit software flow control on the specified UART.

Enables or disables software flow control (XON/XOFF) on transmit. When enabled, the NetBurner device will recognize the special XON and XOFF characters being sent from another device in order to throttle the output.

Parameters

<i>port</i>	UART number
<i>enab</i>	0 disables flow control, 1 enables flow control

14.45.4.11 SerialExpandRxBuffer()

```
void SerialExpandRxBuffer (
    int fd,
    int nb )
```

```
#include <serial.h>
```

Expand the received serial buffer.

This function expands the number of buffer descriptors the specific serial port is allowed to use. Each buffer descriptor counts for 1500 bytes so setting this to 10 would make the serial Rx buffer 15000 bytes.

14.45.4.12 SerialSendComplete()

```
BOOL SerialSendComplete (
    int fd )
```

```
#include <serial.h>
```

Determines if data waiting in transmitter holding/shift registers are already sent out.

return - True if finished, false if data still sending

14.45.4.13 serwriteaddress()

```
int serwriteaddress (
```

```

    int fd,
    const char c )
#include <serial.h>

```

Sends an address character via the UART port number associated with the given file descriptor. This function can only be utilized if the UART is initialized in multidrop mode.

fd - The file descriptor associated with the UART serial port that will be used. c - The address character to be sent. return - '1' if successful; otherwise, one of the error codes is returned (note that SERIAL_ERR_PORT_NOTOPEN is also returned if UART is not initialized to be in multidrop mode): SERIAL_ERR_NOSUCH_PORT (-1) SERIAL_ERR_PORT_NOTOPEN (-2)

14.45.4.14 SetRTS()

```

void SetRTS (
    int port,
    bool val )
#include <serial.h>

```

Sets or clears the Request To Send signal for the specified serial port.

port - The UART port whose RTS signal will be set or cleared. (0 or 1) val - The Boolean value to configure the signal; TRUE sets it, while FALSE clears it.

return - Nothing to return.

14.45.5 Serial Port Error Codes

Macros

- #define SERIAL_ERR_NOSUCH_PORT (-1)
Port number does not exist.
- #define SERIAL_ERR_PORT_NOTOPEN (-2)
Port is not open.
- #define SERIAL_ERR_PORT_ALREADYOPEN (-3)
Port is already open.
- #define SERIAL_ERR_PARAM_ERROR (-4)
Parameter error.

14.45.5.1 Detailed Description

```
#include< serial.h >
```

14.46 Shutdown Notifications

Topics

- [ShutdownReasons](#)
Shutdown Reasons

```
#include< ShutdownNotifications.h >
```

Functions

- bool [NBApproveShutdown](#) (int reason)
Approve action that will result in a reboot.
- void [NBFaultNotify](#) ()
Emergency notification of a fault shutdown.

14.46.1 Detailed Description

```
#include <ShutdownNotifications.h >
```

The NBApproveShutdown callback function can be used by an application to put the system in a safe state before an application update, configuration update, or reboot event occurs. For example, closing active TCP sockets, ensuring Flash and/or file system write operations are complete, and putting critical peripherals in a safe state. The NBApproveShutdown() function as a weak reference to a system function that always returns true by default. If an application creates its own function using the same signature, that function will be used instead.

A reason for the reboot request is passed to the function. The system will automatically call NBApproveShutdown() for the following reasons:

```
#define SHUTDOWN_CODEUPDATE          (1) // A code update is requested
#define SHUTDOWN_CONFIGURE_REBOOT    (2) // Configuration values have been modified with a requested reboot
```

An application can choose to ignore the parameters or add its own. For custom reasons, the application should call NBApproveShutdown() with the appropriate reason:

```
// Custom reboot reason. System reasons start at 1, so pick something much larger
#define SHUTDOWN_CUSTOM_REBOOT 100

if ( NBApproveShutdown (SHUTDOWN_CUSTOM_REBOOT) )
{
    OSTimeDly (TICKS_PER_SECOND * 5);
    ForceReboot ();
}
```

14.46.2 Function Documentation

14.46.2.1 NBApproveShutdown()

```
bool NBApproveShutdown (
    int reason )
#include <ShutdownNotifications.h>
Approve action that will result in a reboot.
```

Note

Called for application updates or configuration changes that include the reboot option

This function will be called when the configuration values have changed with the option to reboot, or for an application update (always requires a reboot).

If the process fails at some time after this notification is approved, the system may not execute a reboot. This function is satisfied as a weak reference in the NetBurner library. In order to use it in your application, create a function of the same name (callback function).

Parameters

<i>reason</i>	The reason for the shutdown request (ShutdownReasons)
---------------	---

Return values

<i>true</i>	Ok to proceed with the modification and reboot
<i>false</i>	Abort the update

14.46.2.2 NBFaultNotify()

```
void NBFaultNotify ( )
#include <ShutdownNotifications.h>
Emergency notification of a fault shutdown.
```

Note

Called after a critical error, such as a trap or memory fault before a reboot

If the system has a critical fault of some kind it will call this function before rebooting. Since this is a severe critical fault, the function is being called in an exception context with a very small stack. It should execute whatever is necessary and return immediately with a minimal number of variables.

It is extremely limited in the actions it can perform. It cannot execute:

- Any RTOS functions
- printf family functions
- Writes to network sockets
- TCP or UDP functions
- Writes to serial ports
- RTOS delay functions
- Writes to Flash memory
- File system operations

Since this is a critical fault condition and the system is unstable, writing directly to I/O registers has the most chance of success.

14.46.3 ShutdownReasons

Shutdown Reasons

```
#include< ShutDownNotifications.h >
```

.

Macros

- #define **SHUTDOWN_CODEUPDATE** (1)
A code update is requested.
- #define **SHUTDOWN_CONFIGURE_REBOOT** (2)
Configuration values have been modified with a requested reboot.

14.46.3.1 Detailed Description

Shutdown Reasons

```
#include< ShutDownNotifications.h >
```

.

14.47 Signed Application Update**Topics**

- [NUpdate Function Return Values](#)

Functions

- void [RegisterAppSigningPublicKey](#) (const char *pKey)
Enable APP Signing by registering a RSA PEM or DER format public key.
- int [ProgramApplication](#) (uint32_t where, uint8_t *pApplImage)
Program an application image into Flash memory.
- int [UpdateFromStream](#) (int fd, AppUpdateRecord *&pu, uint32_t timeout)
Program/update an application image from a data stream.

14.47.1 Detailed Description

```
#include <nbupdate.h >
```

14.47.2 Function Documentation

14.47.2.1 ProgramApplication()

```
int ProgramApplication (
    uint32_t where,
    uint8_t * pAppImage )
#include <nbupdate.h>
Program an application image into Flash memory.
```

Parameters

<i>where</i>	Location in Flash memory
<i>pAppImage</i>	Pointer to the application image to program

Return values

0	Success
-1	Application image pointer invalid
-2	Invalid platform header

14.47.2.2 RegisterAppSigningPublicKey()

```
void RegisterAppSigningPublicKey (
    const char * pKey )
#include <nbupdate.h>
Enable APP Signing by registering a RSA PEM or DER format public key.
This function should be called BEFORE the init\(\) function if you want to guarantee security. It is ok to register a temporary text blob early, then overwrite it once the key via other means.
```

Parameters

<i>pKey</i>	Pointer to the public key to register
-------------	---------------------------------------

14.47.2.3 UpdateFromStream()

```
int UpdateFromStream (
    int fd,
    AppUpdateRecord *& pu,
    uint32_t timeout )
#include <nbupdate.h>
Program/update an application image from a data stream.
```

Parameters

<i>fd</i>	File descriptor of data stream
<i>pu</i>	Application record
<i>timeout</i>	Timeout value in system time ticks (eg TICKS_PER*SECOND * 10)

Return values

0	Success
-1	Application image pointer invalid
-2	Invalid platform header

14.47.3 NBUpdate Function Return Values**Macros**

- #define **NBUP_ERR_NO_ERR** 0
No errors.
- #define **NBUP_ERR_BAD_SOCKET** -1
File descriptor socket is invlaid.
- #define **NBUP_ERR_TIMEOUT** -2
Timeout.
- #define **NBUP_ERR_TOO_LARGE** -3
Application update record is too large.
- #define **NBUP_ERR_WRONG_PLAT** -4
Device platform name does not match.
- #define **NBUP_ERR_BAD_PROG** -5
Programming failed, invalid checksum.
- #define **NBUP_ERR_BAD_AUTH** -6
Application update record authentication failed.

14.47.3.1 Detailed Description

```
#include < nbupdate.h >
```

14.48 Stream Update**Topics**

- [Stream Update Return Values](#)

Functions

- int [ReadBinaryApplicationCodeFromStream](#) (int fd)
Read a binary application image from an input stream and program flash memory.
- int [ReadS19ApplicationCodeFromStream](#) (int fd)
Read an ASCII application image in s-record .s19 format from an input stream and program flash memory.

14.48.1 Detailed Description

```
#include < StreamUpdate.h >
```

Functions to read an application form a source with a file descriptor. Useful for programming/updating an application image from sources such as flash memory cards, posts from other devices, and files received from FTP.

14.48.2 Function Documentation

14.48.2.1 ReadBinaryApplicationCodeFromStream()

```
int ReadBinaryApplicationCodeFromStream (
    int fd )
#include <StreamUpdate.h>
```

Read a binary application image from an input stream and program flash memory.

Read a binary application image from an input stream and program the application image in flash memory. Flash memory will not be modified unless the entire application is received without error.

A reboot is required to run the new application. Before any reboot, the running application should free, close and clean up any items necessary to put the device in a safe state. For example, it would be better to close active TCP or FTP connections rather than just reset so that any connected clients can close normally. If you wish to reboot from a running application you can use the

void [ForceReboot\(\)](#)

function [ForceReboot\(\)](#).

Parameters

<i>fd</i>	The File Descriptor to read the input data stream from
-----------	--

Returns

[Stream Update Return Values](#)

14.48.2.2 ReadS19ApplicationCodeFromStream()

```
int ReadS19ApplicationCodeFromStream (
    int fd )
#include <StreamUpdate.h>
```

Read an ASCII application image in s-record .s19 format from an input stream and program flash memory.

Read a ASCII application image in s-record .s19 format from an input stream and program the application image in flash memory. Flash memory will not be modified unless the entire application is received without error.

A reboot is required to run the new application. Before any reboot, the running application should free, close and clean up any items necessary to put the device in a safe state. For example, it would be better to close active TCP or FTP connections rather than just reset so that any connected clients can close normally. If you wish to reboot from a running application you can use the

void [ForceReboot\(\)](#)

function [ForceReboot\(\)](#).

Parameters

<i>fd</i>	The File Descriptor to read the input data stream from
-----------	--

Returns

[Stream Update Return Values](#)

14.48.3 Stream Update Return Values

Macros

- #define **STREAM_UP_FAIL** (0)
Action failed.
- #define **STREAM_UP_OK** (1)
Action succeeded.

14.48.3.1 Detailed Description

```
#include< StreamUpdate.h >
```

14.49 System Functions

NetBurner General System Functions.

Functions

- int [SaveUserParameters](#) (void *pCopyFrom, int len)
Save data to the on-chip flash memory User Parameter area.
- void * [GetUserParameters](#) (void)
Returns a void pointer to the user parameter area.
- const char * [GetReleaseTag](#) ()
Returns the NNDK release tag information.

14.49.1 Detailed Description

NetBurner General System Functions.

```
#include< system.h >
```

14.49.2 Function Documentation

14.49.2.1 GetReleaseTag()

```
const char * GetReleaseTag ( )  
#include <system.h>  
Returns the NNDK release tag information.
```

Returns

Pointer to a string representing the development tools release tag

14.49.2.2 GetUserParameters()

```
void * GetUserParameters (   
    void )  
#include <system.h>  
Returns a void pointer to the user parameter area.
```

On most platforms the total amount of space is 8k bytes. Typically used to retrieve a structure. This function is here for reverse compatibility with releases prior to NetBurner 3.0. Alternatives are to use the 3.0 configuration tree, or the EDFS STD file system.

Returns

Void pointer to the User Parameter area in flash memory

See also

[SaveUserParameters\(\)](#)

14.49.2.3 SaveUserParameters()

```
int SaveUserParameters (
    void * pCopyFrom,
    int len )
```

```
#include <system.h>
```

Save data to the on-chip flash memory User Parameter area.

On most platforms the total amount of space is 8k bytes. Typically used to save a structure.

This function is here for reverse compatibility with releases prior to NetBurner 3.0. Alternatives are to use the 3.0 configuration tree, or the EFFS STD file system.

Parameters

<i>pCopyFrom</i>	Pointer to the data to copy and save
<i>len</i>	Length of data

Returns

The number of items copied, or <= 0 on failure

See also

[GetUserParameters\(\)](#)

14.50 TCP

- [TCP Socket State](#)
- [TCP Socket Status](#)

Functions

- int [accept](#) (int listening_socket, [IPADDR](#) *address, uint16_t *port, uint16_t timeout)
Accept an incoming connection from a listening socket.
- int [accept](#) (int listening_socket, [IPADDR](#) *address, uint16_t *port, [TickTimeout](#) &timeout)
Accept an incoming connection from a listening socket.
- int [connect](#) (const [IPADDR](#) &ipAddress, uint16_t remotePort, uint32_t timeout)
Make an outgoing TCP connection to a remote host.
- int [connectvia](#) (const [IPADDR](#) &ipAddress, uint16_t remotePort, uint32_t timeout, const [IPADDR](#) &localIpAddress)
Make an outgoing TCP connection to a remote host using the specified local interface IP address.
- int [connectvia](#) (const [IPADDR](#) &ipAddress, uint16_t remotePort, uint32_t timeout, int ifnum)
Make an outgoing TCP connection to a remote host using the specified local interface number.
- int [connectlocal](#) (const [IPADDR](#) &ipAddress, uint16_t localPort, uint16_t remotePort, uint32_t timeout, const [IPADDR](#) &localIpAddress=[IPADDR::NullIP\(\)](#), int intf=-1)
Make an outgoing TCP connection to a remote host using the specified local interface number or IP address.
- int [listen](#) (const [IPADDR](#) &addr, uint16_t port, uint8_t maxpend=5)
Listen for incoming connections on the specified network interface IP address.
- int [listenvia](#) (const [IPADDR](#) &addr, uint16_t port, int ifn, uint8_t maxpend=5)
Listen for incoming connections on the specified network interface IP address.
- int [listenvia](#) (const [IPADDR](#) &addr, uint16_t port, const [IPADDR](#) &localIpAddress, uint8_t maxpend=5)
Listen for incoming connections on the specified network interface IP address.

- int [NoBlockConnect](#) (const [IPADDR](#) &ipAddress, uint16_t remotePort)

Create a file descriptor for a TCP connection and return immediately. This function does not wait for a connection to be established. Before using the file descriptor, the application must verify the connection was successful with [TcpGetSocketState\(fd\)](#). The state will be `TCP_STATE_ESTABLISHED` when the connection has been successfully established. Note: The connection status can also be obtained with the [wireavail\(\)](#) function.
- int [NoBlockConnectVia](#) (const [IPADDR](#) &ipAddress, uint16_t remotePort, const [IPADDR](#) &interfaceIp, Address=IPADDR::NullIP())

Create a file descriptor for a TCP connection and return immediately. This function does not wait for a connection to be established. Before using the file descriptor, the application must verify the connection was successful with [TcpGetSocketState\(fd\)](#). The state will be `TCP_STATE_ESTABLISHED` when the connection has been successfully established. Note: The connection status can also be obtained with the [wireavail\(\)](#) function.
- int [NoBlockConnectVia](#) (const [IPADDR](#) &ipAddress, uint16_t remotePort, int ifnum)

Create a file descriptor for a TCP connection and return immediately. This function does not wait for a connection to be established. Before using the file descriptor, the application must verify the connection was successful with [TcpGetSocketState\(fd\)](#). The state will be `TCP_STATE_ESTABLISHED` when the connection has been successfully established. Note: The connection status can also be obtained with the [wireavail\(\)](#) function.
- int [NoBlockConnectwlocal](#) (const [IPADDR](#) &ipAddress, uint16_t localPort, uint16_t remotePort, [IPADDR](#) interfaceIp, Address=IPADDR::NullIP(), int ifn=-1)

Create a file descriptor for a TCP connection and return immediately. This function does not wait for a connection to be established. Before using the file descriptor, the application must verify the connection was successful with [TcpGetSocketState\(fd\)](#). The state will be `TCP_STATE_ESTABLISHED` when the connection has been successfully established. Note: The connection status can also be obtained with the [wireavail\(\)](#) function.
- [IPADDR GetSocketRemoteAddr](#) (int fd)

Returns the IP address of the remote host associated with the specified file descriptor.
- [IPADDR GetSocketLocalAddr](#) (int fd)

Returns the IP address of the local interface associated with the connection.
- uint16_t [GetSocketRemotePort](#) (int fd)

Returns the port number of the remote host associated with the connection.
- uint16_t [GetSocketLocalPort](#) (int fd)

Returns the local port number associated with the connection.
- uint32_t [TcpGetLastRxTime](#) (int fd)

Returns the value of system Time Ticks when the last packet was received. Used for the TCP Keep Alive feature.
- void [TcpSendKeepAlive](#) (int fd)

Send a TCP keep alive packet to a remote host.
- uint32_t [TcpGetLastRxInterval](#) (int fd)

Returns the number of system Time Ticks since the last packet was received. This is the difference between the current system time and lastRxTime of the socket.
- int [GetTcpRtxCount](#) (int fd)

Returns the number of re-transmits that have occurred on the specified connection.
- uint8_t [SetOutOfOrderBuffers](#) (int fd, uint8_t max)

Set the maximum number of out-of-order TCP buffers for the specified TCP socket.
- int [setsockopt](#) (int fd, int option)

Set TCP socket options.
- int [clrsockopt](#) (int fd, int option)

Clear TCP socket options.
- int [getsockopt](#) (int fd)

Returns the options for the specified TCP socket.
- int [SetSocketUnackBuffers](#) (int fd, uint8_t val)

Set the maximum number of outbound TCP buffers in the transmit un-acknowledged list for the specified TCP socket.
- int [SetSocketRxBuffers](#) (int fd, int n)

Set the number of TCP receive buffers for the specified TCP socket.
- int [SetSocketTxBuffers](#) (int fd, int n)

Set the number of TCP transmit buffers for the specified TCP socket.
- int [abortsocket](#) (int fd)

- Execute an abort on the specified TCP socket.*

 - int [SockReadWithTimeout](#) (int fd, char *buf, int nbytes, uint32_t timeout)

Attempt to read from a TCP socket until the timeout expires.
 - char [SocketPeek](#) (int fd)

Returns the next char that would be read, 0 if no data.
 - int [TcpGetSocketInterface](#) (int fd)

Return the network interface associated with a TCP socket.
 - uint8_t [TcpGetSocketState](#) (int fd)

Return the current state of a TCP socket.
 - uint16_t [TcpGetRxBufferSizeUsed](#) (int fd)

Returns the number of bytes used in a socket's RX buffer.
 - uint16_t [TcpGetTxBufferAvailSpace](#) (int fd)

Returns the number of bytes available in a socket's TX buffer.
 - uint16_t [TcpGetTxDataWaiting](#) (int fd)

Returns the number of bytes waiting to be sent in a socket's TX Buffer.
 - BOOL [TcpAllDataAcked](#) (int socket)

Check the data acknowledged state of a socket.
 - BOOL [WaitForSocketFlush](#) (int fd, uint32_t ticks)

Wait for a socket flush operation to complete. A socket is flushed if all sent data has been acknowledged.

14.50.1 Detailed Description

```
#include <tcp.h >
```

14.50.2 Function Documentation

14.50.2.1 abortsocket()

```
int abortsocket (
    int fd )
```

```
#include <tcp.h>
```

Execute an abort on the specified TCP socket.

Parameters

<i>fd</i>	Socket file descriptor
-----------	------------------------

Returns

[TCP Socket Status](#)

14.50.2.2 accept() [1/2]

```
int accept (
    int listening_socket,
    IPADDR * address,
    uint16_t * port,
    TickTimeout & timeout )
```

```
#include <tcp.h>
```

Accept an incoming connection from a listening socket.

A socket must be listening in order to accept a TCP connection, and a connection request must be accepted before it can be used. Each time a connection request is accepted, a slot is freed in the listen pending queue for that socket.

Parameters

<i>listening_socket</i>	The listening socket from which to accept the connection.
<i>*address</i>	Pointer to an IPADDR object that can store the source IP address of the connection. Can be NULL.
<i>*port</i>	Pointer to a variable to store the source port number of the connection. Can be NULL.
<i>timeout</i>	TickTimeout indicating how long the call should wait, before returning failure

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

See also

[listen\(\)](#), [close\(\)](#)

14.50.2.3 accept() [2/2]

```
int accept (
    int listening_socket,
    IPADDR * address,
    uint16_t * port,
    uint16_t timeout )
```

```
#include <tcp.h>
```

Accept an incoming connection from a listening socket.

A socket must be listening in order to accept a TCP connection, and a connection request must be accepted before it can be used. Each time a connection request is accepted, a slot is freed in the listen pending queue for that socket.

Parameters

<i>listening_socket</i>	The listening socket from which to accept the connection.
<i>*address</i>	Pointer to an IPADDR object that can store the source IP address of the connection. Can be NULL.
<i>*port</i>	Pointer to a variable to store the source port number of the connection. Can be NULL.
<i>timeout</i>	Number of system Time Ticks to wait. A value of 0 waits forever. For example, TICKS_PER_SECOND * 5 waits five seconds.

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

See also

[listen\(\)](#), [close\(\)](#)

14.50.2.4 clrsockoption()

```
int clrsockoption (
    int fd,
    int option )
```

```
#include <tcp.h>
```

Clear TCP socket options.

Parameters

<i>fd</i>	Socket file descriptor.
<i>option</i>	Socket option to clear: TCP Socket Options .

Returns

A bitmask of the options for the specified socket.

See also

[setsockopt\(\)](#), [getsockopt\(\)](#), [SetSocketUnackBuffers\(\)](#), [SetSocketRxBuffers\(\)](#), [SetSocketTxBuffers\(\)](#)

14.50.2.5 connect()

```
int connect (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    uint32_t timeout ) [inline]
```

```
#include <tcp.h>
```

Make an outgoing TCP connection to a remote host.

Parameters

<i>ipAddress</i>	Remote IP address.
<i>remotePort</i>	Remote port number.
<i>timeout</i>	Timeout in system time ticks (use TICKS_PER_SECOND macro).

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

See also

[connectvia\(\)](#), [connectwlocal\(\)](#)

14.50.2.6 connectvia() [1/2]

```
int connectvia (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    uint32_t timeout,
    const IPADDR & localIpAddress ) [inline]
```

```
#include <tcp.h>
```

Make an outgoing TCP connection to a remote host using the specified local interface IP address.

The [connect\(\)](#) function automatically uses the default network interface. The [connectvia\(\)](#) function enables the application to specify a particular local network interface.

Parameters

<i>ipAddress</i>	Remote IP address .
<i>remotePort</i>	Remote port number.
<i>timeout</i>	Timeout in system time ticks (use TICKS_PER_SECOND macro).
<i>localIpAddress</i>	IP address of the local interface. If a value of IPADDR::NULL() is used, it will attempt to use the local interface associated with the remote IP address.

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

See also

[connect\(\)](#), [connectwlocal\(\)](#)

14.50.2.7 connectvia() [2/2]

```
int connectvia (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    uint32_t timeout,
    int ifnum ) [inline]
```

```
#include <tcp.h>
```

Make an outgoing TCP connection to a remote host using the specified local interface number.

The [connect\(\)](#) function automatically uses the default network interface. The [connectvia\(\)](#) function enables the application to specify a particular local network interface.

Parameters

<i>ipAddress</i>	Remote IP address.
<i>remotePort</i>	Remote port number.
<i>timeout</i>	Timeout in system time ticks (use TICKS_PER_SECOND macro).
<i>ifnum</i>	The local interface number. The interface number will override all routing based on the source and destination IP address.

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

See also

[connect\(\)](#), [connectwlocal\(\)](#)

14.50.2.8 connectwlocal()

```
int connectwlocal (
    const IPADDR & ipAddress,
    uint16_t localPort,
    uint16_t remotePort,
    uint32_t timeout,
    const IPADDR & localIpAddress = IPADDR::NullIP(),
    int intf = -1 ) [inline]
```

```
#include <tcp.h>
```

Make an outgoing TCP connection to a remote host using the specified local interface number or IP address.

Warning

Although this function that allows a local port number parameter for extreme edge cases, local port numbers should be avoided. Local port numbers create connectivity failures when a remote host has a half open socket condition.

Parameters

<i>ipAddress</i>	Remote IP address.
<i>localPort</i>	Optional parameter to specify a Local port number. Recommend this always be set to a value of 0 so a random local port number is used. Warning! Specifying a local port number will create connectivity failures if the remote host has a half open socket condition.
<i>remotePort</i>	Remote port number.
<i>timeout</i>	Timeout in system time ticks (use TICKS_PER_SECOND macro).
<i>localIpAddress</i>	Optional IP address of local interface to use for connection. If not used, such as when specifying the <i>intf</i> parameter, set to IPADDR::NullIP() .
<i>intf</i>	Optional local interface number to use for connection. Do not specify if the <i>interfaceIpAddress</i> parameter is used.

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

See also

[connect\(\)](#), [connectvia\(\)](#)

14.50.2.9 GetSocketLocalAddr()

```
IPADDR GetSocketLocalAddr (
    int fd ) [inline]
#include <tcp.h>
```

Returns the IP address of the local interface associated with the connection.

Parameters

<i>fd</i>	The socket file descriptor.
-----------	-----------------------------

Returns

The IP address of the remote host.

See also

[GetSocketRemoteAddr\(\)](#)

14.50.2.10 GetSocketLocalPort()

```
uint16_t GetSocketLocalPort (
    int fd )
#include <tcp.h>
```

Returns the local port number associated with the connection.

Parameters

<i>fd</i>	The socket file descriptor.
-----------	-----------------------------

Returns

The local port number for the connection.

See also

[GetSocketRemotePort\(\)](#)

14.50.2.11 GetSocketRemoteAddr()

```
IPADDR GetSocketRemoteAddr (  
    int fd ) [inline]  
#include <tcp.h>
```

Returns the IP address of the remote host associated with the specified file descriptor.

Parameters

<i>fd</i>	The socket file descriptor.
-----------	-----------------------------

Returns

The IP address of the remote host.

See also

[GetSocketLocalAddr\(\)](#)

14.50.2.12 GetSocketRemotePort()

```
uint16_t GetSocketRemotePort (  
    int fd )  
#include <tcp.h>
```

Returns the port number of the remote host associated with the connection.

Parameters

<i>fd</i>	The socket file descriptor.
-----------	-----------------------------

Returns

The remote host port number.

See also

[GetSocketLocalPort\(\)](#)

14.50.2.13 getsockopt()

```
int getsockopt (  
    int fd )  
#include <tcp.h>
```

Returns the options for the specified TCP socket.

Parameters

<i>fd</i>	Socket file descriptor.
-----------	-------------------------

Returns

A bitmask of the options for the specified socket.

See also

[setsockopt\(\)](#), [clrsockopt\(\)](#), [SetSocketUnackBuffers\(\)](#), [SetSocketRxBuffers\(\)](#), [SetSocketTxBuffers\(\)](#)

14.50.2.14 GetTcpRtxCount()

```
int GetTcpRtxCount (
    int fd )
```

```
#include <tcp.h>
```

Returns the number of re-transmits that have occurred on the specified connection.

Parameters

<i>fd</i>	The socket file descriptor.
-----------	-----------------------------

Returns

The number of system Time Ticks since the last packet was received on the connection.

14.50.2.15 listen()

```
int listen (
    const IPADDR & addr,
    uint16_t port,
    uint8_t maxpend = 5 ) [inline]
```

```
#include <tcp.h>
```

Listen for incoming connections on the specified network interface IP address.

Begin listening for incoming connections. A connection must be accepted with the [accept\(\)](#) function before they can be used. Each time a connection request is accepted is frees up another slot in the pending queue.

Parameters

<i>addr</i>	The address from which to accept connections. INADDR_ANY will accept all connections.
<i>port</i>	The network port number to listen on.
<i>maxpend</i>	The maximum number of pending connection requests allowed for the listen socket.

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

```
int32_t fdListen = listen(INADDR_ANY, 1234);
```

See also

[accept\(\)](#), [listenvia\(\)](#), [close\(\)](#)

14.50.2.16 listenvia() [1/2]

```
int listenvia (
    const IPADDR & addr,
    uint16_t port,
    const IPADDR & localIpAddress,
    uint8_t maxpend = 5 ) [inline]
```

```
#include <tcp.h>
```

Listen for incoming connections on the specified network interface IP address.

Begin listening for incoming connections. A connection must be accepted with the [accept\(\)](#) function before they can be used. Each time a connection request is accepted is frees up another slot in the pending queue.

Parameters

<i>addr</i>	The address from which to accept connections. INADDR_ANY will accept all connections.
<i>port</i>	The network port number to listen on.
<i>maxpend</i>	The maximum number of pending connection requests allowed for the listen socket.
<i>localIpAddress</i>	The IP address of the network interface to listen on. If two interfaces have the same address, the lower numbered interface will be used.

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

See also

[accept\(\)](#), [listen\(\)](#), [close\(\)](#)

14.50.2.17 listenvia() [2/2]

```
int listenvia (
    const IPADDR & addr,
    uint16_t port,
    int ifn,
    uint8_t maxpend = 5 ) [inline]
```

```
#include <tcp.h>
```

Listen for incoming connections on the specified network interface IP address.

Begin listening for incoming connections. A connection must be accepted with the [accept\(\)](#) function before they can be used. Each time a connection request is accepted is frees up another slot in the pending queue.

Parameters

<i>addr</i>	The address from which to accept connections. INADDR_ANY will accept all connections.
<i>port</i>	The network port number to listen on.
<i>maxpend</i>	The maximum number of pending connection requests allowed for the listen socket.
<i>ifn</i>	Interface Number of the network Interface to be used.

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

See also

[accept\(\)](#), [listen\(\)](#), [close\(\)](#)

14.50.2.18 NoBlockConnect()

```
int NoBlockConnect (
    const IPADDR & ipAddress,
    uint16_t remotePort ) [inline]
#include <tcp.h>
```

Create a file descriptor for a TCP connection and return immediately. This function does not wait for a connection to be established. Before using the file descriptor, the application must verify the connection was successful with `TcpGetSocketState(fd)`. The state will be `TCP_STATE_ESTABLISHED` when the connection has been successfully established. Note: The connection status can also be obtained with the `wireavail()` function.

Warning

To free system resources a `close()` must be called, even if the current state is `TCP_STATE_CLOSING`. Otherwise a resource leak will occur.

Parameters

<i>ipAddress</i>	Remote IP address.
<i>remotePort</i>	Remote port number.

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

See also

[NoBlockConnectVia\(\)](#), [TcpGetSocketState\(\)](#), [writeavail\(\)](#), [connect\(\)](#), [connectvia\(\)](#), [connectwlocal\(\)](#)

14.50.2.19 NoBlockConnectVia() [1/2]

```
int NoBlockConnectVia (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    const IPADDR & interfaceIpAddress = IPADDR::NullIP() ) [inline]
#include <tcp.h>
```

Create a file descriptor for a TCP connection and return immediately. This function does not wait for a connection to be established. Before using the file descriptor, the application must verify the connection was successful with `TcpGetSocketState(fd)`. The state will be `TCP_STATE_ESTABLISHED` when the connection has been successfully established. Note: The connection status can also be obtained with the `wireavail()` function.

This function is similar to [NoBlockConnect\(\)](#), with the additional capability of specifying the local interface IP address to use for connection.

Warning

To free system resources a `close()` must be called, even if the current state is `TCP_STATE_CLOSING`. Otherwise a resource leak will occur.

Parameters

<i>ipAddress</i>	Remote IP address
<i>remotePort</i>	Remote port of socket
<i>interfaceIpAddress</i>	Optional parameter to specify which local network interface to use for the connection. The default is <code>IPADDR::NullIP()</code> , which will use the default local interface.

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

See also

[NoBlockConnect\(\)](#), [TcpGetSocketState\(\)](#), [writeavail\(\)](#), [connect\(\)](#), [connectvia\(\)](#), [connectwlocal\(\)](#)

14.50.2.20 NoBlockConnectVia() [2/2]

```
int NoBlockConnectVia (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    int ifnum ) [inline]
```

```
#include <tcp.h>
```

Create a file descriptor for a TCP connection and return immediately. This function does not wait for a connection to be established. Before using the file descriptor, the application must verify the connection was successful with [TcpGetSocketState\(fd\)](#). The state will be `TCP_STATE_ESTABLISHED` when the connection has been successfully established. Note: The connection status can also be obtained with the [writeavail\(\)](#) function.

This function is similar to [NoBlockConnect\(\)](#), with the additional capability of specifying the local interface number to use for connection.

Warning

To free system resources a [close\(\)](#) must be called, even if the current state is `TCP_STATE_CLOSING`. Otherwise a resource leak will occur.

Parameters

<i>ipAddress</i>	Remote IP address.
<i>remotePort</i>	Remote port number.
<i>ifnum</i>	Optional parameter to specify which local network interface to use for the connection by Interface Number. Will override any routing based on destination.

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

See also

[NoBlockConnect\(\)](#), [TcpGetSocketState\(\)](#), [writeavail\(\)](#), [connect\(\)](#), [connectvia\(\)](#), [connectwlocal\(\)](#)

14.50.2.21 NoBlockConnectwlocal()

```
int NoBlockConnectwlocal (
    const IPADDR & ipAddress,
    uint16_t localPort,
    uint16_t remotePort,
    IPADDR interfaceIpAddress = IPADDR::NullIP(),
    int ifn = -1 ) [inline]
```

```
#include <tcp.h>
```

Create a file descriptor for a TCP connection and return immediately. This function does not wait for a connection to be established. Before using the file descriptor, the application must verify the connection was successful with [TcpGetSocketState\(fd\)](#). The state will be `TCP_STATE_ESTABLISHED` when the connection has been successfully established. Note: The connection status can also be obtained with the [writeavail\(\)](#) function.

This function is similar to [NoBlockConnect\(\)](#), with the additional capability of specifying the local interface number or IP address to use for connection. If not specified, it will use the default local interface.

Warning

To free system resources a [close\(\)](#) must be called, even if the current state is `TCP_STATE_CLOSING`. Otherwise a resource leak will occur.

Although this function that allows a local port number parameter for extreme edge cases, local port numbers should be avoided. Local port numbers create connectivity failures when a remote host has a half open socket condition.

Parameters

<i>ipAddress</i>	IP address of the remote host.
<i>localPort</i>	Optional parameter to specify a Local port number. Recommend this always be set to a value of 0 so a random local port number is used. Warning! Specifying a local port number will create connectivity failures if the remote host has a half open socket condition.
<i>remotePort</i>	Remote port number.
<i>interfaceIpAddress</i>	Optional IP address of local interface to use for connection. If not used, such as when specifying the <i>ifn</i> parameter, set to <code>IPADDR::NullIP()</code> .
<i>ifn</i>	Optional parameter to specify which local network interface to use for the connection by Interface Number. Will override any routing based on destination or interface IP address.

Returns

A value greater than 0 on success, representing the socket file descriptor. A value less than 0 on error, [TCP Socket Status](#).

See also

[TcpGetSocketState\(\)](#), [NoBlockConnect\(\)](#), [NoBlockConnectVia\(\)](#)

14.50.2.22 SetOutOfOrderBuffers()

```
uint8_t SetOutOfOrderBuffers (
    int fd,
    uint8_t max ) [inline]
#include <tcp.h>
```

Set the maximum number of out-of-order TCP buffers for the specified TCP socket.

There are three types of buffers assigned to a TCP socket: receive, transmit and out of order. TCP packets may be received in sequence, or out of order. If out of order, they must be either stored for use later, or retransmitted by the sending host. The default value is 5 buffer of approximately 1500 bytes each. The maximum number is 43. A higher number of buffers can increase bulk data throughput, but will increase TCP latency if there is a problem with the connection, such as a reset.

Parameters

<i>fd</i>	Socket file descriptor
<i>max</i>	Maximum number of buffers

Returns

[TCP Socket Status](#)

See also

[setsockopt\(\)](#), [getsockopt\(\)](#), [clrsockopt\(\)](#), [SetSocketRxBuffers\(\)](#), [SetSocketTxBuffers\(\)](#)

14.50.2.23 SetSocketRxBuffers()

```
int SetSocketRxBuffers (
    int fd,
    int n )
```

```
#include <tcp.h>
```

Set the number of TCP receive buffers for the specified TCP socket.

Sets the number of TCP buffers that can be accumulated on the receive socket receive buffer. Each buffer is 1548 bytes. The amount of free space in the receive buffer sets the TCP window size, controlling how much data the other side of the TCP connection is allowed to send.

When data is read from a socket, it frees up space in a buffer, allowing the other side of the TCP connection to send more data. Since the maximum window size is 65536, raising this value beyond 43 buffers has no benefit. The system default value is defined in constants.h with a value of 5 to conserve network buffers. Unless you are transferring large amounts of bulk data into your NetBurner device, the default provides more than enough space.

Parameters

<i>fd</i>	Socket file descriptor
<i>n</i>	Number of buffers

Returns

[TCP Socket Status](#)

See also

[setsockopt\(\)](#), [getsockopt\(\)](#), [clrsockopt\(\)](#), [SetSocketUnackBuffers\(\)](#), [SetSocketTxBuffers\(\)](#)

14.50.2.24 SetSocketTxBuffers()

```
int SetSocketTxBuffers (
    int fd,
    int n )
```

```
#include <tcp.h>
```

Set the number of TCP transmit buffers for the specified TCP socket.

Sets the number of buffers that can be put in the transmit queue. Each buffer is 1548 bytes. The transmit queue accumulates data up to this limit regardless of the state of acknowledged buffers, or window size, from the other side of the TCP connection. This value sets the maximum size for a TCP write operation. Note: you must always check the return value of any write function to determine how many bytes were written.

Parameters

<i>fd</i>	Socket file descriptor
<i>n</i>	Number of buffers

Returns

[TCP Socket Status](#)

See also

[setsockopt\(\)](#), [getsockopt\(\)](#), [clrsockopt\(\)](#), [SetSocketRxBuffers\(\)](#), [SetSocketUnackBuffers\(\)](#), [write\(\)](#), [writeall\(\)](#)

14.50.2.25 SetSocketUnackBuffers()

```
int SetSocketUnackBuffers (
    int fd,
    uint8_t val ) [inline]
```

```
#include <tcp.h>
```

Set the maximum number of outbound TCP buffers in the transmit un-acknowledged list for the specified TCP socket.

Sets the number of outbound TCP buffers allowed as un-acknowledged on a TCP socket. When transmitting, data moves from the TCP transmit queue to the list of un-acknowledged TCP packets once it is sent. When the other side of the TCP connection acknowledges the packet, it is removed from the un-acknowledged list. TCP can only send as many un-acknowledged buffers as the other side's TCP window size will allow.

Increasing this value will increase bulk data throughput on a fast network. Increasing the value could decrease performance on a lossy network without selective acknowledgement. Note: most PC's have selective acknowledgement enabled, many NAT routers do not.

Parameters

<i>fd</i>	Socket file descriptor
<i>val</i>	Number of buffers

Returns

[TCP Socket Status](#)

See also

[setsockopt\(\)](#), [getsockopt\(\)](#), [clrsockopt\(\)](#), [SetSocketRxBuffers\(\)](#), [SetSocketTxBuffers\(\)](#)

14.50.2.26 setsockopt()

```
int setsockopt (
    int fd,
    int option )
```

```
#include <tcp.h>
```

Set TCP socket options.

Parameters

<i>fd</i>	Socket file descriptor.
<i>option</i>	Socket option to set: TCP Socket Options .

Returns

A bitmask of the options for the specified socket.

See also

[clrsockopt\(\)](#), [getsockopt\(\)](#), [SetSocketUnackBuffers\(\)](#), [SetSocketRxBuffers\(\)](#), [SetSocketTxBuffers\(\)](#)

14.50.2.27 SocketPeek()

```
char SocketPeek (
    int fd )
```

```
#include <tcp.h>
```

Returns the next char that would be read, 0 if no data.

Parameters

<i>fd</i>	Socket file descriptor
-----------	------------------------

Returns

The next char that would be read.

14.50.2.28 SockReadWithTimeout()

```
int SockReadWithTimeout (
    int fd,
    char * buf,
    int nbytes,
    uint32_t timeout )
```

```
#include <tcp.h>
```

Attempt to read from a TCP socket until the timeout expires.

The number of bytes parameter is the maximum to read. The function will return when at least 1 byte is available, so the return value must always be checked.

Note

Works with TCP sockets; does not work with TLS sockets.

Parameters

<i>fd</i>	Socket file descriptor
<i>buf</i>	Point to buffer to store received data
<i>nbytes</i>	Maximum number of bytes to read
<i>timeout</i>	Time out in ticks per second. Recommended use is the TICKS_PER_SECOND macro. For example: TICKS_PER_SECOND * 5 for a 5 second delay.

Returns

Number of bytes read, or error [TCP Socket Status](#)

See also

[ReadWithTimeout\(\)](#)

14.50.2.29 TcpAllDataAcked()

```
BOOL TcpAllDataAcked (
    int socket )
```

```
#include <tcp.h>
```

Check the data acknowledged state of a socket.

Parameters

<i>socket</i>	Socket file descriptor.
---------------	-------------------------

Returns

True if all the sent data has been acknowledged by the other side of TCP connection.

See also

[WaitForSocketFlush](#)

14.50.2.30 TcpGetLastRxInterval()

```
uint32_t TcpGetLastRxInterval (
    int fd )
#include <tcp.h>
```

Returns the number of system Time Ticks since the last packet was received. This is the difference between the current system time and lastRxTime of the socket.

Parameters

<i>fd</i>	The socket file descriptor.
-----------	-----------------------------

Returns

The number of system Time Ticks since the last packet was received on the connection.

See also

[TcpGetLastRxTime\(\)](#)

14.50.2.31 TcpGetLastRxTime()

```
uint32_t TcpGetLastRxTime (
    int fd )
#include <tcp.h>
```

Returns the value of system Time Ticks when the last packet was received. Used for the TCP Keep Alive feature. Each TCP connection has a corresponding Socket_struct. One of the elements of this struct is a variable called lastRxTime, which stores the current system time tick every time a packet is received. This function enables you to find out when the last packet was received by returning LastRxTime.

This function is used in conjunction with [TcpSendKeepAlive\(\)](#) to implement the TCP keepalive feature.

- If lastRxTime is the same before and after a keepalive packet is sent, the client has not responded to the keepalive packet and it can be assumed that connection is lost.
- Make sure to allow enough time for the client to respond to the keep alive packet before checking the time.
- Do not call [TcpGetLastRxTime\(\)](#) more often than once every second.

Parameters

<i>fd</i>	The socket file descriptor.
-----------	-----------------------------

Returns

The value of system Time Ticks when the last packet was received on the connection.

See also

[TcpSendKeepAlive\(\)](#)

14.50.2.32 TcpGetRxBufferSpaceUsed()

```
uint16_t TcpGetRxBufferSpaceUsed (
    int fd )
```

```
#include <tcp.h>
```

Returns the number of bytes used in a socket's RX buffer.

Parameters

<i>fd</i>	Socket file descriptor.
-----------	-------------------------

Returns

The number of bytes used

See also

[TcpGetTxBufferAvailSpace](#)

[TcpGetTxDataWaiting](#)

14.50.2.33 TcpGetSocketInterface()

```
int TcpGetSocketInterface (  
    int fd )
```

```
#include <tcp.h>
```

Return the network interface associated with a TCP socket.

Parameters

<i>fd</i>	Socket file descriptor
-----------	------------------------

Returns

The network interface number (undefined for listening sockets)

14.50.2.34 TcpGetSocketState()

```
uint8_t TcpGetSocketState (  
    int fd )
```

```
#include <tcp.h>
```

Return the current state of a TCP socket.

Parameters

<i>fd</i>	Socket file descriptor.
-----------	-------------------------

Returns

The current state of the socket: [TCP Socket State](#)

14.50.2.35 TcpGetTxBufferAvailSpace()

```
uint16_t TcpGetTxBufferAvailSpace (  
    int fd )
```

```
#include <tcp.h>
```

Returns the number of bytes available in a socket's TX buffer.

Parameters

<i>fd</i>	Socket file descriptor.
-----------	-------------------------

Returns

The number of bytes available

See also

[TcpGetRxBufferSpaceUsed](#)

14.50.2.36 TcpGetTxDataWaiting()

```
uint16_t TcpGetTxDataWaiting (
    int fd )
```

```
#include <tcp.h>
```

Returns the number of bytes waiting to be sent in a socket's TX Buffer.

Parameters

<i>fd</i>	Socket file descriptor.
-----------	-------------------------

Returns

The number of bytes used

See also

[TcpGetTxBufferAvailSpace](#)

[TcpGetRxBufferSpaceUsed](#)

14.50.2.37 TcpSendKeepAlive()

```
void TcpSendKeepAlive (
    int fd )
```

```
#include <tcp.h>
```

Send a TCP keep alive packet to a remote host.

Sends an empty packet with a decremented sequence number to a remote host. The sequence number will be one less than the last time a packet was sent. The remote host will respond with a TCP acknowledgment (ACK). This function is used in conjunction with [TcpGetLastRxTime\(\)](#) to implement the TCP keepalive feature.

Parameters

<i>fd</i>	The socket file descriptor
-----------	----------------------------

See also

[TcpGetLastRxTime\(\)](#)

14.50.2.38 WaitForSocketFlush()

```
BOOL WaitForSocketFlush (
    int fd,
    uint32_t ticks )
```

```
#include <tcp.h>
```

Wait for a socket flush operation to complete. A socket is flushed if all sent data has been acknowledged.

Parameters

<i>fd</i>	Socket file descriptor.
-----------	-------------------------

Parameters

<i>ticks</i>	The maximum number of system time ticks to wait.
--------------	--

Return values

<i>true</i>	All the sent data has been acknowledged by the other side of TCP connection.
<i>false</i>	A timeout occurred.

[TcpAllDataAcked](#)

14.50.3 TCP Notify**Typedefs**

- typedef void [tcp_notify_handler](#)(int tcpFd)
TCP notification callback type.

Functions

- void [RegisterTCPReadNotify](#) (int tcpFd, [tcp_notify_handler](#) *notifyHandler)
Register a TCP socket and callback function for read notifications.
- void [RegisterTCPWriteNotify](#) (int tcpFd, [tcp_notify_handler](#) *notifyHandler)
Register a TCP socket and callback function for write notifications.

14.50.3.1 Detailed Description

```
#include <tcp.h>
```

Advanced function for notification of read or write activity on a TCP socket. Callback functions can operate on a TCP socket as they would normally. This functionality provides a method of notification when read or write activities occur:

- A read notification calls the callback function when data is received.
- A write notification calls the callback function when the TCP write buffer can accept more data.

14.50.3.2 Typedef Documentation**14.50.3.2.1 tcp_notify_handler**

```
typedef void tcp_notify_handler(int tcpFd)
#include <tcp.h>
```

TCP notification callback type.

An application creates a callback function of this type to process TCP read and/or write notifications.

Parameters

<i>tcpFd</i>	TCP socket file descriptor of the socket that generated the notification
--------------	--

See also

[RegisterTCPReadNotify\(\)](#), [RegisterTCPWriteNotify\(\)](#)

14.50.3.3 Function Documentation

14.50.3.3.1 RegisterTCPReadNotify()

```
void RegisterTCPReadNotify (
    int tcpFd,
    tcp_notify_handler * notifyHandler )
#include <tcp.h>
```

Register a TCP socket and callback function for read notifications.

The callback function will be called whenever data is read from the TCP socket

Parameters

<i>tcpFd</i>	Existing TCP socket file descriptor to monitor
<i>notifyHandler</i>	Pointer to callback function to process the notification

See also

[RegisterTCPWriteNotify\(\)](#)

14.50.3.3.2 RegisterTCPWriteNotify()

```
void RegisterTCPWriteNotify (
    int tcpFd,
    tcp_notify_handler * notifyHandler )
#include <tcp.h>
```

Register a TCP socket and callback function for write notifications.

The callback function will be called whenever data can be written to the TCP socket buffer

Parameters

<i>tcpFd</i>	Existing TCP socket file descriptor to monitor
<i>notifyHandler</i>	Pointer to callback function to process the notification

See also

[RegisterTCPReadNotify\(\)](#)

14.50.4 TCP Socket Options

Macros

- #define **SO_DEBUG** 1
Reserved.
- #define **SO_NONAGLE** 2
Disable the Nagle algorithm.
- #define **SO_NOPUSH** 4
Disable TCP PUSH feature.

14.50.4.1 Detailed Description

```
#include < tcp.h >
```

Socket options for use with `setsockoptoptions()`.

14.50.5 TCP Socket State

Macros

- `#define TCP_STATE_CLOSED (0)`
Socket Closed.
- `#define TCP_STATE_LISTEN (1)`
Listen Socket.
- `#define TCP_STATE_SYN_SENT (2)`
Packet with synchronization flag sent.
- `#define TCP_STATE_SYN_RCVD (3)`
Packet with synchronisation flag received.
- `#define TCP_STATE_WAIT_FOR_ACCEPT (4)`
Socket waiting for accept.
- `#define TCP_STATE_ESTABLISHED (5)`
TCP session established.
- `#define TCP_STATE_CLOSE_WAIT (6)`
FIN received from client and socket is in the process of closing.
- `#define TCP_STATE_LAST_ACK (7)`
Server is in the process of sending its own FIN signal.
- `#define TCP_STATE_FIN_WAIT_1 (8)`
Connection is active but not currently being used.
- `#define TCP_STATE_FIN_WAIT_2 (9)`
Client has received first ACK of the first FIN signal from server.
- `#define TCP_STATE_CLOSING (10)`
Session is closing, but data may still be processed.
- `#define TCP_STATE_TIME_WAIT (11)`
Client recognizes connection still open, but not currently being used.

14.50.5.1 Detailed Description

`#include <tcp.h >`

The current state of a TCP socket.

14.50.6 TCP Socket Status

Macros

- `#define TCP_ERR_NORMAL (0)`
No errors.
- `#define TCP_ERR_TIMEOUT (-1)`
Socket timed out.
- `#define TCP_ERR_NOCON (-2)`
No connection exists.
- `#define TCP_ERR_CLOSING (-3)`
Socket is in the process of closing.
- `#define TCP_ERR_NOSUCH_SOCKET (-4)`
No such socket exists.
- `#define TCP_ERR_NONE_AVAIL (-5)`
No new sockets are available.
- `#define TCP_ERR_CON_RESET (-6)`
Connection has been reset.
- `#define TCP_ERR_CON_ABORT (-7)`
Connection has been aborted.

14.50.6.1 Detailed Description

```
#include <tcp.h >
```

The current status of a TCP socket. When calling API functions that return a file descriptor, such as [listen\(\)](#), [accept\(\)](#), [connect\(\)](#), etc., a negative value represents an error, while a value greater than 0 represents the file descriptor number.

14.51 TFTP

Topics

- [TFTP Return Codes](#)

Functions

- int [GetTFTP](#) (PCSTR fileName, PCSTR mode, uint8_t buffer, int &len, uint32_t timeout, [IPADDR4](#) server, uint16_t port=IANA_TFTP_PORT)
Get a file from a TFTP server.
- int [SendTFTP](#) (PCSTR fileName, PCSTR mode, uint8_t buffer, int len, uint32_t timeout, uint32_t packet←Timeout, [IPADDR4](#) server, uint16_t port=IANA_TFTP_PORT)
Send a file to a TFTP server.

14.51.1 Detailed Description

```
#include < tftp.h >
```

The NetBurner TFTP Group

14.51.2 Function Documentation

14.51.2.1 GetTFTP()

```
int GetTFTP (
    PCSTR fileName,
    PCSTR mode,
    uint8_t buffer,
    int & len,
    uint32_t timeout,
    IPADDR4 server,
    uint16_t port = IANA_TFTP_PORT )
```

```
#include <tftp.h>
```

Get a file from a TFTP server.

Parameters

<i>fileName</i>	Name of file to retrieve
<i>mode</i>	Transfer mode. 'b' = binary, 't' = text
<i>buffer</i>	Data destination buffer
<i>len</i>	Maximum length when function is called, bytes read upon function return.
<i>timeout</i>	Total amount of time for file transfer, in system TimeTicks
<i>server</i>	IPv4 address of TFTP server
<i>port</i>	Optional TFTP server port number. If not specified the default TFTP port number 69 will be used.

Returns

[TFTP Return Codes](#)

See also

[SendTFTP](#)

14.51.2.2 SendTFTP()

```
int SendTFTP (
    PCSTR fileName,
    PCSTR mode,
    puInt8_t buffer,
    int len,
    uint32_t timeout,
    uint32_t packetTimeout,
    IPADDR4 server,
    uint16_t port = IANA_TFTP_PORT )
```

```
#include <tftp.h>
```

Send a file to a TFTP server.

Parameters

<i>fileName</i>	Name of file to retrieve
<i>mode</i>	Transfer mode. 'b' = binary, 't' = text
<i>buffer</i>	Data destination buffer
<i>len</i>	Length of file to transfer, in bytes
<i>timeout</i>	Total amount of time for file transfer, in system TimeTicks
<i>packetTimeout</i>	Timeout for any single UDP packet to successfully transfer and be acknowledged, in system Time Ticks
<i>server</i>	IPv4 address of TFTP server
<i>port</i>	Optional TFTP server port number. If not specified the default TFTP port number 69 will be used.

Returns

[TFTP Return Codes](#)

See also

[SendTFTP](#)

14.51.3 TFTP Return Codes**Macros**

- #define **TFTP_OK** (0)
Success.
- #define **TFTP_TIMEOUT** (1)
TFTP Timeout.
- #define **TFTP_ERROR** (2)
TFTP Error.

14.51.3.1 Detailed Description

```
#include< tftp.h >
```

14.52 Time

Functions

- `time_t set_time` (`time_t time_to_set`, `uint32_t fraction=0`)
Set the system time to the value passed in the `time_t` parameter.
- `time_t timegm` (`struct tm *bts`)
Returns the value of type `time_t` that represents the GMT time described by the `tm` structure pointed by `bts`.
- `void tzsetchar` (`const char *tzenv`)
Set the system local time.

14.52.1 Detailed Description

#include < [nbttime.h](#) >

The NBTTime library provides methods to set and read the system time. The system time will reset whenever power is lost or the system is reset. On power-up, system time can be set:

- With a NTP server (most common)
- From a real time clock (RTC)
- Manually

Examples are provided in the example section for each of these methods.

Time is always stored as GMT. If you are using an internal or external real-time clock, it should also be set to GMT. Example application function calls are shown below. Refer to the examples for your specific NetBurner platform for RTC functions. Functions with an "_r" are reentrant.

List of common standard Time library functions include:

- `time_t time()` Returns current system GMT time.
- `gmtime_r(time_t &timeT, tm &stmUTC)` Converts given time since epoch (a `time_t` value pointed to by `timeT`) to calendar time, expressed in Coordinated Universal Time (UTC) in the `struct tm` format. The result is stored in the `struct tm` pointed to by `stmUTC`.
- `localtime_r(time_t &tv, tm &tm_struct)` Converts given time since epoch (`time_t`) to calendar time, expressed in local time, in the `struct tm` format. The result is stored in the `tm` struct.
- `strftime()` Creates a formatted time string and stores it in a buffer.
- `double difftime(time_t t1, time_t t2)` Returns the difference between two `time_t` values.

14.52.2 Function Documentation

14.52.2.1 set_time()

```
time_t set_time (
    time_t time_to_set,
    uint32_t fraction = 0 )
```

#include < [nbttime.h](#) >

Set the system time to the value passed in the `time_t` parameter.

Parameters

<i>time_to_set</i>	time_t value to set the system time.
<i>fraction</i>	the fraction (in 1/(2^32) of the second)

Returns

The system time `time_t` value

14.52.2.2 timegm()

```
time_t timegm (
    struct tm * bts )
#include <nbttime.h>
```

Returns the value of type `time_t` that represents the GMT time described by the `tm` structure pointed by `bts`. Performs the reverse conversion `gmtime()`. This is not to be confused with the `mktime()` function, which performs the reverse conversion of the `localtime()` function.

Parameters

<code>bts</code>	Pointer to a <code>tm</code> structure
------------------	--

Returns

`time_t` value of `tm`

14.52.2.3 tzsetchar()

```
void tzsetchar (
    const char * tzenv )
#include <nbttime.h>
```

Set the system local time.

This function initializes the TZ environment variable to contain the local time zone offset information from the standard time (UTC) and, if applicable, daylight saving time (DST). This does not overwrite the system time to the local time. The TZ environment variable is used by the `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions of the standard `time.h` library to calculate the local time.

Once the TZ variable is set, the time library functions use it to determine when DST is in effect, when type conversions are made, or what time zone string is provided in the case of the `strftime()` function.

The system provides time zones around the world that can be referenced in the TZRecords variable in [timezones.h](#). The time zone strings are located in `timezones.cpp`. Please refer to the `timezones` and `RTC` example programs for methods on utilizing these time zone settings.

Parameters

<code>tzenv</code>	The time zone string. For example: <code>tzsetchar("EST5EDT4,M3.2.0/02:00:00,M11.1.0/02:00:00");</code> Eastern
--------------------	---

14.53 Timers

Topics

- [High Resolution Delay Timer](#)
- [Interval Timer](#)
- [Stopwatch Timer](#)

14.53.1 Detailed Description

Hardware based high resolution timers:

- [StopWatch](#) to time events
- Interval Timer for periodic semaphore posts or interrupts

- HiResDelay ([DelayObject](#)) providing microsecond delay functions

14.53.2 High Resolution Delay Timer

Classes

- class [DelayObject](#)
Microsecond Delay Class.

14.53.2.1 Detailed Description

```
#include< HiResDelay.h >
```

The [OSTimeDly\(\)](#) system function has a 20ms tick count, but if you need more precision timing The High Resolution Delay timer provides delays in microseconds.

When a [DelayObject](#) is created, it allocates an available hardware system timer. Once the delay time has expired, and when the object goes out of scope, the hardware timer is freed.

Example Usage:

```
static DelayObject myHiResDelay;    // Create the object
myHiResDelay.DelayUsec(100);        // Delay 100 us
myHiResDelay.DelayUsec(200);        // Delay 200 us
myHiResDelay.DelayUsec(300);        // Delay 300 us
```

See also

- [Interval Timer](#)
- [Stopwatch Timer](#)
- [OSTimeDly\(\)](#)

14.53.3 Interval Timer

Functions

- int [IntervalOSSem](#) ([OS_SEM](#) *p_toSem, int num_per_sec, int timer=[FIRST_UNUSED_TIMER](#))
Posts to a semaphore at the requested interval.
- int [IntervalOSFlag](#) ([OS_FLAGS](#) *p_toFlag, uint32_t flag_value, int num_per_sec, int timer=[FIRST_UNUSED_TIMER](#))
Sets a flag at requested interval.
- int [IntervalInterruptCallback](#) (void(*p_toCallbackFunc)(), int num_per_sec, int timer=[FIRST_UNUSED_TIMER](#))
Calls a function at requested interval. Note that the callback function is called from within the timer's interrupt handler so you should treat your callback function as an interrupt.
- void [IntervalStop](#) (int timer_number)
Stops an existing Interval Timer and frees the resource.

14.53.3.1 Detailed Description

```
#include< IntervalTimer.h >
```

The Interval Timer is used to create a periodic interrupt (IRQ) that can trigger the following:

- Call an Interrupt Service Routine (ISR). An example of this is located in `\nburn\examples`
- Post an OS semaphore
- Post an OS flag

Example: Create an interval timer that posts 20 times per second

```
OS\_SEM timerSem;
timerSem.Init();

int timerNumber = IntervalOSSem(&timerSem, 20);
if(timerNumber < 0)
```

```
{
    iprintf("Error %d\r\n", timerNumber);
    break;
}
```

When you have no further use for the interval timer, call [IntervalStop\(\)](#) so that the hardware timer is released.

See also

[High Resolution Delay Timer](#)

[Stopwatch Timer](#)

[OSTimeDly\(\)](#)

14.53.3.2 Function Documentation

14.53.3.2.1 IntervalInterruptCallback()

```
int IntervalInterruptCallback (
    void(*)() p_toCallbackFunc,
    int num_per_sec,
    int timer = FIRST_UNUSED_TIMER )
```

```
#include <IntervalTimer.h>
```

Calls a function at requested interval. Note that the callback function is called from within the timer's interrupt handler so you should treat your callback function as an interrupt.

Parameters

<i>p_toCallbackFunc</i>	Pointer to the callback function
<i>num_per_sec</i>	Number of posts per second, minimum is 20 posts per second.
<i>timer</i>	Optional parameter, timer number of -1 for first unused timer

Returns

The timer number, -1 if no timer is available, or -2 if *num_per_sec* is invalid.

14.53.3.2.2 IntervalOSFlag()

```
int IntervalOSFlag (
    OS_FLAGS * p_toFlag,
    uint32_t flag_value,
    int num_per_sec,
    int timer = FIRST_UNUSED_TIMER )
```

```
#include <IntervalTimer.h>
```

Sets a flag at requested interval.

Parameters

<i>p_toFlag</i>	Pointer to the semaphore
<i>flag_value</i>	OS Flag value to set
<i>num_per_sec</i>	Number of posts per second, minimum is 20 posts per second.
<i>timer</i>	Optional parameter, timer number of -1 for first unused timer

Returns

The timer number, -1 if no timer is available, or -2 if *num_per_sec* is invalid.

14.53.3.2.3 IntervalOSSem()

```
int IntervalOSSem (
```

```

        OS_SEM * p_toSem,
        int num_per_sec,
        int timer = FIRST_UNUSED_TIMER )
#include <IntervalTimer.h>
Posts to a semaphore at the requested interval.

```

Parameters

<i>p_toSem</i>	Pointer to the semaphore
<i>num_per_sec</i>	Number of posts per second, minimum is 20 posts per second
<i>timer</i>	Optional parameter, timer number of -1 for first unused timer

Returns

The timer number, -1 if no timer is available, or -2 if num_per_sec is invalid.

14.53.3.2.4 IntervalStop()

```

void IntervalStop (
        int timer_number )
#include <IntervalTimer.h>
Stops an existing Interval Timer and frees the resource.

```

Parameters

<i>timer_number</i>	Number of the timer to stop.
---------------------	------------------------------

14.53.4 Stopwatch Timer

Classes

- class [StopWatch](#)
Stopwatch for timing events.

14.53.4.1 Detailed Description

```
#include< stopwatch.h >
```

The [StopWatch](#) class can be used to create a [StopWatch](#) object that can time events. Please refer to the Stopwatch example in `\nburn\examples`

Example

```

StopWatch myStopwatch;

myStopwatch.Start();
for ( volatile int i = 0; i < numLoop; i++ )
{
    count++;
}
myStopwatch.Stop();

```

14.54 UDP Packet Object

The NetBurner UDP protocol API is implemented in two ways:

Topics

- [UDP Error Codes](#)

Classes

- class [UDPPacket](#)
UDP Packet Class.

Functions

- bool [RegisterUDPFifo](#) (uint16_t listenPort, [OS_FIFO](#) *pFifo)
Register a FIFO to receive incoming UDP packets.
- bool [RegisterUDPFifoVia](#) (uint16_t listenPort, [OS_FIFO](#) *pFifo, int interface)
Register a FIFO to receive incoming UDP packets on the specified network interface.
- uint16_t [RegisterEphemeralFifo](#) ([OS_FIFO](#) *pfifo, int ifn=-1)
Register a UDP FIFO with a random port number to receive incoming UDP packets.
- bool [RegisterUDPFifoWithNotify](#) (uint16_t listenPort, [OS_FIFO](#) *pFifo, udp_data_notify *pNotifyFunction)
Register a FIFO to receive incoming UDP packets and a callback function to receive a notification when a packet is received.
- bool [RegisterUDPFifoWithNotifyVia](#) (uint16_t listenPort, [OS_FIFO](#) *pFifo, udp_data_notify *pNotifyFunction, int interface)
Register a FIFO to receive incoming UDP packets and a callback function to receive a notification when a packet is received. Same as [RegisterUDPFifoWithNotify\(\)](#) with the additional parameter to specify the local network interface.
- void [UnregisterUDPFifo](#) (uint16_t listenPort, bool drain=false)
Unregister a UDP FIFO.

14.54.1 Detailed Description

The NetBurner UDP protocol API is implemented in two ways:

1. As a C++ class, which makes memory management easier [UDPPacket](#).
2. Wrapper functions that implement a standard UDP sockets interface. For example, [sendto\(\)](#) and [recvfrom\(\)](#).

```
#include< udp.h >
```

14.54.2 Function Documentation

14.54.2.1 RegisterEphemeralFifo()

```
uint16_t RegisterEphemeralFifo (
    OS_FIFO * pfifo,
    int ifn = -1 )
#include <udp.h>
```

Register a UDP FIFO with a random port number to receive incoming UDP packets.

A [OS_FIFO](#) is used to receive incoming UDP Packets. This function registers an [OS_FIFO](#) to listen on a random unused UDP port number, which can be useful when sending a UDP packet to a remote host that will respond to the received packet source port number.

Parameters

<i>pfifo</i>	Pointer to the OS_FIFO to register
<i>ifn</i>	Optional local interface number to listen on

Returns

The registered port number of success, 0 on failure.

See also

[RegisterUDPFifoWithNotify\(\)](#), [UnregisterUDPFifo\(\)](#)

14.54.2.2 RegisterUDPFifo()

```
bool RegisterUDPFifo (
    uint16_t listenPort,
    OS_FIFO * pFifo )
```

```
#include <udp.h>
```

Register a FIFO to receive incoming UDP packets.

A [OS_FIFO](#) is used to receive incoming UDP Packets. This function registers an [OS_FIFO](#) to listen to a specific UDP port number.

Parameters

<i>listenPort</i>	Port to listen on for incoming packets
<i>pFifo</i>	Pointer to the OS_FIFO to register

Returns

true if successful

See also

[RegisterUDPFifoWithNotify\(\)](#), [UnregisterUDPFifo\(\)](#), [RegisterEphemeralFifo\(\)](#)

14.54.2.3 RegisterUDPFifoVia()

```
bool RegisterUDPFifoVia (
    uint16_t listenPort,
    OS_FIFO * pFifo,
    int interface )
```

```
#include <udp.h>
```

Register a FIFO to receive incoming UDP packets on the specified network interface.

A [OS_FIFO](#) is used to receive incoming UDP Packets. This function registers an [OS_FIFO](#) to listen to a specific UDP port number and local network interface.

Parameters

<i>listenPort</i>	Port to listen on for incoming packets
<i>pFifo</i>	Pointer to the OS_FIFO to register
<i>interface</i>	Local network interface number

Returns

true if successful

See also

[RegisterUDPFifo\(\)](#), [RegisterUDPFifoWithNotify\(\)](#), [UnregisterUDPFifo\(\)](#), [RegisterEphemeralFifo\(\)](#)

14.54.2.4 RegisterUDPFifoWithNotify()

```
bool RegisterUDPFifoWithNotify (
    uint16_t listenPort,
    OS_FIFO * pFifo,
    udp_data_notify * pNotifyFunction )
```

```
#include <udp.h>
```

Register a FIFO to receive incoming UDP packets and a callback function to receive a notification when a packet is received.

A [OS_FIFO](#) is used to receive incoming UDP Packets. This function registers an [OS_FIFO](#) to listen to a specific UDP port number and a notification callback function.

Parameters

<i>listenPort</i>	Port to listen on for incoming packets
<i>pFifo</i>	Pointer to the OS_FIFO to register
<i>pNotifyFunction</i>	Pointer to callback function to receive notification

Returns

true if successful

See also

[RegisterUDPFifo\(\)](#), [UnregisterUDPFifo\(\)](#)

14.54.2.5 RegisterUDPFifoWithNotifyVia()

```
bool RegisterUDPFifoWithNotifyVia (
    uint16_t listenPort,
    OS_FIFO * pFifo,
    udp_data_notify * pNotifyFunction,
    int interface )
```

```
#include <udp.h>
```

Register a FIFO to receive incoming UDP packets and a callback function to receive a notification when a packet is received. Same as [RegisterUDPFifoWithNotify\(\)](#) with the additional parameter to specify the local network interface.

A [OS_FIFO](#) is used to receive incoming UDP Packets. This function registers an [OS_FIFO](#) to listen to a specific UDP port number and a notification callback function.

Parameters

<i>listenPort</i>	Port to listen on for incoming packets
<i>pFifo</i>	Pointer to the OS_FIFO to register
<i>pNotifyFunction</i>	Pointer to callback function to receive notification
<i>interface</i>	Local network interface number

Returns

true if successful

See also

[RegisterUDPFifo\(\)](#), [UnregisterUDPFifo\(\)](#)

14.54.2.6 UnregisterUDPFifo()

```
void UnregisterUDPFifo (
```

```

        uint16_t listenPort,
        bool drain = false )
#include <udp.h>
Unregister a UDP FIFO.

```

Parameters

<i>listenPort</i>	Port to listen on for incoming packets.
<i>drain</i>	Optional, default if false. If set to true, will free all queued pool pointers.

See also

[RegisterUDPFifo\(\)](#), [RegisterUDPFifoWithNotify\(\)](#)

14.54.3 UDP Error Codes

Macros

- #define **UDP_ERR_NOSUCH_SOCKET** (-1)
Socket does not exist.
- #define **UDP_ERR_NOTOPEN_TO_WRITE** (-2)
Socket not open for write.
- #define **UDP_ERR_NOTOPEN_TO_READ** (-3)
Socket not open for read.

14.54.3.1 Detailed Description

```
#include< udp.h >
```

14.55 UDP Socket

The NetBurner UDP protocol Socket API.

Functions

- int [CreateRxUdpSocket](#) (uint16_t listening_port)
Open a UDP socket for receiving incoming UDP packets.
- int [CreateTxUdpSocket](#) (const [IPADDR](#) &send_to_addr, uint16_t remote_port, uint16_t local_port)
Open a UDP socket for transmitting UDP packets.
- int [CreateRxTxUdpSocket](#) (const [IPADDR](#) &send_to_addr, uint16_t send_to_remote_port, uint16_t local_↔ port)
Open a UDP socket that can transmit and receive UDP packets.
- int [sendto](#) (int sock, uint8_t what_to_send, int len_to_send, const [IPADDR](#) &to_addr, uint16_t remote_port)
Send a UDP packet.
- int [sendtovia](#) (int sock, uint8_t what_to_send, int len_to_send, const [IPADDR](#) &to_addr, uint16_t remote_↔ port, int intfnum)
Send a UDP packet on the specified interface.
- int [recvfrom](#) (int sock, uint8_t buffer, int len, [IPADDR](#) *pAddr, uint16_t *pLocal_port, uint16_t *pRemote_↔ port)
Receive a UDP packet.
- int [SendFragmentedUdpPacket](#) (const [IPADDR](#) &to, uint16_t source_port, uint16_t dest_port, uint8_t data, int length)
Send a large fragmented UDP packet.

- int [CreateRxUdpSocketVia](#) (uint16_t listening_port, int interfacenum)
Open a UDP socket for receiving incoming UDP packets on the specified network interface, by interface number.
- int [CreateRxUdpSocketVia](#) (uint16_t listening_port, const IPADDR interfacelp)
Open a UDP socket for receiving incoming UDP packets on the network interface with the specified IP address. If more than one interface has the same IP address, the lower interface number is used.
- int [CreateRxTxUdpSocketVia](#) (const IPADDR send_to_addr, uint16_t send_to_remote_port, uint16_t local_port, int interfacenum)
Open a UDP socket that can transmit and receive UDP packets on the local network interface specified by an interface number.
- int [CreateRxTxUdpSocketVia](#) (const IPADDR send_to_addr, uint16_t send_to_remote_port, uint16_t local_port, IPADDR interfacelp)
Open a UDP socket that can transmit and receive UDP packets on the local network interface specified by an IP address.
- int [CreateTxUdpSocketVia](#) (const IPADDR send_to_addr, uint16_t remote_port, uint16_t local_port, int interfacenum)
Open a UDP socket for transmitting UDP packets on the local network interface specified by the interface number.
- int [CreateTxUdpSocketVia](#) (const IPADDR send_to_addr, uint16_t remote_port, uint16_t local_port, IPADDR interfacelp)
Open a UDP socket for transmitting UDP packets on the local network interface specified by the interface IP address.

14.55.1 Detailed Description

The NetBurner UDP protocol Socket API.

```
#include <udp.h >
```

1. As a C++ class, which makes memory management easier [UDPPacket](#).
2. Wrapper functions that implement a standard UDP sockets interface. For example, [sendto\(\)](#) and [recvfrom\(\)](#).

14.55.2 Function Documentation

14.55.2.1 CreateRxTxUdpSocket()

```
int CreateRxTxUdpSocket (
    const IPADDR & send_to_addr,
    uint16_t send_to_remote_port,
    uint16_t local_port ) [inline]
```

```
#include <udp.h>
```

Open a UDP socket that can transmit and receive UDP packets.

Parameters

<i>send_to_addr</i>	Destination IP address
<i>send_to_remote_port</i>	Destination port number
<i>local_port</i>	Local port number. A value of 0 will select a random port number (recommended)

Returns

The file descriptor for the UDP socket

See also

[CreateRxUdpSocket\(\)](#), [CreateTxUdpSocket\(\)](#)

14.55.2.2 CreateRxTxUdpSocketVia() [1/2]

```
int CreateRxTxUdpSocketVia (
    const IPADDR send_to_addr,
    uint16_t send_to_remote_port,
    uint16_t local_port,
    int interfacenum ) [inline]
```

```
#include <udp.h>
```

Open a UDP socket that can transmit and receive UDP packets on the local network interface specified by an interface number.

Parameters

<i>send_to_addr</i>	Destination IP address
<i>send_to_remote_port</i>	Destination port number
<i>local_port</i>	Local port number. A value of 0 will select a random port number (recommended)
<i>interfacenum</i>	Local network interface number

Returns

The file descriptor for the UDP socket

See also

[CreateRxUdpSocketVia\(\)](#), [CreateTxUdpSocketVia\(\)](#)

14.55.2.3 CreateRxTxUdpSocketVia() [2/2]

```
int CreateRxTxUdpSocketVia (
    const IPADDR send_to_addr,
    uint16_t send_to_remote_port,
    uint16_t local_port,
    IPADDR interfaceIp ) [inline]
```

```
#include <udp.h>
```

Open a UDP socket that can transmit and receive UDP packets on the local network interface specified by an IP address.

Parameters

<i>send_to_addr</i>	Destination IP address
<i>send_to_remote_port</i>	Destination port number
<i>local_port</i>	Local port number. A value of 0 will select a random port number (recommended)
<i>interfaceIp</i>	IP address of local network interface to use

Returns

The file descriptor for the UDP socket

See also

[CreateRxUdpSocketVia\(\)](#), [CreateTxUdpSocketVia\(\)](#)

14.55.2.4 CreateRxUdpSocket()

```
int CreateRxUdpSocket (
    uint16_t listening_port )
#include <udp.h>
```

Open a UDP socket for receiving incoming UDP packets.

Returns a file descriptor that can be used by read functions such as: [read\(\)](#) and [select\(\)](#) to process multiple file descriptors at one time.

Parameters

<i>listening_port</i>	Port to listen on for incoming packets
-----------------------	--

Returns

The file descriptor for the UDP socket

See also

[CreateTxUdpSocket\(\)](#), [CreateRxTxUdpSocket\(\)](#)

14.55.2.5 CreateRxUdpSocketVia() [1/2]

```
int CreateRxUdpSocketVia (
    uint16_t listening_port,
    const IPADDR interfaceIp )
```

```
#include <udp.h>
```

Open a UDP socket for receiving incoming UDP packets on the network interface with the specified IP address. If more than one interface has the same IP address, the lower interface number is used.

Returns a file descriptor that can be used by read functions such as [read\(\)](#) and [select\(\)](#).

Parameters

<i>listening_port</i>	Port to listen on for incoming packets
<i>interfaceIp</i>	IP address of the network interface

Returns

The file descriptor for the UDP socket

See also

[CreateRxUdpSocketVia\(\)](#), [CreateTxUdpSocketVia\(\)](#)

14.55.2.6 CreateRxUdpSocketVia() [2/2]

```
int CreateRxUdpSocketVia (
    uint16_t listening_port,
    int interfacenum )
```

```
#include <udp.h>
```

Open a UDP socket for receiving incoming UDP packets on the specified network interface, by interface number.

Returns a file descriptor that can be used by read functions such as [read\(\)](#) and [select\(\)](#).

Parameters

<i>listening_port</i>	Port to listen on for incoming packets
<i>interfacenum</i>	Network interface number

Returns

The file descriptor for the UDP socket

See also

[CreateTxUdpSocketVia\(\)](#), [CreateRxTxUdpSocketVia\(\)](#)

14.55.2.7 CreateTxUdpSocket()

```
int CreateTxUdpSocket (
    const IPADDR & send_to_addr,
    uint16_t remote_port,
    uint16_t local_port ) [inline]
```

```
#include <udp.h>
```

Open a UDP socket for transmitting UDP packets.

Returns a file descriptor that can be used by transmit functions such as [sendto\(\)](#).

Parameters

<i>send_to_addr</i>	Destination IP address
<i>remote_port</i>	Destination port number
<i>local_port</i>	Local port number. A value of 0 will select a random port number (recommended)

Returns

The file descriptor for the UDP socket

See also

[CreateRxUdpSocket\(\)](#), [CreateRxTxUdpSocket\(\)](#)

14.55.2.8 CreateTxUdpSocketVia() [1/2]

```
int CreateTxUdpSocketVia (
    const IPADDR send_to_addr,
    uint16_t remote_port,
    uint16_t local_port,
    int interfacenum ) [inline]
```

```
#include <udp.h>
```

Open a UDP socket for transmitting UDP packets on the local network interface specified by the interface number.

Returns a file descriptor that can be used by transmit functions such as [sendto\(\)](#).

Parameters

<i>send_to_addr</i>	Destination IP address
<i>remote_port</i>	Destination port number
<i>local_port</i>	Local port number. A value of 0 will select a random port number (recommended)
<i>interfacenum</i>	Local network interface number

Returns

The file descriptor for the UDP socket

See also

[CreateRxUdpSocketVia\(\)](#), [CreateRxTxUdpSocketVia\(\)](#)

14.55.2.9 CreateTxUdpSocketVia() [2/2]

```
int CreateTxUdpSocketVia (
    const IPADDR send_to_addr,
    uint16_t remote_port,
    uint16_t local_port,
    IPADDR interfaceIp ) [inline]
```

```
#include <udp.h>
```

Open a UDP socket for transmitting UDP packets on the local network interface specified by the interface IP address. Returns a file descriptor that can be used by transmit functions such as [sendto\(\)](#).

Parameters

<i>send_to_addr</i>	Destination IP address
<i>remote_port</i>	Destination port number
<i>local_port</i>	Local port number. A value of 0 will select a random port number (recommended)
<i>interfaceIp</i>	IP address of the local network interface

Returns

The file descriptor for the UDP socket

See also

[CreateRxUdpSocketVia\(\)](#), [CreateRxTxUdpSocketVia\(\)](#)

14.55.2.10 recvfrom()

```
int recvfrom (
    int sock,
    uint8_t buffer,
    int len,
    IPADDR * pAddr,
    uint16_t * pLocal_port,
    uint16_t * pRemote_port ) [inline]
```

```
#include <udp.h>
```

Receive a UDP packet.

Parameters

<i>sock</i>	File descriptor from a previous call to CreateRxUdpSocket() or CreateRxTxSocket()
<i>buffer</i>	Pointer to BYTE array buffer to store received UDP packet data
<i>len</i>	Maximum number of bytes to receive
<i>pAddr</i>	Pointer to an IPADDR variable to store the sender's IP address of the packet
<i>pLocal_port</i>	Pointer to WORD variable to store the local port number of the packet
<i>pRemote_port</i>	Pointer to WORD variable to store the sender's port number of the packet

Returns

The number of bytes received, or a negative number if an error occurred [UDP Error Codes](#)

See also

[sendto\(\)](#), [sendtovia\(\)](#)

14.55.2.11 SendFragmentedUdpPacket()

```
int SendFragmentedUdpPacket (
    const IPADDR & to,
    uint16_t source_port,
    uint16_t dest_port,
    puint8_t data,
    int length ) [inline]
```

```
#include <udp.h>
```

Send a large fragmented UDP packet.

Parameters

<i>to</i>	Destination IP address
<i>source_port</i>	Source port number, a value of 0 selects a random source port number (recommended)
<i>dest_port</i>	Destination port number
<i>data</i>	Pointer to data to send
<i>length</i>	Number of bytes to send

Returns

The number of bytes sent, or 0 if an error occurred.

14.55.2.12 sendto()

```
int sendto (
    int sock,
    puint8_t what_to_send,
    int len_to_send,
    const IPADDR & to_addr,
    uint16_t remote_port ) [inline]
```

```
#include <udp.h>
```

Send a UDP packet.

Parameters

<i>sock</i>	Socket to send packet to
<i>what_to_send</i>	Pointer to data to be sent
<i>len_to_send</i>	Number of data bytes to send
<i>to_addr</i>	Destination IP address
<i>remote_port</i>	Destination port number

Returns

The number of bytes sent, or a negative number if an error occurred [UDP Error Codes](#)

See also

[sendtovia\(\)](#), [recvfrom\(\)](#)

14.55.2.13 sendtovia()

```
int sendtovia (
    int sock,
    uint8_t *what_to_send,
    int len_to_send,
    const IPADDR & to_addr,
    uint16_t remote_port,
    int intfnum ) [inline]
```

```
#include <udp.h>
```

Send a UDP packet on the specified interface.

Parameters

<i>sock</i>	Socket to send packet to
<i>what_to_send</i>	Pointer to data to be sent
<i>len_to_send</i>	Number of data bytes to send
<i>to_addr</i>	Destination IP address
<i>remote_port</i>	Destination port number
<i>intfnum</i>	Interface number

Returns

The number of bytes sent, or a negative number if an error occurred [UDP Error Codes](#)

See also

[sendto\(\)](#), [recvfrom\(\)](#)

14.56 User Authorization Manager

Topics

- [Authorization Responses](#)
- [Authorization Types](#)

Classes

- struct [UserAuthRecord](#)

A stored record of a user's authorization credentials. The value is hashed when saved so it can't be read directly. User's can currently only have one authorization record per user name.

- class [UserAuthManager](#)

The user authorization manager class allows application developers the ability to manage user authorization records. The can be loaded and saved to any storage space, including the config system or UserParams. Authorization values are hashed before being saved. Validation compares both the hash as well as the authorization type. Adding, updating, and removing records will automatically call the user devined save functions. For usage, please see the example found in `examples/SSH/sshServerUserAuth`.

Typedefs

- typedef int(* [SaveAuthRecordsFn](#)) (const [UserAuthRecord](#) *authRec)

User provided function for saving user authorization records. This allows the users to dictate where their authorization records are stored.

- typedef int(* [LoadAuthRecordsFn](#)) ([UserAuthRecord](#) *authRec)

User provided function for loading user authorization records. This allows the users to dictate where their authorization records are stored.

14.56.1 Detailed Description

The NetBurner User Authorization Manager

14.56.2 Typedef Documentation

14.56.2.1 LoadAuthRecordsFn

```
typedef int(* LoadAuthRecordsFn) (UserAuthRecord *authRec)
#include <UserAuthManager.h>
```

User provided function for loading user authorization records. This allows the users to dictate where their authorization records are stored.

Parameters

<i>authRec</i>	A pointer to an array of UserAuthRecords where the data will be loaded.
----------------	---

Return values

0	If the authorization records were loaded correctly.
!0	If there was an error loading the authorization records. Error codes are left to application developers to define.

14.56.2.2 SaveAuthRecordsFn

```
typedef int(* SaveAuthRecordsFn) (const UserAuthRecord *authRec)
#include <UserAuthManager.h>
```

User provided function for saving user authorization records. This allows the users to dictate where their authorization records are stored.

Parameters

<i>authRec</i>	A pointer to an array of UserAuthRecords that should be saved.
----------------	--

Return values

0	If the authorization records were saved correctly.
!0	If there was an error saving the authorization records. Error codes are left to application developers to define.

14.56.3 Authorization Responses

Enumerations

- enum [AuthResponse](#) : int16_t {
 - [eAuthSuccess](#) = 1 , [eAuthErrorUserExists](#) = -1 , [eAuthErrorUserDoesNotExist](#) = -2 , [eAuthErrorNoEmptyUserAuthRecords](#) = -3 ,
 - [eAuthErrorUnableToCreateHash](#) = -4 , [eAuthErrorAuthCheckFailed](#) = -5 , [eAuthErrorAuthTypeMismatch](#) = -6 ,
 - [eAuthErrorFailedRecordUpdate](#) = -7 ,
 - [eAuthErrorUnableToAddUser](#) = -8 , [eAuthErrorSaveFailed](#) = -9 }

Response return codes when checking for the authorization status of a user.

14.56.3.1 Detailed Description

14.56.3.2 Enumeration Type Documentation

14.56.3.2.1 AuthResponse

```
enum AuthResponse : int16_t
```

```
#include <UserAuthManager.h>
```

Response return codes when checking for the authorization status of a user.

Enumerator

eAuthSuccess	The authorization request or function was successful.
eAuthErrorUserExists	The user already exists.
eAuthErrorUserDoesNotExist	The user does not exist.
eAuthErrorNoEmptyUserAuthRecords	The authorization records are full.
eAuthErrorUnableToCreateHash	There was an error hashing the authorization value.
eAuthErrorAuthCheckFailed	The authorization check failed.
eAuthErrorAuthTypeMismatch	The authorization type didn't match the request.
eAuthErrorFailedRecordUpdate	The record update failed.
eAuthErrorUnableToAddUser	The user was not added successfully.
eAuthErrorSaveFailed	Unable to save user authorization records.

14.56.4 Authorization Types

Enumerations

- enum `AuthType` : `int8_t` { `eAuthTypeDefault` = 0 , `eAuthTypePassword` = 1 , `eAuthTypeKey` = 2 }

The types of authorization requests that are managed. These just indicate what the has value is, and don't provide any specific processing logic.

14.56.4.1 Detailed Description

14.56.4.2 Enumeration Type Documentation

14.56.4.2.1 AuthType

```
enum AuthType : int8_t
```

```
#include <UserAuthManager.h>
```

The types of authorization requests that are managed. These just indicate what the has value is, and don't provide any specific processing logic.

Enumerator

eAuthTypeDefault	Default value, should be considered an invalid type.
eAuthTypePassword	Password.
eAuthTypeKey	Key.

14.57 Web Client

Topics

- [Web Client Error Codes](#)

Classes

- class [ParsedURI](#)
Parsed Uniform Resource Identifier Class (URI)

Functions

- void [SetHttpDiag](#) (bool b)
Enable/disable Web Client HTTP diagnostics to the console port.
- int [DoMultipartStartPost](#) ([ParsedURI](#) &TheUri, const char *separator, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND, uint32_t contentLength=0)
Start a multipart HTTP post using a pre-parsed URI object.
- int [DoMultipartStartPost](#) (const char *pUrl, const char *separator, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND, uint32_t contentLength=0)
Start a multipart HTTP post using a pointer to a URL.
- void [DoMultipartItem](#) (int tcpfd, const char *Disposition, const char *separator, const unsigned char *data, int len)
Send a multipart item.
- void [DoMultipartBoundary](#) (int tcpfd, const char *Disposition, const char *separator)
Send a multipart boundary.
- bool [DoMultipartFinished](#) (int tcpfd, const char *separator, buffer_object &result_buffer, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
Send a multipart item.
- bool [DoUrlEncodedFormPost](#) ([ParsedURI](#) &TheUri, char *headers, char *form_data, buffer_object &result_buffer, uint16_t TIMEOUT_WAIT)
Post a JSON file using a HTTP Form Post and a [ParsedURI](#) object.
- bool [DoUrlEncodedFormPost](#) (const char *pUrl, char *headers, char *form_data, buffer_object &result_buffer, uint16_t TIMEOUT_WAIT)
Post a JSON file using a HTTP POST and a URL string and pointer to JSON data.
- bool [DoJsonPost](#) (const char *pUrl, const char *Json_Data_To_Post, buffer_object &result_buffer, const char *AdditionalHeaders=NULL, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
Post a JSON file using a HTTP POST and a URL string and pointer to JSON data.
- bool [DoJsonPost](#) ([ParsedURI](#) &TheUri, const char *Json_Data_To_Post, buffer_object &result_buffer, const char *AdditionalHeaders=NULL, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
Post a JSON file using a HTTP POST and a [ParsedURI](#) object.
- bool [DoJsonPost](#) (const char *pUrl, [ParsedJsonDataSet](#) &jsonout, buffer_object &result_buffer, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
Post a JSON file using a HTTP POST and a URL string.
- bool [DoJsonPost](#) ([ParsedURI](#) &TheUri, [ParsedJsonDataSet](#) &jsonout, buffer_object &result_buffer, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
Post a JSON file using HTTP and a [ParsedURI](#) object.
- bool [DoJsonPostHttpFile](#) (const char *pUrl, const char *FragmentName, buffer_object &result_buffer, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
Post a JSON file using HTTP and a URL string.
- bool [DoJsonPostHttpFile](#) ([ParsedURI](#) &TheUri, const char *FragmentName, buffer_object &result_buffer, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
Post a JSON file using HTTP and a [ParsedURI](#) object.
- bool [DoGet](#) ([ParsedURI](#) &TheUri, buffer_object &result_buffer, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
- bool [DoGetEx](#) ([ParsedURI](#) &TheUri, const char *headers, buffer_object &result_buffer, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
- bool [DoGet](#) (const char *pUrl, buffer_object &result_buffer, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
Execute a HTTP/HTTPS GET request using a pointer to a URL string.
- bool [DoGetEx](#) (const char *pUrl, const char *headers, buffer_object &result_buffer, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)

- Execute a HTTP/HTTPS GET request using a pointer to a URL string.*
- int `DoGet` (`ParsedURI &TheUri`, unsigned char *result, int maxl, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
- Execute a HTTP/HTTPS GET request using a reference to a parsed Uniform Resource Identifier (URI)*
- int `DoGetEx` (`ParsedURI &TheUri`, const char *headers, unsigned char *result, int maxl, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
- Execute a HTTP/HTTPS GET request using a reference to a parsed Uniform Resource Identifier (URI)*
- int `DoGet` (const char *pUrl, unsigned char *result, int maxl, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
- Execute a HTTP/HTTPS GET request using a pointer to a URL string.*
- int `DoGetEx` (const char *pUrl, const char *headers, unsigned char *result, int maxl, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
- Execute a HTTP/HTTPS GET request using a pointer to a URL string.*
- int `DoGetUpdate` (`ParsedURI &TheUri`, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
- Execute a firmware update from the specified URI.*
- int `DoGetUpdate` (const char *pUrl, uint16_t TIMEOUT_WAIT=10 *TICKS_PER_SECOND)
- Execute a firmware update from the specified URI.*
- int `PopulateAuthHeader` (const char *user, const char *password, char *buffer, int maxlen)
- Fill in a username and password into a buffer for use as an extra header.*
- bool `DoActualClientRequest` (`ParsedURI &TheUri`, uint16_t &next_time_delay)
- Callback to specify for performing and handle a WebClient request.*
- bool `StartWebClient` (int prio, const char *url1, const char *url2=NULL, bool bDoNtp=false)
- Start the web client using a URL string.*
- bool `StartWebClient` (int prio, const `NBString` &url1, const `NBString` &url2, bool bDoNtp=false)
- Start the web client using a NBString.*
- bool `StartWebClient` (int prio, const `NBString` &url1, bool bDoNtp=false)
- Start the web client using a NBString.*

Variables

- `WebErrorReporterFunc * pWebErrorReporter`
Set this variable to a callback function to specify a handler for errors.

14.57.1 Detailed Description

```
#include< http\_funcs.h >
```

Functions for interacting with the web, like HTTP GET/POST requests.

An easy way to get web data (from our `GetNonJsonFromServer` example):

```
const char *purl = "http://www.example.com/";
int result = 0;
static unsigned char ResultBuffer[5000];

result = DoGet(purl, ResultBuffer, 5000, 60 * TICKS_PER_SECOND);

if (result > 0)
{
    printf("Result = %d\r\n", result);
    for (int i = 0; i < result; i++)
    {
        printf("%c", ResultBuffer[i]);
    }
    printf("]\r\n");
}
else
{
    iprintf("Failed to contact server\r\n");
}

#include< web\_client.h >
```

Functions for instantiating a periodic web client

From our WebClient examples:

```

const char *url = "http://www.example.com";

void HandleErrorState(int state)
{
    if (state == WEB_CLIENT_ERROR_NO_ERROR) return;
    if ((state <= WEB_CLIENT_ERROR_LAST_STATE) && (state > 0))
        fprintf("Set Error state [%d] [%s]\r\n", state, web_error_state_text[state]);
    else
        fprintf("Error state unknown %d\r\n", state);
}

bool DoActualClientRequest(ParsedURI &TheUri, uint16_t &next_time_delay)
{
    static unsigned char ResultBuffer[5000];

    bool result = DoGet(TheUri, ResultBuffer);
    if (result)
    {
        printf("Result = %d\r\n", result);
        for (int i = 0; i < result; i++)
        {
            printf("%c", ResultBuffer[i]);
        }
        printf("]\r\n");
        next_time_delay = 10 * TICKS_PER_SECOND;
        return true;
    }

    next_time_delay = 10 * TICKS_PER_SECOND;
    return false;
}

void UserMain(void *pd)
{
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    pWebErrorReporter = HandleErrorState;
    StartWebClient(MAIN_PRIO - 2, url);

    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND * 1);
    }
}

```

14.57.2 Function Documentation

14.57.2.1 DoActualClientRequest()

```

bool DoActualClientRequest (
    ParsedURI & TheUri,
    uint16_t & next_time_delay )

```

#include <web_client.h>

Callback to specify for performing and handle a WebClient request.

Parameters

<i>TheUri</i>	Pointer to a ParsedURI object (representing the URL)
<i>next_time_delay</i>	Pointer to the number of ticks to wait before the next request

Returns

True on success, false on failure.

14.57.2.2 DoGet() [1/4]

```

bool DoGet (
    const char * pUrl,

```

```

        buffer_object & result_buffer,
        uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )

```

```
#include <http_funcs.h>
```

Execute a HTTP/HTTPS GET request using a pointer to a URL string.

This function will parse the URL string to connect to the host.

Parameters

<i>pUrl</i>	Pointer to a URL string. A DNS lookup will be done if necessary.
<i>&result_buffer</i>	Reference to the memory buffer in which to store the result.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.57.2.3 DoGet() [2/4]

```

int DoGet (
    const char * pUrl,
    unsigned char * result,
    int maxl,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )

```

```
#include <http_funcs.h>
```

Execute a HTTP/HTTPS GET request using a pointer to a URL string.

This function will parse the URL string to connect to the host.

Parameters

<i>pUrl</i>	Pointer to a URL string. A DNS lookup will be done if necessary.
<i>result</i>	Pointer to the buffer in which to store the result.
<i>maxl</i>	Maximum length of the result buffer.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

14.57.2.4 DoGet() [3/4]

```

bool DoGet (
    ParsedURI & TheUri,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )

```

```
#include <http_funcs.h>
```

Parameters

<i>&TheUri</i>	Reference to the pre-parsed URI.
<i>&result_buffer</i>	Reference to the location to store the result.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.57.2.5 DoGet() [4/4]

```
int DoGet (
    ParsedURI & TheUri,
    unsigned char * result,
    int maxl,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
#include <http_funcs.h>
```

Execute a HTTP/HTTPS GET request using a reference to a parsed Uniform Resource Identifier (URI)
This function uses a reference to a parsed URI, providing faster execution and avoiding parsing a URL, DNS, etc.

Parameters

<i>TheUri</i>	Reference to the ParsedURI object.
<i>result</i>	Pointer to the buffer in which to store the result.
<i>maxl</i>	Maximum length of the result buffer.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns**14.57.2.6 DoGetEx() [1/4]**

```
bool DoGetEx (
    const char * pUrl,
    const char * headers,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
#include <http_funcs.h>
```

Execute a HTTP/HTTPS GET request using a pointer to a URL string.
This function will parse the URL string to connect to the host.

Parameters

<i>pUrl</i>	Pointer to a URL string. A DNS lookup will be done if necessary.
<i>headers</i>	Additional HTTP header fields. Multiple header fields should be concatenated together and separated by by <code>\r\n</code> Do not put <code>\r\n</code> for last header (no trailing <code>\r\n</code>)
<i>&result_buffer</i>	Reference to the memory buffer in which to store the result.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.57.2.7 DoGetEx() [2/4]

```
int DoGetEx (
    const char * pUrl,
    const char * headers,
    unsigned char * result,
```

```

    int maxl,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )

```

```
#include <http_funcs.h>
```

Execute a HTTP/HTTPS GET request using a pointer to a URL string.

This function will parse the URL string to connect to the host.

Parameters

<i>pUrl</i>	Pointer to a URL string. A DNS lookup will be done if necessary.
<i>headers</i>	Additional HTTP header fields. Multiple header fields should be concatenated together and separated by by <code>\r\n</code> Do not put <code>\r\n</code> for last header (no trailing <code>\r\n</code>)
<i>result</i>	Pointer to the buffer in which to store the result.
<i>maxl</i>	Maximum length of the result buffer.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

14.57.2.8 DoGetEx() [3/4]

```

bool DoGetEx (
    ParsedURI & TheUri,
    const char * headers,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
#include <http_funcs.h>

```

Parameters

<i>&TheUri</i>	Reference to the pre-parsed URI.
<i>headers</i>	Additional HTTP header fields. Multiple header fields should be concatenated together and separated by by <code>\r\n</code> Do not put <code>\r\n</code> for last header (no trailing <code>\r\n</code>)
<i>&result_buffer</i>	Reference to the location to store the result.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.57.2.9 DoGetEx() [4/4]

```

int DoGetEx (
    ParsedURI & TheUri,
    const char * headers,
    unsigned char * result,
    int maxl,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
#include <http_funcs.h>

```

Execute a HTTP/HTTPS GET request using a reference to a parsed Uniform Resource Identifier (URI)

This function uses a reference to a parsed URI, providing faster execution and avoiding parsing a URL, DNS, etc.

Parameters

<i>TheUri</i>	Reference to the ParsedURI object.
---------------	--

Parameters

<i>headers</i>	Additional HTTP header fields. Multiple header fields should be concatenated together and separated by by <code>\r\n</code> Do not put <code>\r\n</code> for last header (no trailing <code>\r\n</code>)
<i>result</i>	Pointer to the buffer in which to store the result.
<i>maxl</i>	Maximum length of the result buffer.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

14.57.2.10 DoGetUpdate() [1/2]

```
int DoGetUpdate (
    const char * pUrl,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
```

```
#include <http_funcs.h>
```

Execute a firmware update from the specified URI.

Parameters

<i>pUrl</i>	Pointer to a URL string. A DNS lookup will be done if necessary.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

14.57.2.11 DoGetUpdate() [2/2]

```
int DoGetUpdate (
    ParsedURI & TheUri,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
```

```
#include <http_funcs.h>
```

Execute a firmware update from the specified URI.

Parameters

<i>TheUri</i>	Reference to the ParsedURI object.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

14.57.2.12 DoJsonPost() [1/4]

```
bool DoJsonPost (
    const char * pUrl,
    const char * Json_Data_To_Post,
    buffer_object & result_buffer,
    const char * AdditionalHeaders = NULL,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
```

```
#include <http_funcs.h>
```

Post a JSON file using a HTTP POST and a URL string and pointer to JSON data.

Parameters

<i>pUrl</i>	Pointer to a URL string.
<i>Json_Data_To_Post</i>	Pointer to serialized JSON data
<i>&result_buffer</i>	Reference to the location in which to store the result.
<i>AdditionalHeaders</i>	Additional HTTP header fields. Multiple header fields should be concatenated together and separated by by <code>\r\n</code> Do not put <code>\r\n</code> for last header (no trailing <code>\r\n</code>)
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.57.2.13 DoJsonPost() [2/4]

```
bool DoJsonPost (
    const char * pUrl,
    ParsedJsonDataSet & jsonout,
    buffer_object & result_buffer,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
```

```
#include <http_funcs.h>
```

Post a JSON file using a HTTP POST and a URL string.

Parameters

<i>pUrl</i>	Pointer to a URL string.
<i>jsonout</i>	Reference to NetBurner data object. Please ref JSON lexer.
<i>&result_buffer</i>	Reference to the location in which to store the result.
<i>AdditionalHeaders</i>	Additional HTTP header fields. Multiple header fields should be concatenated together and separated by by <code>\r\n</code> Do not put <code>\r\n</code> for last header (no trailing <code>\r\n</code>)
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.57.2.14 DoJsonPost() [3/4]

```
bool DoJsonPost (
    ParsedURI & TheUri,
    const char * Json_Data_To_Post,
    buffer_object & result_buffer,
    const char * AdditionalHeaders = NULL,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
```

```
#include <http_funcs.h>
```

Post a JSON file using a HTTP POST and a [ParsedURI](#) object.

Parameters

<i>&TheUri</i>	Reference to the pre-parsed URI.
<i>Json_Data_To_Post</i>	Serialized JSON data\
<i>&result_buffer</i>	Reference to the location in which to store the result.

Parameters

<i>AdditionalHeaders</i>	Additional HTTP header fields. Multiple header fields should be concatenated together and separated by by <code>\r\n</code> Do not put <code>\r\n</code> for last header (no trailing <code>\r\n</code>)
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.57.2.15 DoJsonPost() [4/4]

```
bool DoJsonPost (
    ParsedURI & TheUri,
    ParsedJsonDataSet & jsonout,
    buffer_object & result_buffer,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
```

```
#include <http_funcs.h>
```

Post a JSON file using HTTP and a [ParsedURI](#) object.

Parameters

<i>&TheUri</i>	Reference to the pre-parsed URI.
<i>jsonout</i>	Reference to NetBurner data object. Please ref JSON lexer.
<i>&result_buffer</i>	Reference to the location in which to store the result.
<i>AdditionalHeaders</i>	Additional HTTP header fields. Multiple header fields should be concatenated together and separated by by <code>\r\n</code> Do not put <code>\r\n</code> for last header (no trailing <code>\r\n</code>)
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.57.2.16 DoJsonPostHttpFile() [1/2]

```
bool DoJsonPostHttpFile (
    const char * pUrl,
    const char * FragmentName,
    buffer_object & result_buffer,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
```

```
#include <http_funcs.h>
```

Post a JSON file using HTTP and a URL string.

Parameters

<i>pUrl</i>	Pointer to a URL string.
<i>FragmentName</i>	
<i>&result_buffer</i>	Reference to the location in which to store the result.
<i>AdditionalHeaders</i>	Additional HTTP header fields. Multiple header fields should be concatenated together and separated by by <code>\r\n</code> Do not put <code>\r\n</code> for last header (no trailing <code>\r\n</code>)
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.57.2.17 DoJsonPostHttpFile() [2/2]

```
bool DoJsonPostHttpFile (
    ParsedURI & TheUri,
    const char * FragmentName,
    buffer_object & result_buffer,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
```

```
#include <http_funcs.h>
```

Post a JSON file using HTTP and a [ParsedURI](#) object.

Parameters

<i>&TheUri</i>	Reference to the pre-parsed URI.
<i>FragmentName</i>	
<i>&result_buffer</i>	Reference to the location in which to store the result.
<i>AdditionalHeaders</i>	
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.57.2.18 DoMultipartBoundary()

```
void DoMultipartBoundary (
    int tcpfd,
    const char * Disposition,
    const char * separator )
```

```
#include <http_funcs.h>
```

Send a multipart boundary.

Parameters

<i>tcpfd</i>	TCP file descriptor returned from DoMultipartStartPost()
<i>Disposition</i>	Content disposition field of multipart body
<i>separator</i>	Separator string to use as the part delimiter between multipart posts.

14.57.2.19 DoMultipartFinished()

```
bool DoMultipartFinished (
    int tcpfd,
    const char * separator,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND )
```

```
#include <http_funcs.h>
```

Send a multipart item.

Parameters

<i>tcpfd</i>	TCP file descriptor returned from DoMultipartStartPost()
--------------	--

Parameters

<i>separator</i>	Separator string to use as the part delimiter between multipart posts.
<i>result_buffer</i>	Reference to buffer to store result of xxxxx
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

***** Need to understand in http_funcs.cpp

14.57.2.20 DoMultipartItem()

```
void DoMultipartItem (
    int tcpfd,
    const char * Disposition,
    const char * separator,
    const unsigned char * data,
    int len )
```

```
#include <http_funcs.h>
```

Send a multipart item.

Parameters

<i>tcpfd</i>	TCP file descriptor returned from DoMultipartStartPost()
<i>Disposition</i>	Content disposition field of multipart body
<i>separator</i>	Separator string to use as the part delimiter between multipart posts.
<i>data</i>	Item data
<i>len</i>	Data length

14.57.2.21 DoMultipartStartPost() [1/2]

```
int DoMultipartStartPost (
    const char * pUrl,
    const char * separator,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND,
    uint32_t contentLength = 0 )
```

```
#include <http_funcs.h>
```

Start a multipart HTTP post using a pointer to a URL.

Parameters

<i>pUrl</i>	Pointer to a URL string.
<i>separator</i>	Separator string to use as the part delimiter between multipart posts.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.
<i>contentLength</i>	If given, content length for the entire multipart post.

Returns

A TCP/TLS file descriptor greater than 0 if a socket was successfully opened, or [TCP Socket Status](#) on failure.

14.57.2.22 DoMultipartStartPost() [2/2]

```
int DoMultipartStartPost (
    ParsedURI & TheUri,
```

```

    const char * separator,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND,
    uint32_t contentLength = 0 )
#include <http_funcs.h>

```

Start a multipart HTTP post using a pre-parsed URI object.

Parameters

<i>&TheUri</i>	Reference to the pre-parsed URI object.
<i>separator</i>	Separator string to use as the part delimiter between multipart posts.
<i>TIMEOUT_WAIT</i>	Timeout in seconds to wait for a response.
<i>contentLength</i>	If given, content length for the entire multipart post.

Returns

A TCP/TLS file descriptor greater than 0 if a socket was successfully opened, or [TCP Socket Status](#) on failure.

14.57.2.23 DoUrlEncodedFormPost() [1/2]

```

bool DoUrlEncodedFormPost (
    const char * pUrl,
    char * headers,
    char * form_data,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT )
#include <http_funcs.h>

```

Post a JSON file using a HTTP POST and a URL string and pointer to JSON data.

Parameters

<i>pUrl</i>	Pointer to a URL string.
<i>headers</i>	Additional HTTP header fields. Multiple header fields should be concatenated together and separated by by <code>\r\n</code> Do not put <code>\r\n</code> for last header (no trailing <code>\r\n</code>)
<i>form_data</i>	Pointer to the JSON data you are posting.
<i>&result_buffer</i>	Reference to the location in which to store the result.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.57.2.24 DoUrlEncodedFormPost() [2/2]

```

bool DoUrlEncodedFormPost (
    ParsedURI & TheUri,
    char * headers,
    char * form_data,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT )
#include <http_funcs.h>

```

Post a JSON file using a HTTP Form Post and a [ParsedURI](#) object.

Parameters

<i>&TheUri</i>	Reference to the pre-parsed URI.
--------------------	----------------------------------

Parameters

<i>headers</i>	Additional HTTP header fields. Multiple header fields should be concatenated together and separated by by <code>\r\n</code> Do not put <code>\r\n</code> for last header (no trailing <code>\r\n</code>)
<i>form_data</i>	Pointer to the JSON data you are posting.
<i>&result_buffer</i>	Reference to the location in which to store the result.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.57.2.25 PopulateAuthHeader()

```
int PopulateAuthHeader (
    const char * user,
    const char * password,
    char * buffer,
    int maxlen )
```

```
#include <http_funcs.h>
```

Fill in a username and password into a buffer for use as an extra header.

Parameters

<i>user</i>	Pointer to username
<i>password</i>	Pointer to password
<i>buffer</i>	Destination buffer to put the authenticate header in.
<i>maxlen</i>	Maximum number of chars to put in buffer

Returns

number of chars written, negative if the buffer was too small.

14.57.2.26 SetHttpDiag()

```
void SetHttpDiag (
    bool b )
```

```
#include <http_funcs.h>
```

Enable/disable Web Client HTTP diagnostics to the console port.

Parameters

<i>b</i>	Set true to enable, false to disable.
----------	---------------------------------------

14.57.2.27 StartWebClient() [1/3]

```
bool StartWebClient (
    int prio,
    const char * url1,
    const char * url2 = NULL,
    bool bDoNtp = false )
```

```
#include <web_client.h>
```

Start the web client using a URL string.

Parameters

<i>prio</i>	Priority
<i>url1</i>	Pointer to a string representing the URL.
<i>url2</i>	Pointer to a second URL. Optional parameter, default is NULL.
<i>bDoNtp</i>	Enable the Network Time Protocol (NTP). Optional parameter, default is false.

Returns

True on success, false on failure.

14.57.2.28 StartWebClient() [2/3]

```
bool StartWebClient (
    int prio,
    const NSString & url1,
    bool bDoNtp = false )
```

```
#include <web_client.h>
```

Start the web client using a [NSString](#).

Parameters

<i>prio</i>	Priority
<i>url1</i>	Reference to a NSString representing the URL.
<i>bDoNtp</i>	Enable the Network Time Protocol (NTP). Optional parameter, default is false.

Returns

True on success, false on failure.

14.57.2.29 StartWebClient() [3/3]

```
bool StartWebClient (
    int prio,
    const NSString & url1,
    const NSString & url2,
    bool bDoNtp = false )
```

```
#include <web_client.h>
```

Start the web client using a [NSString](#).

Parameters

<i>prio</i>	Priority
<i>url1</i>	Reference to a string representing the URL.
<i>url2</i>	Reference to a second URL. Optional parameter, default is NULL.
<i>bDoNtp</i>	Enable the Network Time Protocol (NTP). Optional parameter, default is false.

Returns

True on success, false on failure.

14.57.3 Web Client Error Codes

Macros

- #define **WEB_CLIENT_ERROR_NO_ETHERNET** (1)
No Ethernet connection.
- #define **WEB_CLIENT_ERROR_NO_ADDRESS** (2)
Interface has no IP address.
- #define **WEB_CLIENT_ERROR_NO_GATEWAY** (3)
Interface has no gateway IP address.
- #define **WEB_CLIENT_ERROR_GATEWAY_WRONG** (4)
Interface has incorrect gateway IP address.
- #define **WEB_CLIENT_ERROR_NO_DNS_ADDR** (5)
Interface has a DNS error.
- #define **WEB_CLIENT_ERROR_NO_DNS_RESOLVE** (6)
DNS was not able to resolve the URL name.
- #define **WEB_CLIENT_ERROR_NO_NTP** (7)
NTP failed.
- #define **WEB_CLIENT_ERROR_NO_SERVER_RESPONSE** (8)
No response from server.
- #define **WEB_CLIENT_ERROR_NO_SERVER_CONNECT** (9)
Unable to connect to server.
- #define **WEB_CLIENT_ERROR_NO_ERROR** (10)
No error.

Functions

- nbWifiScanResult * [WifiInitScan_SPI](#) (int irqNum=-1, int moduleNum=-1, int csNum=-1, int connectorNum=-1, int gpioPinNum=-1, int resetPinNum=-1)
Initializes the WiFi hardware, initializes the driver over the SPI bus, and performs an AP scan.
- int [WifiInitScanAndShow_SPI](#) (int irqNum=-1, int moduleNum=-1, int csNum=-1, int connectorNum=-1, int gpioPinNum=-1, int resetPinNum=-1)
Initializes the WiFi hardware, initializes the driver using the SPI bus, performs an AP scan, and prints the scan results via serial output.
- int [InitWifi_SPI](#) (const char *SSID="", const char *password="", int irqNum=-1, int moduleNum=-1, int csNum=-1, int connectorNum=-1, int gpioPinNum=-1, int resetPinNum=-1)
Initializes the WiFi hardware, initializes the driver using the SPI bus, and attempts to establish the specified connection.
- int [InitAP_SPI](#) (const char *SSID="", const char *password="", uint8_t channel=NBWIFI_DEFAULT_WIFICHANNEL, int irqNum=-1, int moduleNum=-1, int csNum=-1, int connectorNum=-1, int gpioPinNum=-1, int resetPinNum=-1)
Initializes the WiFi hardware, initializes the driver using the SPI bus, and attempts to establish the specified access point.
- nbWifiScanResult * [WifiInitScan_Serial](#) (int portNum=-1, int resetPinNum=-1, int connectorNum=-1)
Initializes the WiFi hardware, initializes the driver using the UART interface, performs an AP scan, and prints the scan results via serial output.
- int [WifiInitScanAndShow_Serial](#) (int portNum=-1, int resetPinNum=-1, int connectorNum=-1)
Initializes the WiFi hardware, initializes the driver using the UART interface, performs an AP scan, and prints the scan results via serial output.
- int [InitWifi_Serial](#) (const char *SSID="", const char *password="", int portNum=-1, int resetPinNum=-1, int connectorNum=-1)
Initializes the WiFi hardware, initializes the driver using the UART interface, and attempts to establish the specified access point.
- void [SetWifiSPISpeed](#) (int busSpeed)
Set SPI bus speed.
- void [ScanAndShowNetworks](#) ()
Scan for surrounding access points and print the results via iprintf.
- nbWifiScanResult * [ScanForNetworks](#) ()
Scan for surrounding access points.

14.58.1 Detailed Description

14.58.2 Function Documentation

14.58.2.1 InitAP_SPI()

```
int InitAP_SPI (
    const char * SSID = "",
    const char * password = "",
    uint8_t channel = NBWIFI_DEFAULT_WIFICHANNEL,
    int irqNum = -1,
    int moduleNum = -1,
    int csNum = -1,
    int connectorNum = -1,
    int gpioPinNum = -1,
    int resetPinNum = -1 )
```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver using the SPI bus, and attempts to establish the specified access point.

Parameters

in	<i>SSID</i>	Service Set Identity (SSID), nullptr uses SSID stored in the configuration record.
----	-------------	--

Parameters

in	<i>password</i>	key shared with access point/peer; nullptr uses the key stored in the configuration record.
in	<i>channel</i>	802.11 channel to establish an access point on.
in	<i>irqNum</i>	IRQ signal used to communicate with the WiFi module.
in	<i>moduleNum</i>	SPI module number used to communicate with the WiFi module.
in	<i>csNum</i>	Chip Select signal used for SPI communication.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.
in	<i>gpioPinNum</i>	GPIO pin number to use for the SPI chip select if not using the SPI module's native chip select signal.
in	<i>resetPinNum</i>	pin number to use as a reset signal output to the wifi module.

Returns

returns the Wifi interface number, if successful. Otherwise, returns [NB::Error::GeneralErrors](#) or [NB::Error::Init::InitializationErrors](#)

14.58.2.2 InitWifi_Serial()

```
int InitWifi_Serial (
    const char * SSID = "",
    const char * password = "",
    int portNum = -1,
    int resetPinNum = -1,
    int connectorNum = -1 )
```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver using the UART interface, and attempts to establish the specified access point.

NOTE: Serial functions pertaining to WiFi are only available for the NBWIFIIN.

Parameters

in	<i>SSID</i>	Service Set Identity (SSID), nullptr uses SSID stored in the configuration record.
in	<i>password</i>	key shared with access point/peer; nullptr uses the key stored in the configuration record.
in	<i>portNum</i>	UART number
in	<i>resetPinNum</i>	pin number to use as a reset signal output to the wifi module.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.

Returns

returns zero if successful, otherwise returns [NB::Error::GeneralErrors](#) or [NB::Error::Init::InitializationErrors](#)

14.58.2.3 InitWifi_SPI()

```
int InitWifi_SPI (
    const char * SSID = "",
    const char * password = "",
    int irqNum = -1,
    int moduleNum = -1,
    int csNum = -1,
    int connectorNum = -1,
    int gpioPinNum = -1,
    int resetPinNum = -1 )
```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver using the SPI bus, and attempts to establish the specified connection.

Parameters

in	<i>SSID</i>	Service Set Identity (SSID), nullptr uses SSID stored in the configuration record.
in	<i>password</i>	key shared with access point/peer; nullptr uses the key stored in the configuration record.
in	<i>irqNum</i>	IRQ signal used to communicate with the WiFi module.
in	<i>moduleNum</i>	SPI module number used to communicate with the WiFi module.
in	<i>csNum</i>	Chip Select signal used for SPI communication.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.
in	<i>gpioPinNum</i>	GPIO pin number to use for the SPI chip select, if not using the SPI's native chip select signal.
in	<i>resetPinNum</i>	pin number to use as an reset signal output to the wifi module.

Returns

returns the Wifi interface number, if successful. Otherwise, returns [NB::Error::GeneralErrors](#) or [NB::Error::Init::InitializationErrors](#)

14.58.2.4 ScanAndShowNetworks()

```
void ScanAndShowNetworks ( )
#include <wifi.h>
Scan for surrounding access points and print the results via iprintf.
This function is bus interface agnostic.
```

14.58.2.5 ScanForNetworks()

```
nbWifiScanResult * ScanForNetworks ( )
#include <wifi.h>
Scan for surrounding access points.
```

Returns

nbWifiScanResult Head of linked list containing the AP scan results. nullptr if scan failed or no access points were found

This function is bus interface agnostic.

14.58.2.6 SetWifiSPISpeed()

```
void SetWifiSPISpeed (
    int busSpeed )
#include <wifi.h>
Set SPI bus speed.
```

Parameters

in	<i>busSpeed</i>	Bus speed in Hz.
----	-----------------	------------------

14.58.2.7 WifiInitScan_Serial()

```
nbWifiScanResult * WifiInitScan_Serial (
    int portNum = -1,
```

```

        int resetPinNum = -1,
        int connectorNum = -1 )
#include <wifi.h>

```

Initializes the WiFi hardware, initializes the driver using the UART interface, performs an AP scan, and prints the scan results via serial output.

NOTE: Serial functions pertaining to WiFi are only available for the NBWIFIIN.

Parameters

in	<i>portNum</i>	UART number
in	<i>resetPinNum</i>	pin number to use as an reset signal output to the wifi module.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.

Returns

nbWifiScanResult Head of linked list containing the AP scan results. nullptr if scan failed or no access points were found

14.58.2.8 WifilnitScan_SPI()

```

nbWifiScanResult * WifiInitScan_SPI (
    int irqNum = -1,
    int moduleNum = -1,
    int csNum = -1,
    int connectorNum = -1,
    int gpioPinNum = -1,
    int resetPinNum = -1 )

```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver over the SPI bus, and performs an AP scan.

Parameters

in	<i>irqNum</i>	IRQ signal used to communicate with the WiFi module.
in	<i>moduleNum</i>	SPI module number used to communicate with the WiFi module.
in	<i>csNum</i>	Chip Select signal used for SPI communication.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.
in	<i>gpioPinNum</i>	GPIO pin number to use for the SPI chip select if not using the SPI's native chip select signal.
in	<i>resetPinNum</i>	pin number to use as an reset signal output to the wifi module.

Returns

nbWifiScanResult Head of linked list containing the AP scan results. nullptr if scan failed or no access points were found

Initializes the WiFi Driver to communicate with the WiFi module over the SPI bus and performs a scan for surrounding access points (AP). The result of the scan is returned as the head of a linked list that contains the scan results. If the WiFi driver has already been initialized by a previous call to one of the Wifilnit function variations, then only a scan will be performed.

14.58.2.9 WifilnitScanAndShow_Serial()

```

int WifiInitScanAndShow_Serial (
    int portNum = -1,
    int resetPinNum = -1,
    int connectorNum = -1 )

```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver using the UART interface, performs an AP scan, and prints the scan results via serial output.

NOTE: Serial functions pertaining to WiFi are only available for the NBWIFIIN.

Parameters

in	<i>portNum</i>	UART number
in	<i>resetPinNum</i>	pin number to use as an reset signal output to the wifi module.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.

Returns

the Wifi interface number if successful. Otherwise, returns [NB::Error::GeneralErrors](#) or [NB::Error::Init::InitializationErrors](#)

14.58.2.10 WifInitScanAndShow_SPI()

```
int WifInitScanAndShow_SPI (
    int irqNum = -1,
    int moduleNum = -1,
    int csNum = -1,
    int connectorNum = -1,
    int gpioPinNum = -1,
    int resetPinNum = -1 )
```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver using the SPI bus, performs an AP scan, and prints the scan results via serial output.

Parameters

in	<i>irqNum</i>	IRQ signal used to communicate with the WiFi module.
in	<i>moduleNum</i>	SPI module number used to communicate with the WiFi module.
in	<i>csNum</i>	Chip Select signal used for SPI communication.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.
in	<i>gpioPinNum</i>	GPIO pin number to use for the SPI chip select if not using the SPI's native chip select signal.
in	<i>resetPinNum</i>	pin number to use as an reset signal output to the wifi module.

Returns

returns the Wifi interface number, if successful. Otherwise, returns [NB::Error::GeneralErrors](#) or [NB::Error::Init::InitializationErrors](#)

14.58.3 BSS Options

Option list BSS type values.

Macros

- #define **BSSTYPE_VALUE_INFR** (0x00)
Infrastructure.
- #define **BSSTYPE_VALUE_ADHOC** (0x01)
ADHOC.
- #define **BSSTYPE_VALUE_ANY** (0x02)
Any.

- #define **BSSTYPE_VALUE_UNKNOWN** (0xFF)
Unknown.

14.58.3.1 Detailed Description

Option list BSS type values.

14.58.4 Cipher Options

Macros

- #define **CIPH_VALUE_NONE** (0x00)
Option list cipher value: No cipher.
- #define **CIPH_VALUE_TKIP** (0x01)
Option list cipher value: TKIP.
- #define **CIPH_VALUE_AES** (0x02)
Option list cipher value: AES.
- #define **CIPH_VALUE_MIXED** (0x03)
Option list cipher value: Mixed TKIP/AES.
- #define **CIPH_VALUE_UNKNOWN** (0xFF)
Option list cipher value: Unknown cipher.

14.58.4.1 Detailed Description

14.58.5 Configuration Errors

Macros

- #define **CONFIG_ERR_SUCCESS** 0
Success.
- #define **CONFIG_ERR_MSG_LENGTH** -1
Message length.
- #define **CONFIG_ERR_SSID_LEN_SHORT** -2
SSID length too short.
- #define **CONFIG_ERR_SSID_LEN_LONG** -3
SSID length too long.
- #define **CONFIG_ERR_PASSWD_LEN_LONG** -4
Password length too long.
- #define **CONFIG_ERR_INVALID_TABLE** -5
Invalid table.
- #define **CONFIG_ERR_INVALID_OPTION** -6
Invalid option.
- #define **CONFIG_ERR_BSSID_OVERRUN** -7
BSSID overrun.
- #define **CONFIG_ERR_BSSID_UNDERRUN** -8
BSSID underrun.
- #define **CONFIG_ERR_MULTI_CHANNEL** -9
Multi-channel.
- #define **CONFIG_ERR_CONNECTED** -10
Already connected.
- #define **CONFIG_ERR_UNKNOWN** 1
Unknown.

14.58.5.1 Detailed Description

14.58.6 Connect Request Errors

Macros

- #define **CONNECT_ERR_SUCCESS** 0
Successfull connect request.
- #define **CONNECT_ERR_NOT_CONFIG** -1
Paramaters not configured.
- #define **CONNECT_ERR_INVALID_CONFIG_NUM** -2
Invalid config number.
- #define **CONNECT_ERR_CONNECTED** -3
Already connected.
- #define **CONNECT_ERR_SSID_NOT_FOUND** -4
SSID not found.
- #define **CONNECT_ERR_BSSID_NOT_FOUND** -5
BSSID not found.
- #define **CONNECT_ERR_SEC_MISMATCH** -6
Security mismatch.
- #define **CONNECT_ERR_CIPH_MISMATCH** -7
Cipher mismatch.
- #define **CONNECT_ERR_INVALID_KEY** -8
Invalid password.
- #define **CONNECT_ERR_UNKNOWN** 1
Unknown error.

14.58.6.1 Detailed Description

14.58.7 Save Config Record Errors

Macros

- #define **SAVE_CONF_ERR_SUCCESS** 0
Success.
- #define **SAVE_CONF_ERR_INVALID_CONFIG_NUM** -1
Invalid configuration number.
- #define **SAVE_CONF_ERR_NOT_CONFIGURED** -2
Not configured.
- #define **SAVE_CONF_ERR_UNKNOWN** 1
Unknown error.

14.58.7.1 Detailed Description

14.58.8 Scan Request Errors

Macros

- #define **SCAN_ERR_SUCCESS** 0
Success.
- #define **SCAN_ERR_MSG_LENGTH** -1
Invalid message length.
- #define **SCAN_ERR_IN_PROGRESS** -2
Scan in progress.
- #define **SCAN_ERR_SSID_LEN_LONG** -3
SSID length too long.

- #define **SCAN_ERR_INVALID_TABLE** -4
Invalid table.
- #define **SCAN_ERR_INVALID_OPTION** -5
Invalid option.
- #define **SCAN_ERR_TOO_MANY_CHANNELS** -6
Too many channels.
- #define **SCAN_ERR_UNKNOWN** 1
Unknown error.

14.58.8.1 Detailed Description

14.58.9 Security Options

Macros

- #define **SEC_VALUE_OPEN** (0x00)
Option list security value: Open network.
- #define **SEC_VALUE_WEP** (0x01)
Option list security value: WEP.
- #define **SEC_VALUE_WPA** (0x02)
Option list security value: WPA.
- #define **SEC_VALUE_WPA2** (0x03)
Option list security value: WPA2.
- #define **SEC_VALUE_WPS** (0x04)
Option list security value: WPS.
- #define **SEC_VALUE_ANY** (0xFE)
Option list security value: Any, used to connect as a client regardless of how security is configured for AP.
- #define **SEC_VALUE_UNKNOWN** (0xFF)
Option list security value: Unknown security.

14.58.9.1 Detailed Description

Chapter 15

Namespace Documentation

15.1 canMCF5441x Namespace Reference

[canMCF5441x](#) namespace

Classes

- class [CanRxMessage](#)
Class to hold received CAN messages.

15.1.1 Detailed Description

[canMCF5441x](#) namespace

15.2 DHCP Namespace Reference

[DHCP](#) Namespace.

Classes

- class [BlockAllocator](#)
Basic allocator that handles multiple leases in a contiguous IP block.
- struct [DhcpInfo](#)
DHCP Info.
- struct [DhcpLeaseData](#)
Lease Data.
- struct [DhcpLeaseRequest](#)
Lease Request.
- class [LeaseAllocator](#)
Base class/interface for lease allocators for the DHCP server.
- class [MacPrefixAllocator](#)
Derived from [BlockAllocator](#) Has the ability to whitelist/blacklist certain mac address ranges based on a mask. Useful for allocating addresses based on device manufacturer.
- class [Server](#)
DHCP Server class Requires a lease allocator to be added in order to function.
- class [SingleAllocator](#)
Stripped down allocator Fails to conform to many standard behaviors, but shows the basics of what needs to be implemented.

Typedefs

- typedef enum [DHCP::LeaseState](#) **LeaseState_t**
Lease State.

Enumerations

- enum [LeaseState](#) {
[LEASE_OPEN](#) = 0x0 , [LEASE_OFFERED](#) = 0x1 , [LEASE_TAKEN](#) = 0x2 , [LEASE_STATIC](#) = 0x3 ,
[ARP_CONFLICT](#) = 0x4 }
Lease State.

15.2.1 Detailed Description

[DHCP](#) Namespace.

15.2.2 Enumeration Type Documentation

15.2.2.1 LeaseState

enum [DHCP::LeaseState](#)
Lease State.

Enumerator

LEASE_OPEN	
LEASE_OFFERED	
LEASE_TAKEN	
LEASE_STATIC	
ARP_CONFLICT	

15.3 mcanMODM7AE70 Namespace Reference

[mcanMODM7AE70](#) namespace

Classes

- class [CanRxMessage](#)
Class to hold received CAN messages.
- class [mcan_config](#)
MCAN configuration structure.
- class [mcan_module](#)
MCAN Module Class.

Variables

MCAN Constants

- const uint32_t [CONF_MCAN_RX_FIFO_0_NUM](#) = 32
Range: 1..64.
- const uint32_t [CONF_MCAN_RX_FIFO_1_NUM](#) = 1
Range: 1..64.
- const uint32_t [CONF_MCAN_RX_BUFFER_NUM](#) = 1
Range: 1..64.
- const uint32_t [CONF_MCAN_TX_BUFFER_NUM](#) = 8
Range: 1..16.

- const uint32_t **CONF_MCAN_TX_FIFO_QUEUE_NUM** = 1
Range: 1..16.
- const uint32_t **CONF_MCAN_TX_EVENT_FIFO** = 8
Range: 1..32.
- const uint32_t **CONF_MCAN_RX_STANDARD_ID_FILTER_NUM** = 32
Range: 1..128.
- const uint32_t **CONF_MCAN_RX_EXTENDED_ID_FILTER_NUM** = 32
Range: 1..64.

15.3.1 Detailed Description

[mcanMODM7AE70](#) namespace

15.4 NB::Error Namespace Reference

Namespaces

- namespace [Connect](#)
- namespace [Init](#)
- namespace [Scan](#)

Enumerations

- enum [GeneralErrors](#) {
[NoError](#) = 0 , [Timeout](#) = -256 , [BusTimeout](#) = -257 , [InvalidArgument](#) = -258 ,
[TooManyPendingCommands](#) = -259 , [InvalidRequest](#) = -512 }

15.4.1 Detailed Description

[NB::Error](#) namespace that describes WiFi request errors. See also [InitWifi_SPI\(\)](#), [InitAP_SPI\(\)](#), [InitWifi_Serial\(\)](#), [NB::Master::ConnectToAP\(\)](#), [NB::Master::StartAP\(\)](#), [WifiInitScanAndShow_SPI\(\)](#), [WifiInitScanAndShow_Serial\(\)](#)

15.4.2 Enumeration Type Documentation

15.4.2.1 GeneralErrors

enum [NB::Error::GeneralErrors](#)

15.4.3 GeneralErrors

8 bit values reserved for command specific errors

Enumerator

NoError	Successful execution.
Timeout	Request timed out.
BusTimeout	Request timed out on the bus.
InvalidArgument	Parameter/argument not defined or is invalid.
TooManyPendingCommands	Too many pending commands.
InvalidRequest	Invalid request.

15.5 NB::Error::Connect Namespace Reference

Enumerations

- enum [ConnectErrors](#) {
[Success](#) = 0 , [NotInitialized](#) = -1 , [AlreadyConnected](#) = -2 , [Option](#) = -3 ,
[CouldNotConfig](#) = -4 , [SSID_NotFound](#) = -5 , [BSSID_NotFound](#) = -6 , [Sec_NotFound](#) = -7 ,
[Cipher_NotFound](#) = -8 , [ConnectFailed](#) = -9 }

15.5.1 Detailed Description

[NB::Error::Connect](#) namespace that describes WiFi connect request errors. See also [InitWifi_SPI\(\)](#), [InitAP_SPI\(\)](#), [InitWifi_Serial\(\)](#), [NB::Master::ConnectToAP\(\)](#), [NB::Master::StartAP\(\)](#)

15.5.2 Enumeration Type Documentation

15.5.2.1 ConnectErrors

```
enum NB::Error::Connect::ConnectErrors
```

15.5.3 ConnectErrors

Enumerator

Success	Success.
NotInitialized	Not Initialized.
AlreadyConnected	Already Connected.
Option	Option.
CouldNotConfig	Could Not Configure.
SSID_NotFound	SSID Not Found.
BSSID_NotFound	BSSID Not Found.
Sec_NotFound	Sec Not Found.
Cipher_NotFound	Cipher Not Found.
ConnectFailed	Connect Failed.

15.6 NB::Error::Init Namespace Reference

Enumerations

- enum [InitializationErrors](#) {
[Success](#) = 0 , [AlreadyInit](#) = -1 , [NoDevice](#) = -2 , [InvalidInfo](#) = -3 ,
[DevFirmVer](#) = -4 , [DevHwVer](#) = -5 , [OptionTables](#) = -6 }

15.6.1 Detailed Description

[NB::Error::Init](#) namespace that describes WiFi initialization request errors. See also [WifiInitScanAndShow_SPI\(\)](#), [WifiInitScanAndShow_Serial\(\)](#), [InitWifi_SPI\(\)](#), [InitAP_SPI\(\)](#), [InitWifi_Serial\(\)](#)

15.6.2 Enumeration Type Documentation

15.6.2.1 InitializationErrors

```
enum NB::Error::Init::InitializationErrors
```

15.6.3 InitializationErrors

Enumerator

Success	Success.
AlreadyInit	Already Initialized.
NoDevice	No Device detected or attempting to use WiFi functions on an un-initialized device.
InvalidInfo	Invalid Info.
DevFirmVer	Device Firmware Version.
DevHwVer	Device Hardware Version.
OptionTables	Option Tables.

15.7 NB::Error::Scan Namespace Reference

Enumerations

- enum [ScanErrors](#) { [Success](#) = 0 , [NotInitialized](#) = -1 , [InProgress](#) = -2 , [Option](#) = -3 }

15.7.1 Detailed Description

[NB::Error::Scan](#) namespace that describes WiFi access point scan request errors. See also [WifilnitScanAndShow_SPI\(\)](#), [WifilnitScanAndShow_Serial\(\)](#)

15.7.2 Enumeration Type Documentation

15.7.2.1 ScanErrors

```
enum NB::Error::Scan::ScanErrors
```

15.7.3 ScanErrors

Enumerator

Success	Success.
NotInitialized	Not Initialized.
InProgress	In Progress.
Option	Option.

Chapter 16

Class Documentation

16.1 `_EthernetFrameHeader` Struct Reference

Ethernet Type II Frame Header.
`#include <ethernet.h>`

Public Attributes

- `MACADDRESS_48 destinationMacAddress`
Destination MAC address.
- `MACADDRESS_48 sourceMacAddress`
Source MAC address.
- `beuint16_t etherType`
Protocol.

16.1.1 Detailed Description

Ethernet Type II Frame Header.
The documentation for this struct was generated from the following file:

- [ethernet.h](#)

16.2 `_FlexSPIConfig` Struct Reference

FlexSPI Memory Configuration Block.
`#include <evkmimxrt1060_flexspi_nor_config.h>`

Public Attributes

- `uint32_t tag`
[0x000-0x003] Tag, fixed value 0x42464346UL
- `uint32_t version`
[0x004-0x007] Version, [31:24] - 'V', [23:16] - Major, [15:8] - Minor, [7:0] - bugfix
- `uint32_t reserved0`
[0x008-0x00b] Reserved for future use
- `uint8_t readSampleClkSrc`
[0x00c-0x00c] Read Sample Clock Source, valid value: 0/1/3
- `uint8_t csHoldTime`
[0x00d-0x00d] CS hold time, default value: 3
- `uint8_t csSetupTime`
[0x00e-0x00e] CS setup time, default value: 3

- [uint8_t columnAddressWidth](#)
- [uint8_t deviceModeCfgEnable](#)
Serial NAND, need to refer to datasheet.
- [uint8_t deviceModeType](#)
- [uint16_t waitTimeCfgCommands](#)
Generic configuration, etc.
- [flexspi_lut_seq_t deviceModeSeq](#)
DPI/QPI/OPI switch or reset command.
- [uint32_t deviceModeArg](#)
sequence number, [31:16] Reserved

[0x068-0x06b] data pad setting override value
- [uint32_t dqsPadSettingOverride](#)
[0x06c-0x06f] DQS pad setting override value
- [uint32_t timeoutInMs](#)
[0x070-0x073] Timeout threshold for read status command
- [uint32_t commandInterval](#)

- [0x074-0x077] CS deselect interval between two commands*
- uint16_t **dataValidTime** [2]
 - [0x078-0x07b] CLK edge to data valid time for PORT A and PORT B, in terms of 0.1ns*
- uint16_t **busyOffset**
 - [0x07c-0x07d] Busy offset, valid value: 0-31*
- uint16_t **busyBitPolarity**
- uint32_t **lookupTable** [64]
 - busy flag is 0 when flash device is busy*
- flexspi_lut_seq_t **lutCustomSeq** [12]
 - [0x180-0x1af] Customizable LUT Sequences*
- uint32_t **reserved4** [4]
 - [0x1b0-0x1bf] Reserved for future use*

16.2.1 Detailed Description

FlexSPI Memory Configuration Block.

16.2.2 Member Data Documentation

16.2.2.1 busyBitPolarity

uint16_t _FlexSPIConfig::busyBitPolarity
 [0x07e-0x07f] Busy flag polarity, 0 - busy flag is 1 when flash device is busy, 1 -

16.2.2.2 columnAddressWidth

uint8_t _FlexSPIConfig::columnAddressWidth
 [0x00f-0x00f] Column Address with, for HyperBus protocol, it is fixed to 3, For

16.2.2.3 controllerMiscOption

uint32_t _FlexSPIConfig::controllerMiscOption
 [0x040-0x043] Controller Misc Options, see Misc feature bit definitions for more

16.2.2.4 deviceModeArg

uint32_t _FlexSPIConfig::deviceModeArg
 sequence number, [31:16] Reserved
 [0x018-0x01b] Argument/Parameter for device configuration

16.2.2.5 deviceModeCfgEnable

uint8_t _FlexSPIConfig::deviceModeCfgEnable
 Serial NAND, need to refer to datasheet.
 [0x010-0x010] Device Mode Configure enable flag, 1 - Enable, 0 - Disable

16.2.2.6 deviceModeSeq

flexspi_lut_seq_t _FlexSPIConfig::deviceModeSeq
 DPI/QPI/OPI switch or reset command.
 [0x014-0x017] Device mode sequence info, [7:0] - LUT sequence id, [15:8] - LUT

16.2.2.7 deviceModeType

uint8_t _FlexSPIConfig::deviceModeType
 [0x011-0x011] Specify the configuration command type:Quad Enable, DPI/QPI/OPI switch,

16.3 _IpHeaderIPv4 Struct Reference

IP Header (IPv4)

```
#include <ip.h>
```

Public Attributes

- uint8_t **versionNLength**
Version and header length nibbles [IPPKT::bVerHdrLen](#).
- uint8_t **diffServNEcn**
Service and congestion related [IPPKT::bTos](#).
- beuint16_t **totalLength**
Datagram size including IP header [IPPKT::wLength](#).
- beuint16_t **identification**
Fragment identification [IPPKT::wpktId](#).
- beuint16_t **flagsNFragmentOffset**
Flags and fragment offset fields [IPPKT::wFlags_Frag](#).
- uint8_t **timeToLive**
Usually hop count [IPPKT::bTTL](#).

- `uint8_t protocol`
IANA protocol number [IPPKT::proto](#).
- `beuint16_t headerChecksum`
16-bit one's complement of the one's complement sum of all 16-bit words in the header [IPPKT::hCSum](#)
- `beuint32_t sourceAddress`
IP address of source 4 8-bit octets [IPPKT::ipSrc](#).
- `beuint32_t destinationAddress`
IP destination address 4 8-bit octets [IPPKT::ipDst](#).

16.3.1 Detailed Description

IP Header (IPv4)

Can contain options, determined by header length. No options header length is 5 for 5 32 bit words (20 bytes)
IETF RFC 791 September 1981, MIL-STD-1777

The documentation for this struct was generated from the following file:

16.4 _lut_sequence Struct Reference

FlexSPI LUT Sequence structure.

```
#include <evkmimxrt1060_flexspi_nor_config.h>
```

Public Attributes

- `uint8_t seqNum`
Sequence Number, valid number: 1-16.
- `uint8_t seqId`
Sequence Index, valid number: 0-15.

16.4.1 Detailed Description

FlexSPI LUT Sequence structure.

The documentation for this struct was generated from the following file:

- [evkmimxrt1060_flexspi_nor_config.h](#)

16.5 _PinVector Class Reference

GPIO Pin Vector Base Class.

```
#include <cpu_pins.h>
```

Inherited by [PinVector< n >](#).

Public Member Functions

- `uint32_t operator=` (uint32_t val)
Assign a value to the [_PinVector](#) Bus.
- `PinIO operator[]` (int idx)
Access the [PinIO](#) for a specific bit position in the [_PinVector](#).
- void `config` (uint32_t idx, [PinIO](#) cfg)
Set the [PinIO](#) that will be used for a given bit position in the [_PinVector](#).
- void `config` ([PinIO](#) *pinCfgs, uint32_t count)
Configure the [_PinVector](#) based on an array of [PinIO](#)s. The index of the [PinIO](#) in the configuration array will determine the bit position within the [_PinVector](#) that that [PinIO](#) represents.
- `operator uint32_t` () const
Read the line state of the [_PinVector](#) bus.

16.5.1 Detailed Description

GPIO Pin Vector Base Class.

This class is for building semi-parallel buses using GPIO pins. It facilitates driving a numeric value across a parallel bus of GPIO pins. It should not be confused with a true parallel bus, as each individual pin in the bus is modified sequentially/independently during a bus assignment.

Parameters

<code>_Pin::len</code>	Number of pins managed by the <code>_PinVector</code> .
------------------------	---

16.5.2 Member Function Documentation

16.5.2.1 `config()` [1/2]

```
void _PinVector::config (
    PinIO * pinCfgs,
    uint32_t count )
```

Configure the `_PinVector` based on an array of PinIOs. The index of the `PinIO` in the configuration array will determine the bit position within the `_PinVector` that that `PinIO` represents.

Parameters

<code>pinCfgs</code>	The configuration to be used.
<code>count</code>	The number of PinIOs in the configuration array to be used.

16.5.2.2 `config()` [2/2]

```
void _PinVector::config (
    uint32_t idx,
    PinIO cfg )
```

Set the `PinIO` that will be used for a given bit position in the `_PinVector`.

Parameters

<code>idx</code>	The bit position to be configured.
<code>cfg</code>	The <code>PinIO</code> that bit position will represent.

16.5.2.3 `operator uint32_t()`

```
_PinVector::operator uint32_t ( ) const
```

Read the line state of the `_PinVector` bus.

Returns

The current bus value as read from the line state.

16.5.2.4 `operator=()`

```
uint32_t _PinVector::operator= (
    uint32_t val )
```

Assign a value to the `_PinVector` Bus.

Parameters

<code>val</code>	The value to assign to the bus.
------------------	---------------------------------

Returns

The value driven on the bus.

16.5.2.5 operator[]()

```
PinIO _PinVector::operator[] (
    int idx )
```

Access the [PinIO](#) for a specific bit position in the [_PinVector](#).

Parameters

<i>idx</i>	The bit index to access in the _PinVector .
------------	---

Returns

The [PinIO](#) for the given bit position.

The documentation for this class was generated from the following file:

- [cortex-m7/cpu/SAME70/include/cpu_pins.h](#)

16.6 AcmeServletObject Class Reference

Main ACME Client Class.

```
#include <acmeRFC8555Servlet.h>
```

Inherits [DiagItemClass](#), and [WebClientServlet](#).

Inherited by [BuyPassAcmeServletObject](#), and [LetsEncryptAcmeServletObject](#).

Public Member Functions

- void [Delete_Everything_Restart](#) ()
Re-request the ACME certificate.
- void [SetDiag](#) (bool v)
Turn on diagnostic printf messages to the console.
- [NBString](#) [GetGlobalStateString](#) ()
Returns the detailed state of the ACME process.
- [NBString](#) [GetStateString](#) ()
Returns the specific state condition of the acmeservlet.
- const char * [GetStateCC](#) ()
Returns the specific state condition of the acmeservlet.
- [AcmeServletObject](#) (const char *pUrlDir)
ACME Client Constructor.

Friends

- [CertGenData](#) * [GetDataForCertGen](#) ()
A function to be overridden to pass certificate details to the certificate generator.

16.6.1 Detailed Description

Main ACME Client Class.

16.6.2 Constructor & Destructor Documentation

16.6.2.1 AcmeServletObject()

```
AcmeServletObject::AcmeServletObject (
    const char * pUrlDir ) [inline]
```

ACME Client Constructor.

Parameters

<code>pUrlDir</code>	URL for the ACME API directory endpoint (required, i.e. https://acme.example.com/dir)
----------------------	---

16.6.3 Member Function Documentation

16.6.3.1 Delete_Everything_Restart()

```
void AcmeServletObject::Delete_Everything_Restart ( )
```

Re-request the ACME certificate.

Once the system has loaded valid keys and certificate It sleeps and does not do much. If you want to change the names, or want to re-run the ACME protocol for debugging/diagnostic purposes, this function erases all keys, the certificate, and restarts the certificate issuing process.

16.6.3.2 GetStateCC()

```
const char * AcmeServletObject::GetStateCC ( )
```

Returns the specific state condition of the acmeservlet.

16.6.4 Friends And Related Symbol Documentation

16.6.4.1 GetDataForCertGen

```
CertGenData * GetDataForCertGen ( ) [friend]
```

A function to be overridden to pass certificate details to the certificate generator.

The library provides this function as a weak reference. The values returned by this weak reference are likely wrong for any real application and the user should provide their own function. Applicable for both self signed and ACME certificates generated onboard.

Returns

pointer to a [CertGenData](#) struct

The documentation for this class was generated from the following file:

- [acmeRFC8555Servlet.h](#)

16.7 aes_context Struct Reference

AES context structure.

```
#include <aes.h>
```

Public Attributes

- unsigned long [erk](#) [64]
- unsigned long [drk](#) [64]
- int [nr](#)

16.7.1 Detailed Description

AES context structure.

16.7.2 Member Data Documentation

16.7.2.1 drk

unsigned long aes_context::drk[64]
decryption round keys

16.7.2.2 erk

unsigned long aes_context::erk[64]
encryption round keys

16.7.2.3 nr

int aes_context::nr
number of rounds

The documentation for this struct was generated from the following file:

- aes.h

16.8 ARM_MPU_Region_t Struct Reference

```
#include <mpu_armv7.h>
```

Public Attributes

- uint32_t **RBAR**
The region base address register value (RBAR)
- uint32_t **RASR**
The region attribute and size register value (RASR)

16.8.1 Detailed Description

Struct for a single MPU Region

The documentation for this struct was generated from the following file:

- mpu_armv7.h

16.9 BBI2C Class Reference

I2C Peripheral Class.

```
#include <bb_i2c.h>
```

Public Types

- enum [Result_t](#) {
I2C_RES_ACK, I2C_RES_NACK, I2C_RES_ARB_LST, I2C_RES_BUSY,
I2C_RES_ARG, I2C_RES_IN_PROGRESS, I2C_RES_ERR }

Public Member Functions

- [BBI2C](#) (PinIO scl, PinIO sda)
Constructor for the I2C peripheral module.
- void [setup](#) (uint32_t maxBusSpeed)
Setup the I2C peripheral interface.
- void [resetBus](#) ()
Reset the I2C bus.

- void `setNumAddressBytes` (uint8_t numAddressBytes=1)
Specify the register address size for a read or write transaction. A number of bytes, from 0 to 3, can be sent to specify an address up to 24-bit (3 bytes): 0 = none, 1 = 8-bits, 2 = 16-bits, 3 = 24-bits.
- virtual `Result_t writeReg8` (uint8_t devAddr, uint32_t reg, uint8_t data)
Write an 8-bit value to a I2C slave device register.
- virtual `Result_t readReg8` (uint8_t devAddr, uint32_t reg, uint8_t &data)
Read an 8-bit value form an I2C slave device register.
- virtual `Result_t writeRegN` (uint8_t devAddr, uint32_t reg, uint8_t *buf, uint32_t blen)
Write a number of 8-bit values to an I2C slave to the specified register address.
- virtual `Result_t readRegN` (uint8_t devAddr, uint32_t reg, uint8_t *buf, uint32_t blen)
Read a number of 8-bit values from an I2C slave at the specified register address.
- void `SetMaxBusDelay` (uint16_t milliseconds)
Set the maximum duration that the bus is allowed to be in use without being clocked before being forcibly reset.

Friends

- class `WireIntf`

16.9.1 Detailed Description

I2C Peripheral Class.

For I2C communication, you can choose the `WireIntf` class, or the `I2C` class. The `WireIntf` class is simpler to use, while the `I2C` class provides more low level control.

Note that the system automatically instantiates `I2C` and `WireIntf` objects for each of the I2C peripheral modules. The `WireIntf` objects can be accessed with: `Wire`, `Wire1` and `Wire2`. The `I2C` objects can be accesses with `I2C[0]`, `I2C[1]` and `I2C[2]`.

16.9.2 Member Enumeration Documentation

16.9.2.1 Result_t

```
enum BBI2C::Result_t
```

Enumerator

I2C_RES_ACK	Acknowledged.
I2C_RES_NACK	Not acknowledged.
I2C_RES_ARB_LST	Arbitration listening.
I2C_RES_BUSY	Bus is busy.
I2C_RES_ARG	Bad argument.
I2C_RES_IN_PROGRESS	Another transaction is currently in progress.
I2C_RES_ERR	Unknown Error.

16.9.3 Constructor & Destructor Documentation

16.9.3.1 BBI2C()

```
BBI2C::BBI2C (
    PinIO scl,
    PinIO sda )
```

Constructor for the I2C peripheral module.

Parameters

<code>scl</code>	
<code>sda</code>	

16.9.4 Member Function Documentation

16.9.4.1 readReg8()

```
virtual Result_t BBI2C::readReg8 (
    uint8_t devAddr,
    uint32_t reg,
    uint8_t & data ) [virtual]
```

Read an 8-bit value form an I2C slave device register.

Parameters

<i>devAddr</i>	Address of I2C device
<i>reg</i>	Register address to read
<i>data</i>	Reference to variable in which to store the register data

Returns

Result_t

16.9.4.2 readRegN()

```
virtual Result_t BBI2C::readRegN (
    uint8_t devAddr,
    uint32_t reg,
    uint8_t * buf,
    uint32_t blen ) [virtual]
```

Read a number of 8-bit values from an I2C slave at the specified register address.

Parameters

<i>devAddr</i>	Address of I2C device
<i>reg</i>	Register address to read
<i>*buf</i>	Pointer to buffer to store received data
<i>blen</i>	Number of bytes to read

Returns

Result_t

16.9.4.3 SetMaxBusDelay()

```
void BBI2C::SetMaxBusDelay (
    uint16_t milliseconds )
```

Set the maximum duration that the bus is allowed to be in use without being clocked before being forcibly reset.

Parameters

<i>milliseconds</i>	Maximum number of milliseconds before triggering a bus reset
---------------------	--

16.9.4.4 setNumAddressBytes()

```
void BBI2C::setNumAddressBytes (
    uint8_t numAddressBytes = 1 ) [inline]
```

Specify the register address size for a read or write transaction. A number of bytes, from 0 to 3, can be sent to

specify an address up to 24-bit (3 bytes): 0 = none, 1 = 8-bits, 2 = 16-bits, 3 = 24-bits.

If you are using a single I2C device, or all devices use the same address size, this function only needs to be called once. If you have multiple I2C devices with different address/register bit sizes, then this function should be called before each read/write operation for each different device.

Parameters

<i>numAddressBytes</i>	The number of address bytes to send: 0 - 3. The default value is 1 byte.
------------------------	--

16.9.4.5 setup()

```
void BBI2C::setup (
    uint32_t maxBusSpeed )
```

Setup the I2C peripheral interface.

Parameters

<i>maxBusSpeed</i>	Target bus speed. If the specified speed cannot be achieved, a lower bus speed may be enabled.
--------------------	--

16.9.4.6 writeReg8()

```
virtual Result_t BBI2C::writeReg8 (
    uint8_t devAddr,
    uint32_t reg,
    uint8_t data ) [virtual]
```

Write an 8-bit value to a I2C slave device register.

Parameters

<i>devAddr</i>	Address of I2C device
<i>reg</i>	Register address to write
<i>data</i>	Data to write to register

Returns

Result_t

16.9.4.7 writeRegN()

```
virtual Result_t BBI2C::writeRegN (
    uint8_t devAddr,
    uint32_t reg,
    uint8_t * buf,
    uint32_t blen ) [virtual]
```

Write a number of 8-bit values to an I2C slave to the specified register address.

Executing this function will send the following: a start bit, the slave device address and read/write bit, the 8-bit data bytes, and finally a stop bit. Note that the address is not incremented with each 8-bit data value.

Parameters

<i>devAddr</i>	Address of I2C device
<i>reg</i>	Register address to write
<i>*buf</i>	Pointer to buffer containing data to write
<i>blen</i>	Number of bytes to write

Returns

[Result_t](#)

The documentation for this class was generated from the following file:

- [bb_i2c.h](#)

16.10 DHCP::BlockAllocator Class Reference

Basic allocator that handles multiple leases in a contiguous IP block.

```
#include <dhcpd.h>
```

Inherits [DHCP::LeaseAllocator](#).

Inherited by [DHCP::MacPrefixAllocator](#), and [MyModAlloc](#).

16.10.1 Detailed Description

Basic allocator that handles multiple leases in a contiguous IP block.

The documentation for this class was generated from the following file:

- [dhcpd.h](#)

16.11 BuyPassAcmeServletObject Class Reference

ACME Client for BuyPass.

```
#include <acmeRFC8555Servlet.h>
```

Inherits [AcmeServletObject](#).

Public Member Functions

- **BuyPassAcmeServletObject** ()
Enable the BuyPass ACME client.

Public Member Functions inherited from [AcmeServletObject](#)

- void **Delete_Everything_Restart** ()
Re-request the ACME certificate.
- void **SetDiag** (bool v)
Turn on diagnostic printf messages to the console.
- **NBString GetGlobalStateString** ()
Returns the detailed state of the ACME process.
- **NBString GetStateString** ()
Returns the specific state condition of the acmeservlet.
- const char * **GetStateCC** ()
Returns the specific state condition of the acmeservlet.
- **AcmeServletObject** (const char *pUrlDir)
ACME Client Constructor.

16.11.1 Detailed Description

ACME Client for BuyPass.

The documentation for this class was generated from the following file:

- [acmeRFC8555Servlet.h](#)

16.12 CallbackFunctionPageHandler Class Reference

Implements the [HtmlPageHandler](#) class as a function pointer callback for GET requests.

#include <http.h>

Inherits [HtmlPageHandler](#).

Public Member Functions

- virtual int [ProcessRaw](#) (int sock, [HTTP_Request](#) &pdt)
This class will do a callback with data for each request to the specified url.
- [CallbackFunctionPageHandler](#) (const char *pUrl, [http_gethandlerfunc](#) *pFunction, [HTTP_RequestTypes](#) reqType=[tGet](#), int accessGroup=0, bool beforeFiles=false)
Constructor for HTTP GET callback function.
- [CallbackFunctionPageHandler](#) (const char *pUrl, [http_gethandlerfunc](#) *pFunction, [http_matchhandlerfunc](#) *pMatchFunction, [HTTP_RequestTypes](#) reqType=[tGet](#), int accessGroup=0, bool beforeFiles=false)
Constructor for HTTP GET callback function, includes option for function to match the requested name.

Public Member Functions inherited from [HtmlPageHandler](#)

- [HtmlPageHandler](#) (const char *url, [HTTP_RequestTypes](#) rt=[tGet](#), int accessGroup=0, bool BeforeFiles=false)
Register handler.
- int [GetGroup](#) ()
Returns access group setting.

Additional Inherited Members

Protected Member Functions inherited from [HtmlPageHandler](#)

- void [InsertSort](#) ([HtmlPageHandler](#) *&ph)
Insert sort.
- int [SortValue](#) ([HtmlPageHandler](#) *pv)
Returns the value of the sort compare: -1, 0, 1.

Protected Attributes inherited from [HtmlPageHandler](#)

- [HtmlPageHandler](#) * [m_pNextHandler](#)
Pointer to next page handle object.
- const char * [m_pUrlName](#)
Pointer to URL. Performs a length match, an empty string matches everything.
- int [m_access_group](#)
The access group for this request see [CheckHttpAccess](#).
- [HTTP_RequestTypes](#) [m_requestTypes](#)
Type of request, [HTTP_RequestTypes](#).

16.12.1 Detailed Description

Implements the [HtmlPageHandler](#) class as a function pointer callback for GET requests.

16.12.2 Constructor & Destructor Documentation

16.12.2.1 CallbackFunctionPageHandler() [1/2]

```
CallbackFunctionPageHandler::CallbackFunctionPageHandler (
    const char * pUrl,
    http_gethandlerfunc * pFunction,
    HTTP_RequestTypes reqType = tGet,
    int accessGroup = 0,
    bool beforeFiles = false ) [inline]
```

Constructor for HTTP GET callback function.

Parameters

<i>pUrl</i>	Pointer to the URL to intercept from normal system processing
<i>pFunction</i>	Pointer to the function to call for the requested URL
<i>reqType</i>	Optional type of request to intercept, HTTP_RequestTypes . Default is tGet
<i>accessGroup</i>	Optional password group access level. Default is 0 = no password
<i>beforeFiles</i>	Optional parameter to specify a check for just a name, or the name of an actual file in the system. true = intercept before checking for a file of the same name false = check for any files of the requested name before intercepting

16.12.2.2 CallbackFunctionPageHandler() [2/2]

```
CallbackFunctionPageHandler::CallbackFunctionPageHandler (
    const char * pUrl,
    http_gethandlerfunc * pFunction,
    http_matchhandlerfunc * pMatchFunction,
    HTTP_RequestTypes reqType = tGet,
    int accessGroup = 0,
    bool beforeFiles = false ) [inline]
```

Constructor for HTTP GET callback function, includes option for function to match the requested name.

Parameters

<i>pUrl</i>	Pointer to the URL to intercept from normal system processing
<i>pFunction</i>	Pointer to the function to call for the requested URL
<i>pMatchFunction</i>	Pointer to function to perform the match check
<i>reqType</i>	Optional type of request to intercept, HTTP_RequestTypes . Default is tGet
<i>accessGroup</i>	Optional parameter to set a password group access level. Default is 0 = no password.
<i>beforeFiles</i>	Optional parameter to process a file name before checking for a compiled-in file of the same name. Default is false = check for any files of the requested name before intercepting

16.12.3 Member Function Documentation

16.12.3.1 ProcessRaw()

```
virtual int CallbackFunctionPageHandler::ProcessRaw (
    int sock,
    HTTP_Request & pd ) [inline], [virtual]
```

This class will do a callback with data for each request to the specified url.

Returns

0 if the request was not processed.

Implements [HtmlPageHandler](#).

The documentation for this class was generated from the following file:

- [http.h](#)

16.13 CallbackFunctionPostHandler Class Reference

Implements the HtmlPostHandler class as a function pointer callback for POST requests.

```
#include <httppost.h>
```

Inherits HtmlPostHandler.

Public Member Functions

- virtual int [ProcessRaw](#) (int sock, [HTTP_Request](#) &pdt)

This class will do a callback with data for each request to the specified url.

16.13.1 Detailed Description

Implements the HtmlPostHandler class as a function pointer callback for POST requests.

16.13.2 Member Function Documentation

16.13.2.1 ProcessRaw()

```
virtual int CallbackFunctionPostHandler::ProcessRaw (
    int sock,
    HTTP\_Request & pd ) [inline], [virtual]
```

This class will do a callback with data for each request to the specified url.

Returns

0 if the request was not processed.

Implements [HtmlPageHandler](#).

The documentation for this class was generated from the following file:

- [httppost.h](#)

16.14 canMCF5441x::CanRxMessage Class Reference

Class to hold received CAN messages.

```
#include <multican.h>
```

Public Member Functions

- uint8_t [GetLength](#) ()

Returns the amount of data stored in the message.
- uint8_t [GetData](#) (uint8_t *buffer, uint8_t max_len)

Copy the data in the message up to max_len.
- uint32_t [GetId](#) ()

Returns the ID of the message.
- uint16_t [GetTimeStamp](#) ()

Returns the time stamp of the message.
- BOOL [IsValid](#) ()

Check to verify the [CanRxMessage](#) is a valid message.

- [CanRxMessage](#) ([OS_FIFO](#) *pFifo, uint16_t timeout)
Build a [CanRxMessage](#) from a FIFO.
- [CanRxMessage](#) (int moduleNum, uint32_t id, uint16_t timeout)
Constructor that sends out a RTR request to ID and waits for a response.
- [~CanRxMessage](#) ()
Destructor.
- [BOOL](#) [GetNewMessage](#) ([OS_FIFO](#) *pFifo, uint16_t timeout)
Get a new message from the FIFO. If no message is available, wait up to the timeout for one to be received.

16.14.1 Detailed Description

Class to hold received CAN messages.

16.14.2 Constructor & Destructor Documentation

16.14.2.1 CanRxMessage() [1/2]

```
canMCF5441x::CanRxMessage::CanRxMessage (
    OS_FIFO * pFifo,
    uint16_t timeout )
```

Build a [CanRxMessage](#) from a FIFO.

The FIFO must be registered to listen for incoming messages. If no messages are received in the timeout interval, the returned [CanRxMessage](#) will be marked as not valid. A Timeout value of 0 will wait forever.

Parameters

<i>pFifo</i>	Pointer to an OS_FIFO to store the message
<i>timeout</i>	Message timeout in TICKS_PER_SECOND

16.14.2.2 CanRxMessage() [2/2]

```
canMCF5441x::CanRxMessage::CanRxMessage (
    int moduleNum,
    uint32_t id,
    uint16_t timeout )
```

Constructor that sends out a RTR request to ID and waits for a response.

The CAN system uses any unused channel to send and receive the buffer. The constructor can return an invalid message for two reasons:

1. The timeout interval has expired
2. There were no free CAN channels available to send the request

Parameters

<i>moduleNum</i>	CAN module number
<i>id</i>	CAN ID number
<i>timeout</i>	Message timeout in TICKS_PER_SECOND. A value of 0 will wait forever.

16.14.3 Member Function Documentation

16.14.3.1 GetData()

```
uint8_t canMCF5441x::CanRxMessage::GetData (
    uint8_t * buffer,
```

```
uint8_t max_len )
```

Copy the data in the message up to max_len.

Parameters

<i>buffer</i>	Pointer to destination storage buffer
<i>max_len</i>	Maximum number of bytes to copy

Returns

The number of bytes copied

16.14.3.2 GetNewMessage()

```
BOOL canMCF5441x::CanRxMessage::GetNewMessage (
    OS_FIFO * pFifo,
    uint16_t timeout )
```

Get a new message from the FIFO. If no message is available, wait up to the timeout for one to be received.

Parameters

<i>pFifo</i>	Pointer to the OS_FIFO .
<i>timeout</i>	Timeout to wait if no messages are currently available. Value is in TICKS_PER_SECOND, a value of 0 will wait forever.

16.14.3.3 IsValid()

```
BOOL canMCF5441x::CanRxMessage::IsValid ( )
```

Check to verify the [CanRxMessage](#) is a valid message.

Please refer to the [CanRxMessage\(\)](#) constructor for further information on valid messages.

The documentation for this class was generated from the following file:

- [multican.h](#)

16.15 mcanMODM7AE70::CanRxMessage Class Reference

Class to hold received CAN messages.

```
#include <mcan.h>
```

Public Member Functions

- `uint8_t GetLength ()`
Returns the amount of data stored in the message.
- `uint8_t CopyData (uint8_t *buffer, uint8_t max_len)`
Copy the data in the message up to max_len.
- `const uint8_t * GetData ()`
Returns a pointer to the message data.
- `uint32_t GetId ()`
Returns the ID of the message.
- `uint16_t GetTimeStamp ()`
Returns the time stamp of the message.
- `BOOL IsValid ()`
Check to verify the [CanRxMessage](#) is a valid message.
- `CanRxMessage (OS_FIFO *pFifo, uint32_t timeout=WAIT_FOREVER)`

Build a [CanRxMessage](#) from a FIFO.

- `~CanRxMessage ()`

Destructor.

- `BOOL GetNewMessage (OS_FIFO *pFifo, uint32_t timeout=WAIT_FOREVER)`

Get a new message from the FIFO. If no message is available, wait up to the timeout for one to be received.

16.15.1 Detailed Description

Class to hold received CAN messages.

16.15.2 Constructor & Destructor Documentation

16.15.2.1 CanRxMessage()

```
mcanMODM7AE70::CanRxMessage::CanRxMessage (
    OS_FIFO * pFifo,
    uint32_t timeout = WAIT_FOREVER )
```

Build a [CanRxMessage](#) from a FIFO.

The FIFO must be registered to listen for incoming messages. If no messages are received in the timeout interval, the returned [CanRxMessage](#) will be marked as not valid. A Timeout value of 0 will wait forever.

Parameters

<i>pFifo</i>	Pointer to an OS_FIFO to store the message
<i>timeout</i>	Optional message timeout in TICKS_PER_SECOND

16.15.3 Member Function Documentation

16.15.3.1 CopyData()

```
uint8_t mcanMODM7AE70::CanRxMessage::CopyData (
    uint8_t * buffer,
    uint8_t max_len )
```

Copy the data in the message up to max_len.

Parameters

<i>buffer</i>	Pointer to destination storage buffer
<i>max_len</i>	Maximum number of bytes to copy

Returns

The number of bytes copied

16.15.3.2 GetData()

```
const uint8_t * mcanMODM7AE70::CanRxMessage::GetData ( )
```

Returns a pointer to the message data.

Warning

Invalid after destructor is called

16.15.3.3 GetId()

```
uint32_t mcanMODM7AE70::CanRxMessage::GetId ( )
```

Returns the ID of the message.

Returns

The message ID

16.15.3.4 GetLength()

```
uint8_t mcanMODM7AE70::CanRxMessage::GetLength ( )
```

Returns the amount of data stored in the message.

Returns

Length of data stored

16.15.3.5 GetNewMessage()

```
BOOL mcanMODM7AE70::CanRxMessage::GetNewMessage (
    OS_FIFO * pFifo,
    uint32_t timeout = WAIT_FOREVER )
```

Get a new message from the FIFO. If no message is available, wait up to the timeout for one to be received.

Parameters

<i>pFifo</i>	Pointer to the OS_FIFO
<i>timeout</i>	Optional parameter to wait if no messages are currently available. Value is in TICKS_PER_SECOND, a value of 0 will wait forever.

Returns

True on success, otherwise false

16.15.3.6 GetTimeStamp()

```
uint16_t mcanMODM7AE70::CanRxMessage::GetTimeStamp ( )
```

Returns the time stamp of the message.

For timestamp generation the MCAN supplies a 16-bit wrap-around counter. A prescaler TSCC.TCP can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable via MCAN_TSCV.TSC. A write access to the Timestamp Counter Value register (MCAN_TSCV) resets the counter to zero. When the timestamp counter wraps around, interrupt flag MCAN_IR.TSW is set. On start of frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer / Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

The internal/external Timestamp Counter value is captured on start of frame (both Receive and Transmit). When MCAN_TSCC.TSS = 1, the Timestamp Counter is incremented in multiples of CAN bit times [1-16] depending on the configuration of MCAN_TSCC.TCP. A wrap around sets interrupt flag MCAN_IR.TSW. Write access resets the counter to zero.

Returns

Time stamp of the message

16.15.3.7 IsValid()

```
BOOL mcanMODM7AE70::CanRxMessage::IsValid ( )
```

Check to verify the [CanRxMessage](#) is a valid message.

Please refer to the [CanRxMessage\(\)](#) constructor for further information on valid messages.

Returns

True if valid, otherwise false

Object constructor with the parent/owner leaf parameter.
- [config_bool](#) (bool def_val, const char *name, const char *desc=NULL)
Object constructor.
- [operator bool](#) () const
Return the object value.
- [config_bool](#) & [operator=](#) (const bool v)
Assign the [config_bool](#) object value to the specified bool value.
- [config_bool](#) & [operator=](#) (const [config_bool](#) &cb)
Copy one [config_bool](#) object to another.
- [config_bool](#) & [operator=](#) (const int i)
Assign a [config_bool](#) object value to the specified integer value.
- virtual void [GetTypeValue](#) ([NBString](#) &s)
Copy the object type value to the specified [NBString](#) object.

Additional Inherited Members

Protected Member Functions inherited from [config_value](#)

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.18.1 Detailed Description

Boolean Configuration Variable.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.18.2 Constructor & Destructor Documentation

16.18.2.1 [config_bool](#)() [1/2]

```
config_bool::config_bool (
    config\_obj & owner,
    bool def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.

Parameters

<i>owner</i>	Reference to parent leaf
<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.18.2.2 config_bool() [2/2]

```
config_bool::config_bool (
    bool def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.

Parameters

<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description, used for info/tool tips

16.18.3 Member Function Documentation

16.18.3.1 GetTextValue()

```
virtual void config_bool::GetTextValue (
    NBString & s ) [inline], [virtual]
```

Copy the object value as a text string to the specified [NBString](#) object.

Writes either "true" or "false". This is a virtual function that can be overridden in a derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result
----------	--

Implements [config_value](#).

16.18.3.2 GetTypeValue()

```
virtual void config_bool::GetTypeValue (
    NBString & s ) [inline], [virtual]
```

Copy the object type value to the specified [NBString](#) object.

Parameters

<i>s</i>	NBString object to hold the type value string
----------	---

16.18.3.3 operator bool()

```
config_bool::operator bool ( ) const [inline]
```

Return the object value.

Returns

The object value as a bool

Example: for a variable named `configInt` of type [config_double](#):

```
bool boolValue = bool(NV_Settings.m_nvBool);
iprintf("boolValue: %d\r\n", boolValue);
```

16.18.3.4 operator=() [1/3]

```
config_bool & config_bool::operator= (
    const bool v ) [inline]
```

Assign the [config_bool](#) object value to the specified bool value.

Parameters

<i>v</i>	Value of type bool
----------	--------------------

16.18.3.5 operator=() [2/3]

```
config_bool & config_bool::operator= (
    const config_bool & cb ) [inline]
```

Copy one [config_bool](#) object to another.

Parameters

<i>cb</i>	Reference to a config_bool object
-----------	---

16.18.3.6 operator=() [3/3]

```
config_bool & config_bool::operator= (
    const int i ) [inline]
```

Assign a [config_bool](#) object value to the specified integer value.

Parameters

<i>i</i>	Integer value, either 0 (false) or 1 (true)
----------	---

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.19 config_chooser Class Reference

Chooser Configuration Variable - Select From a List of Items.

```
#include <config_obj.h>
```

Inherits [config_obj](#).

Public Member Functions

- [config_chooser](#) ([config_obj](#) &owner, const char *name, const char *in_value, const char *in_choices, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_chooser](#) (const char *name, const char *in_value, const char *in_choices, const char *desc=NULL)
Object constructor.
- bool [IsSelected](#) (const char *choice)
Check if a particular choice option is selected.
- bool [IsSelected](#) (const [NBString](#) &s)
Check if a particular choice option is selected.
- bool [IsInChoices](#) (const char *str, size_t strLen)
Check if a string is in the list of possible choices. A comparison will continue until a null character is found, or the length of the longer of the two strings being compared is reached (strLen is used to determine if str is longer than the current element being compared.)
- bool [IsInChoices](#) (const [NBString](#) &str, size_t strLen)
Check if a string is in the list of possible choices. A comparison will continue until a null character is found, or the length of the longer of the two strings being compared is reached (strLen is used to determine if str is longer than the current element being compared.)
- const [config_string](#) & [GetChoices](#) ()

- Get the list of choices.*

 - `const config_string & SetChoices (const char *in_choices)`

Set the list of choices.

 - `operator NBString () const`

Returns the object value.

 - `config_chooser & operator= (const char *p)`

Assign the selected list item from a const char value.*

 - `config_chooser & operator= (const NBString &s)`

Assign the config_string object value from a NBString object.

 - `config_chooser & operator= (const config_chooser &ci)`

Copy one config_chooser object to another.

 - `virtual void GetTypeValue (NBString &s)`

Assigns the object type value to the specified NBString object.

Public Member Functions inherited from config_obj

- `config_obj (config_obj &owner, const char *name, const char *desc)`
- Object constructor with the parent/owner leaf parameter.*
- `config_obj (const char *name, const char *desc)`
- Object constructor.*
- `virtual void GetTextValue (NBString &s)`
- Get the object value as a text string to the specified NBString object.*

16.19.1 Detailed Description

Chooser Configuration Variable - Select From a List of Items.

The `config_chooser` class provides a list of options with the ability to select one. If used on a web page it would appear as a drop down box. For example, the choices could be "one", "two", or "three", and "two" could be the item selected. Since the items are JSON, the selected item is identified by the option name, not a list index.

Note

All modifications to configuration objects are marked as pending. A call to `SaveConfigToStorage` is required to save changes to flash memory.

16.19.2 Constructor & Destructor Documentation

16.19.2.1 config_chooser() [1/2]

```
config_chooser::config_chooser (
    config_obj & owner,
    const char * name,
    const char * in_value,
    const char * in_choices,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>name</i>	Field name assigned to the value
<i>in_value</i>	The option value selected
<i>in_choices</i>	The list of option choices
<i>desc</i>	Description used for info/tool tip

16.19.2.2 config_chooser() [2/2]

```
config_chooser::config_chooser (
    const char * name,
    const char * in_value,
    const char * in_choices,
    const char * desc = NULL ) [inline]
```

Object constructor.

Parameters

<i>name</i>	Field name assigned to the value
<i>in_value</i>	The option value selected
<i>in_choices</i>	The list of option choices
<i>desc</i>	Description used for info/tool tip

16.19.3 Member Function Documentation**16.19.3.1 GetChoices()**

```
const config_string & config_chooser::GetChoices ( ) [inline]
```

Get the list of choices.

Returns

A [config_string](#) object containing the list of choices

16.19.3.2 GetTypeValue()

```
virtual void config_chooser::GetTypeValue (
    NBString & s ) [inline], [virtual]
```

Assigns the object type value to the specified [NBString](#) object.

The type value "object" is written to the [NBString](#) object.

Parameters

<i>s</i>	NBString object to hold the type value string
----------	---

Reimplemented from [config_obj](#).

16.19.3.3 IsInChoices() [1/2]

```
bool config_chooser::IsInChoices (
    const char * str,
    size_t strLen ) [inline]
```

Check if a string is in the list of possible choices. A comparison will continue until a null character is found, or the length of the longer of the two strings being compared is reached (strLen is used to determine if str is longer than the current element being compared.)

Parameters

<i>str</i>	NBString to attempt to find inside the list of choices
<i>strLen</i>	Length of str. This value is used to determine the amount of characters to compare for each element in the list of choices.

Return values

<i>true</i>	if str is found as an option in list of choices
<i>false</i>	if str is not found in the list of choices

16.19.3.4 IsInChoices() [2/2]

```
bool config_chooser::IsInChoices (
    const NBString & str,
    size_t strLen ) [inline]
```

Check if a string is in the list of possible choices. A comparison will continue until a null character is found, or the length of the longer of the two strings being compared is reached (strLen is used to determine if str is longer than the current element being compared.)

Parameters

<i>str</i>	NBString to attempt to find inside the list of choices
<i>strLen</i>	Length of str. This value is used to determine the amount of characters to compare for each element in the list of choices.

Return values

<i>true</i>	if str is found as an option in list of choices
<i>false</i>	if str is not found in the list of choices

16.19.3.5 IsSelected() [1/2]

```
bool config_chooser::IsSelected (
    const char * choice ) [inline]
```

Check if a particular choice option is selected.

Parameters

<i>choice</i>	Choice to test as a string type
---------------	---------------------------------

Return values

<i>true</i>	Selected
<i>false</i>	Not Selected

16.19.3.6 IsSelected() [2/2]

```
bool config_chooser::IsSelected (
    const NBString & s ) [inline]
```

Check if a particular choice option is selected.

Parameters

<i>s</i>	Choice to test as a NBString type
----------	-----------------------------------

Return values

<i>true</i>	Selected
<i>false</i>	Not Selected

16.19.3.7 operator NBString()

`config_chooser::operator NBString () const [inline]`
Returns the object value.

Returns

The currently selected list option as a [NBString](#)

16.19.3.8 operator=() [1/3]

`config_chooser & config_chooser::operator= (const char * p) [inline]`

Assign the selected list item from a `const char*` value.

Parameters

<i>p</i>	Selected list item to assign
----------	------------------------------

16.19.3.9 operator=() [2/3]

`config_chooser & config_chooser::operator= (const config_chooser & ci) [inline]`

Copy one [config_chooser](#) object to another.

Parameters

<i>ci</i>	Reference to a config_chooser object
-----------	--

16.19.3.10 operator=() [3/3]

`config_chooser & config_chooser::operator= (const NBString & s) [inline]`

Assign the [config_string](#) object value from a [NBString](#) object.

Parameters

<i>s</i>	Reference to a NBString object
----------	--

16.19.3.11 SetChoices()

`const config_string & config_chooser::SetChoices (const char * in_choices) [inline]`

Set the list of choices.

Parameters

<i>in_choices</i>	The list of option choices
-------------------	----------------------------

Returns

A [config_string](#) object containing the list of choices

The documentation for this class was generated from the following file:

Object constructor.

16.20.1 Detailed Description

Double Float Configuration Variable.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.20.2 Constructor & Destructor Documentation

16.20.2.1 `config_double()` [1/2]

```
config_double::config_double (
    config_obj & owner,
    double def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.

Parameters

<i>owner</i>	Reference to parent leaf
<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.20.2.2 `config_double()` [2/2]

```
config_double::config_double (
    double def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.

Parameters

<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.20.3 Member Function Documentation

16.20.3.1 `GetTextValue()`

```
virtual void config_double::GetTextValue (
    NBString & s ) [inline], [virtual]
```

Copy the object value as a text string to the specified [NBString](#) object. This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result
----------	--

Implements [config_value](#).

16.20.3.2 `GetTypeValue()`

```
virtual void config_double::GetTypeValue (
    NBString & s ) [inline], [virtual]
```

Copy the object type value in the specified [NBString](#) object. The type value "float" is written to the [NBString](#) object.

Parameters

<i>s</i>	Reference to a NBString object
----------	--

16.20.3.3 operator double()

```
config_double::operator double ( ) const [inline]
```

Returns the object value as a double float.

Returns

The double float value of the object

Example: for a variable named configInt of type [config_double](#):

```
double value = double(configInt);
iprintf("int = %f\r\n", value);
```

16.20.3.4 operator float()

```
config_double::operator float ( ) const [inline]
```

Return the object value as a float.

Returns

The float value of the object

Example: for a variable named configFloat of type [config_double](#):

```
float value = float(configFloat);
iprintf("int = %f\r\n", value);
```

16.20.3.5 operator int()

```
config_double::operator int ( ) const [inline]
```

Return the object value as an int.

Returns

The integer value of the object

Example: for a variable named configInt of type [config_double](#):

```
int value = int(configInt);
iprintf("int = %d\r\n", value);
```

16.20.3.6 operator=() [1/2]

```
config_double & config_double::operator= (
    const config_double & ci ) [inline]
```

Copy one [config_double](#) object to another.

Parameters

<i>ci</i>	Reference to a config_double object
-----------	---

16.20.3.7 operator=() [2/2]

```
config_double & config_double::operator= (
    const double d ) [inline]
```

Assign the [config_double](#) object value from a double value.

Parameters

<i>d</i>	Value of type double
----------	----------------------

The documentation for this class was generated from the following file:

16.21.1 Detailed Description

Signed 32-bit Integer Configuration Variable.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.21.2 Constructor & Destructor Documentation

16.21.2.1 config_int() [1/2]

```
config_int::config_int (
    config_obj & owner,
    int def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.21.2.2 config_int() [2/2]

```
config_int::config_int (
    int def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.

Parameters

<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.21.3 Member Function Documentation

16.21.3.1 GetTextValue()

```
virtual void config_int::GetTextValue (
    NBString & s ) [inline], [virtual]
```

Copy the object value to the specified [NBString](#) object.

This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result
----------	--

Implements [config_value](#).

16.21.3.2 GetTypeValue()

```
virtual void config_int::GetTypeValue (
    NBString & s ) [inline], [virtual]
```

Copy the object type value in the specified [NBString](#) object.

The type value "integer" is written to the [NBString](#) object.

Parameters

<i>s</i>	Reference to a NBString object
----------	--

16.21.3.3 operator int()

```
config_int::operator int ( ) const [inline]
```

Return the object value as an int.

Returns

The integer value of the object

Example: for a variable named configInt of type [config_int](#):

```
int value = int(configInt);
iprintf("int = %d\r\n", value);
```

16.21.3.4 operator=() [1/2]

```
config_int & config_int::operator= (
    const config_int & ci ) [inline]
```

Copy one [config_int](#) object to another.

Parameters

<i>ci</i>	Reference to a config_int object
-----------	--

16.21.3.5 operator=() [2/2]

```
config_int & config_int::operator= (
    const int i ) [inline]
```

Assign the [config_int](#) object value to the specified int value.

Parameters

<i>i</i>	Integer value
----------	---------------

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.22 config_IPADDR Class Reference

Configuration Variable for IPADDR (IPv6) object type.

```
#include <config_obj.h>
```

Inherits [config_value](#).

Public Member Functions

- virtual void [GetTextValue](#) (NBString &s)

16.22.1 Detailed Description

Configuration Variable for IPADDR (IPv6) object type.

See also

[config_IPADDR4](#)

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.22.2 Constructor & Destructor Documentation

16.22.2.1 config_IPADDR() [1/4]

```
config_IPADDR::config_IPADDR (
    config_obj & owner,
    IPADDR def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.
Default value assigned with an IPADDR object

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type IPADDR
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.22.2.2 config_IPADDR() [2/4]

```
config_IPADDR::config_IPADDR (
    IPADDR def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.
Default value assigned with an IPADDR object

Parameters

<i>def_val</i>	Default value of type NBString
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.22.2.3 config_IPADDR() [3/4]

```
config_IPADDR::config_IPADDR (
    config_obj & owner,
    const char * def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value assigned with an const char * string. IP address is converted using the SetFromAscii() IPADDR member function.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type char * in IPv6 format
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.22.2.4 config_IPADDR() [4/4]

```
config_IPADDR::config_IPADDR (
    const char * def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.

Default value assigned with an const char * string. IP address is converted using the SetFromAscii() IPADDR member function.

Parameters

<i>def_val</i>	Default value of type char * in IPv6 format
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.22.3 Member Function Documentation**16.22.3.1 GetTextValue()**

```
virtual void config_IPADDR::GetTextValue (
    NBString & s ) [inline], [virtual]
```

Get the object value as a text string with quotations to the specified NBString object.

This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result
----------	--

Implements [config_value](#).

16.22.3.2 GetTypeValue()

```
virtual void config_IPADDR::GetTypeValue (
    NBString & s ) [inline], [virtual]
```

Copy the object type value to the specified NBString object.

The type value "string" is written to the NBString object.

Parameters

<i>s</i>	NBString object to hold the type value string
----------	---

16.22.3.3 IsNull()

```
bool config_IPADDR::IsNull ( ) const [inline]
```

Check if the IP address is null.

Return values

<i>true</i>	if the IP address value is null
-------------	---------------------------------

See also

[NotNull\(\)](#)

16.22.3.4 NotNull()

```
bool config_IPADDR::NotNull ( ) const [inline]
```

Check if the IP address is not null.

Return values

<i>true</i>	if the IP address value is not null
-------------	-------------------------------------

See also

[IsNull\(\)](#)

16.22.3.5 operator IPADDR()

```
config_IPADDR::operator IPADDR ( ) const [inline]
```

Returns the object value.

Returns

The value of the object as an IPADDR object

16.22.3.6 operator=() [1/2]

```
config_IPADDR & config_IPADDR::operator= (
    const config_IPADDR & ci ) [inline]
```

Copy one [config_IPADDR](#) object to another.

Parameters

<i>ci</i>	Reference to a config_IPADDR object
-----------	---

16.22.3.7 operator=() [2/2]

```
config_IPADDR & config_IPADDR::operator= (
    const IPADDR & i6 ) [inline]
```

Copy an IPADDR object value to a [config_IPADDR](#) object.

Parameters

<i>i6</i>	Reference to an IPADDR object
-----------	-------------------------------

The documentation for this class was generated from the following file:

16.23.1 Detailed Description

Configuration Variable for [IPADDR4](#) (IPv4) object types.

See also

[config_IPADDR](#)

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.23.2 Constructor & Destructor Documentation

16.23.2.1 config_IPADDR4() [1/4]

```
config_IPADDR4::config_IPADDR4 (
    config_obj & owner,
    IPADDR4 def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value assigned with an [IPADDR4](#) object

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type IPADDR4
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.23.2.2 config_IPADDR4() [2/4]

```
config_IPADDR4::config_IPADDR4 (
    IPADDR4 def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.

Default value assigned with an [IPADDR4](#) object

Parameters

<i>def_val</i>	Default value of type NBString
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.23.2.3 config_IPADDR4() [3/4]

```
config_IPADDR4::config_IPADDR4 (
    config_obj & owner,
    const char * def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value assigned with an const char * string. IP address is converted using the [IPADDR4](#) [SetFromAscii\(\)](#) member function.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type char *. Format is: "xxx.xxx.xxx.xxx". For example, "10.1.1.100"
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.23.2.4 config_IPADDR4() [4/4]

```
config_IPADDR4::config_IPADDR4 (
    const char * def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.

Default value assigned with an const char * string. IP address is converted using the [IPADDR4 SetFromAscii\(\)](#) member function.

Parameters

<i>def_val</i>	Default value of type char *. Format is: "xxx.xxx.xxx.xxx". For example, "10.1.1.100"
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.23.3 Member Function Documentation**16.23.3.1 GetTextValue()**

```
virtual void config_IPADDR4::GetTextValue (
    NBString & s ) [inline], [virtual]
```

Get the object value as a text string with quotations to the specified [NBString](#) object.

The format of the string is: "xxx.xxx.xxx.xxx". This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result
----------	--

Implements [config_value](#).

16.23.3.2 GetTypeValue()

```
virtual void config_IPADDR4::GetTypeValue (
    NBString & s ) [inline], [virtual]
```

Copy the object type value to the specified [NBString](#) object.

The type value "string" is written to the [NBString](#) object.

Parameters

<i>s</i>	NBString object to hold the type value string
----------	---

16.23.3.3 IsNull()

```
bool config_IPADDR4::IsNull ( ) const [inline]
```

Check if the IP address is null.

Return values

<code>true</code>	if the IP address value is null
-------------------	---------------------------------

See also

[NotNull\(\)](#), [SetNull\(\)](#)**16.23.3.4 NotNull()**

```
bool config_IPADDR4::NotNull ( ) const [inline]
```

Check if the IP address is not null.

Return values

<code>true</code>	if the IP address value is not null
-------------------	-------------------------------------

See also

[IsNull\(\)](#), [SetNull\(\)](#)**16.23.3.5 operator IPADDR4()**

```
config_IPADDR4::operator IPADDR4 ( ) const [inline]
```

Returns the object value.

Returns

The value of the object as an [IPADDR4](#)

16.23.3.6 operator=() [1/2]

```
config_IPADDR4 & config_IPADDR4::operator= (
    const config_IPADDR4 & ci ) [inline]
```

Copy one [config_IPADDR4](#) object to another.

Parameters

<code>ci</code>	Reference to a config_IPADDR4 object
-----------------	--

16.23.3.7 operator=() [2/2]

```
config_IPADDR4 & config_IPADDR4::operator= (
    const IPADDR4 & i4 ) [inline]
```

Copy an [IPADDR4](#) object value to a [config_IPADDR4](#) object.

Parameters

<code>i4</code>	Reference to an IPADDR4 object
-----------------	--

16.23.3.8 SetNull()

```
void config_IPADDR4::SetNull ( ) [inline]
```

Set the IP address to null.

See also

 - Object constructor.

16.24.1 Detailed Description

Configure device network name.

16.24.2 Constructor & Destructor Documentation

16.24.2.1 `config_localname()` [1/4]

```
config_localname::config_localname (
    config_obj & owner,
    NBString def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.
Default value is assigned with a `NBString`

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type <code>NBString</code>
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.24.2.2 `config_localname()` [2/4]

```
config_localname::config_localname (
    NBString def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.
Default value is assigned with a `NBString`

Parameters

<i>def_val</i>	Default value of type <code>NBString</code>
----------------	---

Parameters

<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.24.2.3 config_localname() [3/4]

```
config_localname::config_localname (
    config_obj & owner,
    const char * def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.
Default value is assigned with a character string

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type char *
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.24.2.4 config_localname() [4/4]

```
config_localname::config_localname (
    const char * def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.
Default value is assigned with a character string

Parameters

<i>def_val</i>	Default value of type char *
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.24.3 Member Function Documentation**16.24.3.1 operator NBString()**

```
config_localname::operator NBString ( ) const [inline]
```

Returns the object value.

Returns

The value of the object as a [NBString](#)

16.24.3.2 operator=() [1/4]

```
config_localname & config_localname::operator= (
    const char * p ) [inline]
```

Assign the [config_localname](#) object value from a const char* value.

Parameters

<i>p</i>	String to assign
----------	------------------

16.24.3.3 operator=() [2/4]

```
config_localname & config_localname::operator= (
    const config_localname & ci ) [inline]
```

Copy one [config_localname](#) object to another.

Parameters

<i>ci</i>	Reference to a config_localname object
-----------	--

16.24.3.4 operator=() [3/4]

```
config_localname & config_localname::operator= (
    const config_string & ci ) [inline]
```

Copy a [config_string](#) object to a [config_localname](#) object.

Parameters

<i>ci</i>	Reference to a config_string object
-----------	---

16.24.3.5 operator=() [4/4]

```
config_localname & config_localname::operator= (
    const NBString & s ) [inline]
```

Assign the [config_localname](#) object value from a [NBString](#) object.

Parameters

<i>s</i>	Reference to a NBString object
----------	--

The documentation for this class was generated from the following file:

Object constructor.

16.25.1 Detailed Description

Configuration Variable for [MACADR](#) object type.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.25.2 Constructor & Destructor Documentation

16.25.2.1 [config_MACADR](#)() [1/4]

```
config_MACADR::config_MACADR (
    config_obj & owner,
    MACADR def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value assigned with an [MACADR](#) object

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type MACADR
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.25.2.2 [config_MACADR](#)() [2/4]

```
config_MACADR::config_MACADR (
    MACADR def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.

Default value assigned with an [MACADR](#) object

Parameters

<i>def_val</i>	Default value of type MACADR
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.25.2.3 config_MACADR() [3/4]

```
config_MACADR::config_MACADR (
    config_obj & owner,
    const char * def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value is assigned with a `const char * string`. The `AsciiToMac()` function is used to convert the string to a [MACADR](#).

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default MAC Address value of type <code>char *</code> . The hexidical format must be 6 octets, with or without ':' separators. For example, "0123456789AB", or "01:23:45:67:89:AB"
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.25.2.4 config_MACADR() [4/4]

```
config_MACADR::config_MACADR (
    const char * def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.

Default value is assigned with a `const char * string`. The `AsciiToMac()` function is used to convert the string to a [MACADR](#).

Parameters

<i>def_val</i>	Default MAC Address value of type <code>char *</code> . The hexidical format must be 6 octets, with or without ':' separators. For example, "0123456789AB", or "01:23:45:67:89:AB"
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.25.3 Member Function Documentation

16.25.3.1 GetTextValue()

```
virtual void config_MACADR::GetTextValue (
    NBString & s ) [inline], [virtual]
```

Get the object value as a text string with quotations to the specified [NBString](#) object.

The format is the hexadecimal address: "xx:xx:xx:xx:xx:xx" This is a virtual function that can be overridden in any derived class.

Parameters

<code>s</code>	Reference to a NBString object to store the result
----------------	--

Implements [config_value](#).

16.25.3.2 GetTypeValue()

```
virtual void config_MACADR::GetTypeValue (
    NBString & s ) [inline], [virtual]
```

Copy the object type value to the specified [NBString](#) object. The type value "string" is written to the [NBString](#) object.

Parameters

<code>s</code>	NBString object to hold the type value string
----------------	---

16.25.3.3 operator MACADR()

```
config_MACADR::operator MACADR ( ) const [inline]
```

Returns the object value.

Returns

The value of the object as a [MACADR](#)

16.25.3.4 operator=() [1/2]

```
config_MACADR & config_MACADR::operator= (
    const config_MACADR & ci ) [inline]
```

Copy one [config_MACADR](#) object to another.

Parameters

<code>ci</code>	Reference to a config_IPADDR object
-----------------	---

16.25.3.5 operator=() [2/2]

```
config_MACADR & config_MACADR::operator= (
    const MACADR & ci ) [inline]
```

Copy a [MACADR](#) object value to a [MACADR](#) object.

Parameters

<code>ci</code>	Reference to an MACADR object
-----------------	---

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.26 config_obj Class Reference

Base class used to create configuration objects.

```
#include <config_obj.h>
```

Inherits [config_leaf](#).

Inherited by AcmeObject, [CertData](#), ControlSet, EmailNotify, [I4Record](#), [I6Record](#), [InterfaceBlock](#), LLDPEntity, MonitorRecord, NV_OneI2CPortSetting, NV_OnePortSetting, [NV_SettingsStruct](#), OneConfigRecord, PIDSet, SysRecord, TempRange, TempRange, TempRange, ThermoGroup, Thermostat1, cfg_class_slot, cfg_class_slots, [config_chooser](#), config_preserver_obj, config_uart, detached_root_obj, empty_config_obj, and root_obj.

Public Member Functions

- [config_obj](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_obj](#) (const char *name, const char *desc)
Object constructor.
- virtual void [GetTextValue](#) ([NBString](#) &s)
Get the object value as a text string to the specified [NBString](#) object.
- virtual void [GetTypeValue](#) ([NBString](#) &s)
Assigns the object type value to the specified [NBString](#) object.

16.26.1 Detailed Description

Base class used to create configuration objects.

Base that can be used to create your own custom configuration objects in a JSON compatible format. The object can hold any number of JSON compatible types: integer, boolean, null, string, object or array.

A [config_obj](#) can hold multiple values in a JSON object. A [config_value](#) holds only a single JSON value.

See also

[config_value](#)

The example below demonstrates how to create a thermostat object with a temperature range derived from a [config_obj](#):

Note

Please check the Configuration Class example in the `\nburn\examples` folder for the latest code updates.

The use of config objects should be done at a global scope. They can contain any number of members, which should be given a `default` value and a name used as an identifier. The name value for each member variable should be unique, otherwise it can lead to issues inside the config tree.

```
class TempRange : public config_obj
{
public:
    // Class variables
    config_int m_maxTemp{100, "MaxTemp"};
    config_int m_setTemp{30, "SetTemp"};
    config_int m_minTemp{10, "MinTemp"};
    ConfigEndMarker; // No new data members below this line

    // Class constructors
    TempRange(const char *name, const char *desc = nullptr) : config_obj(name, desc){};
    TempRange(config_obj &owner, const char *name, const char *desc = nullptr) : config_obj(owner, name,
        desc){};
};

class Thermostat : public TempRange
{
public:
    config_int m_tempRec1{101, "TempRecord_1"};
    config_int m_tempRec2{102, "TempRecord_2"};
    config_bool m_active{true, "Active"};
    config_string m_location{"Warehouse 1", "Thermostat Location"};
    config_chooser m_tempScale{"Temperature Scale", "Fahrenheit", "Fahrenheit,Celsius,Kelvin"};
    ConfigEndMarker; // No new data members below this line

    Thermostat(const char *name, const char *desc = nullptr) : TempRange(name, desc){};
    Thermostat(config_obj &owner, const char *name, const char *desc = nullptr) : TempRange(owner, name,
        desc){};
};

static Thermostat thermo(appdata, "Thermostat", "The primary thermostat");
```

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.26.2 Constructor & Destructor Documentation

16.26.2.1 config_obj() [1/2]

```
config_obj::config_obj (
    config_obj & owner,
    const char * name,
    const char * desc ) [inline]
```

Object constructor with the parent/owner leaf parameter.

For example,

```
myObject(config_obj &owner, const char *name, const char *desc = nullptr) : config_obj(owner, name, desc){};
```

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>name</i>	Field name
<i>desc</i>	Description used for info/tool tip

16.26.2.2 config_obj() [2/2]

```
config_obj::config_obj (
    const char * name,
    const char * desc ) [inline]
```

Object constructor.

This constructor should be called as part of the derived class constructor. For example,

```
myObject(const char *name, const char *desc = nullptr) : config_obj(name, desc){}
```

Parameters

<i>name</i>	Field name
<i>desc</i>	Description used for info/tool tip

16.26.3 Member Function Documentation

16.26.3.1 GetTextValue()

```
virtual void config_obj::GetTextValue (
    NBString & s ) [virtual]
```

Get the object value as a text string to the specified [NBString](#) object.

This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result
----------	--

16.26.3.2 GetTypeValue()

```
virtual void config_obj::GetTypeValue (
    NBString & s ) [inline], [virtual]
```

Assigns the object type value to the specified [NBString](#) object.

The type value "object" is written to the [NBString](#) object.

Parameters

<i>s</i>	NBString object to hold the type value string
----------	---

Reimplemented in [config_chooser](#).

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.27 config_pass Class Reference

Password string Configuration Variable.

```
#include <config_obj.h>
```

Inherits [config_string](#).

- Object constructor.

16.27.1 Detailed Description

Password string Configuration Variable.

A `config_pass` is like a `config_string`, but the data is hidden by '*' characters.

Note

All modifications to configuration objects are marked as pending. A call to `SaveConfigToStorage` is required to save changes to flash memory.

16.27.2 Constructor & Destructor Documentation

16.27.2.1 `config_pass()` [1/4]

```
config_pass::config_pass (
    config_obj & owner,
    NBString def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value is assigned with a `NBString`

Parameters

<code>owner</code>	Reference to owner/parent leaf
<code>def_val</code>	Default value of type <code>NBString</code>
<code>name</code>	Field name assigned to the value
<code>desc</code>	Description used for info/tool tip

16.27.2.2 `config_pass()` [2/4]

```
config_pass::config_pass (
    NBString def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.

Default value is assigned with a [NBString](#)

Parameters

<i>def_val</i>	Default value of type NBString
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.27.2.3 config_pass() [3/4]

```
config_pass::config_pass (
    config_obj & owner,
    const char * def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value is assigned with a character string

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type char *
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.27.2.4 config_pass() [4/4]

```
config_pass::config_pass (
    const char * def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.

Default value is assigned with a character string

Parameters

<i>def_val</i>	Default value of type char *
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.27.3 Member Function Documentation

16.27.3.1 GetRawValue()

```
virtual void config_pass::GetRawValue (
    NBString & s ) [virtual]
```

Copy the raw [config_string](#) object value to the [NBString](#) object.

Parameters

<i>s</i>	Reference to a NBString object
----------	--

This is a virtual function that can be overridden in any derived class.

16.27.3.2 GetTextValue()

```
virtual void config_pass::GetTextValue (
    NBString & s ) [virtual]
```

Get the `config_pass` object value as a text string.

This is a virtual function that can be overridden in any derived class.

Parameters

<code>s</code>	Reference to a <code>NBString</code> object to store the result
----------------	---

Reimplemented from `config_string`.

16.27.3.3 operator NBString()

```
config_pass::operator NBString ( ) const [inline]
```

Returns the object value.

Returns

The value of the object as a `NBString`

16.27.3.4 operator=() [1/4]

```
config_pass & config_pass::operator= (
    const char * p ) [inline]
```

Assign the `config_pass` object value from a `const char*` value.

Parameters

<code>p</code>	String to assign
----------------	------------------

16.27.3.5 operator=() [2/4]

```
config_pass & config_pass::operator= (
    const config_pass & ci ) [inline]
```

Copy one `config_pass` object to another.

Parameters

<code>ci</code>	Reference to a <code>config_pass</code> object
-----------------	--

16.27.3.6 operator=() [3/4]

```
config_pass & config_pass::operator= (
    const config_string & ci ) [inline]
```

Copy a `config_string` object to a `config_pass` object.

Parameters

<code>ci</code>	Reference to a <code>config_string</code> object
-----------------	--

16.27.3.7 operator=() [4/4]

```
config_pass & config_pass::operator= (
    const NBString & s ) [inline]
```

Assign the [config_pass](#) object value from a [NBString](#) object.

Parameters

s	Reference to a NBString object
---	--

The documentation for this class was generated from the following file:

    const char * def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.
Default value assigned with a character string

Parameters

<i>def_val</i>	Default value of type char *
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.28.3 Member Function Documentation**16.28.3.1 c_str()**

```
const char * config_string::c_str ( ) const [inline]
```

Returns the object value as a string.

Returns

String value of object

16.28.3.2 GetTextValue()

```
virtual void config_string::GetTextValue (
    NBString & s ) [virtual]
```

Get the object value (as a text string with quotations) to the specified [NBString](#) object.
This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result
----------	--

Implements [config_value](#).

Reimplemented in [config_pass](#).

16.28.3.3 GetTypeValue()

```
virtual void config_string::GetTypeValue (
    NBString & s ) [inline], [virtual]
```

Copy the object type value to the specified [NBString](#) object. The type value "string" is written to the [NBString](#) object.

Parameters

<code>s</code>	NBString object to hold the type value string
----------------	---

Reimplemented in [config_time_t](#).

16.28.3.4 length()

```
size_t config_string::length ( ) const [inline]
```

Returns the string length in bytes.

Returns

String length

16.28.3.5 operator NBString()

```
config_string::operator NBString ( ) const [inline]
```

Return the object value.

Returns

The value of the object as a [NBString](#)

16.28.3.6 operator=() [1/3]

```
config_string & config_string::operator= (
    const char * p ) [inline]
```

Assign the [config_string](#) object value from a const char* string.

Parameters

<code>p</code>	String to assign
----------------	------------------

16.28.3.7 operator=() [2/3]

```
config_string & config_string::operator= (
    const config_string & ci ) [inline]
```

Copy one [config_string](#) object to another.

Parameters

<code>ci</code>	Reference to a config_string object
-----------------	---

16.28.3.8 operator=() [3/3]

```
config_string & config_string::operator= (
```

```
const NBString & s ) [inline]
```

Assign the `config_string` object value from a `NBString` object.

Parameters

<code>s</code>	Reference to a <code>NBString</code> object
----------------	---

16.28.3.9 operator[]()

```
const char & config_string::operator[] (
    size_t pos ) const [inline]
```

Return the value of a character in the string.

Parameters

<code>pos</code>	Character index/position in the string
------------------	--

Returns

Character value at the specified index

16.28.3.10 SetEnumList()

```
void config_string::SetEnumList (
    NBString s ) [inline]
```

Renders the data used to explain the schema/descriptions for the list of choices.

Parameters

<code>s</code>	Enumerated list that is a string with choices separated by commas (',') with no spaces. For example, "one,two,three"
----------------	--

The documentation for this class was generated from the following file:

- size_t [length](#) () const
 - Returns the string length in bytes.*
- const char & [operator\[\]](#) (size_t pos) const
 - Return the value of a character in the string.*

Static Public Member Functions

- static [NBString](#) **TimeToNBString** (time_t tv, bool bUtc=true)
- static time_t **ParseTime** (const char *cp, bool bUtc=true)
- static time_t **ParseTime** ([NBString](#) &ns, bool bUtc=true)

Additional Inherited Members**Protected Member Functions inherited from [config_value](#)**

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.29.1 Detailed Description

Class to hold time configuration.

16.29.2 Constructor & Destructor Documentation**16.29.2.1 config_time_t() [1/4]**

```
config_time_t::config_time_t (
    config_obj & owner,
    time_t def_val,
    const char * name,
    const char * desc = NULL,
    bool bUserSeesGmt = false ) [inline]
```

Object constructor with the parent/owner leaf parameter.
Default value assigned with a time_t

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type time_t
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip
<i>bUserSeesGmt</i>	If true, the user sees GMT time when displaying/reading time values. If false, localtime is used.

16.29.2.2 config_time_t() [2/4]

```
config_time_t::config_time_t (
    config_obj & owner,
    const char * def_val,
    const char * name,
    const char * desc = NULL,
    bool bUserSeesGmt = false ) [inline]
```

Object constructor with the parent/owner leaf parameter.
Default value assigned with a time_t

Parameters

<i>owner</i>	Reference to owner/parent leaf
--------------	--------------------------------

Parameters

<i>def_val</i>	Default value of type <code>time_t</code>
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip
<i>bUserSeesGmt</i>	If true, the user sees GMT time when displaying/reading time values. If false, localtime is used.

16.29.2.3 config_time_t() [3/4]

```
config_time_t::config_time_t (
    const char * def_val,
    const char * name,
    const char * desc = NULL,
    bool bUserSeesGmt = false ) [inline]
```

Object constructor.

Default value assigned with a `time_t`

Parameters

<i>def_val</i>	Default value of type <code>time_t</code>
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip
<i>bUserSeesGmt</i>	If true, the user sees GMT time when displaying/reading time values. If false, localtime is used.

16.29.2.4 config_time_t() [4/4]

```
config_time_t::config_time_t (
    time_t def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.

Parameters

<i>def_val</i>	Default value of type <code>time_t</code>
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.29.3 Member Function Documentation**16.29.3.1 operator time_t()**

```
config_time_t::operator time_t ( ) const [inline]
```

Return the object value

Returns

The value of the object as a `time_t`

16.29.3.2 operator=() [1/2]

```
config_time_t & config_time_t::operator= (
    const config_time_t & ci ) [inline]
```

Copy one `config_string` object to another.

Parameters

<i>ci</i>	Reference to a config_string object
-----------	---

16.29.3.3 operator=() [2/2]

```
config_time_t & config_time_t::operator= (
    time_t t ) [inline]
```

Assign the [config_time_t](#) object value from a anotherNBString object.

Parameters

<i>t</i>	time↔ _t
----------	-------------

The documentation for this class was generated from the following file:

- [config_time.h](#)

16.30 config_uint Class Reference

Unsigned 32-bit Integer Configuration Variable.

```
#include <config_obj.h>
```

Inherits [config_value](#).

Inherited by [config_hex_uint](#).

Public Member Functions

- virtual void [GetTextValue](#) (NBString &s)
Copy the object value to the specified NBString object.
- [config_uint](#) (config_obj &owner, uint32_t def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_uint](#) (uint32_t def_val, const char *name, const char *desc=NULL)
Object constructor.
- [operator uint32_t](#) () const
Return the object value.
- [config_uint](#) & [operator=](#) (const uint32_t i)
Assign the config_uint object value from a uint32_t value.
- [config_uint](#) & [operator=](#) (const [config_uint](#) &ci)
Copy one config_uint object to another.
- virtual void [GetTypeValue](#) (NBString &s)
Copy the object type value to the specified NBString object.

Additional Inherited Members**Protected Member Functions inherited from [config_value](#)**

- [config_value](#) (config_obj &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.30.1 Detailed Description

Unsigned 32-bit Integer Configuration Variable.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.30.2 Constructor & Destructor Documentation

16.30.2.1 config_uint() [1/2]

```
config_uint::config_uint (
    config_obj & owner,
    uint32_t def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor with the parent/owner leaf parameter.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.30.2.2 config_uint() [2/2]

```
config_uint::config_uint (
    uint32_t def_val,
    const char * name,
    const char * desc = NULL ) [inline]
```

Object constructor.

Parameters

<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.30.3 Member Function Documentation

16.30.3.1 GetTextValue()

```
virtual void config_uint::GetTextValue (
    NBString & s ) [inline], [virtual]
```

Copy the object value to the specified [NBString](#) object.

This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result
----------	--

Implements [config_value](#).

16.30.3.2 GetTypeValue()

```
virtual void config_uint::GetTypeValue (
    NBString & s ) [inline], [virtual]
```

Copy the object type value to the specified [NBString](#) object. The type value "integer" is written to the [NBString](#) object.

Parameters

<i>s</i>	NBString object to hold the type value string
----------	---

16.30.3.3 operator uint32_t()

```
config_uint::operator uint32_t ( ) const [inline]
```

Return the object value.

Returns

The value of the object as a `uint32_t`

Example: for a variable named `configuint` of type [config_uint](#):

```
uint32_t value = uint32_t(configuint);
iprintf("int = %ld\r\n", value);
```

16.30.3.4 operator=() [1/2]

```
config_uint & config_uint::operator= (
    const config_uint & ci ) [inline]
```

Copy one [config_uint](#) object to another.

Parameters

<i>ci</i>	Reference to a config_uint object
-----------	---

16.30.3.5 operator=() [2/2]

```
config_uint & config_uint::operator= (
    const uint32_t i ) [inline]
```

Assign the [config_uint](#) object value from a `uint32_t` value.

Parameters

<i>i</i>	<code>uint32_t</code> value
----------	-----------------------------

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.31 config_value Class Reference

Base class used to create a configuration value.

```
#include <config_obj.h>
```

Inherits [config_leaf](#).

Inherited by [CUR_IPADDR4](#), [Dynamic_IPADDR](#), [config_IPADDR](#), [config_IPADDR4](#), [config_MACADR](#), [config_bool](#), [config_double](#), [config_int](#), [config_report](#), [config_string](#), and [config_uint](#).

Protected Member Functions

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.31.1 Detailed Description

Base class used to create a configuration value.

Base class that can be used to create custom configuration values in a JSON compatible format. The JSON compatible types are: integer, boolean, null, string, object or array.

The system already provides the common JSON value types, including: [config_int](#), [config_uint](#), [config_bool](#), [config_chooser](#), [config_string](#), [config_pass](#), [config_IPADDR4](#), [config_IPADDR](#), [config_MACADR](#),
A [config_obj](#) can hold multiple values in a JSON object. A [config_value](#) holds only a single JSON value.

See also

[config_obj](#)

16.31.2 Constructor & Destructor Documentation

16.31.2.1 config_value() [1/2]

```
config_value::config_value (
    config_obj & owner,
    const char * name,
    const char * desc ) [inline], [protected]
```

Object constructor with the parent/owner leaf parameter.

For example,

```
myValue(config\_obj &owner, const char *name, const char *desc = nullptr) : config\_value(owner, name, desc){};
```

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>name</i>	Field name
<i>desc</i>	Description used for info/tool tip

16.31.2.2 config_value() [2/2]

```
config_value::config_value (
    const char * name,
    const char * desc ) [inline], [protected]
```

Object constructor.

This constructor should be called as part of the derived class constructor. For example,

```
myValue(const char *name, const char *desc = nullptr) : config\_value(name, desc){}
```

Parameters

<i>name</i>	Field name
<i>desc</i>	Description used for info/tool tip

16.33 DelayObject Class Reference

Microsecond Delay Class.

```
#include <HiResDelay.h>
```

Public Member Functions

- [DelayObject](#) (int Timer=[FIRST_UNUSED_TIMER](#))
Microsecond Delay Timer Constructor.
- void [DelayUsec](#) (uint32_t usec)
Microsecond Delay Timer.
- bool [valid](#) ()
Verify a valid delay object was constructed.

16.33.1 Detailed Description

Microsecond Delay Class.

Creates a high resolution microsecond timer object by allocating one a free processor system timer. Once the delay has expired, the system timer is released back to the free pool.

Example Usage:

```
static DelayObject myHiResDelay;    // Create the object
myHiResDelay.DelayUsec(100);       // Delay 100 us
myHiResDelay.DelayUsec(200);       // Delay 200 us
myHiResDelay.DelayUsec(300);       // Delay 300 us
```

See also

[Interval Timer](#)

16.33.2 Constructor & Destructor Documentation

16.33.2.1 DelayObject()

```
DelayObject::DelayObject (
    int Timer = FIRST_UNUSED_TIMER )
```

Microsecond Delay Timer Constructor.

Parameters

<i>Timer</i>	Optional parameter to select a specific time. Recommend use is the to not specify a timer so the first free timer will be used.
--------------	---

16.33.3 Member Function Documentation

16.33.3.1 DelayUsec()

```
void DelayObject::DelayUsec (
    uint32_t usec )
```

Microsecond Delay Timer.

Parameters

<i>usec</i>	The number of microseconds to delay
-------------	-------------------------------------

16.33.3.2 valid()

```
bool DelayObject::valid ( ) [inline]
```

Verify a valid delay object was constructed.

Return values

<i>True</i>	- A timer was correctly allocated and initialized
<i>False</i>	- No free timers were available

16.34 DHCP::DhcpInfo Struct Reference

DHCP Info.

```
#include <dhcpcd.h>
```

Public Attributes

- **IPADDR4 netmask**
Netmask for the lease offered.
- **IPADDR4 gateway**
gateway to be offered
- **IPADDR4 dns_1**
primary DNS Server
- **IPADDR4 dns_2**
secondary DNS Server
- **IPADDR4 logServ**
Syslog Server.
- **IPADDR4 smtpServ**
SMTP Server.
- **IPADDR4 ntpServ**
NTP Server.
- const char * **domain_name**
Domain name for hosts.
- char * **hostname**
Hostname.
- char * **tftp_name**
tftp server name/dotted ip, null terminated
- char * **bootfile**
tftp boot file, null terminated
- uint16_t **bonusLength**
Length of any additional options, pre written.
- uint8_t * **bonusOpts**
additional options, pre written

[DHCP](#) client class.

```
#include <dhcpcclient.h>
```

Inherits [TimeOutElement](#).

Public Member Functions

- void [StartDHCP](#) ()
Manually start the [DHCP](#) Client.
- void [StopDHCP](#) ()
Manually stop the [DHCP](#) client and release the [DHCP](#) lease.
- void [RestartDHCP](#) ()
Manually stop are resetart the [DHCP](#) client.
- bool [bDoFallBack](#) ()
Returns true if a [DHCP](#) fallback event has occurred.
- void [RenewDHCP](#) ()
Manually force a [DHCP](#) renew of a lease.
- void [RebindDHCP](#) ()
Manually force a [DHCP](#) rebind of a lease.
- **BOOL** [ValidDhcpLease](#) ()
Returns the status of a [DHCP](#) lease.
- **uint32_t** [GetRemainingDhcpLeaseTime](#) ()

- Returns number of seconds remaining for current lease.*

 - uint32_t [GetDhcpRenewTime](#) ()

Returns number of seconds remaining before the lease will be renewed.

 - uint32_t [GetDhcpRebindTime](#) ()

Returns number of seconds remaining before the current lease will have to rebind.

 - uint32_t [GetDhcpExpirationTime](#) ()

Returns number of seconds remaining before the current lease will expire.

 - int32_t [GetDHCPState](#) ()

*Returns current state of the **DHCP** lease.*

16.37.1 Detailed Description

DHCP client class.

16.37.2 Member Function Documentation

16.37.2.1 bDoFallback()

```
bool DhcpObject::bDoFallback ( )
```

Returns true if a **DHCP** fallback event has occurred.

The [init\(\)](#) function called at the beginning of an application will handle **DHCP** client services for all network interfaces. It is rare that you would need to call these functions manually.

If the fallback functionality has been enabled in the device configuration, this function can be used to determine if a fallback to a static IP settings has occurred.

Returns

True if a fallback condition has occurred.

16.37.2.2 GetDhcpExpirationTime()

```
uint32_t DhcpObject::GetDhcpExpirationTime ( ) [inline]
```

Returns number of seconds remaining before the current lease will expire.

Returns

The number of seconds remaining before the current lease will expire.

See also

[GetRemainingDhcpLeaseTime\(\)](#), [GetDhcpRenewTime\(\)](#), [GetDhcpRebindTime\(\)](#)

16.37.2.3 GetDhcpRebindTime()

```
uint32_t DhcpObject::GetDhcpRebindTime ( ) [inline]
```

Returns number of seconds remaining before the current lease will have to rebind.

Returns

The number of seconds remaining before the current lease will have to rebind.

See also

[GetRemainingDhcpLeaseTime\(\)](#), [GetDhcpRenewTime\(\)](#), [GetDhcpExpirationTime\(\)](#)

16.37.2.4 GetDhcpRenewTime()

```
uint32_t DhcpObject::GetDhcpRenewTime ( ) [inline]
```

Returns number of seconds remaining before the lease will be renewed.

Returns

The number of seconds remaining before the lease will be renewed.

See also

[GetRemainingDhcpLeaseTime\(\)](#), [GetDhcpRebindTime\(\)](#), [GetDhcpExpirationTime\(\)](#)

16.37.2.5 GetDHCPState()

```
int32_t DhcpObject::GetDHCPState ( )
```

Returns current state of the [DHCP](#) lease.

Returns

[DHCP State](#)

See also

[ValidDhcpLease\(\)](#)

16.37.2.6 GetRemainingDhcpLeaseTime()

```
uint32_t DhcpObject::GetRemainingDhcpLeaseTime ( )
```

Returns number of seconds remaining for current lease.

Returns

The number of seconds remaining for current lease.

See also

[GetDhcpRenewTime\(\)](#), [GetDhcpRebindTime\(\)](#), [GetDhcpExpirationTime\(\)](#)

16.37.2.7 RebindDHCP()

```
void DhcpObject::RebindDHCP ( )
```

Manually force a [DHCP](#) rebind of a lease.

The [init\(\)](#) function called at the beginning of an application will handle [DHCP](#) client services for all network interfaces. It is rare that you would need to call these functions manually.

See also

[RenewDHCP\(\)](#)

16.37.2.8 RenewDHCP()

```
void DhcpObject::RenewDHCP ( )
```

Manually force a [DHCP](#) renew of a lease.

The [init\(\)](#) function called at the beginning of an application will handle [DHCP](#) client services for all network interfaces. It is rare that you would need to call these functions manually.

See also

[RebindDHCP\(\)](#)

16.37.2.9 RestartDHCP()

```
void DhcpObject::RestartDHCP ( )
```

Manually stop and restart the [DHCP](#) client.

The [init\(\)](#) function called at the beginning of an application will handle [DHCP](#) client services for all network interfaces. It is rare that you would need to call these functions manually.

See also

[DhcpObject::StartDHCP\(\)](#), [DhcpObject::StopDHCP\(\)](#)

16.37.2.10 StartDHCP()

```
void DhcpObject::StartDHCP ( )
```

Manually start the [DHCP](#) Client.

The [init\(\)](#) function called at the beginning of an application will handle [DHCP](#) client services for all network interfaces. It is rare that you would need to call these functions manually.

This function will start the [DHCP](#) client and return immediately. Check the [DHCP](#) status to verify you have successfully obtained a lease via [GetDHCPState\(\)](#)

See also

[DhcpObject::StopDHCP\(\)](#)

16.37.2.11 StopDHCP()

```
void DhcpObject::StopDHCP ( )
```

Manually stop the [DHCP](#) client and release the [DHCP](#) lease.

The [init\(\)](#) function called at the beginning of an application will handle [DHCP](#) client services for all network interfaces. It is rare that you would need to call these functions manually.

See also

[DhcpObject::StartDHCP\(\)](#)

16.37.2.12 ValidDhcpLease()

```
BOOL DhcpObject::ValidDhcpLease ( )
```

Returns the status of a [DHCP](#) lease.

Returns

True if the interface has a valid lease.

See also

[RenewDHCP\(\)](#)

Max transmit data throughput.
- **uint8_t security**
Security used: WEP, WPA, WPA2, open, unknown.
- **uint8_t cipher**
refer to [OPTIONLISTCIPH](#) for defenitions
- **MACADR bssid**
Basic Service Set Identifier.
- **uint8_t bssType**
refer to [OPTIONLISTBSSTYPE](#) for defenitions
- **char ssid** [SSID_MAX_LEN+1]
Placeholder for char array pointer.
- **uint32_t tickLastUpdated**
CPU tick count of when this struct was last updated.

16.43.1 Detailed Description

A struct used to describe the status of the current network connection.
The documentation for this struct was generated from the following file:

- [wifiDriver.h](#)

16.44 dspidMAStruct Struct Reference

```
#include <dspidMA.h>
```

Public Attributes

- **bool enabled**
Whether or not the driver is using DMA for the transfer.
- **uint8_t byteCount**
The bytes transferred per DMA call.
- **bool rxPresent**
rxPresent
- **bool txPresent**
txPresent
- **dspidMAstruct savedDSPI**
savedDSPI
- **bool csState**
csState

16.44.1 Detailed Description

The documentation for this struct was generated from the following file:

- [coldfire/cpu/MCF5441X/include/dspi.h](#)

16.45 dspiDriverStruct Struct Reference

Major variables/configurations used for a DSPI transfer.

```
#include <dspi.h>
```

Public Attributes

- volatile uint8_t * **pDSPIRxbuf**
Track memory location where data will be read or written to the peripheral.
- volatile uint8_t * **pDSPITxbuf**
Track memory location where data will be read or written to the peripheral.
- uint8_t **BitsPerQueue**
Number of bits per transfer, (value = 8 - 32)
- uint32_t **DSPI_SizeLeft**
Number of bytes left in the transfer.
- uint16_t **Command_Mask**
Partial configuration for the queue's command reg.
- [csReturnType](#) **csReturnToInactive**
- [OS_SEM](#) * **DSPI_Sem**
Pointer to an external semaphore provided by [DSPIStart\(\)](#)
- volatile uint8_t **DSPI_INT_STATUS**
Status of the spi device.
- uint32_t **WordsToWrite**
Number of words to write to the command/TX Queues and Read from RX.
- uint32_t **LastWordsToWrite**
The amount from the previous ISR.
- volatile BOOL **DSPIfinished**
- [dspiDMAStruct](#) **dma**

16.45.1 Detailed Description

Major variables/configurations used for a DSPI transfer.

Initialize a DSPI module.

16.46.1 Detailed Description

[DSPIModule](#) is a SPI communications driver. It is an object based driver, which allows for low overhead multiplexing between peripherals with different bus configurations.

16.46.2 Constructor & Destructor Documentation

16.46.2.1 DSPIModule() [1/2]

```
DSPIModule::DSPIModule (
    uint8_t SPIModule )
```

The minimum [DSPIModule](#) Constructor. Requires that configuration settings be applied after construction before use.

Parameters

SPIModule	The DSPI module to use, from 1 to 3. Default is 1.
---------------------------	--

See also

[DSPIModule::DSPIModule\(uint8_t SPIModule, uint32_t baudRateInBps, uint8_t transferSizeInBits, uint8_t peripheralChipSelects, uint8_t chipSelectPolarity, uint8_t clockPolarity, uint8_t clockPhase, BOOL doutHiz, uint8_t csToClockDelay, uint8_t delayAfterTransfer\)](#)

16.46.2.2 DSPIModule() [2/2]

```
DSPIModule::DSPIModule (
    uint8_t SPIModule,
    uint32_t baudRateInBps,
    uint8_t transferSizeInBits = 8,
    uint8_t peripheralChipSelects = 0x00,
    uint8_t chipSelectPolarity = 0x0F,
    uint8_t clockPolarity = 0,
    uint8_t clockPhase = 1,
    BOOL doutHiz = TRUE,
    uint8_t csToClockDelay = 0,
    uint8_t delayAfterTransfer = 0 )
```

[DSPIModule](#) Full [DSPIModule](#) Constructor. Will initialize all hardware settings.

Parameters

SPIModule	The DSPI module to use, from 1 to 3. Default is 1.
baudRateInBps	Maximum master clock frequency for SPI Bus in bits per second.
transferSizeInBits	Bit width of the transfers to be made.
peripheralChipSelects	Bit mask of which chipselects are active during transfers.
chipSelectPolarity	Bit mask of the inactive state of chipselects.
clockPolarity	Inactive level for the clock signal.
clockPhase	Clock phase: <ul style="list-style-type: none"> • 0: data captured on leading edge of DSPI_CLK, changed on following edge. • 1: data changed on leading edge of DSPI_CLK, captured on following edge.

Parameters

doutHiz	Data output is high impedance between transfers (instead of driven).
-------------------------	--

Parameters

<i>csToClockDelay</i>	Delay from chip select to valid clock. The default of 0 will set the delay as close to 1/2 DSPI_CLK without going under, keeping with the interface to QSPI driver.
<i>delayAfterTransfer</i>	Delay between data transfers. The default of 0 is 17/(system clock / 2), in keeping with interface to QSPI

16.46.3 Member Function Documentation

16.46.3.1 ClrSem()

```
bool DSPIModule::ClrSem ( ) [inline]
```

Clears the semaphore registration.

Returns

Returns whether the registration was successfully cleared.

16.46.3.2 DisableDMA()

```
bool DSPIModule::DisableDMA ( ) [inline]
```

DisableDMA disables DMA for all transactions.

Returns

Returns whether DMA is allowed

16.46.3.3 Done() [1/2]

```
bool DSPIModule::Done ( ) [inline]
```

Returns whether the previously started transaction is complete.

Returns

Whether the previously started transaction is complete

16.46.3.4 Done() [2/2]

```
static BOOL DSPIModule::Done (
    uint8_t SPIModule ) [static]
```

Returns whether the previously started transaction for a given hardware module is complete.

Parameters

<i>SPIModule</i>	The hardware instance to check the transaction state for.
------------------	---

Returns

Whether the previously started transaction is complete

16.46.3.5 EnableDMA()

```
bool DSPIModule::EnableDMA (
    bool enableDMA = true )
```

EnableDMA configures whether DMA is allowed for qualifying transactions.

Parameters

<i>enableDMA</i>	Whether DMA is allowed
------------------	------------------------

Returns

Returns whether DMA is allowed

16.46.3.6 GetActualBaudrate()

```
uint32_t DSPIModule::GetActualBaudrate ( ) [inline]
```

Returns the actual bus speed to be used.

Returns

The actual bus speed to be used.

16.46.3.7 GetSem()

```
OS_SEM * DSPIModule::GetSem ( ) [inline]
```

Gets a pointer to the registered Semaphore.

Returns

Pointer to the registered Semaphore

16.46.3.8 Init()

```
uint8_t DSPIModule::Init (
    uint32_t baudRateInBps = 2000000,
    uint8_t transferSizeInBits = 8,
    uint8_t peripheralChipSelects = 0x00,
    uint8_t chipSelectPolarity = 0x0F,
    uint8_t clockPolarity = 0,
    uint8_t clockPhase = 1,
    BOOL doutHiz = TRUE,
    uint8_t csToClockDelay = 0,
    uint8_t delayAfterTransfer = 0 )
```

DSPIModule Full **DSPIModule** Constructor. Will initialize all hardware settings.

param **SPIModule** The instance number of the hardware module to use with this driver context.

Parameters

<i>baudRateInBps</i>	Maximum master clock frequency for SPI Bus
<i>transferSizeInBits</i>	Bit width of the transfers to be made
<i>peripheralChipSelects</i>	Bit mask of which chipselects are active during transfers
<i>chipSelectPolarity</i>	Bit mask of the inactive state of chipselects
<i>clockPolarity</i>	Inactive level for the clock signal

Parameters

<i>clockPhase</i>	<ul style="list-style-type: none"> • 0: data captured on leading edge of DSPI_CLK, changed on following edge • 1: data changed on leading edge of DSPI_CLK, captured on following edge
-------------------	--

Parameters

<i>doutHiz</i>	Data output is high impedance between transfers (instead of driven)
<i>csToClockDelay</i>	Delay from chip select to valid clock. The default of 0 will set the delay as close to 1/2 DSPI_CLK without going under, keeping with the interface to QSPI driver.
<i>delayAfterTransfer</i>	Delay between data transfers. The default of 0 is 17/(system clock / 2), in keepin with interface to QSPI

See also

DSPIModule::DSPIModule(uint8_t SPIModule, uint32_t baudRateInBps, uint8_t transferSizeInBits, uint8_t peripheralChipSelects, uint8_t chipSelectPolarity, uint8_t clockPolarity, uint8_t clockPhase, BOOL doutHiz, uint8_t csToClockDelay, uint8_t delayAfterTransfer)

16.46.3.9 RegisterSem()

```
bool DSPIModule::RegisterSem (
    OS_SEM * finishedSem )
```

Registers a semaphore to be posted to upon completion of transactions.

Parameters

<i>finishedSem</i>	A pointer to the semaphore to be posted to.
--------------------	---

Returns

Returns whether the semaphore was successfully registered.

16.46.3.10 Rx()

```
uint8_t DSPIModule::Rx (
    uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    int csReturnToInactive = DEASSERT_AFTER_LAST ) [inline]
```

Rx begins a receive only SPI transaction using the provided buffer. Holds output line low during transfers.

Parameters

<i>receiveBufferPtr</i>	A pointer to the buffer to write received data to. If the buffer is NULL, then receive data will silently be discarded.
<i>byteCount</i>	The number of bytes to send and receive in this transaction. The value must be a multiple of the number of bytes in each individual transfer.
<i>csReturnToInactive</i>	Configures when the ChipSelect that is used for the transaction should be deasserted and return to being inactive.

See also

[csReturnType](#)

Returns

Non-zero on error

16.46.3.11 SetCS()

```
bool DSPIModule::SetCS (
    uint8_t CS ) [inline]
```

Modifies the chip select configuration for the driver context such that only the requested chip select is active during transfers.

Parameters

CS	The chip select number to assert during transfers.
----	--

Returns

Whether the active chip select was successfully updated.

16.46.3.12 Start()

```
uint8_t DSPIModule::Start (
    uint8_t * transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    int csReturnToInactive = DEASSERT_AFTER_LAST )
```

Start begins a SPI transaction using the provided buffers.

Parameters

<i>transmitBufferPtr</i>	A pointer to the buffer containing data to be sent out. If the buffer is NULL, the bus will be held low instead.
<i>receiveBufferPtr</i>	A pointer to the buffer to write received data to. If the buffer is NULL, then receive data will silently be discarded.
<i>byteCount</i>	The number of bytes to send and receive in this transaction. The value must be a multiple of the number of bytes in each individual transfer.
<i>csReturnToInactive</i>	Configures when the ChipSelect that is used for the transaction should be deasserted and return to being inactive.

See also

[csReturnType](#)

Returns

Non-zero on error

16.46.3.13 Tx()

```
uint8_t DSPIModule::Tx (
    uint8_t * transmitBufferPtr,
    uint32_t byteCount,
    int csReturnToInactive = DEASSERT_AFTER_LAST ) [inline]
```

Tx begins a transmit only SPI transaction using the provided buffer. Silently discards the received data.

Parameters

<i>transmitBufferPtr</i>	A pointer to the buffer containing data to be sent out. If the buffer is NULL, the bus will be held low instead.
<i>byteCount</i>	The number of bytes to send and receive in this transaction. The value must be a multiple of the number of bytes in each individual transfer.
<i>csReturnToInactive</i>	Configures when the ChipSelect that is used for the transaction should be deasserted and return to being inactive.

See also

[csReturnType](#)

Returns

Non-zero on error

16.46.4 Friends And Related Symbol Documentation

16.46.4.1 DSPIInit

```
uint8_t DSPIInit (
    uint8_t SPIModule,
    uint32_t Baudrate,
    uint8_t QueueBitSize,
    uint8_t CS,
    uint8_t CSPol,
    uint8_t ClkPolarity,
    uint8_t ClkPhase,
    BOOL DoutHiz,
    uint8_t QCD,
    uint8_t DTL ) [friend]
```

Initialize a DSPI module.

Notes:

- The maximum baud rate is CPU_CLOCK / 3
- Will initialize to the highest available baud rate that does not exceed the maximum
- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for greater than 8 bits per transfer then the data must be uint16_t aligned
- If configured for greater than 16 bits per transfer then the data must be uint32_t aligned
- Chip select is based on chipSelectPolarity
- 0 data captured leading edge of DSPI_CLK, changed following edge.
- 1 data changed leading edge of DSPI_CLK, captured following edge.
- 0 default is as close to 1/2 DSPI_CLK without going under, keeping with the interface to SPI
- 0 default is 17/(system clock / 2), in keeping with interface to QSPI

Parameters

<i>SPIModule</i>	SPI module number, 0 - 1
<i>Baudrate</i>	Maximum baud rate requested
<i>QueueBitSize</i>	Number of bits per transfer: 8, 16 or 32
<i>CS</i>	SPI chip selects to use for transfer

Parameters

<i>CSPol</i>	0 = inactive logic level low, 1 = high
<i>ClkPolarity</i>	0 = inactive logic level low, 1 = high
<i>ClkPhase</i>	0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge.
<i>DoutHiz</i>	Data output high impedance between transfers
<i>QCD</i>	Delay from chip select to valid clock (default is 0). QCD is a value in the QDLYR register and will change the delay between the assertion of the chip select and the start of the DSPI clock. Default setting of one half DSPI clk will be used if parameter is specified as 0x0 or not included.
<i>DTL</i>	DTL is a value in the QDLYR register and will change the delay following a transfer of a single uint16_t in the DSPI queue. Default reset value of 17/(fsys/2) will be used if parameter is specified 0 or not included.

Returns

Current stat of DSPI bus [MOD5441xDspiStates](#)

Notes:

- The maximum baud rate is CPU_CLOCK / 3
- Will initialize to the highest available baud rate that does not exceed the maximum
- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for greater than 8 bits per transfer then the data must be uint16_t aligned
- If configured for greater than 16 bits per transfer then the data must be uint32_t aligned
- Chip select is based on chipSelectPolarity
- 0 data captured leading edge of DSPI_CLK, changed following edge.
- 1 data changed leading edge of DSPI_CLK, captured following edge.
- 0 default is as close to 1/2 DSPI_CLK without going under, keeping with the interface to SPI
- 0 default is 17/(system clock / 2), in keeping with interface to QSPI

Parameters

<i>SPIModule</i>	SPI module number, 0 - 1
<i>Baudrate</i>	Maximum baud rate requested
<i>QueueBitSize</i>	Number of bits per transfer: 8, 16 or 32
<i>CS</i>	SPI chip selects to use for transfer
<i>CSPol</i>	0 = inactive logic level low, 1 = high
<i>ClkPolarity</i>	0 = inactive logic level low, 1 = high
<i>ClkPhase</i>	0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge.
<i>DoutHiz</i>	Data output high impedance between transfers
<i>QCD</i>	Delay from chip select to valid clock (default is 0)
<i>DTL</i>	Chip select mode dspIChipSelectMode

Returns

Current stat of DSPI bus [dspiState](#)

16.49 HtmlPageHandler Class Reference

Base class for all GET handlers. To handle GET requests for a specific URL in your application, build a GET handler object for that specific URL. A NULL name will be a catch all for all GET requests.

```
#include <http.h>
```

Inherited by [AcmeAuthItem](#), [CallBackFunctionPageHandler](#), [CallBackWSEndPoint](#), [HtmlConfigExposer](#), and [HtmlPostHandler](#).

Public Member Functions

- [HtmlPageHandler](#) (const char *url, [HTTP_RequestTypes](#) rt=tGet, int accessGroup=0, bool Before_Files=false)
Register handler.
- virtual int [ProcessRaw](#) (int sock, [HTTP_Request](#) &pd)=0
This class will do a callback with data for each request to the specified url.
- int [GetGroup](#) ()
Returns access group setting.

Protected Member Functions

- void [InsertSort](#) ([HtmlPageHandler](#) *&ph)
Insert sort.
- int [SortValue](#) ([HtmlPageHandler](#) *pv)
Returns the value of the sort compare: -1, 0, 1.

Protected Attributes

- [HtmlPageHandler](#) * [m_pNextHandler](#)
Pointer to next page handle object.
- const char * [m_pUrlName](#)
Pointer to URL. Performs a length match, an empty string matches everything.
- int [m_access_group](#)
The access group for this request see [CheckHttpAccess](#).
- [HTTP_RequestTypes](#) [m_requestTypes](#)
Type of request, [HTTP_RequestTypes](#).

16.49.1 Detailed Description

Base class for all GET handlers. To handle GET requests for a specific URL in your application, build a GET handler object for that specific URL. A NULL name will be a catch all for all GET requests.

16.49.2 Constructor & Destructor Documentation

16.49.2.1 HtmlPageHandler()

```
HtmlPageHandler::HtmlPageHandler (
    const char * url,
    HTTP\_RequestTypes rt = tGet,
    int accessGroup = 0,
    bool Before_Files = false )
```

Register handler.

Parameters

<i>url</i>	The URL name to register. A NULL string matches everything
<i>rt</i>	The GET request type to respond to
<i>accessGroup</i>	Access group of the URL
<i>Before_Files</i>	Specify if the response should be before or after the compiled in HTML files

16.49.3 Member Function Documentation

16.49.3.1 GetGroup()

```
int HtmlPageHandler::GetGroup ( ) [inline]
```

Returns access group setting.

Returns

[HTTP_ACCESS](#)

16.49.3.2 ProcessRaw()

```
virtual int HtmlPageHandler::ProcessRaw (
    int sock,
    HTTP_Request & pd ) [pure virtual]
```

This class will do a callback with data for each request to the specified url.

Returns

0 if the request was not processed.

Implemented in [CallBackFunctionPageHandler](#), and [CallBackFunctionPostHandler](#).

Public Member Functions

- [HtmlPostVariableListCallback](#) (const char *pUrl, postvarhandler *pCallback, int accessGroup=0)
Custom HTTP POST handler callback function constructor.

16.50.1 Detailed Description

Implements the HtmlPostVariableListHandler class as a function pointer callback for HTTP POST submissions.

16.50.2 Constructor & Destructor Documentation

16.50.2.1 HtmlPostVariableListCallback()

```
HtmlPostVariableListCallback::HtmlPostVariableListCallback (
    const char * pUrl,
    postvarhandler * pCallback,
    int accessGroup = 0 ) [inline]
```

Custom HTTP POST handler callback function constructor.

Parameters

<i>pUrl</i>	Pointer to URL character string
<i>pCallback</i>	Pointer to callback function that will process the POST
<i>accessGroup</i>	Password group access

The documentation for this class was generated from the following file:

- [httpost.h](#)

16.51 HTTP_Request Struct Reference

HTTP Request Structure.

```
#include <http.h>
```

Public Member Functions

- void **ProcessLine** (PSTR startofline)
internal function
- int **Respond** (int socket)
internal function
- bool **ExtractAuthentication** (char **pPassword, char **pUser)
used to extract user name and password in authentication test

Public Attributes

- PSTR **pURL**
Request URL.
- PSTR **pAuthorization**
Authorization header if present, otherwise null.
- PSTR **pFirstCookie**
First cookie if present, otherwise null. More may follow.
- PSTR **pData**
Pointer to entire data set. Note: not null terminated.
- PSTR **pSep**
Separator for multipart forms, null if not present.
- PSTR **pHost**
Pointer to host record null if not present.
- PSTR **last_datarx**
Pointer to last data read, internal use only.
- PSTR **wsKey**
Web socket ket, internal use only.
- PSTR **wsProtocol**
Web socket prototocl, internal use only.
- uint16_t **sep_len**
Length of separator for multipart forms.
- uint32_t **content_length**
Content length field from HTML header.
- uint32_t **rx_length**
Total bytes receive from request, internal use only.
- [IPADDR](#) **client_IPaddr**
IP address of client.
- uint8_t **websocketFlags**
Web socket flags.
- [HTTP_RequestTypes](#) **req**
Type of request [HTTP_RequestTypes](#).

16.51.1 Detailed Description

HTTP Request Structure.

This structure is populated before a HTTP request is sent out.

The documentation for this struct was generated from the following file:

- [http.h](#)

16.52 I2C Class Reference

I2C Peripheral Class.

```
#include <i2c.h>
```

Public Types

- enum [Result_t](#) {
[I2C_RES_ACK](#), [I2C_RES_NACK](#), [I2C_RES_ARB_LST](#), [I2C_RES_BUSY](#),
[I2C_RES_ARG](#) }

Return result types.

Public Member Functions

- [I2C](#) (int module)
Constructor for the I2C peripheral module.
- void [setup](#) (uint32_t busSpeed)
Setup the I2C peripheral interface.
- void [resetBus](#) ()
Reset the I2C bus.
- [Result_t DoTransaction](#) (I2CTxn_t *pTransaction, bool bRepeatedStart=false)
Start an I2C transaction.
- void [setNumAddressBytes](#) (uint8_t numAddressBytes=1)
Specify the register address size for a read or write transaction. A number of bytes, from 0 to 3, can be sent to specify an address up to 24-bit (3 bytes): 0 = none, 1 = 8-bits, 2 = 16-bits, 3 = 24-bits.
- [Result_t writeReg8](#) (uint8_t devAddr, uint32_t reg, uint8_t data)
Write an 8-bit value to a I2C slave device register.
- [Result_t readReg8](#) (uint8_t devAddr, uint32_t reg, uint8_t &data)
Read an 8-bit value form an I2C slave device register.
- [Result_t writeRegN](#) (uint8_t devAddr, uint32_t reg, const uint8_t *buf, uint32_t blen)
Write a number of 8-bit values to an I2C slave to the specified register address.
- [Result_t readRegN](#) (uint8_t devAddr, uint32_t reg, uint8_t *buf, uint32_t blen)
Read a number of 8-bit values from an I2C slave at the specified register address.

Friends

- class [WireIntf](#)

16.52.1 Detailed Description

I2C Peripheral Class.

For I2C communication, you can choose the [WireIntf](#) class, or the [I2C](#) class. The [WireIntf](#) class is simpler to use, while the [I2C](#) class provides more low level control.

Note that the system automatically instantiates [I2C](#) and [WireIntf](#) objects for each of the [I2C](#) peripheral modules. The [WireIntf](#) objects can be accessed with: [Wire](#), [Wire1](#) and [Wire2](#). The [I2C](#) objects can be accesses with [I2C\[0\]](#), [I2C\[1\]](#) and [I2C\[2\]](#).

16.52.2 Member Enumeration Documentation

16.52.2.1 Result_t

enum `I2C::Result_t`

Return result types.

Enumerator

<code>I2C_RES_ACK</code>	Acknowledged.
<code>I2C_RES_NACK</code>	Not acknowledged.
<code>I2C_RES_ARB_LST</code>	Arbitration listening.
<code>I2C_RES_BUSY</code>	Bus is busy.
<code>I2C_RES_ARG</code>	Bad argument.

16.52.3 Constructor & Destructor Documentation

16.52.3.1 I2C()

```
I2C::I2C (
    int module )
```

Constructor for the `I2C` peripheral module.

Parameters

<code>module</code>	The <code>I2C</code> module to instantiate (0, 1 or 2)
---------------------	--

16.52.4 Member Function Documentation

16.52.4.1 DoTransaction()

```
Result_t I2C::DoTransaction (
    I2CTxn_t * pTransaction,
    bool bRepeatedStart = false )
```

Start an `I2C` transaction.

Execute the transaction pointed to by `pTransaction`

Parameters

<code>*pTransaction</code>	Pointer to the transaction to execute
<code>bRepeatedStart</code>	Repeat the <code>I2C</code> start sequence

Returns

`Result_t`

16.52.4.2 readReg8()

```
Result_t I2C::readReg8 (
    uint8_t devAddr,
    uint32_t reg,
    uint8_t & data )
```

Read an 8-bit value form an `I2C` slave device register.

Parameters

<i>devAddr</i>	Address of I2C device
<i>reg</i>	Register address to read
<i>data</i>	Reference to variable in which to store the register data

Returns

[Result_t](#)

16.52.4.3 readRegN()

```
Result_t I2C::readRegN (
    uint8_t devAddr,
    uint32_t reg,
    uint8_t * buf,
    uint32_t blen )
```

Read a number of 8-bit values from an [I2C](#) slave at the specified register address.

Parameters

<i>devAddr</i>	Address of I2C device
<i>reg</i>	Register address to read
<i>*buf</i>	Pointer to buffer to store received data
<i>blen</i>	Number of bytes to read

Returns

[Result_t](#)

16.52.4.4 setNumAddressBytes()

```
void I2C::setNumAddressBytes (
    uint8_t numAddressBytes = 1 ) [inline]
```

Specify the register address size for a read or write transaction. A number of bytes, from 0 to 3, can be sent to specify an address up to 24-bit (3 bytes): 0 = none, 1 = 8-bits, 2 = 16-bits, 3 = 24-bits.

If you are using a single [I2C](#) device, or all devices use the same address size, this function only needs to be called once. If you have multiple [I2C](#) devices with different address/register bit sizes, then this function should be called before each read/write operation for each different device.

Parameters

<i>numAddressBytes</i>	The number of address bytes to send: 0 - 3. The default value is 1 byte.
------------------------	--

16.52.4.5 setup()

```
void I2C::setup (
    uint32_t busSpeed )
```

Setup the [I2C](#) peripheral interface.

Parameters

<i>busSpeed</i>	Target bus speed. If the specified speed cannot be achieved, a lower bus speed may be enabled.
-----------------	--

16.52.4.6 writeReg8()

```
Result_t I2C::writeReg8 (
    uint8_t devAddr,
    uint32_t reg,
    uint8_t data )
```

Write an 8-bit value to a [I2C](#) slave device register.

Parameters

<i>devAddr</i>	Address of I2C device
<i>reg</i>	Register address to write
<i>data</i>	Data to write to register

Returns

[Result_t](#)

16.52.4.7 writeRegN()

```
Result_t I2C::writeRegN (
    uint8_t devAddr,
    uint32_t reg,
    const uint8_t * buf,
    uint32_t blen )
```

Write a number of 8-bit values to an [I2C](#) slave to the specified register address.

Executing this function will send the following: a start bit, the slave device address and read/write bit, the 8-bit data bytes, and finally a stop bit. Note that the address is not incremented with each 8-bit data value.

Parameters

<i>devAddr</i>	Address of I2C device
<i>reg</i>	Register address to write
<i>*buf</i>	Pointer to buffer containing data to write
<i>blen</i>	Number of bytes to write

Returns

[Result_t](#)

The documentation for this class was generated from the following file:

- [i2c.h](#)

16.53 I2CDevice Class Reference

[I2C](#) Device Class (recommended)

```
#include <i2c.h>
```

Public Member Functions

- [I2CDevice](#) ([I2C](#) &pInterface, uint8_t deviceAddress, uint8_t numAddressBytes=1)
Initialize the I2C module.
- uint8_t [getI2CAddress](#) ()
Get device's I2C address.
- void [setup](#) (uint32_t busSpeed)

- *Setup the I2C peripheral module.*
- void **resetBus** ()
Reset the I2C bus.
- **I2C::Result_t writeReg8** (uint32_t reg, uint8_t data)
Write an 8-bit value to an I2C slave device register.
- **I2C::Result_t readReg8** (uint32_t reg, uint8_t &data)
Read an 8-bit value form an I2C slave device register.
- **I2C::Result_t writeRegN** (uint32_t reg, const uint8_t *buf, uint32_t blen)
Write a number of 8-bit values to an I2C slave to the specified register address.
- **I2C::Result_t readRegN** (uint32_t reg, uint8_t *buf, uint32_t blen)
Read a number of 8-bit values from an I2C slave at the specified register address.

16.53.1 Detailed Description

I2C Device Class (recommended)

For I2C communication, you can choose the [I2CDevice](#) class, the [I2C](#) class, or the [WireIntf](#) class. The recommended interface is the [I2CDevice](#) class.

For example, to create an object for an analog to digital converter:

```
I2CDevice AdcDevice(i2c[I2C_MODULE_NUM], I2C_ADC_ADDRESS);
```

To read a 16 bit value:

```
uint8_t I2CStat = AdcDevice.readRegN(0x00, buf, 2);
```

16.53.2 Constructor & Destructor Documentation

16.53.2.1 I2CDevice()

```
I2CDevice::I2CDevice (
    I2C & pInterface,
    uint8_t deviceAddress,
    uint8_t numAddressBytes = 1 ) [inline]
```

Initialize the [I2C](#) module.

Parameters

<i>pInterface</i>	Pointer to the I2C interface to use. This will normally be one of the preallocated I2C modules in the <code>i2c[]</code> array: <code>i2c[0]</code> (default), <code>i2c[1]</code> or <code>i2c[2]</code> .
<i>deviceAddress</i>	I2C device address
<i>numAddressBytes</i>	Number of address bytes to send to specify the register or address to access for a read or write operation. Refer to your I2C device data sheet to determine the correct number. The I2C address range is 24-bits maximum (3 bytes). The default value is 1 byte, representing an address range of 0 to 255.

16.53.3 Member Function Documentation

16.53.3.1 getI2CAddress()

```
uint8_t I2CDevice::getI2CAddress ( ) [inline]
```

Get device's [I2C](#) address.

Note that the return address will be just the [I2C](#) address bits, not including the read/write bit. If your device data sheet specifies the address byte to include the read/write bit, that value would be this address left shifted by 1. For example, if a device data sheet specifies the address as 0xA2 and includes the read/write bit, the actual address would be 0x51.

Returns

The device's [I2C](#) address

16.53.3.2 readReg8()

```
I2C::Result_t I2CDevice::readReg8 (
    uint32_t reg,
    uint8_t & data ) [inline]
```

Read an 8-bit value form an [I2C](#) slave device register.

Parameters

<i>reg</i>	Register address to read
<i>data</i>	Reference to variable in which to store the register data

Returns

[I2C::Result_t](#)

16.53.3.3 readRegN()

```
I2C::Result_t I2CDevice::readRegN (
    uint32_t reg,
    uint8_t * buf,
    uint32_t blen ) [inline]
```

Read a number of 8-bit values from an [I2C](#) slave at the specified register address.

Parameters

<i>reg</i>	Register address to read
<i>*buf</i>	Pointer to buffer to store received data
<i>blen</i>	Number of bytes to read

Returns

[I2C::Result_t](#)

16.53.3.4 setup()

```
void I2CDevice::setup (
    uint32_t busSpeed ) [inline]
```

Setup the [I2C](#) peripheral module.

Parameters

<i>busSpeed</i>	Target bus speed. If the specified speed cannot be achieved, a lower bus speed may be enabled.
-----------------	--

16.53.3.5 writeReg8()

```
I2C::Result_t I2CDevice::writeReg8 (
    uint32_t reg,
    uint8_t data ) [inline]
```

Write an 8-bit value to an [I2C](#) slave device register.

Parameters

<i>reg</i>	Register address to write
<i>data</i>	Data to write to register

Returns

[I2C::Result_t](#)

16.53.3.6 writeRegN()

```
I2C::Result_t I2CDevice::writeRegN (
    uint32_t reg,
    const uint8_t * buf,
    uint32_t blen ) [inline]
```

Write a number of 8-bit values to an [I2C](#) slave to the specified register address.

Executing this function will send the following: a start bit, the slave device address and read/write bit, the 8-bit data bytes, and finally a stop bit. Note that the address is not incremented with each 8-bit data value.

Parameters

<i>reg</i>	Register address to write
<i>*buf</i>	Pointer to buffer containing data to write
<i>blen</i>	Number of bytes to write

Returns

[I2C::Result_t](#)

Get the object value as a text string to the specified [NBString](#) object.
- virtual void [GetTypeValue](#) (NBString &s)
Assigns the object type value to the specified [NBString](#) object.

16.56.1 Detailed Description

Network interface configuration block class for interface control and configuration.

Network Interfaces are configured and controlled C++ [InterfaceBlock](#) objects. The [InterfaceBlock](#) contains variables and member functions for things such as:

- The Configuration Server interface
- IP settings for both IPv4 and IPv6 types
- Configuration to static or [DHCP](#), and [DHCP](#) status (both v4 and v6)
- Multihome
- Routing
- AutoIP

Note

While the recommended method for getting and setting network interface parameters is to obtain a pointer to an [InterfaceBlock](#), there are also non-member functions of the object that can be used for situations that are best served by a single function call, such as just getting a single IP address of an interface. When using those functions pay special attention to the return value type. While [IPADDR](#) should be used because it supports both [IPADDR4](#) and [IPADDR6](#) types automatically, some of these helper functions may specifically return an [IPADDR4](#) type.

16.56.2 Constructor & Destructor Documentation

16.56.2.1 InterfaceBlock() [1/2]

```
InterfaceBlock::InterfaceBlock (
    const char * name,
    const char * desc = NULL )
```

Constructor with interface name and description.

Parameters

<i>name</i>	Interface name.
<i>desc</i>	Interface description. If not used, default is null.

16.56.2.2 InterfaceBlock() [2/2]

```
InterfaceBlock::InterfaceBlock (
    config_obj & owner,
    const char * name,
    const char * desc = NULL )
```

Constructor with [config_obj](#) owner, interface name and description.

Parameters

<i>owner</i>	Reference to config_obj owner of the interface
<i>name</i>	Interface name.
<i>desc</i>	Interface description. If not used, default is null.

16.56.3 Member Function Documentation

16.56.3.1 EnableMulticast()

```
virtual void InterfaceBlock::EnableMulticast (
    MACADR macAddress,
    BOOL addAddress ) [pure virtual]
```

Enable Multicast on this interface.

Calls registered interface multicast routine.

Parameters

<i>macAddress</i>	Multicast MAC address.
<i>addAddress</i>	True to add address/interface, false to remove it

See also

[EnableMulticast\(MACADR macAddress, int interface\)](#), [DisableMulticast\(\)](#)

16.56.3.2 GetInterfaceName()

```
virtual const char * InterfaceBlock::GetInterfaceName ( ) [virtual]
```

Returns the interface name network interface.

Returns

Pointer to a character string containing the name of the network interface

See also

[InterfaceName\(\)](#)

16.56.3.3 GetInterfaceNumber()

```
int InterfaceBlock::GetInterfaceNumber ( ) [inline]
```

Returns the Interface Number of the network interface.

Returns

Interface number of the [InterfaceBlock](#).

See also

[GetInterfaceNumber\(InterfaceBlock *pifb\)](#)

16.56.3.4 InterfaceLinkChange()

```
void InterfaceBlock::InterfaceLinkChange (
    bool link )
```

Change the link status of the network interface.

Parameters

<i>link</i>	Set link active status to true or false
-------------	---

16.56.3.5 IsRootInterface()

```
bool InterfaceBlock::IsRootInterface ( ) [inline]
```

Returns true if this is the first interface in the interface list.

Returns

True if this is the first interface in the interface list, otherwise false

16.56.3.6 LinkActive()

```
virtual bool InterfaceBlock::LinkActive ( ) [pure virtual]
```

Returns the link status of the network interface.

Returns

True if link is active, otherwise false

See also

[GetInterfaceLink\(\)](#), [InterfaceLinkActive\(\)](#)

16.56.3.7 LinkDuplex()

```
virtual bool InterfaceBlock::LinkDuplex ( ) [pure virtual]
```

Returns the full or half link duplex of the network interface.

Returns

True if full duplex, false if half duplex

See also

[InterfaceLinkDuplex\(\)](#)

16.56.3.8 LinkSpeed()

```
virtual int InterfaceBlock::LinkSpeed ( ) [pure virtual]
```

Returns the link speed of the network interface.

Returns

10 or 100 representing the Mbps speed

See also

[InterfaceLinkSpeed\(\)](#)

16.56.3.9 RegisterInterface()

```
void InterfaceBlock::RegisterInterface ( )
```

Register a network interface with system.

[InterfaceBlock](#) member function to register a new network interface

See also

[Removeinterface\(\)](#), [EnableMulticast\(\)](#), [DisableMulticast\(\)](#)

16.57 IPADDR4 Class Reference

Used to store and manipulate IPv4 addresses in dual stack mode.

```
#include <nettypes.h>
```

Public Member Functions

- **IPADDR4** ()=default
Constructor to create an IPv4 object initialized to null.
- **IPADDR4** (const **IPADDR4** &v)=default
*Constructor to create an IPv4 object initialized to to the specified **IPADDR4** IP address.*
- bool **IsNull** () const
Check if the IP address is null.
- bool **NotNull** () const
Check if the IP address is not null.
- void **SetNull** ()
Set the IP address to null.
- bool **IsLoopBack** () const
Check if the IP address is the loopback address for the interface.
- bool **IsMultiCast** () const
*Check if the **IPADDR4** object contains a Multicast IP address the interface.*
- bool **IsMdns** ()
*Check if the **IPADDR4** object contains a mDNS IP address the interface.*
- bool **IsGlobalBroadCast** () const
*Check if the **IPADDR4** object contains a global broadcast address: 255.255.255.255.*
- bool **IsAutoIP** ()
*Check if the **IPADDR4** object contains an AutoIP address.*
- void **print** () const
Print an IPv4 address to the stdout serial port.
- void **fdprint** (int fd) const
Print an IPv4 address to the specified file descriptor.
- int **sprintf** (char *cp, int maxlen) const
sprintf an IPv4 address to the specified buffer
- void **SetFromAscii** (const char *cp)
Set the IPv4 address from a character string.

Static Public Member Functions

- static **IPADDR4 NullIP** ()
C++ static function for a null IP address.
- static **IPADDR4 GlobalBroadCast** ()
C++ static function for a global broadcast IP address.

Friends

- class **CUR_IPADDR4**

16.57.1 Detailed Description

Used to store and manipulate IPv4 addresses in dual stack mode.

It is recommended to use the **IPADDR** object, which can hold either an IPv4 or IPv6 address, rather than explicitly specifying IPv4.

16.57.2 Constructor & Destructor Documentation

16.57.2.1 IPADDR4()

```
IPADDR4::IPADDR4 (
    const IPADDR4 & v ) [default]
```

Constructor to create an IPv4 object initialized to to the specified **IPADDR4** IP address.

Parameters

<i>v</i>	IPADDR4 object used for initialization.
----------	---

16.57.3 Member Function Documentation

16.57.3.1 fdprint()

```
void IPADDR4::fdprint (
    int fd ) const
```

Print an IPv4 address to the specified file descriptor.

Parameters

<i>fd</i>	File descriptor used to send IP address
-----------	---

16.57.3.2 IsAutoIP()

```
bool IPADDR4::IsAutoIP ( ) [inline]
```

Check if the IPADDR4 object contains an AutoIP address.

Return values

<i>true</i>	if the IP address value is an AutoIP address
-------------	--

See also

[IsLoopBack\(\)](#), [IsLinkLocal\(\)](#)

16.57.3.3 IsGlobalBroadcast()

```
bool IPADDR4::IsGlobalBroadcast ( ) const [inline]
```

Check if the IPADDR4 object contains a global broadcast address: 255.255.255.255.

Return values

<i>true</i>	if the IP address value is a global broadcast
-------------	---

See also

[IsLoopBack\(\)](#), [IsLinkLocal\(\)](#)

16.57.3.4 IsLoopBack()

```
bool IPADDR4::IsLoopBack ( ) const [inline]
```

Check if the IP address is the loopback address for the interface.

Return values

<i>true</i>	if the IP address value is the loopback address
-------------	---

See also

[IsMultiCast\(\)](#), [IsLinkLocal\(\)](#)

16.57.3.5 IsmDns()

```
bool IPADDR4::IsmDns ( ) [inline]
```

Check if the [IPADDR4](#) object contains a mDNS IP address the interface.

Return values

<i>true</i>	if the IP address value is a mDNS address
-------------	---

See also

[IsLoopBack\(\)](#), [IsLinkLocal\(\)](#)

16.57.3.6 IsMultiCast()

```
bool IPADDR4::IsMultiCast ( ) const [inline]
```

Check if the [IPADDR4](#) object contains a Multicast IP address the interface.

Return values

<i>true</i>	if the IP address value is a Multicast address
-------------	--

See also

[IsLoopBack\(\)](#), [IsLinkLocal\(\)](#)

16.57.3.7 IsNull()

```
bool IPADDR4::IsNull ( ) const [inline]
```

Check if the IP address is null.

Return values

<i>true</i>	if the IP address value is null
-------------	---------------------------------

See also

[NotNull\(\)](#), [SetNull\(\)](#)

16.57.3.8 NotNull()

```
bool IPADDR4::NotNull ( ) const [inline]
```

Check if the IP address is not null.

Return values

<i>true</i>	if the IP address value is not null
-------------	-------------------------------------

See also

[IsNull\(\)](#), [SetNull\(\)](#)

16.57.3.9 SetFromAscii()

```
void IPADDR4::SetFromAscii (
    const char * cp )
```

Set the IPv4 address from a character string.

Parameters

<i>cp</i>	Character string. For example, "192.168.1.10"
-----------	---

16.57.3.10 SetNull()

```
void IPADDR4::SetNull ( ) [inline]
```

Set the IP address to null.

See also

[IsNull\(\)](#), [NotNull\(\)](#)

16.57.3.11 sprintf()

```
int IPADDR4::sprintf (
    char * cp,
    int maxlen ) const
```

sprintf an IPv4 address to the specified buffer

Parameters

<i>cp</i>	Destination character buffer
<i>maxl</i>	Maximum number of characters

Returns

Number of characters

The documentation for this class was generated from the following file:

16.58 IPADDR6 Class Reference

Used to hold and manipulate IPv4 and IPv6 addresses in dual stack mode.

```
#include <ipv6_addr.h>
```

Public Member Functions

- bool [IsEmbeddedIPv4](#) () const
An IPADDR6 object can store a IPv4 or IPv6 address. This function returns true if the instance contains an IPv4 address.
- [IPADDR4 Extract4](#) () const
Extracts an IPv4 address from the object.
- bool [IsNull](#) () const
Check if the IP address is null.
- bool [NotNull](#) () const
Check if the IP address is not null.
- bool [IsLoopBack](#) () const

- Check if the IP address is the loopback address for the interface.*

 - bool `IsMultiCast ()` const
- Check if the `IPADDR6` object contains a Multicast IP address the interface.*

 - bool `IsLinkLocal ()` const
- Check if the IP address is the link-local address for the interface.*

 - `MACADR McastMac ()` const
- Return the MAC address used for Multicasts for the interface.*

 - void `print (bool bCompact=true, bool bShowV4Raw=false)` const
- Print the IP address value to stdout.*

 - void `fdprint (int fd, bool bCompact=true, bool bShowV4Raw=false)` const
- Print the IP address to the specified file descriptor.*

 - int `sprintf (char *cp, int maxlen, bool bCompact=true, bool bShowV4Raw=false)` const
- Print the IP address to the specified buffer.*

 - void `SetFromAscii (const char *cp, bool bembed_v4addresses=true)`
- Set the IP address value of an `IPADDR6` object.*

 - void `SetFromIP4 (IPADDR4 ip)`
- Set the IP address value of an `IPADDR6` object from an `IPADDR4` object.*

 - void `SetFromUint32Shortcut (uint32_t w0, uint32_t w1, uint32_t w2, uint32_t w3)`
- Set the IP address value of an `IPADDR6` object from 4 discrete `uint32_t` values.*

 - void `SetNull ()`
- Set the IP address value of an `IPADDR6` object to null.*

Static Public Member Functions

- static `IPADDR6 AsciiToIp6 (const char *cp, bool bembed_v4addresses=true)`
- Static function to return an `IPADDR6` object created from an ASCII value IPv4 or IPv6 address.*
- static `IPADDR6 NullIP ()`
- Static function to return a null `IPADDR6` object.*

16.58.1 Detailed Description

Used to hold and manipulate IPv4 and IPv6 addresses in dual stack mode.

Note

It is recommended to use the `IPADDR` object, which can hold either an IPv4 or IPv6 address, rather than explicitly specifying IPv6.

16.58.2 Member Function Documentation

16.58.2.1 AsciiToIp6()

```
static IPADDR6 IPADDR6::AsciiToIp6 (
    const char * cp,
    bool bembed_v4addresses = true ) [static]
```

Static function to return an `IPADDR6` object created from an ASCII value IPv4 or IPv6 address.

Parameters

<code>*cp</code>	Pointer to the ASCII string representing an IPv4 or IPv6 address
<code>bembed_v4addresses</code>	If false function will only process an IPv6 address

Return values

<code>IPADDR6</code>	object
----------------------	--------

See also

[NullIP\(\)](#)

16.58.2.2 Extract4()

```
IPADDR4 IPADDR6::Extract4 ( ) const [inline]
```

Extracts an IPv4 address from the object.

Return values

IPADDR4	Value of the IPv4 address
-------------------------	---------------------------

16.58.2.3 fdprint()

```
void IPADDR6::fdprint (
    int fd,
    bool bCompact = true,
    bool bShowV4Raw = false ) const
```

Print the IP address to the specified file descriptor.

Parameters

<i>fd</i>	Valid file descriptor to send the data
<i>bCompact</i>	Display IPv6 address in compact notation
<i>bShowV4Raw</i>	Normally set to false. If set to true, will display the IPv4 address 128-bits of the IP address object in the raw format "::FFFF:xx.xx.xx.xx"

See also

[print\(\)](#), [sprintf\(\)](#)

16.58.2.4 IsEmbeddedIPv4()

```
bool IPADDR6::IsEmbeddedIPv4 ( ) const [inline]
```

An [IPADDR6](#) object can store a IPv4 or IPv6 address. This function returns true if the instance contains an IPv4 address.

Internally, an IPv4 address is stored in the format: "::FFFF:xx.xx.xx.xx"

Return values

<i>true</i>	If the IPADDR6 object contains and IPv4 address
<i>false</i>	Otherwise

16.58.2.5 IsLinkLocal()

```
bool IPADDR6::IsLinkLocal ( ) const [inline]
```

Check if the IP address is the link-local address for the interface.

Link local is

```
FE80::/10
```

. Masks the top 10 bits and check.

Return values

<i>true</i>	if the IP address value is the link-local address
-------------	---

See also

[IsLoopBack\(\)](#), [IsMultiCast\(\)](#)

16.58.2.6 IsLoopBack()

```
bool IPADDR6::IsLoopBack ( ) const [inline]
```

Check if the IP address is the loopback address for the interface.

Return values

<i>true</i>	if the IP address value is the loopback address
-------------	---

See also

[IsMultiCast\(\)](#), [IsLinkLocal\(\)](#)

16.58.2.7 IsMultiCast()

```
bool IPADDR6::IsMultiCast ( ) const [inline]
```

Check if the [IPADDR6](#) object contains a Multicast IP address the interface.

Return values

<i>true</i>	if the IP address value is a Multicast address
-------------	--

See also

[IsLoopBack\(\)](#), [IsLinkLocal\(\)](#)

16.58.2.8 IsNull()

```
bool IPADDR6::IsNull ( ) const [inline]
```

Check if the IP address is null.

Return values

<i>true</i>	if the IP address value is null
-------------	---------------------------------

See also

[NotNull\(\)](#)

16.58.2.9 McastMac()

```
MACADR IPADDR6::McastMac ( ) const
```

Return the MAC address used for Multicasts for the interface.

Return values

MACADR	if a Multicast address exists
<i>null</i>	otherwise

16.58.2.10 NotNull()

```
bool IPADDR6::NotNull ( ) const [inline]
```

Check if the IP address is not null.

Return values

<i>true</i>	if the IP address value is not null
-------------	-------------------------------------

See also

[IsNull\(\)](#)

16.58.2.11 NullIP()

```
static IPADDR6 IPADDR6::NullIP ( ) [static]
```

Static function to return a null [IPADDR6](#) object.

Static functions can be called without a specific C++ object. For example,

```
if ( myIPAddress == IPADDR6::NullIP() )
    iprintf("myIPAddress is null\r\n");
else
    iprintf("myIPAddress = %I\r\n", myIPAddress);
```

[IPADDR6::NullIP\(\)](#) can be used on [IPADDR](#), [IPADDR4](#) and [IPADDR6](#) objects.

Return values

<i>null</i>	IPADDR6 object
-------------	--------------------------------

See also

[AsciiToIp6\(\)](#)

16.58.2.12 print()

```
void IPADDR6::print (
    bool bCompact = true,
    bool bShowV4Raw = false ) const
```

Print the IP address value to stdout.

Parameters

<i>bCompact</i>	Display IPv6 address in compact notation
<i>bShowV4Raw</i>	Normally set to false. if set to true, will display the IPv4 address 128-bits of the IP address object in the raw format "::FFFF:xx.xx.xx.xx"

See also

[fdprint\(\)](#), [sprintf\(\)](#)

16.58.2.13 SetFromAscii()

```
void IPADDR6::SetFromAscii (
    const char * cp,
    bool bembed_v4addresses = true )
```

Set the IP address value of an [IPADDR6](#) object.

Parameters

<i>*cp</i>	Pointer to the ASCII string representing an IPv4 or IPv6 address
<i>bembed_v4addresses</i>	If false function will only process an IPv6 address

See also

[SetFromIP4\(\)](#), [SetNull\(\)](#)

16.58.2.14 SetFromIP4()

```
void IPADDR6::SetFromIP4 (
    IPADDR4 ip )
```

Set the IP address value of an [IPADDR6](#) object from an [IPADDR4](#) object.

Parameters

<i>ip</i>	IPADDR4 object
-----------	--------------------------------

See also

[SetFromAscii\(\)](#), [SetNull\(\)](#)

16.58.2.15 SetFromUint32Shortcut()

```
void IPADDR6::SetFromUint32Shortcut (
    uint32_t w0,
    uint32_t w1,
    uint32_t w2,
    uint32_t w3 ) [inline]
```

Set the IP address value of an [IPADDR6](#) object from 4 discrete `uint32_t` values.

Parameters

<i>w0</i>	Unsigned 32-bit integer
<i>w1</i>	Unsigned 32-bit integer
<i>w2</i>	Unsigned 32-bit integer
<i>w3</i>	Unsigned 32-bit integer

See also

[SetFromAscii\(\)](#), [SetFromIP4\(\)](#), [SetNull\(\)](#)

16.58.2.16 SetNull()

```
void IPADDR6::SetNull ( ) [inline]
```

Set the IP address value of an [IPADDR6](#) object to null.

See also

[SetFromAscii\(\)](#), [SetFromIP4\(\)](#)

16.58.2.17 sprintf()

```
int IPADDR6::sprintf (
    char * cp,
```

```

    int maxl,
    bool bCompact = true,
    bool bShowV4Raw = false ) const

```

Print the IP address to the specified buffer.

Parameters

<i>*cp</i>	Pointer to the destination buffer to store the data
<i>maxl</i>	Maximum number of bytes to write to buffer
<i>bCompact</i>	Display IPv6 address in compact notation
<i>bShowV4Raw</i>	Normally set to false. if set to true, will display the IPv4 address 128-bits of the IP address object in the raw format "::FFFF:xx.xx.xx.xx"

Returns

Number of bytes copied to buffer

16.60 JsonAllocString Struct Reference

A list of large strings that are created with malloc.

```
#include <json_lexer.h>
```

Public Attributes

- [JsonAllocString](#) * **pNext**
A pointer to the next string.
- char **data** []
The current string data.

16.60.1 Detailed Description

A list of large strings that are created with malloc.

The documentation for this struct was generated from the following file:

- [json_lexer.h](#)

16.61 JsonLexerFDAdapter Class Reference

Get the type name of the JSON primitive type passed in.

```
#include <json_lexer.h>
```

Inherits [ParsedJsonDataSet](#), and [fd_adapter](#).

Additional Inherited Members

Public Member Functions inherited from [ParsedJsonDataSet](#)

- void **EnableLargeStrings** (bool b)
Call to allow allocation of strings larger than 1500 bytes.
- virtual int **WriteData** (const unsigned char *pCopyFrom, int numBytes)
Writes the passed in data to the JSON data set.
- virtual int **ReadFrom** (int fd)
Reads in data from the specified file descriptor and parses it into the JSON data set.
- bool **CopyObject** ([ParsedJsonDataSet](#) &src_set)
Copies the provided JSON data set into the current one.
- void **ClearObject** ()
Clears all data from the object and resets it to its initial state.

- [JsonRef](#) **operator[]** (int i)
Get a [JsonRef](#) from an array by numerical index.
- [JsonRef](#) **operator()** (const char *name)
Get a [JsonRef](#) representing any entity from a parent object by key name.
- [JsonRef](#) **name** (const char *name)
Get a [JsonRef](#) representing any entity from a parent object by key name.
- [JsonRef](#) **object** (const char *name)
Get a [JsonRef](#) representing an object from a parent object by key name.

- [JsonRef](#) **start** ()
Begin traversal: check for ref validity and reset the position.
- [JsonRef](#) **next** ()
Traverse: check for ref validity and increment the position.
- [json_primitive_type](#) **GetFirst** ()
Get the first element of the JSON data set.
- [json_primitive_type](#) **GetNext** ()
Get the element at the next position of the JSON data set.
- [json_primitive_type](#) **GetCurrent** ()
Get the element at the current position of the JSON data set.
- [json_primitive_type](#) **GetRawCurrent** ()
Get the element at the current position of the JSON data set, including non-public types.
- [json_primitive_type](#) **GetNextName** ()
Iterates the current element of the JSON data set until it finds one of type NAME.
- [json_primitive_type](#) **GetNextObject** ()
Get the next element of type name that exists in the current OBJECT after the current position.
- [json_primitive_type](#) **GetNextArray** ()
Iterates the current element of the JSON data set until it finds one of type BEGIN_ARRAY.
- [json_primitive_type](#) **GetNextNameInCurrentObject** ()
Get the next element of type NAME that exists in the current OBJECT after the current position.
- [json_primitive_type](#) **GetNextNameInCurrentArray** ()
Get the next element of type NAME that exists in the current ARRAY after the current position.
- [json_primitive_type](#) **GetNextNumberInCurrentArray** ()
Get the next element of type NUMBER that exists in the current ARRAY after the current position.
- [json_primitive_type](#) **GetNextStringInCurrentArray** ()
Get the next element of type STRING that exists in the current ARRAY after the current position.
- [json_primitive_type](#) **GetNextBoolInCurrentArray** ()
Get the next element of type TRUE_EL that exists in the current ARRAY after the current position.

- [json_primitive_type GetNextObjectInCurrentArray \(\)](#)
Get the next element of type BEGIN_OBJECT that exists in the current ARRAY after the current position.
- [json_primitive_type SkipCurrentValue \(\)](#)
Skips over the current value, and get the next element. If called inside an ARRAY or OBJECT, it will walk to the end of the ARRAY or OBJECT and return the next element it finds. If it reaches the end of the ARRAY or OBJECT before it finds a value, it will return NOTFOUND.
- void [ResetPosition \(\)](#)
Resets the parser position to the beginning of the JSON data set.
- [JsonRef GetParsePosition \(\)](#)
Gets the current parse position object for the JSON data set.
- [JsonRef SetParsePosition \(JsonRef pos\)](#)
Sets the current parse position object for the JSON data set.
- [json_primitive_type FindFullName \(const char *name\)](#)
Find the element in the data set with the given name and move the parser to the next element. This searches a full name path, such as ob1.ob2.ob3.ob4.
- [json_primitive_type FindFullAtName \(const char *name\)](#)
Find the element in the data set with the given name and move the parser to that element. This searches a full name path, such as ob1.ob2.ob3.ob4.
- [json_primitive_type FindElementAfterName \(const char *name\)](#)
Finds name in current object points at element after name. This only supports simple, single element names. This searches from the current position to the end.
- [json_primitive_type FindGlobalElementAfterName \(const char *name\)](#)
Finds name in current object points at element after name. This only supports simple, single element names. It starts the search from the parser's current position, and if it doesn't find it, it will start the search over from the beginning.
- [json_primitive_type FindElementAfterNameInCurrentObject \(const char *name\)](#)
Looks for elements with the current name in the current OBJECT only. Does not search sub objects.
- [json_primitive_type FindElementAfterNameInCurrentArray \(const char *name\)](#)
Looks for elements with the current name in the current ARRAY only. Does not search sub arrays.
- bool [CurrentBool \(\)](#)
Returns true if the current element a TRUE_EL primitive type.
- bool [PermissiveCurrentBool \(\)](#)
Returns true if the current element a TRUE_EL primitive type, is "True", "true", or is a non-zero number.
- double [CurrentNumber \(\)](#)
Get the number value of the current element.
- const char * [CurrentString \(\)](#)
Get the string value of the current element.
- const char * [CurrentName \(\)](#)
Get the name of the current element.
- bool [FindFullNameBoolean \(const char *name\)](#)
Find the boolean value of a given element.
- bool [FindGlobalBoolean \(const char *name\)](#)
Find the boolean value of a given element. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.
- bool [FindBoolean \(const char *name\)](#)
Find the boolean value of the element after the element with the given name.
- bool [FindBooleanInCurentObject \(const char *name\)](#)
Find the boolean value of the element within the current object. Does not search sub-objects.
- bool [FindFullNamePermissiveBoolean \(const char *name\)](#)
Find the permissive boolean value of a given element.
- bool [FindGlobalPermissiveBoolean \(const char *name\)](#)
Find the permissive boolean value of a given element. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.

- bool [FindPermissiveBoolean](#) (const char *name)
Find the permissive boolean value of the element after the element with the provided name.
- bool [FindPermissiveBooleanInCurentObject](#) (const char *name)
Find the permissive boolean value of the element with the given name in the current object. Does not search sub-objects.
- const char * [FindFullNameString](#) (const char *name)
Find the string value of the element with the given name in the current object.
- const char * [FindGlobalString](#) (const char *name)
Find the string value of a given element. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.
- const char * [FindString](#) (const char *name)
Find the string value of the element after the element with the given name.
- const char * [FindStringInCurentObject](#) (const char *name)
Find the string value of the element with the given name in the current object. Does not search sub-objects.
- double [FindFullNameNumber](#) (const char *name)
Find the number value of the element with the given name in the current object.
- double [FindGlobalNumber](#) (const char *name)
Find the number value of a given element. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.
- double [FindNumber](#) (const char *name)
Find the number value of the element after the element with the given name.
- double [FindNumberInCurentObject](#) (const char *name)
Find the number value of the element with the given name in the current object. Does not search sub-objects.
- bool [FindGlobalObject](#) (const char *name)
Find the OBJECT with the given name. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.
- bool [FindObject](#) (const char *name)
Find the OBJECT of the element after the element with the given name.
- bool [FindObjectInCurentObject](#) (const char *name)
Find the OBJECT of the element with the given name in the current OBJECT. Does not search sub-objects.
- void **DumpState** ()
Outputs what's in the parse tree to stdout.
- int [PrintObject](#) (bool pretty=false)
Prints the JSON data set to stdout.
- int [PrintObjectToBuffer](#) (char *buffer, int maxlen, bool pretty=false)
Prints the JSON data set to a provided buffer.
- int [PrintObjectToFd](#) (int fd, bool pretty=false)
Prints the JSON data set to a specified file descriptor.
- int [PrintObjectToString](#) (NBString &s, bool pretty=false)
Prints the JSON data set to a NBString object.
- int **PrintChildren** (bool pretty=false)
Output child objects of this [JsonRef](#) as JSON text to stdout.
- int **PrintChildrenToFd** (int fd, bool pretty=false)
Output child objects of this [JsonRef](#) as JSON text to a file descriptor.
- int **PrintChildrenToBuffer** (char *buffer, int maxlen, bool pretty=false)
Output child objects of this [JsonRef](#) as JSON text to a buffer pointer.
- int [GetPrintSize](#) (bool pretty=false)
Calculates how many characters the JSON data set would take to print.
- [ParsedJsonDataSet](#) * **StartBuilding** ()
Use to start building the JSON data set.

- [ParsedJsonDataSet * AddObjectStart](#) (const char *name)
Use to start an object in the JSON data set.
- [ParsedJsonDataSet * AddMyMac](#) (const char *name)
Add the device MAC address to the JSON data set.
- [ParsedJsonDataSet * Add](#) (const char *name, int i)
Add a name/value pair to the JSON data set where the value is an int.
- [ParsedJsonDataSet * Add](#) (const char *name, short i)
Add a name/value pair to the JSON data set where the value is a short.
- [ParsedJsonDataSet * Add](#) (const char *name, long i)
Add a name/value pair to the JSON data set where the value is a long.
- [ParsedJsonDataSet * Add](#) (const char *name, unsigned int i)
Add a name/value pair to the JSON data set where the value is an unsigned int.
- [ParsedJsonDataSet * Add](#) (const char *name, unsigned short i)
Add a name/value pair to the JSON data set where the value is a unsigned short.
- [ParsedJsonDataSet * Add](#) (const char *name, unsigned long i)
Add a name/value pair to the JSON data set where the value is a unsigned long.
- [ParsedJsonDataSet * Add](#) (const char *name, double d)
Add a name/value pair to the JSON data set where the value is a double.
- [ParsedJsonDataSet * Add](#) (const char *name, const char *str)
Add a name/value pair to the JSON data set where the value is a string.
- [ParsedJsonDataSet * Add](#) (const char *name, bool b)
Add a name/value pair to the JSON data set where the value is a bool.
- [ParsedJsonDataSet * Add](#) (const char *name, IPADDR4 i4)
Add a name/value pair to the JSON data set where the value is an IPv4 address.
- [ParsedJsonDataSet * Add](#) (const char *name, const IPADDR &i)
Add a name/value pair to the JSON data set where the value is an IP address.
- [ParsedJsonDataSet * Add](#) (const char *name, const MACADR &ma)
Add a name/value pair to the JSON data set where the value is a MAC address.
- [ParsedJsonDataSet * AddNull](#) (const char *name)
Add a name/value pair to the JSON data set where the value is null.
- [ParsedJsonDataSet * AddArrayStart](#) (const char *name)
Add an ARRAY start to the JSON data set.
- [ParsedJsonDataSet * EndArray](#) ()
Add an ARRAY end to the JSON data set.
- [ParsedJsonDataSet * AddArrayElement](#) (int i)
Add an integer value to the current array.
- [ParsedJsonDataSet * AddArrayElement](#) (short i)
Add a short value to the current array.
- [ParsedJsonDataSet * AddArrayElement](#) (long i)
Add a long value to the current array.
- [ParsedJsonDataSet * AddArrayElement](#) (unsigned int i)
Add an unsigned int value to the current array.
- [ParsedJsonDataSet * AddArrayElement](#) (unsigned short i)
Add an unsigned short value to the current array.
- [ParsedJsonDataSet * AddArrayElement](#) (unsigned long i)
Add an unsigned long value to the current array.
- [ParsedJsonDataSet * AddArrayElement](#) (double d)
Add a double to the current array.
- [ParsedJsonDataSet * AddArrayElement](#) (const char *str)
Add a string to the current array.
- [ParsedJsonDataSet * AddArrayElement](#) (bool b)

- Add a bool to the current array.*

 - [ParsedJsonDataSet](#) * [AddArrayElement](#) (const [IPADDR](#) &i)

Add an IP address to the current array.
- [ParsedJsonDataSet](#) * [AddArrayElementArray](#) ()

Add the start of an array element to the current array.
- [ParsedJsonDataSet](#) * [AddArrayObjectStart](#) ()

Add the start of an object element to the current array.
- [ParsedJsonDataSet](#) * [AddNullArrayElement](#) ()

Add a null element to the current array.
- [ParsedJsonDataSet](#) * [EndObject](#) ()

Add an end to the current object.
- [ParsedJsonDataSet](#) * [DoneBuilding](#) ()

Add an end JSON data set and finish building.

16.61.1 Detailed Description

Get the type name of the JSON primitive type passed in.

Parameters

<i>t</i>	The JSON primitive type to get the name of.
----------	---

Returns

The name of the JSON primitive type passed in.

The documentation for this class was generated from the following file:

- [json_lexer.h](#)

16.62 JsonRef Class Reference

Represents a positional reference (pointer) of a location inside a [ParsedJsonDataSet](#) object

```
#include <json_lexer.h>
```

Public Member Functions

Querying the Data Structure

Allows easy retrieval of entities by array index or object key name

Example

```
printf("User %d name %s",
      (int)myJsonRef("users")[0]("id"),
      (const char *)myJsonRef("users")[0]("name")
);
```

- [JsonRef operator\[\]](#) (int i)
 - Get a [JsonRef](#) from an array by numerical index.*
- [JsonRef object](#) (const char *name)
 - Get a [JsonRef](#) representing an object from a parent object by key name.*
- [JsonRef name](#) (const char *name)
 - Get a [JsonRef](#) representing any entity from a parent object by key name.*
- [JsonRef operator\(\)](#) (const char *namev)
 - Get a [JsonRef](#) representing any entity from a parent object by key name.*

Types and Operators

Allows casting of a [JsonRef](#) to the desired type

Example

```
bool b = (bool)myJsonRef("user")("isEnabled");
int i = (int)myJsonRef("user")("id");
const char *str = (const char *)myJsonRef("user")("name");
```

- **operator bool () const**
Operator to return a JSON element of type boolean.
- **operator float () const**
Operator to return a JSON element of type float.
- **operator double () const**
Operator to return a JSON element of type double.
- **operator uint8_t () const**
Operator to return a JSON element of type uint8_t.
- **operator int () const**
Operator to return a JSON element of type int.
- **operator uint16_t () const**
Operator to return a JSON element of type uint16_t.
- **operator uint32_t () const**
Operator to return a JSON element of type uint32_t.
- **operator int8_t () const**
Operator to return a JSON element of type int8_t.
- **operator int16_t () const**
Operator to return a JSON element of type int16_t.
- **operator int32_t () const**
Operator to return a JSON element of type int32_t.
- **operator time_t () const**
Operator to return a JSON element of type time_t.
- **operator const char * () const**
*Operator to return a JSON element of type const char *.*
- **operator NBString () const**
Operator to return a JSON element of type NBString.

Checking Validity

- bool **IsNumber ()**
Check if the current [JsonRef](#) is a valid JSON number element.
- bool **IsObject ()**
Check if the current [JsonRef](#) is a valid JSON object element.
- bool **IsString ()**
Check if the current [JsonRef](#) is a valid JSON string element.
- bool **IsBool ()**
Check if the current [JsonRef](#) is a valid JSON boolean element.
- bool **IsNull ()**
Check if the current [JsonRef](#) is a valid JSON null element.
- bool **IsArray ()**
Check if the current [JsonRef](#) is a valid JSON array element.
- bool **Valid () const**
Check if the current [JsonRef](#) is a valid JSON position.

Traversing the Data Structure

- **JsonRef start ()**
Begin traversal: check for ref validity and reset the position.
- **JsonRef next () const**
Traverse: check for ref validity and increment the position.
- bool **IncPosition ()**
Increment the position index of the [ParsedJsonDataSet](#).
- bool **JumpPosition (int siz)**
Jump to a specific position index in the [ParsedJsonDataSet](#).
- void **ResetPosition ()**

- void **SkipElement** ()
Reset the position index of the [ParsedJsonDataSet](#) to the beginning.
- void **SkipArray** ()
Increment the position index of the [ParsedJsonDataSet](#) beyond this element.
- void **SkipObject** ()
Increment the position index of the [ParsedJsonDataSet](#) beyond this array.
- void **SkipObject** ()
Increment the position index of the [ParsedJsonDataSet](#) beyond this object.

Utility

- int **PrintChildren** (bool pretty=false)
Output child objects of this [JsonRef](#) as JSON text to stdout.
- int **PrintChildrenToFd** (int fd, bool pretty=false)
Output child objects of this [JsonRef](#) as JSON text to a file descriptor.
- int **PrintChildrenToBuffer** (char *buffer, int maxlen, bool pretty=false)
Output child objects of this [JsonRef](#) as JSON text to a buffer pointer.
- int **PrintChildrenToString** (NBString &s, bool pretty=false)
Output child objects of this [JsonRef](#) as JSON text to a [NBString](#).
- int **GetChildPrintSize** (bool pretty=false)
Return the length of the child objects' JSON text as written with the [PrintChildren](#) functions.*
- void **DiagDump** (const char *lab)
Output a verbose diagnostic report of the [ParsedJsonDatSet](#) to stdout.
- void **MakeInvalid** ()

Friends

- class **ParsedJsonDataSet**

16.62.1 Detailed Description

Represents a positional reference (pointer) of a location inside a [ParsedJsonDataSet](#) object

A [JsonRef](#) can be used as a pointer to a variable or sub object inside a [ParsedJsonDataSet](#) object to make decoding the hierarchy much simpler and easier to understand. A [JsonRef](#) is not limited to just pointing at internal objects; it can point to any JSON parsed token/type.

16.62.2 Member Function Documentation

16.62.2.1 GetChildPrintSize()

```
int JsonRef::GetChildPrintSize (
    bool pretty = false )
```

Return the length of the child objects' JSON text as written with the [PrintChildren*](#) functions.

Parameters

<i>pretty</i>	Whether indentation and new lines should be provided between elements.
---------------	--

Returns

The number of characters needed to print the JSON data set.

16.62.2.2 IsArray()

```
bool JsonRef::IsArray ( ) [inline]
```

Check if the current [JsonRef](#) is a valid JSON array element.

Returns

True if parsed JSON element is an array, otherwise false.

16.62.2.3 IsBool()

```
bool JsonRef::IsBool ( ) [inline]
```

Check if the current [JsonRef](#) is a valid JSON boolean element.

Returns

True if parsed JSON element is a boolean, otherwise false.

16.62.2.4 IsNull()

```
bool JsonRef::IsNull ( ) [inline]
```

Check if the current [JsonRef](#) is a valid JSON null element.

Returns

True if parsed JSON element is a null, otherwise false.

16.62.2.5 IsNumber()

```
bool JsonRef::IsNumber ( ) [inline]
```

Check if the current [JsonRef](#) is a valid JSON number element.

Returns

True if parsed JSON element is a number, otherwise false.

16.62.2.6 IsObject()

```
bool JsonRef::IsObject ( ) [inline]
```

Check if the current [JsonRef](#) is a valid JSON object element.

Returns

True if parsed JSON element is an object, otherwise false.

16.62.2.7 IsString()

```
bool JsonRef::IsString ( ) [inline]
```

Check if the current [JsonRef](#) is a valid JSON string element.

Returns

True if parsed JSON element is a string, otherwise false. A string can be of type `char *`, or a [NBString](#) object.

16.62.2.8 MakeInvalid()

```
void JsonRef::MakeInvalid ( ) [inline]
```

16.62.2.9 name()

```
JsonRef JsonRef::name (
    const char * name )
```

Get a [JsonRef](#) representing any entity from a parent object by key name.

Useful if more than one JSON object/element has the same name.

Example

```
JsonRef userThree = myJsonRef.name("users")[3];
```

Parameters

<i>*name</i>	Pointer to name of the entity to find
--------------	---------------------------------------

Returns

The reference to the entity of type [JsonRef](#)

See also

[JsonRef::operator\(\)\(\)](#), [JsonRef::object\(\)](#)

16.62.2.10 object()

```
JsonRef JsonRef::object (  
    const char * name ) [inline]
```

Get a [JsonRef](#) representing an object from a parent object by key name.

Example

```
JsonRef john = myJsonRef.object("users").object("john");
```

Parameters

<i>*name</i>	Pointer to name of the object to find
--------------	---------------------------------------

Returns

The reference to the object of type [JsonRef](#)

16.62.2.11 operator bool()

```
JsonRef::operator bool ( ) const [inline]
```

Operator to return a JSON element of type boolean.

Returns

Boolean value

16.62.2.12 operator const char *()

```
JsonRef::operator const char * ( ) const [inline]
```

Operator to return a JSON element of type const char *.

Returns

const char * value

16.62.2.13 operator double()

```
JsonRef::operator double ( ) const [inline]
```

Operator to return a JSON element of type double.

Returns

double value

16.62.2.14 operator float()

```
JsonRef::operator float ( ) const [inline]
```

Operator to return a JSON element of type float.

Returns

float value

16.62.2.15 operator int()

```
JsonRef::operator int ( ) const [inline]
```

Operator to return a JSON element of type int.

Returns

integer value

16.62.2.16 operator int16_t()

```
JsonRef::operator int16_t ( ) const [inline]
```

Operator to return a JSON element of type int16_t.

Returns

int16_t value

16.62.2.17 operator int32_t()

```
JsonRef::operator int32_t ( ) const [inline]
```

Operator to return a JSON element of type int32_t.

Returns

int32_t value

16.62.2.18 operator int8_t()

```
JsonRef::operator int8_t ( ) const [inline]
```

Operator to return a JSON element of type int8_t.

Returns

int8_t value

16.62.2.19 operator NBString()

```
JsonRef::operator NBString ( ) const [inline]
```

Operator to return a JSON element of type [NBString](#).

Returns

[NBString](#) object

16.62.2.20 operator time_t()

```
JsonRef::operator time_t ( ) const [inline]
```

Operator to return a JSON element of type time_t.

Returns

time_t value

16.62.2.21 operator uint16_t()

```
JsonRef::operator uint16_t ( ) const [inline]
```

Operator to return a JSON element of type `uint16_t`.

Returns

`uint16_t` value

16.62.2.22 operator uint32_t()

```
JsonRef::operator uint32_t ( ) const [inline]
```

Operator to return a JSON element of type `uint32_t`.

Returns

`uint32_t` value

16.62.2.23 operator uint8_t()

```
JsonRef::operator uint8_t ( ) const [inline]
```

Operator to return a JSON element of type `uint8_t`.

Returns

`uint8_t` value

16.62.2.24 operator>()()

```
JsonRef JsonRef::operator() (
    const char * namev ) [inline]
```

Get a [JsonRef](#) representing any entity from a parent object by key name.
Shortcut for [JsonRef::name\(\)](#)

Example

```
JsonRef allUsers = myJsonRef("users");
```

Parameters

<code>*namev</code>	Pointer to name of the entity to find
---------------------	---------------------------------------

Returns

The reference to the entity of type [JsonRef](#)

See also

[JsonRef::name\(\)](#), [JsonRef::object\(\)](#)

16.62.2.25 operator[]()

```
JsonRef JsonRef::operator[] (
    int i )
```

Get a [JsonRef](#) from an array by numerical index.

Example

```
JsonRef userThree = myJsonRef("users")[3];
```

Returns

A [JsonRef](#) if array element is found

16.62.2.26 Valid()

```
bool JsonRef::Valid ( ) const [inline]
```

Check if the current [JsonRef](#) is a valid JSON position.

Returns

True if a JSON element exists, otherwise false.

The documentation for this class was generated from the following file:

- [json_lexer.h](#)

16.63 DHCP::LeaseAllocator Class Reference

Base class/interface for lease allocators for the [DHCP](#) server.

```
#include <dhcpd.h>
```

Inherited by [DHCP::BlockAllocator](#), [DHCP::SingleAllocator](#), and [SpecialAllocator](#).

16.63.1 Detailed Description

Base class/interface for lease allocators for the [DHCP](#) server.

The documentation for this class was generated from the following file:

- [dhcpd.h](#)

16.64 LetsEncryptAcmeServletObject Class Reference

ACME Client for Let's Encrypt.

```
#include <acmeRFC8555Servlet.h>
```

Inherits [AcmeServletObject](#).

Public Member Functions

- [LetsEncryptAcmeServletObject](#) (const bool useStaging=false)
Enable the Let's Encrypt ACME client.

Public Member Functions inherited from [AcmeServletObject](#)

- void [Delete_Everything_Restart](#) ()
Re-request the ACME certificate.
- void [SetDiag](#) (bool v)
Turn on diagnostic printf messages to the console.
- [NBString](#) [GetGlobalStateString](#) ()
Returns the detailed state of the ACME process.
- [NBString](#) [GetStateString](#) ()
Returns the specific state condition of the acmeservlet.
- const char * [GetStateCC](#) ()
Returns the specific state condition of the acmeservlet.
- [AcmeServletObject](#) (const char *pUrlDir)
ACME Client Constructor.

16.64.1 Detailed Description

ACME Client for Let's Encrypt.

16.64.2 Constructor & Destructor Documentation

16.64.2.1 LetsEncryptAcmeServletObject()

```
LetsEncryptAcmeServletObject::LetsEncryptAcmeServletObject (
    const bool useStaging = false ) [inline]
```

Enable the Let's Encrypt ACME client.

Parameters

<i>useStaging</i>	Optional boolean to use the Let's Encrypt staging server for testing (default false)
-------------------	--

The documentation for this class was generated from the following file:

- [acmeRFC8555Servlet.h](#)

16.65 MACADR Class Reference

Used to store and manipulate MAC addresses.

```
#include <nettypes.h>
```

Public Member Functions

- bool **IsNull** ()
Checks if MAC is null.
- bool **IsMultiCast** ()
Checks if MAC is a Multicast MAC.
- bool **IsBroadCast** ()
Checks if MAC is a Broadcast MAC.
- uint8_t **GetByte** (int n) const
Get the nth byte of the MAC.
- void **SetFromBytes** (const uint8_t *pb)
Set the MAC Address from a pointer to an array of 6 bytes.
- void **fdprint** (int fd)
print the MAC to a file descriptor
- void **print** ()
print the MAC to file descriptor 1
- [MACADR operator+](#) (uint32_t rhs)

16.65.1 Detailed Description

Used to store and manipulate MAC addresses.

16.65.2 Member Function Documentation

16.65.2.1 operator+()

```
MACADR MACADR::operator+ (
    uint32_t rhs ) [inline]
```

The documentation for this class was generated from the following file:

16.67.1 Detailed Description

MCAN configuration structure.

Configuration structure for an MCAN instance. This structure should be initialized by the `mcan_get_config_defaults()` function before being modified by the user application.

16.67.2 Member Function Documentation

16.67.2.1 `set_config_defaults()`

```
void mcanMODM7AE70::mcan_config::set_config_defaults ( ) [inline]
```

Initializes an MCAN configuration structure to defaults.

Initializes a given MCAN configuration struct to a set of known default values. This function should be called on any new instance of the configuration struct before being modified by the user application.

The default configuration is as follows:

- Not run in standby mode
- Disable Watchdog
- Transmit pause enabled
- Edge filtering during bus integration enabled
- Protocol exception handling enabled
- Automatic retransmission enabled
- Clock stop request disabled
- Clock stop acknowledge disabled
- Timestamp Counter Prescaler 1
- Timeout Period with 0xFFFF
- Timeout Mode: Continuous operation
- Disable Timeout
- Transmitter Delay Compensation Offset is 0
- Transmitter Delay Compensation Filter Window Length is 0
- Reject nonmatching standard frames
- Reject nonmatching extended frames
- Reject remote standard frames
- Reject remote extended frames
- Extended ID Mask is 0x1FFFFFFF
- Rx FIFO 0 Operation Mode: overwrite
- Disable Rx FIFO 0 Watermark
- Rx FIFO 1 Operation Mode: overwrite
- Disable Rx FIFO 1 Watermark
- Tx FIFO/Queue Mode: FIFO
- Disable Tx Event FIFO Watermark

16.67.3 Member Data Documentation

16.67.3.1 automatic_retransmission

`bool mcanMODM7AE70::mcan_config::automatic_retransmission`
Automatic Retransmission.

16.67.3.2 clock_stop_acknowledge

`bool mcanMODM7AE70::mcan_config::clock_stop_acknowledge`
Clock Stop Acknowledge.

16.67.3.3 clock_stop_request

`bool mcanMODM7AE70::mcan_config::clock_stop_request`
Clock Stop Request.

16.67.3.4 delay_compensation_filter_window_length

`uint8_t mcanMODM7AE70::mcan_config::delay_compensation_filter_window_length`
Transmitter Delay Compensation Filter Window Length : 0x0-0x7F

16.67.3.5 delay_compensation_offset

`uint8_t mcanMODM7AE70::mcan_config::delay_compensation_offset`
Transmitter Delay Compensation Offset : 0x0-0x7F

16.67.3.6 edge_filtering

`bool mcanMODM7AE70::mcan_config::edge_filtering`
Edge Filtering during Bus Integration.

16.67.3.7 extended_id_mask

`uint32_t mcanMODM7AE70::mcan_config::extended_id_mask`
Extended ID Mask: 0x0-0x1FFFFFFF.

16.67.3.8 nonmatching_frames_action_extended

`enum mcan_nonmatching_frames_action mcanMODM7AE70::mcan_config::nonmatching_frames_action_↔
extended`
Nonmatching frames action for extended frames.

16.67.3.9 nonmatching_frames_action_standard

`enum mcan_nonmatching_frames_action mcanMODM7AE70::mcan_config::nonmatching_frames_action_↔
standard`
Nonmatching frames action for standard frames.

16.67.3.10 protocol_exception_handling

`bool mcanMODM7AE70::mcan_config::protocol_exception_handling`
Protocol Exception Handling.

16.67.3.11 remote_frames_extended_reject

`bool mcanMODM7AE70::mcan_config::remote_frames_extended_reject`
Reject Remote Extended Frames.

16.67.3.12 remote_frames_standard_reject

bool mcanMODM7AE70::mcan_config::remote_frames_standard_reject
Reject Remote Standard Frames.

16.67.3.13 run_in_standby

bool mcanMODM7AE70::mcan_config::run_in_standby
MCAN run in standby control.

16.67.3.14 rx_fifo_0_overwrite

bool mcanMODM7AE70::mcan_config::rx_fifo_0_overwrite
Rx FIFO 0 Operation Mode.

16.67.3.15 rx_fifo_0_watermark

uint8_t mcanMODM7AE70::mcan_config::rx_fifo_0_watermark
Rx FIFO 0 Watermark: 1-64, other value disable it.

16.67.3.16 rx_fifo_1_overwrite

bool mcanMODM7AE70::mcan_config::rx_fifo_1_overwrite
Rx FIFO 1 Operation Mode.

16.67.3.17 rx_fifo_1_watermark

uint8_t mcanMODM7AE70::mcan_config::rx_fifo_1_watermark
Rx FIFO 1 Watermark: 1-64, other value disable it.

16.67.3.18 tdc_enable

bool mcanMODM7AE70::mcan_config::tdc_enable
Transceiver Delay Compensation enable.

16.67.3.19 timeout_enable

bool mcanMODM7AE70::mcan_config::timeout_enable
Timeout enable.

16.67.3.20 timeout_mode

enum mcan_timeout_mode mcanMODM7AE70::mcan_config::timeout_mode
Timeout Mode.

16.67.3.21 timeout_period

uint16_t mcanMODM7AE70::mcan_config::timeout_period
Timeout Period.

16.67.3.22 timestamp_prescaler

uint8_t mcanMODM7AE70::mcan_config::timestamp_prescaler
Timestamp Counter Prescaler: 0x0-0xF

16.67.3.23 transmit_pause

bool mcanMODM7AE70::mcan_config::transmit_pause
Transmit Pause.

16.67.3.24 tx_event_fifo_watermark

uint8_t mcanMODM7AE70::mcan_config::tx_event_fifo_watermark
Tx Event FIFO Watermark: 1-32, other value disable it.

16.67.3.25 tx_queue_mode

bool mcanMODM7AE70::mcan_config::tx_queue_mode
Tx FIFO/Queue Mode, 0 for FIFO and 1 for Queue.

16.67.3.26 watchdog_configuration

uint8_t mcanMODM7AE70::mcan_config::watchdog_configuration
Start value of the Message RAM Watchdog Counter
The documentation for this class was generated from the following file:

- [mcan.h](#)

16.68 mcan_extended_message_filter_element Class Reference

MCAN extended message ID filter element structure.
#include <mcan_internal.h>

16.68.1 Detailed Description

MCAN extended message ID filter element structure.
Common element structure for extended message ID filter element.
The documentation for this class was generated from the following file:

- [mcan_internal.h](#)

16.69 mcanMODM7AE70::mcan_module Class Reference

MCAN Module Class.
#include <mcan.h>

Public Member Functions

- [mcan_module](#) (Mcan *hw, uint32_t baud)
Create a MCAN module instance.
- void [init](#) (Mcan *hw, struct [mcan_config](#) *config, uint32_t baud)
Initialize a MCAN module.
- void [send_message](#) (uint32_t id_value, uint8_t *data, uint32_t data_length, [OS_SEM](#) *pSem=0)
Send a MCAN message.
- bool [blocking_send_message](#) (uint32_t id_value, uint8_t *data, uint32_t data_length, uint32_t TimeOut)
Send a MCAN message and block until sent.
- int [RegisterRxFifo](#) (uint32_t composite_id, [OS_FIFO](#) *pFifo, int channel=-1)
Register a FIFO to receive CAN messages.
- int [RegisterRxFifoMask](#) (uint32_t composite_id, uint32_t mask, [OS_FIFO](#) *pFifo, int channel=-1)
Register a FIFO to receive messages as specified by the address bit mask. A value of 1 = match, a value of 0 = does not match.
- int [RegisterRxFifoRange](#) (uint32_t composite_id_low, uint32_t composite_id_hi, [OS_FIFO](#) *pFifo, int channel=-1)
Register a FIFO to receive messages in the specified numeric range of addresses from low to high.
- int [UnRegisterFifo](#) (int channel)
Unregister the FIFO for the specified CAN channel.

- int [MultiCanSetRTRMessage](#) (uint32_t id, uint8_t *data, uint8_t len, int channel=-1)
Enable an auto-reply to a CAN RTR message for the specified CAN ID. The reply message is specified by the data parameter.
- int [MultiCanReplaceRTRMessage](#) (int channel, uint8_t *data, uint8_t len)
Modifies/updates the response for the RTR message registered with [MultiCanSetRTRMessage\(\)](#).
- int [MultiCanStopRTRMessage](#) (int channel)
Unregister the RTR message for the specified channel.

16.69.1 Detailed Description

MCAN Module Class.

Class to control a MCAN modules (peripherals) on the MODM7AE70

16.69.2 Constructor & Destructor Documentation

16.69.2.1 mcan_module()

```
mcanMODM7AE70::mcan_module::mcan_module (
    Mcan * hw,
    uint32_t baud )
```

Create a MCAN module instance.

Parameters

<i>hw</i>	MCAN hardware peripheral, MCAN0 or MCAN 1
<i>baud</i>	MCAN baud rate. For example, 500000

16.69.3 Member Function Documentation

16.69.3.1 blocking_send_message()

```
bool mcanMODM7AE70::mcan_module::blocking_send_message (
    uint32_t id_value,
    uint8_t * data,
    uint32_t data_length,
    uint32_t TimeOut )
```

Send a MCAN message and block until sent.

Parameters

<i>id_value</i>	CAN ID, 11-bit standard or 29-bit extended
<i>data</i>	Pointer to message data
<i>data_length</i>	Length of data in bytes
<i>TimeOut</i>	Time out value in system time ticks. For example, TICKS_PER_SECOND * 1

16.69.3.2 init()

```
void mcanMODM7AE70::mcan_module::init (
    Mcan * hw,
    struct mcan_config * config,
    uint32_t baud )
```

Initialize a MCAN module.

Parameters

<i>hw</i>	MCAN hardware peripheral, MCAN0 or MCAN 1
-----------	---

Parameters

<i>config</i>	Pointer to a mcan_config object, initialized with appropriate values.
<i>baud</i>	MCAN baud rate. For example, 500000

16.69.3.3 MultiCanReplaceRTRMessage()

```
int mcanMODM7AE70::mcan_module::MultiCanReplaceRTRMessage (
    int channel,
    uint8_t * data,
    uint8_t len )
```

Modifies/updates the response for the RTR message registered with [MultiCanSetRTRMessage\(\)](#).

Returns

The channel number registered for the RTR message.

See also

[MultiCanSetRTRMessage\(\)](#), [MultiCanStopRTRMessage\(\)](#)

16.69.3.4 MultiCanSetRTRMessage()

```
int mcanMODM7AE70::mcan_module::MultiCanSetRTRMessage (
    uint32_t id,
    uint8_t * data,
    uint8_t len,
    int channel = -1 )
```

Enable an auto-reply to a CAN RTR message for the specified CAN ID. The reply message is specified by the data parameter.

The response message can be modified with [MultiCanReplaceRTRMessage\(\)](#).

Parameters

<i>id</i>	CAN ID, 11-bit standard or 29-bit extended
<i>data</i>	Pointer to message data
<i>len</i>	Length of message
<i>channel</i>	Optional CAN channel

Returns

The channel number corresponding to the ID and RTR message.

See also

[MultiCanReplaceRTRMessage\(\)](#), [MultiCanStopRTRMessage\(\)](#)

16.69.3.5 MultiCanStopRTRMessage()

```
int mcanMODM7AE70::mcan_module::MultiCanStopRTRMessage (
    int channel )
```

Unregister the RTR message for the specified channel.

Parameters

<i>channel</i>	CAN channel number
----------------	--------------------

Returns

OS_NO_ERR on success

See also

[MultiCanSetRTRMessage\(\)](#), [MultiCanReplaceRTRMessage\(\)](#)

16.69.3.6 RegisterRxFifo()

```
int mcanMODM7AE70::mcan_module::RegisterRxFifo (
    uint32_t composite_id,
    OS_FIFO * pFifo,
    int channel = -1 )
```

Register a FIFO to receive CAN messages.

Parameters

<i>composite_id</i>	CAN ID, 11-bit standard or 29-bit extended
<i>pFifo</i>	Pointer to OS_FIFO for received data
<i>channel</i>	Optional CAN channel

Returns

OS_NO_ERR on success

16.69.3.7 RegisterRxFifoMask()

```
int mcanMODM7AE70::mcan_module::RegisterRxFifoMask (
    uint32_t composite_id,
    uint32_t mask,
    OS_FIFO * pFifo,
    int channel = -1 )
```

Register a FIFO to receive messages as specified by the address bit mask. A value of 1 = match, a value of 0 = does not match.

Parameters

<i>composite_id</i>	CAN ID, 11-bit standard or 29-bit extended
<i>mask</i>	Id mask
<i>pFifo</i>	Pointer to OS_FIFO for received data
<i>channel</i>	Optional CAN channel

Returns

OS_NO_ERR on success

16.69.3.8 RegisterRxFifoRange()

```
int mcanMODM7AE70::mcan_module::RegisterRxFifoRange (
    uint32_t composite_id_low,
    uint32_t composite_id_hi,
    OS_FIFO * pFifo,
    int channel = -1 )
```

Register a FIFO to receive messages in the specified numeric range of addresses from low to high.

Parameters

<i>composite_id_low</i>	Composite ID low value
<i>composite_id_hi</i>	Composite ID high value
<i>pFifo</i>	Pointer to OS_FIFO for received data
<i>channel</i>	Optional CAN channel

Returns

OS_NO_ERR on success

16.69.3.9 send_message()

```
void mcanMODM7AE70::mcan_module::send_message (
    uint32_t id_value,
    uint8_t * data,
    uint32_t data_length,
    OS_SEM * pSem = 0 )
```

Send a MCAN message.

Parameters

<i>id_value</i>	CAN ID, 11-bit standard or 29-bit extended
<i>data</i>	Pointer to message data
<i>data_length</i>	Length of data in bytes
<i>pSem</i>	Optional pointer to semaphore to post to, default is no post

16.69.3.10 UnRegisterFifo()

```
int mcanMODM7AE70::mcan_module::UnRegisterFifo (
    int channel )
```

Unregister the FIFO for the specified CAN channel.

Parameters

<i>channel</i>	CAN channel number
----------------	--------------------

Returns

OS_NO_ERR on success

The documentation for this class was generated from the following file:

16.70 mcan_rx_element_buffer Struct Reference

MCAN receive element structure for buffer.

```
#include <mcan_internal.h>
```

16.70.1 Detailed Description

MCAN receive element structure for buffer.

The documentation for this struct was generated from the following file:

- [mcan_internal.h](#)

16.71 mcan_tx_element Struct Reference

MCAN transfer element structure.

```
#include <mcan_internal.h>
```

16.71.1 Detailed Description

MCAN transfer element structure.

Common element structure for transfer buffer and FIFO/QUEUE.

The documentation for this struct was generated from the following file:

- [mcan_internal.h](#)

16.72 mcan_tx_event_element Struct Reference

MCAN transfer event FIFO element structure.

```
#include <mcan_internal.h>
```

16.72.1 Detailed Description

MCAN transfer event FIFO element structure.

Common element structure for transfer event FIFO.

The documentation for this struct was generated from the following file:

16.73 NBRtosInitObj Class Reference

A simple class to derive from if you are creating tasks that are constructed at global scope and need to do RTOS initialization.

```
#include <nbrtos.h>
```

Public Member Functions

- virtual void **Notify** ()=0

This will be called when the RTOS has been setup in initialization.

16.73.1 Detailed Description

A simple class to derive from if you are creating tasks that are constructed at global scope and need to do RTOS initialization.

The virtual function **Notify** will be called once the RTOS internals are setup so you can create a task, allocate buffers, etc. If you need to do network I/O, then you this will not be sufficient as you will need register to be notified when link is active on the interface.

See also

[NetInterface::LinkActiveFuncPtr](#)

The documentation for this class was generated from the following file:

16.74 NBString Class Reference

Lightweight alternative to C++ CString class.

```
#include <nbstring.h>
```

Inherited by [NBInterpolatedString](#).

Public Member Functions

- **NSString** ()
Construct a [NSString](#) object.
- **NSString** (const **NSString** &str)
Construct a new [NSString](#) object from an existing [NSString](#) object.
- **NSString** (const **NSString** &str, size_t pos, size_t len=npos)
Construct a new [NSString](#) object from a substring of an existing [NSString](#) object.
- **NSString** (const char *s)
Construct a [NSString](#) object from a character string (null terminated array of characters)
- **NSString** (const char *s, size_t n)
Construct a [NSString](#) object from a character string up to the specified amount.
- **~NSString** ()
[NSString](#) destructor.
- const char * **c_str** () const
*Method to pass a [NSString](#) as a constant char *.*
- **NSString substr** (size_t pos=0, size_t len=npos) const
Creates a new [NSString](#) object from a substring of the existing [NSString](#) object.
- int **compare** (const **NSString** &str) const
Compares two [NSString](#) objects.
- int **compare** (const char *s) const
Compares the [NSString](#) object to a character string.
- size_t **find** (const **NSString** str, size_t pos=0) const
Find a substring within a [NSString](#) object.
- size_t **find** (const char *str, size_t pos=0) const
Find a substring within a character string.
- size_t **find** (const char *s, size_t pos, size_t n) const
Find a substring within a character string.
- size_t **find** (char c, size_t pos=0) const
Find the first occurrence of a character within the [NSString](#) object.
- size_t **replace** (const char *findStr, char rep, size_t startPos=0, size_t end=0)
Replace all occurrences of all "<findStr>" characters within the [NSString](#) object.
- size_t **replace** (char c, char rep, size_t startPos=0, size_t end=0)
Replace all occurrences of all "<findStr>" characters within the [NSString](#) object.
- size_t **size** () const
Returns the current size of memory allocated for the string.
- size_t **length** () const
Returns the length of the string.
- void **clear** ()
Clear a [NSString](#) object and free allocated memory.
- bool **empty** () const
Check if a string is empty.
- **NSString & Append** (const char *str, size_t len)
Append a string to an existing [NSString](#) object.
- **NSString & FdAppend** (int fd, size_t len)
Append from a file descriptor to an existing [NSString](#) object.
- **NSString & Reserve** (size_t len)
Reserve an additional buffer amount.
- int **vsprintf** (const char *format, va_list &vl)
Print to a string with formatting.
- int **sprintf** (const char *format,...)

- *sprintf* to a string with formatting to a character array
- int `sprintf` (NBString const format,...)
 - *sprintf* to a string with formatting as a NBString object
- int `siprintf` (const char *format,...)
 - *isprintf* (integer) to a string with formatting to a character array
- int `siprintf` (NBString const format,...)
 - *isprintf* (integer) to a string with formatting to a NBString object
- int `stoi` () const
 - Parse the string and convert to an integer number.
- long `stol` () const
 - Parse the string value and convert to a long integer number.
- unsigned int `stoui` () const
 - Parse the string value and convert to a const integer number.
- unsigned long `stoul` () const
 - Parse the string value and convert to a const unsigned long integer number.
- double `stod` () const
 - Parse the string value and convert to a const double float number.
- `IPADDR to_ipaddr` () const
 - Parse the string value and convert to an IPADDR IP address.
- `size_t copy` (char *s, size_t len, size_t pos=0) const
 - Copy a substring, does not null terminate.
- `size_t strcpy` (char *s, size_t len, size_t pos=0) const
 - Copy a substring, with null termination.

Friends

- void `swap` (NBString &x, NBString &y)
 - Swaps the contents of two NBString objects.

16.74.1 Detailed Description

Lightweight alternative to C++ CString class.

16.74.2 Constructor & Destructor Documentation

16.74.2.1 NBString() [1/4]

```
NBString::NBString (
    const NBString & str )
```

Construct a new NBString object from an existing NBString object.

Parameters

<code>str</code>	Existing NBString object
------------------	--------------------------

16.74.2.2 NBString() [2/4]

```
NBString::NBString (
    const NBString & str,
    size_t pos,
    size_t len = npos )
```

Construct a new NBString object from a substring of an existing NBString object.

Parameters

<i>str</i>	Existing NBString object
<i>pos</i>	Starting position to copy
<i>len</i>	Ending position to copy

16.74.2.3 NBString() [3/4]

```
NBString::NBString (
    const char * s )
```

Construct a [NBString](#) object from a character string (null terminated array of characters)

Parameters

<i>s</i>	String to initialize object
----------	-----------------------------

16.74.2.4 NBString() [4/4]

```
NBString::NBString (
    const char * s,
    size_t n )
```

Construct a [NBString](#) object from a character string up to the specified amount.

Parameters

<i>s</i>	String to initialize object
<i>n</i>	Number of characters to copy

16.74.3 Member Function Documentation**16.74.3.1 Append()**

```
NBString & NBString::Append (
    const char * str,
    size_t len )
```

Append a string to an existing [NBString](#) object.

Append a string to an existing [NBString](#) object

Parameters

<i>str</i>	String to append
<i>len</i>	Number of characters to append

Returns

The updated [NBString](#) object

16.74.3.2 c_str()

```
const char * NBString::c_str ( ) const
```

Method to pass a [NBString](#) as a constant char *.

Will cause an allocation if it is pointing to a constant string longer than the currently allocated length.

Returns

A null terminated character array representing the string

16.74.3.3 clear()

```
void NBString::clear ( )
```

Clear a [NBString](#) object and free allocated memory.

Clear a [NBString](#) object and free allocated memory

16.74.3.4 compare() [1/2]

```
int NBString::compare (
    const char * s ) const
```

Compares the [NBString](#) object to a character string.

Parameters

<i>s</i>	String to compare
----------	-------------------

Return values

<i>0</i>	If identical
<i>-1</i>	If NBString object is less than str
<i>1</i>	If NBString object is greater than str

16.74.3.5 compare() [2/2]

```
int NBString::compare (
    const NBString & str ) const
```

Compares two [NBString](#) objects.

Parameters

<i>str</i>	NBString object to compare
------------	--

Return values

<i>0</i>	If identical
<i>-1</i>	If NBString object is less than str
<i>1</i>	If NBString object is greater than str

16.74.3.6 copy()

```
size_t NBString::copy (
    char * s,
    size_t len,
    size_t pos = 0 ) const
```

Copy a substring, does not null terminate.

Parameters

<i>s</i>	Destination
----------	-------------

Parameters

<i>len</i>	Size of destination
<i>pos</i>	Starting position of copy

Returns

Number of bytes copied

16.74.3.7 empty()

```
bool NSString::empty ( ) const
```

Check if a string is empty.

Check if a [NSString](#) object is empty

Return values

<i>true</i>	String is null
<i>false</i>	String contains data

16.74.3.8 FdAppend()

```
NSString & NSString::FdAppend (
    int fd,
    size_t len )
```

Append from a file descriptor to an existing [NSString](#) object.

Append from a file descriptor to an existing [NSString](#) object

Parameters

<i>fd</i>	File descriptor to append from
<i>len</i>	Number of characters to append

Returns

The updated [NSString](#) object

16.74.3.9 find() [1/4]

```
size_t NSString::find (
    char c,
    size_t pos = 0 ) const
```

Find the first occurrence of a character within the [NSString](#) object.

Parameters

<i>c</i>	Character to search for
<i>pos</i>	Starting position to start search

Return values

≥ 0	Position in string
-1	If character not found

16.74.3.10 find() [2/4]

```
size_t NBString::find (
    const char * s,
    size_t pos,
    size_t n ) const
```

Find a substring within a character string.

Parameters

<i>s</i>	String to search
<i>pos</i>	Starting position to start search
<i>n</i>	Number of characters that have to match

Return values

≥ 0	Position in searched string
-1	If substring not found

16.74.3.11 find() [3/4]

```
size_t NBString::find (
    const char * str,
    size_t pos = 0 ) const
```

Find a substring within a character string.

Parameters

<i>str</i>	String to search
<i>pos</i>	Starting position to start search

Return values

≥ 0	Position in searched string
-1	If substring not found

16.74.3.12 find() [4/4]

```
size_t NBString::find (
    const NBString str,
    size_t pos = 0 ) const
```

Find a substring within a [NBString](#) object.

Parameters

<i>str</i>	NString object to search
<i>pos</i>	Starting position to start search

Return values

≥ 0	Position in searched string
-1	If substring not found

16.74.3.13 length()

```
size_t NSString::length ( ) const
```

Returns the length of the string.

Returns

The length of the string

16.74.3.14 replace() [1/2]

```
size_t NSString::replace (
    char c,
    char rep,
    size_t startPos = 0,
    size_t end = 0 )
```

Replace all occurrences of all "<findStr>" characters within the [NSString](#) object.

Parameters

<i>c</i>	Character to be replaced within the NSString
<i>rep</i>	Character to replace with
<i>startPos</i>	Starting position to start replacing
<i>end</i>	Replace all matching characters before this position, 0 = end of NSString

Return values

>0	Number of Replaced Characters
-1	If no matching character found

16.74.3.15 replace() [2/2]

```
size_t NSString::replace (
    const char * findStr,
    char rep,
    size_t startPos = 0,
    size_t end = 0 )
```

Replace all occurrences of all "<findStr>" characters within the [NSString](#) object.

Parameters

<i>findStr</i>	String of characters to be replaced within the NSString
<i>rep</i>	Character to replace with
<i>startPos</i>	Starting position to start replacing
<i>end</i>	Replace all matching characters before this position, 0 = end of NSString

Return values

>0	Number of Replaced Characters
-1	If no matching character found

16.74.3.16 Reserve()

```
NBString & NBString::Reserve (
    size_t len )
```

Reserve an additional buffer amount.

Reserve an additional buffer amount to prepare for a series of Appends

Parameters

<i>len</i>	Number of additional characters to prepare to store
------------	---

Returns

The updated [NBString](#) object

16.74.3.17 sprintf() [1/2]

```
int NBString::sprintf (
    const char * format,
    ... )
```

isprintf (integer) to a string with formatting to a character array

Parameters

<i>format</i>	printf style formatting
---------------	-------------------------

16.74.3.18 sprintf() [2/2]

```
int NBString::sprintf (
    NBString const format,
    ... )
```

isprintf (integer) to a string with formatting to a [NBString](#) object

Parameters

<i>format</i>	printf style formatting
---------------	-------------------------

16.74.3.19 size()

```
size_t NBString::size ( ) const
```

Returns the current size of memory allocated for the string.

Returns

Total size of the object in bytes

16.74.3.20 sprintf() [1/2]

```
int NBString::sprintf (
    const char * format,
    ... )
```

sprintf to a string with formatting to a character array

Parameters

<i>format</i>	printf style formatting
---------------	-------------------------

16.74.3.21 sprintf() [2/2]

```
int NSString::sprintf (
    NSString const format,
    ... )
```

sprintf to a string with formatting as a [NSString](#) object

Parameters

<i>format</i>	printf style formatting
---------------	-------------------------

16.74.3.22 stod()

```
double NSString::stod ( ) const
```

Parse the string value and convert to a const double float number.

Returns

const double float value

16.74.3.23 stoi()

```
int NSString::stoi ( ) const
```

Parse the string and convert to an integer number.

Returns

integer value

16.74.3.24 stol()

```
long NSString::stol ( ) const
```

Parse the string value and convert to a long integer number.

Returns

long integer value

16.74.3.25 stoui()

```
unsigned int NSString::stoui ( ) const
```

Parse the string value and convert to a const integer number.

Returns

unsigned integer value

16.74.3.26 stoul()

```
unsigned long NSString::stoul ( ) const
```

Parse the string value and convert to a const unsigned long integer number.

Returns

unsigned long integer value

16.74.3.27 strcpy()

```
size_t NBString::strcpy (
    char * s,
    size_t len,
    size_t pos = 0 ) const
```

Copy a substring, with null termination.

Parameters

<i>s</i>	Destination
<i>len</i>	Size of destination
<i>pos</i>	Starting position of copy

Returns

Number of bytes copied

16.74.3.28 substr()

```
NSString NSString::substr (
    size_t pos = 0,
    size_t len = npos ) const
```

Creates a new [NSString](#) object from a substring of the existing [NSString](#) object.

Parameters

<i>pos</i>	Starting position of substring
<i>len</i>	Number of characters to copy

Returns

A [NSString](#) object

16.74.3.29 to_ipaddr()

```
IPADDR NSString::to_ipaddr ( ) const
```

Parse the string value and convert to an IPADDR IP address.

Returns

const double float value

16.74.3.30 vsiprintf()

```
int NSString::vsiprintf (
    const char * format,
    va_list & vl )
```

Print to a string with formatting.

Parameters

<i>format</i>	printf style formatting
<i>vl</i>	Variable argument list

16.74.4 Friends And Related Symbol Documentation**16.74.4.1 swap**

```
void swap (
    NSString & x,
    NSString & y ) [friend]
```

Swaps the contents of two [NSString](#) objects.

Useful for optimizing sorts. Friend function that takes two [NBString](#) objects as parameters and swaps their contents. The documentation for this class was generated from the following file:

- [nbstring.h](#)

16.75 NV_SettingsStruct Struct Reference

Configuration Settings.

```
#include <serialburnerdata.h>
```

Inherits [config_obj](#).

Additional Inherited Members

Public Member Functions inherited from [config_obj](#)

- [config_obj](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_obj](#) (const char *name, const char *desc)
Object constructor.
- virtual void [GetTextValue](#) ([NBString](#) &s)
Get the object value as a text string to the specified [NBString](#) object.
- virtual void [GetTypeValue](#) ([NBString](#) &s)
Assigns the object type value to the specified [NBString](#) object.

16.75.1 Detailed Description

Configuration Settings.

DeviceName - Device name for [DHCP](#) NetBIOSName - NetBIOS name

- SSL and SSH * CertificateRsaLength - Certificate length CertificateData - Certificate KeyHttpsRsaLength - RSA key for HTTPS length, 0 is none KeyHttpsRsaData - RSA key for HTTPS KeyRsaLength - RSA key length, 0 is none KeyRsaData - RSA key KeyDsaLength - DSA key length, 0 is none KeyDsaData - DSA key
- Version change key * VerifyKey - Version change key

16.76 OS_CRIT Struct Reference

An [OS_CRIT](#) object is used to establish critical sections of code that can only be run by one task at a time. Tasks that try to claim a critical section which is currently claimed by another task will stop and wait for that task to release the critical section before continuing execution.

```
#include <nbrtos.h>
```

Inherits [OS_TASK_DLY_OBJ](#).

Public Member Functions

- [OS_CRIT](#) ()
Create and initialize an [OS_CRIT](#) object.
- [uint8_t Init](#) ()
Initialize an [OS_CRIT](#) object to its default state.
- [uint8_t LockAndEnter](#) (uint32_t timeoutTicks=[WAIT_FOREVER](#))
Locks the current task to prevent task switching and claims the critical section.
- [uint8_t Enter](#) (TickTimeout &t)
Request to Enter/Claim the critical section.
- [uint8_t Enter](#) (uint32_t timeoutTicks=[WAIT_FOREVER](#))
Request to Enter/Claim the critical section, with a time out parameter.
- [uint8_t EnterNoWait](#) ()
Request to Enter/Claim the critical section. Does not wait if a critical section is not available.
- [uint8_t Leave](#) ()
Release the critical section.
- [uint8_t LeaveAndUnlock](#) ()
Leave/release the critical section and unlock the task.
- [bool UsedFromISR](#) ()
Check if critical section [UsedFromISR](#) flag is set.
- [void SetUseFromISR](#) (bool enableFromISR)
Set critical section [UsedFromISR](#) flag.
- [bool OwnedByCurTask](#) ()
Check if critical section owned by the current task.
- [uint32_t CurDepth](#) ()
Returns the critical section depth count.

Friends

- [void ForceReboot](#) (bool fromIRQ)
Forces the system hardware to perform a soft reset.

16.76.1 Detailed Description

An [OS_CRIT](#) object is used to establish critical sections of code that can only be run by one task at a time. Tasks that try to claim a critical section which is currently claimed by another task will stop and wait for that task to release the critical section before continuing execution.

16.76.2 Constructor & Destructor Documentation

16.76.2.1 OS_CRIT()

```
OS_CRIT::OS_CRIT ( ) [inline]
```

Create and initialize an [OS_CRIT](#) object.

See also

[Init\(\)](#)

16.76.3 Member Function Documentation

16.76.3.1 CurDepth()

```
uint32_t OS_CRIT::CurDepth ( ) [inline]
```

Returns the critical section depth count.

Returns

Depth count value

16.76.3.2 Enter() [1/2]

```
uint8_t OS_CRIT::Enter (
    TickTimeout & t )
```

Request to Enter/Claim the critical section.

Note

You must call [Leave\(\)](#) once for each successful [Enter\(\)](#) call to release the critical section so that another task can run it.

Parameters

<i>t</i>	The number of TickTimeout time ticks to wait for the critical section. A timeout of 0 (zero) waits forever.
----------	---

Return values

<i>OS_NO_ERR</i>	If we were successful in claiming the critical section or if our task owns it
<i>OS_TIMEOUT</i>	If we were unable to claim the section NBRtos Error Codes

See also

[NBRtos Error Codes](#), [EnterNoWait\(\)](#), [Leave\(\)](#)

16.76.3.3 Enter() [2/2]

```
uint8_t OS_CRIT::Enter (
    uint32_t timeoutTicks = WAIT_FOREVER ) [inline]
```

Request to Enter/Claim the critical section, with a time out parameter.

Note

You must call [Leave\(\)](#) once for each successful [Enter\(\)](#) call to release the critical section so that another task can run it.

Parameters

<i>timeoutTicks</i>	The number of sytem TimeTicks to wait for the critical section. A timeout of 0 (zero) waits forever.
---------------------	--

Return values

<i>OS_NO_ERR</i>	If we were successful in claiming the critical section or if our task owns it
<i>OS_TIMEOUT</i>	If we were unable to claim the section NBRtos Error Codes

See also

[NBRtos Error Codes](#), [EnterNoWait\(\)](#), [Leave\(\)](#)

16.76.3.4 EnterNoWait()

```
uint8_t OS_CRIT::EnterNoWait ( )
```

Request to Enter/Claim the critical section. Does not wait if a critical section is not available.

Note

You must call [Leave\(\)](#) once for each successful [Enter\(\)](#) call to release the critical section so that another task can run it.

Return values

<code>OS_NO_ERR</code>	If we were successful in claiming the critical section or if our task owns it
<code>OS_TIMEOUT</code>	If we were unable to claim the section NBRDOS Error Codes

See also

[NBRDOS Error Codes](#), [Enter\(\)](#), [Leave\(\)](#)

16.76.3.5 Init()

```
uint8_t OS_CRIT::Init ( )
```

Initialize an [OS_CRIT](#) object to its default state.

Returns

`OS_NO_ERR` if successful, otherwise [NBRDOS Error Codes](#)

See also

[NBRDOS Error Codes](#)

16.76.3.6 Leave()

```
uint8_t OS_CRIT::Leave ( )
```

Release the critical section.

Note

This function must be called once for each successful [Enter\(\)](#) or [EnterNoWait\(\)](#) call to release the critical section so another task can run it.

Return values

<code>OS_NO_ERR</code>	If we were successful in claiming the critical section or if our task owns it
<code>OS_CRIT_ERR</code>	If we are trying to release a critical section that we do not own NBRDOS Error Codes

See also

[NBRDOS Error Codes](#), [Enter\(\)](#), [EnterNoWait\(\)](#)

16.76.3.7 LeaveAndUnlock()

```
uint8_t OS_CRIT::LeaveAndUnlock ( )
```

Leave/release the critical section and unlock the task.

Note

This function must be called once for each successful [LockAndEnter\(\)](#) call to both unlock and release the critical section so another task can run it.

Returns

OS_NO_ERR on success, otherwise [NBRRTOS Error Codes](#)

See also

[NBRRTOS Error Codes](#), [LockAndEnter\(\)](#)

16.76.3.8 LockAndEnter()

```
uint8_t OS_CRIT::LockAndEnter (
    uint32_t timeoutTicks = WAIT_FOREVER )
```

Locks the current task to prevent task switching and claims the critical section.

Note

If it is unable to claim the critical section and times out, then the lock will be released. Otherwise [LeaveAndUnlock\(\)](#) must be called once for each successful [LockAndEnter\(\)](#) call to both unlock and release the critical section so that another task might run it.

Parameters

<i>timeoutTicks</i>	The number of TickTimeout time ticks to wait for the critical section. A timeout of 0 (zero) waits forever.
---------------------	---

Return values

<i>OS_NO_ERR</i>	If we were successful in claiming the critical section or if our task owns it
<i>OS_TIMEOUT</i>	If we were unable to claim the section

See also

[NBRRTOS Error Codes](#), [LeaveAndUnlock\(\)](#), [Enter\(\)](#)

16.76.3.9 SetUseFromISR()

```
void OS_CRIT::SetUseFromISR (
    bool enableFromISR ) [inline]
```

Set critical section UsedFromISR flag.

Parameters

<i>enableFromISR</i>	Set true to set flag
----------------------	----------------------

See also

[UsedFromISR\(\)](#)

16.76.3.10 UsedFromISR()

```
bool OS_CRIT::UsedFromISR ( ) [inline]
```

Check if critical section UsedFromISR flag is set.

See also

[SetUseFromISR\(\)](#)

16.77.1 Detailed Description

A FIFO is similar to a queue, but is specifically designed to pass pointers to [OS_FIFO](#) structures. The first parameter of the structure must be a (void *) element, which is used by the operating system to create a linked list of FIFOs. When initializing a FIFO, you do not specify the maximum number of entries as with a queue. Instead, your application has the ability (and responsibility) to allocate memory (static or dynamic) in which to store the structures. This can be done statically by declaring global variables, or dynamically by allocating memory from the heap. As with a queue, the first message posted to the FIFO will be the first message extracted from the queue.

16.77.2 Constructor & Destructor Documentation

16.77.2.1 OS_FIFO()

```
OS_FIFO::OS_FIFO ( ) [inline]
```

Create and initialize a FIFO object.

See also

[Init\(\)](#)

16.77.3 Member Function Documentation

16.77.3.1 Init()

```
uint8_t OS_FIFO::Init ( )
```

Sets the FIFO object to its initial state.

Returns

OS_NO_ERR if successful, otherwise [NBRRTOS Error Codes](#)

See also

[NBRRTOS Error Codes](#)

16.77.3.2 Pend() [1/3]

```
OS_FIFO_EL * OS_FIFO::Pend (
    TickTimeout & t,
    uint8_t & result )
```

Wait the specified number of [TickTimeout](#) ticks for some other task to post to the FIFO.

Parameters

<i>t</i>	The number of system ticks to wait. A value of 0 will wait forever.
<i>result</i>	Reference to store the status of the function call, NBRRTOS Error Codes . OS_NO_ERR if successful, OS_TIMEOUT if it timed out.

Return values

<i>OS_FIFO_EL</i>	Pointer to OS_FIFO_EL if successful
<i>NULL</i>	If it timed out

See also

[NBRRTOS Error Codes](#), [PendNoWait\(\)](#), [PendUntil\(\)](#)

16.77.3.3 Pend() [2/3]

```
OS_FIFO_EL * OS_FIFO::Pend (
    uint32_t timeoutTicks,
    uint8_t & result ) [inline]
```

Wait the specified number of time ticks for some other task to post to the FIFO.

Parameters

<i>timeoutTicks</i>	The number of system ticks to wait. A value of 0 will wait forever.
<i>result</i>	Reference to store the status of the function call, NBRRTOS Error Codes . OS_NO_ERR if successful, OS_TIMEOUT if it timed out.

Return values

<i>OS_FIFO_EL</i>	Pointer to OS_FIFO_EL if successful
<i>NULL</i>	If it timed out

See also

[NBRRTOS Error Codes](#), [PendNoWait\(\)](#), [Pend\(\)](#)

16.77.3.4 Pend() [3/3]

```
OS_FIFO_EL * OS_FIFO::Pend (
    uint32_t timeoutTicks = WAIT_FOREVER ) [inline]
```

Pend on a FIFO for the specified number of system TimeTicks.

Parameters

<i>timeoutTicks</i>	The number of system TimeTicks to wait. If not specified, will wait forever.
---------------------	--

Return values

<i>OS_FIFO_EL</i>	Pointer to OS_FIFO_EL if successful
<i>NULL</i>	If it timed out

See also

16.77.3.5 PendNoWait() [1/2]

```
OS_FIFO_EL * OS_FIFO::PendNoWait ( ) [inline]
```

Attempts to pend a structure to the FIFO, but does not wait.

Return values

<i>OS_FIFO_EL</i>	Pointer to OS_FIFO_EL if successful
<i>NULL</i>	If it timed out

See also

[NBRRTOS Error Codes](#), [Pend\(\)](#), [PendUntil\(\)](#)

16.77.3.6 PendNoWait() [2/2]

```
OS_FIFO_EL * OS_FIFO::PendNoWait (
    uint8_t & result )
```

Attempts to pend a structure to the FIFO, but does not wait.

Parameters

<i>result</i>	Reference to store the status of the function call, NBRRTOS Error Codes . OS_NO_ERR if successful, OS_TIMEOUT if it timed out.
---------------	--

Return values

<i>OS_FIFO_EL</i>	Pointer to OS_FIFO_EL if successful
<i>NULL</i>	If it timed out

See also

[NRTOS Error Codes](#), [Pend\(\)](#), [PendUntil\(\)](#)

16.77.3.7 PendUntil()

```
OS_FIFO_EL * OS_FIFO::PendUntil (
    uint32_t timeoutTime,
    uint8_t & result ) [inline]
```

Wait the specified TimeTicks value for some other task to post to the FIFO.

Parameters

<i>timeoutTime</i>	The value of system TimeTicks to wait for
<i>result</i>	Reference to store the status of the function call, NRTOS Error Codes . OS_NO_ERR if successful, OS_TIMEOUT if it timed out.

Return values

<i>OS_FIFO_EL</i>	Pointer to OS_FIFO_EL if successful
<i>NULL</i>	If it timed out

See also

[NRTOS Error Codes](#), [PendNoWait\(\)](#), [Pend\(\)](#)

16.77.3.8 Post()

```
uint8_t OS_FIFO::Post (
    OS_FIFO_EL * pToPost )
```

Post a message to the next available location in the FIFO.

Parameters

<i>pToPost</i>	A pointer to the structure cast as an OS_FIFO_EL to be posted to the FIFO.
----------------	--

Return values

<i>OS_NO_ERR</i>	If successful
<i>OS_Q_FULL</i>	If the queue is full, NRTOS Error Codes

See also

[PostFirst\(\)](#), [PostUnique\(\)](#), [Pend\(\)](#)

16.77.3.9 PostFirst()

```
uint8_t OS_FIFO::PostFirst (
    OS_FIFO_EL * pToPost )
```

Post a message to the head of the FIFO.

Parameters

<i>pToPost</i>	A pointer to the user's structure cast as an OS_FIFO_EL to be posted to the FIFO.
----------------	---

Return values

<code>OS_NO_ERR</code>	If successful
<code>OS_Q_FULL</code>	If the queue is full, NBRtos Error Codes

See also

## 16.79 OS\_FLAGS Struct Reference

OSFlags enables a function or task to pend on multiple flags or events.

```
#include <nbrtos.h>
```

### Public Member Functions

- [OS\\_FLAGS](#) ()  
*Create and initialize an [OS\\_FLAG](#) object.*
- void [Init](#) ()  
*Initialize an [OS\\_FLAG](#) object to its default value.*
- void [Set](#) (uint32\_t bits\_to\_set)  
*Sets the specified flag bits.*
- void [Clear](#) (uint32\_t bits\_to\_clr)  
*Clear the specified flag bits.*
- void [Write](#) (uint32\_t bits\_to\_force)  
*Set the flag bits to match the specified value.*
- uint32\_t [State](#) ()

Returns the current values of the flags stored in the `OS_FLAGS` object.

- `uint8_t PendAny` (`uint32_t bit_mask`, `uint16_t timeout=WAIT_FOREVER`)  
Wait the specified number of system `TimeTicks` for any of the flags in the bit mask to be set.
- `uint8_t PendAny` (`uint32_t bit_mask`, `TickTimeout &timeout`)  
Wait the specified number of `TickTimeout` time ticks for any of the flags in the bit mask to be set.
- `uint8_t PendAnyUntil` (`uint32_t bit_mask`, `uint32_t end_time`)  
Wait until the specified system `TimeTicks` value for any of the flags in the bit mask to be set.
- `uint8_t PendAnyNoWait` (`uint32_t bit_mask`)  
Check for the specified flags and return immediately.
- `uint8_t PendAll` (`uint32_t bit_mask`, `uint16_t timeout=WAIT_FOREVER`)  
Wait the specified number of system time ticks until all the specified flags are set.
- `uint8_t PendAll` (`uint32_t bit_mask`, `TickTimeout &timeout`)  
Wait the specified number of `TickTimeout` time ticks until all the specified flags are set.
- `uint8_t PendAllUntil` (`uint32_t bit_mask`, `uint32_t end_time`)  
Wait until the specified system `TimeTicks` value for all of the flags in the bit mask to be set.
- `uint8_t PendAllNoWait` (`uint32_t bit_mask`)  
Wait the specified number of system time ticks until all the specified flags are set.

### 16.79.1 Detailed Description

OSFlags enables a function or task to pend on multiple flags or events.

In contrast to a OSSemaphore which can pend on only a single event. The OSFlag implementation is essentially a 32-bit bitmap in which each bit position represents a flag. You create a OSFlag object with `OSFlagCreate()`, then set, clean and read the flags with the appropriate function. There are a number of functions used to monitor or pend on the flags, and provide the ability to pend on any one or more of the flags being set, or pending on all of flags being set at one time.

### 16.79.2 Constructor & Destructor Documentation

#### 16.79.2.1 OS\_FLAGS()

```
OS_FLAGS::OS_FLAGS ()
```

Create and initialize an OS\_FLAG object.

See also

[Init\(\)](#)

### 16.79.3 Member Function Documentation

#### 16.79.3.1 Clear()

```
void OS_FLAGS::Clear (
 uint32_t bits_to_clr)
```

Clear the specified flag bits.

Parameters

|                          |                                    |
|--------------------------|------------------------------------|
| <code>bits_to_clr</code> | A bit or set of bits to be cleared |
|--------------------------|------------------------------------|

See also

[Set\(\)](#), [State\(\)](#)

#### 16.79.3.2 Init()

```
void OS_FLAGS::Init ()
```

Initialize an OS\_FLAG object to its default value.

See also

[OS\\_FLAGS\(\)](#)

### 16.79.3.3 PendAll() [1/2]

```
uint8_t OS_FLAGS::PendAll (
 uint32_t bit_mask,
 TickTimeout & timeout)
```

Wait the specified number of [TickTimeout](#) time ticks until all the specified flags are set.

Parameters

|                 |                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------|
| <i>bit_mask</i> | A bit or set of bits to wait on.                                                                |
| <i>timeout</i>  | Number of time ticks to wait for all specified flag bits to be set. A value of 0 waits forever. |

Return values

|                   |                                     |
|-------------------|-------------------------------------|
| <i>OS_NO_ERR</i>  | If the flags condition is satisfied |
| <i>OS_TIMEOUT</i> | If the timeout expired              |

See also

[PendAllNoWait\(\)](#), [PendAny\(\)](#)

### 16.79.3.4 PendAll() [2/2]

```
uint8_t OS_FLAGS::PendAll (
 uint32_t bit_mask,
 uint16_t timeout = WAIT_FOREVER) [inline]
```

Wait the specified number of system time ticks until all the specified flags are set.

Parameters

|                 |                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------|
| <i>bit_mask</i> | A bit or set of bits to wait on.                                                                |
| <i>timeout</i>  | Number of time ticks to wait for all specified flag bits to be set. A value of 0 waits forever. |

Return values

|                   |                                     |
|-------------------|-------------------------------------|
| <i>OS_NO_ERR</i>  | If the flags condition is satisfied |
| <i>OS_TIMEOUT</i> | If the timeout expired              |

See also

[PendAllNoWait\(\)](#), [PendAny\(\)](#)

### 16.79.3.5 PendAllNoWait()

```
uint8_t OS_FLAGS::PendAllNoWait (
 uint32_t bit_mask)
```

Wait the specified number of system time ticks until all the specified flags are set.

## Parameters

|                 |                                  |
|-----------------|----------------------------------|
| <i>bit_mask</i> | A bit or set of bits to wait on. |
|-----------------|----------------------------------|

## Returns

OS\_NO\_ERR on success, otherwise [NBRDOS Error Codes](#)

## See also

[PendAll\(\)](#), [PendAnyNoWait\(\)](#)

**16.79.3.6 PendAllUntil()**

```
uint8_t OS_FLAGS::PendAllUntil (
 uint32_t bit_mask,
 uint32_t end_time) [inline]
```

Wait until the specified system TimeTicks value for all of the flags in the bit mask to be set.

## Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <i>bit_mask</i> | A bit or set of bits to wait on.   |
| <i>end_time</i> | System TimeTick value to wait for. |

## Return values

|            |                                                                |
|------------|----------------------------------------------------------------|
| OS_NO_ERR  | At least one of the flag bits are set before <i>end_time</i> . |
| OS_TIMEOUT | None of the flag bits are set before <i>end_time</i> .         |

## See also

[NBRDOS Error Codes](#), [PendAnyNoWait\(\)](#), [PendAll\(\)](#)

**16.79.3.7 PendAny() [1/2]**

```
uint8_t OS_FLAGS::PendAny (
 uint32_t bit_mask,
 TickTimeout & timeout)
```

Wait the specified number of [TickTimeout](#) time ticks for any of the flags in the bit mask to be set.

## Parameters

|                 |                                                                                                              |
|-----------------|--------------------------------------------------------------------------------------------------------------|
| <i>bit_mask</i> | A bit or set of bits to wait on.                                                                             |
| <i>timeout</i>  | Number of time ticks to wait for all specified flag bits to be set. If not specified or 0 will wait forever. |

## Return values

|            |                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------|
| OS_NO_ERR  | At least one of the flag bits are set before <i>timeout</i> expires. A value of 0 waits forever. |
| OS_TIMEOUT | None of the flag bits are set before <i>timeout</i> expires.                                     |

### 16.79.3.10 PendAnyUntil()

```
uint8_t OS_FLAGS::PendAnyUntil (
 uint32_t bit_mask,
 uint32_t end_time) [inline]
```

Wait until the specified system TimeTicks value for any of the flags in the bit mask to be set.

Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <i>bit_mask</i> | A bit or set of bits to wait on.   |
| <i>end_time</i> | System TimeTick value to wait for. |

## Return values

|                         |                                                                      |
|-------------------------|----------------------------------------------------------------------|
| <code>OS_NO_ERR</code>  | At least one of the flag bits are set before <code>end_time</code> . |
| <code>OS_TIMEOUT</code> | None of the flag bits are set before <code>end_time</code> .         |

### 16.80.1 Detailed Description

Mailboxes single value storage locations used to communicate between tasks.

A mailbox is a storage location large enough to hold a single void pointer value, access to which is controlled so that it may be safely utilized by multiple tasks. If a task writes to a mailbox, it is then full and no task can send/post to it until a task does a read/pend on the mailbox or the mailbox is reset.

The void pointer can represent anything, such as a pointer to a variable, object, string, or just used as a 32-bit value. How it is used is defined by the tasks that post and pend to it.

#### Note

A "Message" is defined as any value other than null.

### 16.80.2 Constructor & Destructor Documentation

#### 16.80.2.1 OS\_MBOX() [1/2]

```
OS_MBOX::OS_MBOX () [inline]
```

Create and initialize a mailbox object with no default message.

#### See also

[Init\(\)](#)

#### 16.80.2.2 OS\_MBOX() [2/2]

```
OS_MBOX::OS_MBOX (
 void * msg) [inline]
```

Create and initialize a mailbox object with the specified message.

## Parameters

|            |                                                     |
|------------|-----------------------------------------------------|
| <i>msg</i> | Message that the mailbox should be initialized with |
|------------|-----------------------------------------------------|

## See also

Init()

### 16.80.3 Member Function Documentation

#### 16.80.3.1 Init()

```
uint8_t OS_MBOX::Init (
 void * msg = NULL)
```

Sets the mailbox object to its initial state.

If called without a msg parameter, it will default to a value of null.

## Parameters

|            |                                                     |
|------------|-----------------------------------------------------|
| <i>msg</i> | Message that the mailbox should be initialized with |
|------------|-----------------------------------------------------|

## Returns

OS\_NO\_ERR on success, otherwise [NBRDOS Error Codes](#)

#### 16.80.3.2 Pend() [1/3]

```
void * OS_MBOX::Pend (
 TickTimeout & t,
 uint8_t & result)
```

Wait the specified number of [TickTimeout](#) ticks for some other task to post to the mailbox.

## Parameters

|               |                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>t</i>      | The number of <a href="#">TicksTimeout</a> ticks to wait. 0 will wait forever.                                                                |
| <i>result</i> | Reference to store the status of the function call, <a href="#">NBRDOS Error Codes</a> . OS_NO_ERR if successful, OS_TIMEOUT if it timed out. |

## Return values

|                |                 |
|----------------|-----------------|
| <i>Message</i> | If successful   |
| <i>NULL</i>    | If it timed out |

## See also

### 16.81.1 Detailed Description

A message queue is an object that enables tasks and interrupt service routines to pend and post pointer sized messages. The pointer values typically point to some type of object or structure that contains the actual message or data. A queue functions as a fixed size First In First Out (FIFO) storage for 32-bit void pointers that can be used for communication between tasks.

A queue can be thought of as an array of void pointers, unlike a mailbox which can store only one void pointer. Access is controlled so that the queue can be safely utilized by multiple tasks. Tasks write to the queue using a Post function, and read from the queue using a Pend function.

The void pointer can represent anything, such as a pointer to a variable, object, string, or just used as a 32-bit value. How it is used is defined by the tasks that post and pend to it.

**Note**

If you need to store more than a simple value as with this [OS\\_Q](#) class, please refer to the [OS\\_FIFO](#) class which can store structures.

**16.81.2 Constructor & Destructor Documentation****16.81.2.1 OS\_Q()**

```
OS_Q::OS_Q (
 void ** pQueueStorage,
 uint8_t size) [inline]
```

Create and initialize a queue object.

The queue storage must be allocated in your application. A pointer to the storage area is then passed to the queue constructor. For example,

```
#define MY_QUEUE_SIZE (20) // Number of storage locations (void pointers) in the queue.
// In this case, 20.
void *myQueueData[MY_QUEUE_SIZE]; // Declare the array of void pointers and a pointer to the array
OS_Q myQ(myQueueData,MY_QUEUE_SIZE); // Create an instance of the queue
```

**Parameters**

|                      |                                                                    |
|----------------------|--------------------------------------------------------------------|
| <i>pQueueStorage</i> | A pointer to an array of (void *) pointers to hold queue messages. |
| <i>size</i>          | The number of pointers the queue can store.                        |

**16.81.3 Member Function Documentation****16.81.3.1 Init()**

```
uint8_t OS_Q::Init (
 void ** pQueueStorage,
 uint8_t size)
```

Set the queue object to its initial state.

**Parameters**

|                      |                                                                    |
|----------------------|--------------------------------------------------------------------|
| <i>pQueueStorage</i> | A pointer to an array of (void *) pointers to hold queue messages. |
| <i>size</i>          | The number of pointers the queue can store.                        |

**Returns**

OS\_NO\_ERR on success, otherwise [NBRDOS Error Codes](#)

**16.81.3.2 Pend() [1/3]**

```
void * OS_Q::Pend (
 TickTimeout & t,
 uint8_t & result)
```

Wait the specified number of [TickTimeout](#) ticks for some other task to post to the queue.

**Parameters**

|               |                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>t</i>      | The number of system ticks to wait. A value of 0 will wait forever.                                                                           |
| <i>result</i> | Reference to store the status of the function call, <a href="#">NBRDOS Error Codes</a> . OS_NO_ERR if successful, OS_TIMEOUT if it timed out. |

## Return values

|                |                 |
|----------------|-----------------|
| <i>Message</i> | If successful   |
| <i>NULL</i>    | If it timed out |

void * OS_Q::PendNoWait (
 uint8_t & result)
```

Checks if a message is available in the queue and returns immediately.

#### Parameters

|               |                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>result</i> | Reference to store the status of the function call, <a href="#">NBRTOS Error Codes</a> . OS_NO_ERR if successful, OS_TIMEOUT if it timed out. |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|

#### Return values

|                |                 |
|----------------|-----------------|
| <i>Message</i> | If successful   |
| <i>NULL</i>    | If it timed out |

#### See also

[NBRTOS Error Codes](#), [Pend\(\)](#), [PendUntil\(\)](#)

### 16.81.3.7 PendUntil()

```
void * OS_Q::PendUntil (
 uint32_t timeoutTime,
 uint8_t & result) [inline]
```

Wait the specified TimeTicks value for some other task to post to the queue.

#### Parameters

|                    |                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>timeoutTime</i> | The value of system TimeTicks to wait for                                                                                                     |
| <i>result</i>      | Reference to store the status of the function call, <a href="#">NBRTOS Error Codes</a> . OS_NO_ERR if successful, OS_TIMEOUT if it timed out. |

#### Return values

|                |                 |
|----------------|-----------------|
| <i>Message</i> | If successful   |
| <i>NULL</i>    | If it timed out |

**16.81.3.8 Post()**

```
uint8_t OS_Q::Post (
 void * pItem)
```

Post a message to the next available location in the queue.

**Parameters**

|              |                                |
|--------------|--------------------------------|
| <i>pItem</i> | Message (void pointer) to post |
|--------------|--------------------------------|

**Return values**

|                  |                                                         |
|------------------|---------------------------------------------------------|
| <i>OS_NO_ERR</i> | If successful                                           |
| <i>OS_Q_FULL</i> | If the queue is full, <a href="#">NRTOS Error Codes</a> |

**See also**

**16.81.3.9 PostFirst()**

```
uint8_t OS_Q::PostFirst (
 void * pItem)
```

Post a message to the head of the queue.

**Parameters**

|              |                                |
|--------------|--------------------------------|
| <i>pItem</i> | Message (void pointer) to post |
|--------------|--------------------------------|

**Return values**

|                  |                                                         |
|------------------|---------------------------------------------------------|
| <i>OS_NO_ERR</i> | If successful                                           |
| <i>OS_Q_FULL</i> | If the queue is full, <a href="#">NRTOS Error Codes</a> |

**See also**

[Post\(\)](#), [PostUniqueFirst\(\)](#), [Pend\(\)](#)

**16.81.3.10 PostUnique()**

```
uint8_t OS_Q::PostUnique (
 void * pItem)
```

Post the specified message to the next available location in the queue, but only if the message is unique and does not exist anywhere else in the queue.

**Parameters**

|              |                                |
|--------------|--------------------------------|
| <i>pItem</i> | Message (void pointer) to post |
|--------------|--------------------------------|

**Return values**

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <i>OS_NO_ERR</i>   | If successful                                                                |
| <i>OS_Q_EXISTS</i> | If the message already exists in the queue <a href="#">NRTOS Error Codes</a> |

## Return values

|                        |                                                         |
|------------------------|---------------------------------------------------------|
| <code>OS_Q_FULL</code> | If the queue is full <a href="#">NBRtos Error Codes</a> |
|------------------------|---------------------------------------------------------|

**16.81.3.11 PostUniqueFirst()**

```
uint8_t OS_Q::PostUniqueFirst (
 void * msg)
```

Post the specified message to the first location in the queue, but only if the message is unique and does not exist anywhere else in the queue.

## Parameters

|                  |                                |
|------------------|--------------------------------|
| <code>msg</code> | Message (void pointer) to post |
|------------------|--------------------------------|

## Return values

|                          |                                                                               |
|--------------------------|-------------------------------------------------------------------------------|
| <code>OS_NO_ERR</code>   | If successful                                                                 |
| <code>OS_Q_EXISTS</code> | If the message already exists in the queue <a href="#">NBRtos Error Codes</a> |
| <code>OS_Q_FULL</code>   | If the queue is full <a href="#">NBRtos Error Codes</a>                       |

*Wait timeout ticks for the value of the semaphore to be non zero.*
- `uint8_t PendUntil` (uint32\_t timeout\_time)  
*Wait until the specified timeout time for a task to post to the semaphore.*
- `uint8_t Pend` ([TickTimeout](#) &t)

Wait for the specified number of system time ticks for a task to post to the semaphore.

- `uint8_t PendNoWait ()`

Pend on a semaphore with no waiting period.

- `uint32_t Avail ()`

Returns the number of semaphore counts available.

## 16.82.1 Detailed Description

Semaphores are used to control access to shared resources or to communicate between tasks in a multithreaded system or with interrupt service routines. Semaphores can be 0 or 1, or they can be counting semaphores that increment and decrement based on calls to [Pend\(\)](#) and [Post\(\)](#) functions.

## 16.82.2 Constructor & Destructor Documentation

### 16.82.2.1 OS\_SEM()

```
OS_SEM::OS_SEM (
 int32_t cnt = 0) [inline]
```

Create and initialize a semaphore.

#### Parameters

|                  |                                                                 |
|------------------|-----------------------------------------------------------------|
| <code>cnt</code> | Starting semaphore count value. If not specified, default is 0. |
|------------------|-----------------------------------------------------------------|

#### See also

[Init\(int32\\_t cnt = 0\)](#)

## 16.82.3 Member Function Documentation

### 16.82.3.1 Avail()

```
uint32_t OS_SEM::Avail () [inline]
```

Returns the number of semaphore counts available.

Difference between the number of counts used and the total count value.

#### Returns

The number of available semaphore counts

#### See also

[Pend\(\)](#), [Post\(\)](#)

### 16.82.3.2 Init()

```
uint8_t OS_SEM::Init (
 int32_t cnt = 0)
```

Initialize the semaphore object count value.

#### Warning

This must be done before using the semaphore.

#### Parameters

|                  |                                                                 |
|------------------|-----------------------------------------------------------------|
| <code>cnt</code> | Starting semaphore count value. If not specified, default is 0. |
|------------------|-----------------------------------------------------------------|

**Returns**

OS\_NO\_ERR on success, otherwise [NBRDOS Error Codes](#)

**16.82.3.3 Pend() [1/2]**

```
uint8_t OS_SEM::Pend (
 TickTimeout & t)
```

Wait for the specified number of system time ticks for a task to post to the semaphore.

**Parameters**

|          |                                                                          |
|----------|--------------------------------------------------------------------------|
| <i>t</i> | The number of TickTiemout ticks to wait. A value of 0 will wait forever. |
|----------|--------------------------------------------------------------------------|

**Returns**

OS\_NO\_ERR on success, otherwise [NBRDOS Error Codes](#)

**See also**

[PendNoWait\(\)](#), [PendUntil\(\)](#)

**16.82.3.4 Pend() [2/2]**

```
uint8_t OS_SEM::Pend (
 uint32_t timeoutTicks = WAIT_FOREVER) [inline]
```

Wait timeout ticks for the value of the semaphore to be non zero.

**Parameters**

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| <i>timeoutTicks</i> | Number of system time ticks to wait. If not specified, will wait forever. |
|---------------------|---------------------------------------------------------------------------|

**Returns**

OS\_NO\_ERR on success, otherwise [NBRDOS Error Codes](#)

**See also**

[PendNoWait\(\)](#), [PendUntil\(\)](#)

**16.82.3.5 PendNoWait()**

```
uint8_t OS_SEM::PendNoWait ()
```

Pend on a semaphore with no waiting period.

Identical to the [Pend\(\)](#) function, but it does not wait.

**Returns**

OS\_NO\_ERR on success, otherwise [NBRDOS Error Codes](#)

**See also**

[Pend\(\)](#), [PendUntil\(\)](#)

**16.82.3.6 PendUntil()**

```
uint8_t OS_SEM::PendUntil (
 uint32_t timeout_time) [inline]
```

Wait until the specified timeout time for a task to post to the semaphore.

## Parameters

|                           |                                         |
|---------------------------|-----------------------------------------|
| <code>timeout_time</code> | The system TimeTick value to wait until |
|---------------------------|-----------------------------------------|

## Returns

OS\_NO\_ERR on success, otherwise [NBRtos Error Codes](#)

## See also

[PendNoWait\(\)](#), [Pend\(\)](#)

**16.82.3.7 Post()**

```
uint8_t OS_SEM::Post ()
```

Posts to the semaphore, increasing it's value by 1.

If a higher priority task was pending on the semaphore it will be released.

## Returns

OS\_NO\_ERR on success, otherwise [NBRtos Error Codes](#)

## See also

[Pend\(\)](#), [PendUntil\(\)](#), [PendNoWait\(\)](#)

## 16.85 OSLockObj Class Reference

A simple wrapper class that helps use OS locks effectively.

```
#include <nrtos.h>
```

### Public Member Functions

- **OSLockObj** ()  
*Initialize the [OSLockObj](#) and calls [OSLock\(\)](#).*
- **~OSLockObj** ()  
*Destructs the [OSLockObj](#) and calls [OSUnlock\(\)](#).*

### 16.85.1 Detailed Description

A simple wrapper class that helps use OS locks effectively.

When an [OSLockObj](#) is constructed it locks the OS. When it is destructed it unlocks the OS. If you have a function that needs an OS lock and has multiple points of exit, create an [OSLockObj](#) at the beginning of the function.

#### Note

No matter how you leave the function, the destructor will release the lock.

#### See also

[OSLock\(\)](#), [OSUnlock\(\)](#)

The documentation for this class was generated from the following file:

- [nrtos.h](#)

## 16.86 OSSpinCrit Class Reference

A simple wrapper class that uses an [OS\\_CRIT](#) object to try and claim a critical section, and will continue the attempt until it is able to do so.

```
#include <nrtos.h>
```

### Public Member Functions

- **OSSpinCrit** ([OS\\_CRIT](#) &ocrit)  
*Initialize the [OSSpinCrit](#) object, and then call [EnterNoWait\(\)](#) repeatedly on the [OS\\_CRIT](#) object that is passed in until it is able to claim the critical section.*
- **~OSSpinCrit** ()  
*Call [Leave\(\)](#) on the [OS\\_CRIT](#) object, and then destruct/.*

### 16.86.1 Detailed Description

A simple wrapper class that uses an [OS\\_CRIT](#) object to try and claim a critical section, and will continue the attempt until it is able to do so.

The way this class is implemented allows the task to continue to be made active by the scheduler. When an [OSSpinCrit](#) is constructed, it calls [EnterNoWait\(\)](#) repeatedly on the [OS\\_CRIT](#) object passed in until it is able to claim the critical section. When the object is deconstructed, it calls [Leave\(\)](#) on the [OS\\_CRIT](#) object.

#### See also

[OS\\_CRIT::EnterNoWait\(\)](#), [OS\\_CRIT::Leave\(\)](#)

## 16.86.2 Constructor & Destructor Documentation

### 16.86.2.1 OSSpinCrit()

```
OSSpinCrit::OSSpinCrit (
 OS_CRIT & ocrit) [inline]
```

Initialize the [OSSpinCrit](#) object, and then call `EnterNoWait()` repeatedly on the [OS\\_CRIT](#) object that is passed in until it is able to claim the critical section.

#### Parameters

|                         |                                                                       |
|-------------------------|-----------------------------------------------------------------------|
| <code>&amp;ocrit</code> | The object that will be used to enter and leave the critical section. |
|-------------------------|-----------------------------------------------------------------------|

The documentation for this class was generated from the following file:

- [nrtos.h](#)

## 16.87 ParsedJsonDataSet Class Reference

A class to create, read, and modify a JSON object.

```
#include <json_lexer.h>
```

Inherits `buffer_object`.

Inherited by `AcmeJsonBuffer`, `AcmeServletBuffer`, and [JsonLexerFDAdapter](#).

### Public Member Functions

#### Parsing

*Ingesting raw JSON data from some source, or resetting. Enables compatibility with `buffer_object` and `WebClient`.*

- void **EnableLargeStrings** (bool b)  
*Call to allow allocation of strings larger than 1500 bytes.*
- virtual int **WriteData** (const unsigned char \*pCopyFrom, int numBytes)  
*Writes the passed in data to the JSON data set.*
- virtual int **ReadFrom** (int fd)  
*Reads in data from the specified file descriptor and parses it into the JSON data set.*
- bool **CopyObject** ([ParsedJsonDataSet](#) &src\_set)  
*Copies the provided JSON data set into the current one.*
- void **ClearObject** ()  
*Clears all data from the object and resets it to its initial state.*

#### Querying the Data Structure

*Allows easy retrieval of entities by array index or object key name*

#### Example

```
printf("User %d name %s",
 (int)myJsonRef("users")[0]("id"),
 (const char *)myJsonRef("users")[0]("name")
);
```

- [JsonRef operator\[\]](#) (int i)  
*Get a `JsonRef` from an array by numerical index.*
- [JsonRef operator\(\)](#) (const char \*name)  
*Get a `JsonRef` representing any entity from a parent object by key name.*
- [JsonRef name](#) (const char \*name)  
*Get a `JsonRef` representing any entity from a parent object by key name.*
- [JsonRef object](#) (const char \*name)  
*Get a `JsonRef` representing an object from a parent object by key name.*

#### Traversing the Data Structure

*Used for scanning through the JSON elements*

- [JsonRef start \(\)](#)  
*Begin traversal: check for ref validity and reset the position.*
- [JsonRef next \(\)](#)  
*Traverse: check for ref validity and increment the position.*
- [json\\_primitive\\_type GetFirst \(\)](#)  
*Get the first element of the JSON data set.*
- [json\\_primitive\\_type GetNext \(\)](#)  
*Get the element at the next position of the JSON data set.*
- [json\\_primitive\\_type GetCurrent \(\)](#)  
*Get the element at the current position of the JSON data set.*
- [json\\_primitive\\_type GetRawCurrent \(\)](#)  
*Get the element at the current position of the JSON data set, including non-public types.*
- [json\\_primitive\\_type GetNextName \(\)](#)  
*Iterates the current element of the JSON data set until it finds one of type NAME.*
- [json\\_primitive\\_type GetNextObject \(\)](#)  
*Get the next element of type name that exists in the current OBJECT after the current position.*
- [json\\_primitive\\_type GetNextArray \(\)](#)  
*Iterates the current element of the JSON data set until it finds one of type BEGIN\_ARRAY.*
- [json\\_primitive\\_type GetNextNameInCurrentObject \(\)](#)  
*Get the next element of type NAME that exists in the current OBJECT after the current position.*
- [json\\_primitive\\_type GetNextNameInCurrentArray \(\)](#)  
*Get the next element of type NAME that exists in the current ARRAY after the current position.*
- [json\\_primitive\\_type GetNextNumberInCurrentArray \(\)](#)  
*Get the next element of type NUMBER that exists in the current ARRAY after the current position.*
- [json\\_primitive\\_type GetNextStringInCurrentArray \(\)](#)  
*Get the next element of type STRING that exists in the current ARRAY after the current position.*
- [json\\_primitive\\_type GetNextBoolInCurrentArray \(\)](#)  
*Get the next element of type TRUE\_EL that exists in the current ARRAY after the current position.*
- [json\\_primitive\\_type GetNextObjectInCurrentArray \(\)](#)  
*Get the next element of type BEGIN\_OBJECT that exists in the current ARRAY after the current position.*
- [json\\_primitive\\_type SkipCurrentValue \(\)](#)  
*Skips over the current value, and get the next element. If called inside an ARRAY or OBJECT, it will walk to the end of the ARRAY or OBJECT and return the next element it finds. If it reaches the end of the ARRAY or OBJECT before it finds a value, it will return NOTFOUND.*
- void [ResetPosition \(\)](#)  
*Resets the parser position to the beginning of the JSON data set.*
- [JsonRef GetParsePosition \(\)](#)  
*Gets the current parse position object for the JSON data set.*
- [JsonRef SetParsePosition \(JsonRef pos\)](#)  
*Sets the current parse position object for the JSON data set.*

### Advanced Finding and Returning

Advanced functions for scanning and returning specific objects. All of these can return NOTFOUND.

#### Example

This function works with dotted string notation to find sub elements:

```
{
 "SUCCESS": true,
 "ACTION": null,
 "JDATA": {
 "foo": 7,
 "bar": {
 "b1": "Sb1",
 "b2": {
 "s1": "Sub1",
 "s2": "Sub2",
 "s3": "Sub3",
 "s4": {
 "Sub4a": "Test4a",
 "Sub4b": "Test4b"
 },
 "s5": "Sub5",
 "s6": "Sub6"
 },
 "b3": true,
 }
 }
}
```

```

 "b4": null
 },
 "bogus": "Bstring",
 "nubog": 1234.57,
 "av": [
 1,
 2,
 3,
 4,
 5,
 6,
 7,
 8,
 9,
 10
],
 "aftaav": true
}
}

```

You could return the "Sub4b" element's "Test4b" string with:

```
myParsedJsonDataSet.FindFullName("JDATA.bar.b2.s4.Sub4b");
```

- [json\\_primitive\\_type FindFullName](#) (const char \*name)  
*Find the element in the data set with the given name and move the parser to the next element. This searches a full name path, such as ob1.ob2.ob3.ob4.*
- [json\\_primitive\\_type FindFullAtName](#) (const char \*name)  
*Find the element in the data set with the given name and move the parser to that element. This searches a full name path, such as ob1.ob2.ob3.ob4.*
- [json\\_primitive\\_type FindElementAfterName](#) (const char \*name)  
*Finds name in current object points at element after name. This only supports simple, single element names. This searches from the current position to the end.*
- [json\\_primitive\\_type FindGlobalElementAfterName](#) (const char \*name)  
*Finds name in current object points at element after name. This only supports simple, single element names. It starts the search from the parser's current position, and if it doesn't find it, it will start the search over from the beginning.*
- [json\\_primitive\\_type FindElementAfterNameInCurrentObject](#) (const char \*name)  
*Looks for elements with the current name in the current OBJECT only. Does not search sub objects.*
- [json\\_primitive\\_type FindElementAfterNameInCurrentArray](#) (const char \*name)  
*Looks for elements with the current name in the current ARRAY only. Does not search sub arrays.*
- bool [CurrentBool](#) ()  
*Returns true if the current element a TRUE\_EL primitive type.*
- bool [PermissiveCurrentBool](#) ()  
*Returns true if the current element a TRUE\_EL primitive type, is "True", "true", or is a non-zero number.*
- double [CurrentNumber](#) ()  
*Get the number value of the current element.*
- const char \* [CurrentString](#) ()  
*Get the string value of the current element.*
- const char \* [CurrentName](#) ()  
*Get the name of the current element.*
- bool [FindFullNameBoolean](#) (const char \*name)  
*Find the boolean value of a given element.*
- bool [FindGlobalBoolean](#) (const char \*name)  
*Find the boolean value of a given element. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.*
- bool [FindBoolean](#) (const char \*name)  
*Find the boolean value of the element after the element with the given name.*
- bool [FindBooleanInCurentObject](#) (const char \*name)  
*Find the boolean value of the element within the current object. Does not search sub-objects.*
- bool [FindFullNamePermissiveBoolean](#) (const char \*name)  
*Find the permissive boolean value of a given element.*
- bool [FindGlobalPermissiveBoolean](#) (const char \*name)  
*Find the permissive boolean value of a given element. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.*
- bool [FindPermissiveBoolean](#) (const char \*name)  
*Find the permissive boolean value of the element after the element with the provided name.*
- bool [FindPermissiveBooleanInCurentObject](#) (const char \*name)

- Find the permissive boolean value of the element with the given name in the current object. Does not search sub-objects.*

  - const char \* [FindFullNameString](#) (const char \*name)
- Find the string value of the element with the given name in the current object.*

  - const char \* [FindGlobalString](#) (const char \*name)
- Find the string value of a given element. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.*

  - const char \* [FindString](#) (const char \*name)
- Find the string value of the element after the element with the given name.*

  - const char \* [FindStringInCurentObject](#) (const char \*name)
- Find the string value of the element with the given name in the current object. Does not search sub-objects.*

  - double [FindFullNameNumber](#) (const char \*name)
- Find the number value of the element with the given name in the current object.*

  - double [FindGlobalNumber](#) (const char \*name)
- Find the number value of a given element. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.*

  - double [FindNumber](#) (const char \*name)
- Find the number value of the element after the element with the given name.*

  - double [FindNumberInCurentObject](#) (const char \*name)
- Find the number value of the element with the given name in the current object. Does not search sub-objects.*

  - bool [FindGlobalObject](#) (const char \*name)
- Find the OBJECT with the given name. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.*

  - bool [FindObject](#) (const char \*name)
- Find the OBJECT of the element after the element with the given name.*

  - bool [FindObjectInCurentObject](#) (const char \*name)
- Find the OBJECT of the element with the given name in the current OBJECT. Does not search sub-objects.*

## Utility

*Ingesting raw JSON data from some source, or resetting*

- void **DumpState** ()
  - Outputs what's in the parse tree to stdout.*
- int [PrintObject](#) (bool pretty=false)
  - Prints the JSON data set to stdout.*
- int [PrintObjectToBuffer](#) (char \*buffer, int maxlen, bool pretty=false)
  - Prints the JSON data set to a provided buffer.*
- int [PrintObjectToFd](#) (int fd, bool pretty=false)
  - Prints the JSON data set to a specified file descriptor.*
- int [PrintObjectToString](#) (NBString &s, bool pretty=false)
  - Prints the JSON data set to a NBString object.*
- int **PrintChildren** (bool pretty=false)
  - Output child objects of this [JsonRef](#) as JSON text to stdout.*
- int **PrintChildrenToFd** (int fd, bool pretty=false)
  - Output child objects of this [JsonRef](#) as JSON text to a file descriptor.*
- int **PrintChildrenToBuffer** (char \*buffer, int maxlen, bool pretty=false)
  - Output child objects of this [JsonRef](#) as JSON text to a buffer pointer.*
- int [GetPrintSize](#) (bool pretty=false)
  - Calculates how many characters the JSON data set would take to print.*

## Building

*Programmatically creating or modifying a JSON dataset*

- [ParsedJsonDataSet](#) \* **StartBuilding** ()
  - Use to start building the JSON data set.*
- [ParsedJsonDataSet](#) \* [AddObjectStart](#) (const char \*name)
  - Use to start an object in the JSON data set.*
- [ParsedJsonDataSet](#) \* [AddMyMac](#) (const char \*name)
  - Add the device MAC address to the JSON data set.*
- [ParsedJsonDataSet](#) \* [Add](#) (const char \*name, int i)

- Add a name/value pair to the JSON data set where the value is an int.*
- [ParsedJsonDataSet \\* Add](#) (const char \*name, short i)
- Add a name/value pair to the JSON data set where the value is a short.*
- [ParsedJsonDataSet \\* Add](#) (const char \*name, long i)
- Add a name/value pair to the JSON data set where the value is a long.*
- [ParsedJsonDataSet \\* Add](#) (const char \*name, unsigned int i)
- Add a name/value pair to the JSON data set where the value is an unsigned int.*
- [ParsedJsonDataSet \\* Add](#) (const char \*name, unsigned short i)
- Add a name/value pair to the JSON data set where the value is a unsigned short.*
- [ParsedJsonDataSet \\* Add](#) (const char \*name, unsigned long i)
- Add a name/value pair to the JSON data set where the value is a unsigned long.*
- [ParsedJsonDataSet \\* Add](#) (const char \*name, double d)
- Add a name/value pair to the JSON data set where the value is a double.*
- [ParsedJsonDataSet \\* Add](#) (const char \*name, const char \*str)
- Add a name/value pair to the JSON data set where the value is a string.*
- [ParsedJsonDataSet \\* Add](#) (const char \*name, bool b)
- Add a name/value pair to the JSON data set where the value is a bool.*
- [ParsedJsonDataSet \\* Add](#) (const char \*name, IPADDR4 i4)
- Add a name/value pair to the JSON data set where the value is an IPv4 address.*
- [ParsedJsonDataSet \\* Add](#) (const char \*name, const IPADDR &i)
- Add a name/value pair to the JSON data set where the value is an IP address.*
- [ParsedJsonDataSet \\* Add](#) (const char \*name, const MACADR &ma)
- Add a name/value pair to the JSON data set where the value is a MAC address.*
- [ParsedJsonDataSet \\* AddNull](#) (const char \*name)
- Add a name/value pair to the JSON data set where the value is null.*
- [ParsedJsonDataSet \\* AddArrayStart](#) (const char \*name)
- Add an ARRAY start to the JSON data set.*
- [ParsedJsonDataSet \\* EndArray](#) ()
- Add an ARRAY end to the JSON data set.*
- [ParsedJsonDataSet \\* AddArrayElement](#) (int i)
- Add an integer value to the current array.*
- [ParsedJsonDataSet \\* AddArrayElement](#) (short i)
- Add a short value to the current array.*
- [ParsedJsonDataSet \\* AddArrayElement](#) (long i)
- Add a long value to the current array.*
- [ParsedJsonDataSet \\* AddArrayElement](#) (unsigned int i)
- Add an unsigned int value to the current array.*
- [ParsedJsonDataSet \\* AddArrayElement](#) (unsigned short i)
- Add an unsigned short value to the current array.*
- [ParsedJsonDataSet \\* AddArrayElement](#) (unsigned long i)
- Add an unsigned long value to the current array.*
- [ParsedJsonDataSet \\* AddArrayElement](#) (double d)
- Add a double to the current array.*
- [ParsedJsonDataSet \\* AddArrayElement](#) (const char \*str)
- Add a string to the current array.*
- [ParsedJsonDataSet \\* AddArrayElement](#) (bool b)
- Add a bool to the current array.*
- [ParsedJsonDataSet \\* AddArrayElement](#) (const IPADDR &i)
- Add an IP address to the current array.*
- [ParsedJsonDataSet \\* AddArrayElementArray](#) ()
- Add the start of an array element to the current array.*
- [ParsedJsonDataSet \\* AddArrayObjectStart](#) ()
- Add the start of an object element to the current array.*
- [ParsedJsonDataSet \\* AddNullArrayElement](#) ()
- Add a null element to the current array.*
- [ParsedJsonDataSet \\* EndObject](#) ()
- Add an end to the current object.*
- [ParsedJsonDataSet \\* DoneBuilding](#) ()
- Add an end JSON data set and finish building.*

**Friends**

- class **JsonRef**

**16.87.1 Detailed Description**

A class to create, read, and modify a JSON object.

Many of the methods on [ParsedJsonDataSet](#) return a [JsonRef](#) which is a pointer to a variable or sub object inside the [ParsedJsonDataSet](#). So, once data is parsed and traversal or querying has begun most of the work will be inside the [JsonRef](#) class.

**16.87.2 Member Function Documentation****16.87.2.1 Add() [1/12]**

```
ParsedJsonDataSet * ParsedJsonDataSet::Add (
 const char * name,
 bool b)
```

Add a name/value pair to the JSON data set where the value is a bool.

**Parameters**

|             |                         |
|-------------|-------------------------|
| <i>name</i> | The name of the pair.   |
| <i>b</i>    | The value for the pair. |

**16.87.2.2 Add() [2/12]**

```
ParsedJsonDataSet * ParsedJsonDataSet::Add (
 const char * name,
 const char * str)
```

Add a name/value pair to the JSON data set where the value is a string.

**Parameters**

|             |                                      |
|-------------|--------------------------------------|
| <i>name</i> | The name of the pair.                |
| <i>str</i>  | A pointer to the value for the pair. |

**16.87.2.3 Add() [3/12]**

```
ParsedJsonDataSet * ParsedJsonDataSet::Add (
 const char * name,
 const IPADDR & i)
```

Add a name/value pair to the JSON data set where the value is an IP address.

**Parameters**

|             |                        |
|-------------|------------------------|
| <i>name</i> | The name of the pair.  |
| <i>i</i>    | The IP address to add. |

**16.87.2.4 Add() [4/12]**

```
ParsedJsonDataSet * ParsedJsonDataSet::Add (
 const char * name,
 const MACADDR & ma)
```

Add a name/value pair to the JSON data set where the value is a MAC address.

## Parameters

|             |                         |
|-------------|-------------------------|
| <i>name</i> | The name of the pair.   |
| <i>ma</i>   | The MAC address to add. |

**16.87.2.5 Add()** [5/12]

```
ParsedJsonDataSet * ParsedJsonDataSet::Add (
 const char * name,
 double d)
```

Add a name/value pair to the JSON data set where the value is a double.

## Parameters

|             |                         |
|-------------|-------------------------|
| <i>name</i> | The name of the pair.   |
| <i>d</i>    | The value for the pair. |

**16.87.2.6 Add()** [6/12]

```
ParsedJsonDataSet * ParsedJsonDataSet::Add (
 const char * name,
 int i)
```

Add a name/value pair to the JSON data set where the value is an int.

## Parameters

|             |                         |
|-------------|-------------------------|
| <i>name</i> | The name of the pair.   |
| <i>i</i>    | The value for the pair. |

**16.87.2.7 Add()** [7/12]

```
ParsedJsonDataSet * ParsedJsonDataSet::Add (
 const char * name,
 IPADDR4 i4)
```

Add a name/value pair to the JSON data set where the value is an IPv4 address.

## Parameters

|             |                          |
|-------------|--------------------------|
| <i>name</i> | The name of the pair.    |
| <i>i4</i>   | The IPv4 address to add. |

**16.87.2.8 Add()** [8/12]

```
ParsedJsonDataSet * ParsedJsonDataSet::Add (
 const char * name,
 long i)
```

Add a name/value pair to the JSON data set where the value is a long.

## Parameters

|             |                         |
|-------------|-------------------------|
| <i>name</i> | The name of the pair.   |
| <i>i</i>    | The value for the pair. |

**16.87.2.9 Add()** [9/12]

```
ParsedJsonDataSet * ParsedJsonDataSet::Add (
 const char * name,
 short i)
```

Add a name/value pair to the JSON data set where the value is a short.

**Parameters**

|             |                         |
|-------------|-------------------------|
| <i>name</i> | The name of the pair.   |
| <i>i</i>    | The value for the pair. |

**16.87.2.10 Add()** [10/12]

```
ParsedJsonDataSet * ParsedJsonDataSet::Add (
 const char * name,
 unsigned int i)
```

Add a name/value pair to the JSON data set where the value is an unsigned int.

**Parameters**

|             |                         |
|-------------|-------------------------|
| <i>name</i> | The name of the pair.   |
| <i>i</i>    | The value for the pair. |

**16.87.2.11 Add()** [11/12]

```
ParsedJsonDataSet * ParsedJsonDataSet::Add (
 const char * name,
 unsigned long i)
```

Add a name/value pair to the JSON data set where the value is a unsigned long.

**Parameters**

|             |                         |
|-------------|-------------------------|
| <i>name</i> | The name of the pair.   |
| <i>i</i>    | The value for the pair. |

**16.87.2.12 Add()** [12/12]

```
ParsedJsonDataSet * ParsedJsonDataSet::Add (
 const char * name,
 unsigned short i)
```

Add a name/value pair to the JSON data set where the value is a unsigned short.

**Parameters**

|             |                         |
|-------------|-------------------------|
| <i>name</i> | The name of the pair.   |
| <i>i</i>    | The value for the pair. |

**16.87.2.13 AddArrayElement()** [1/10]

```
ParsedJsonDataSet * ParsedJsonDataSet::AddArrayElement (
 bool b)
```

Add a bool to the current array.

## Parameters

|          |                        |
|----------|------------------------|
| <i>b</i> | The bool value to add. |
|----------|------------------------|

**16.87.2.14 AddArrayElement()** [2/10]

```
ParsedJsonDataSet * ParsedJsonDataSet::AddArrayElement (
 const char * str)
```

Add a string to the current array.

## Parameters

|            |                                              |
|------------|----------------------------------------------|
| <i>str</i> | A char* pointing to the string value to add. |
|------------|----------------------------------------------|

**16.87.2.15 AddArrayElement()** [3/10]

```
ParsedJsonDataSet * ParsedJsonDataSet::AddArrayElement (
 const IPADDR & i)
```

Add an IP address to the current array.

## Parameters

|          |                        |
|----------|------------------------|
| <i>i</i> | The IP address to add. |
|----------|------------------------|

**16.87.2.16 AddArrayElement()** [4/10]

```
ParsedJsonDataSet * ParsedJsonDataSet::AddArrayElement (
 double d)
```

Add a double to the current array.

## Parameters

|          |                          |
|----------|--------------------------|
| <i>d</i> | The double value to add. |
|----------|--------------------------|

**16.87.2.17 AddArrayElement()** [5/10]

```
ParsedJsonDataSet * ParsedJsonDataSet::AddArrayElement (
 int i)
```

Add an integer value to the current array.

## Parameters

|          |                           |
|----------|---------------------------|
| <i>i</i> | The integer value to add. |
|----------|---------------------------|

**16.87.2.18 AddArrayElement()** [6/10]

```
ParsedJsonDataSet * ParsedJsonDataSet::AddArrayElement (
 long i)
```

Add a long value to the current array.

## Parameters

|          |                        |
|----------|------------------------|
| <i>i</i> | The long value to add. |
|----------|------------------------|

**16.87.2.19 AddArrayElement()** [7/10]

```
ParsedJsonDataSet * ParsedJsonDataSet::AddArrayElement (
 short i)
```

Add a short value to the current array.

**Parameters**

|          |                         |
|----------|-------------------------|
| <i>i</i> | The short value to add. |
|----------|-------------------------|

**16.87.2.20 AddArrayElement()** [8/10]

```
ParsedJsonDataSet * ParsedJsonDataSet::AddArrayElement (
 unsigned int i)
```

Add an unsigned int value to the current array.

**Parameters**

|          |                                |
|----------|--------------------------------|
| <i>i</i> | The unsigned int value to add. |
|----------|--------------------------------|

**16.87.2.21 AddArrayElement()** [9/10]

```
ParsedJsonDataSet * ParsedJsonDataSet::AddArrayElement (
 unsigned long i)
```

Add an unsigned long value to the current array.

**Parameters**

|          |                                 |
|----------|---------------------------------|
| <i>i</i> | The unsigned long value to add. |
|----------|---------------------------------|

**16.87.2.22 AddArrayElement()** [10/10]

```
ParsedJsonDataSet * ParsedJsonDataSet::AddArrayElement (
 unsigned short i)
```

Add an unsigned short value to the current array.

**Parameters**

|          |                                  |
|----------|----------------------------------|
| <i>i</i> | The unsigned short value to add. |
|----------|----------------------------------|

**16.87.2.23 AddArrayStart()**

```
ParsedJsonDataSet * ParsedJsonDataSet::AddArrayStart (
 const char * name)
```

Add an ARRAY start to the JSON data set.

**Parameters**

|             |                                 |
|-------------|---------------------------------|
| <i>name</i> | The name of the array to start. |
|-------------|---------------------------------|

**16.87.2.24 AddMyMac()**

```
ParsedJsonDataSet * ParsedJsonDataSet::AddMyMac (
```

```
const char * name)
```

Add the device MAC address to the JSON data set.

#### Parameters

|             |                                                   |
|-------------|---------------------------------------------------|
| <i>name</i> | The name of the field containing the MAC address. |
|-------------|---------------------------------------------------|

#### 16.87.2.25 AddNull()

```
ParsedJsonDataSet * ParsedJsonDataSet::AddNull (
 const char * name)
```

Add a name/value pair to the JSON data set where the value is null.

#### Parameters

|             |                       |
|-------------|-----------------------|
| <i>name</i> | The name of the pair. |
|-------------|-----------------------|

#### 16.87.2.26 AddObjectStart()

```
ParsedJsonDataSet * ParsedJsonDataSet::AddObjectStart (
 const char * name)
```

Use to start an object in the JSON data set.

#### Parameters

|             |                                  |
|-------------|----------------------------------|
| <i>name</i> | The name of the object to start. |
|-------------|----------------------------------|

#### 16.87.2.27 CopyObject()

```
bool ParsedJsonDataSet::CopyObject (
 ParsedJsonDataSet & src_set)
```

Copies the provided JSON data set into the current one.

#### Return values

|              |                     |
|--------------|---------------------|
| <i>true</i>  | The copy succeeded. |
| <i>false</i> | The copy failed.    |

#### 16.87.2.28 CurrentBool()

```
bool ParsedJsonDataSet::CurrentBool () [inline]
```

Returns true if the current element a TRUE\_EL primitive type.

#### Return values

|              |                                                         |
|--------------|---------------------------------------------------------|
| <i>true</i>  | If the current element is a TRUE_EL primitive type.     |
| <i>false</i> | If the current element is not a TRUE_EL primitive type. |

#### 16.87.2.29 CurrentName()

```
const char * ParsedJsonDataSet::CurrentName () [inline]
```

Get the name of the current element.

**Returns**

A pointer to the name of the current element, if it has one. If it does not, it returns a 0.

**16.87.2.30 CurrentNumber()**

```
double ParsedJsonDataSet::CurrentNumber () [inline]
```

Get the number value of the current element.

**Returns**

The number value if the current element's primitive type is NUMBER. Otherwise it returns a quite NAN.

**16.87.2.31 CurrentString()**

```
const char * ParsedJsonDataSet::CurrentString () [inline]
```

Get the string value of the current element.

**Returns**

The a pointer to the string value of the current element if it is of primitive type STRING or ALLOC\_STRING. Otherwise it returns a 0.

**16.87.2.32 FindBoolean()**

```
bool ParsedJsonDataSet::FindBoolean (
 const char * name) [inline]
```

Find the boolean value of the element after the element with the given name.

**Parameters**

|             |                                  |
|-------------|----------------------------------|
| <i>name</i> | The name of the element to find. |
|-------------|----------------------------------|

**Return values**

|              |                                                      |
|--------------|------------------------------------------------------|
| <i>true</i>  | If the element is of the TRUE_EL primitive type.     |
| <i>false</i> | If the element is not of the TRUE_EL primitive type. |

**16.87.2.33 FindBooleanInCurentObject()**

```
bool ParsedJsonDataSet::FindBooleanInCurentObject (
 const char * name) [inline]
```

Find the boolean value of the element within the current object. Does not search sub-objects.

**Parameters**

|             |                                  |
|-------------|----------------------------------|
| <i>name</i> | The name of the element to find. |
|-------------|----------------------------------|

**Return values**

|              |                                                      |
|--------------|------------------------------------------------------|
| <i>true</i>  | If the element is of the TRUE_EL primitive type.     |
| <i>false</i> | If the element is not of the TRUE_EL primitive type. |

**16.87.2.34 FindElementAfterName()**

```
json_primitive_type ParsedJsonDataSet::FindElementAfterName (
 const char * name) [inline]
```

Finds name in current object points at element after name. This only supports simple, single element names. This searches from the current position to the end.

**Parameters**

|             |                       |
|-------------|-----------------------|
| <i>name</i> | The name to look for. |
|-------------|-----------------------|

**Returns**

The type that the parser is now currently set to.

**Return values**

|                 |                                               |
|-----------------|-----------------------------------------------|
| <i>NOTFOUND</i> | If the an element with the name wasn't found. |
|-----------------|-----------------------------------------------|

**16.87.2.35 FindElementAfterNameInCurrentArray()**

```
json_primitive_type ParsedJsonDataSet::FindElementAfterNameInCurrentArray (
 const char * name) [inline]
```

Looks for elements with the current name in the current ARRAY only. Does not search sub arrays.

**Parameters**

|             |                       |
|-------------|-----------------------|
| <i>name</i> | The name to look for. |
|-------------|-----------------------|

**Returns**

The type that the parser is now currently set to.

**Return values**

|                 |                                               |
|-----------------|-----------------------------------------------|
| <i>NOTFOUND</i> | If the an element with the name wasn't found. |
|-----------------|-----------------------------------------------|

**16.87.2.36 FindElementAfterNameInCurrentObject()**

```
json_primitive_type ParsedJsonDataSet::FindElementAfterNameInCurrentObject (
 const char * name) [inline]
```

Looks for elements with the current name in the current OBJECT only. Does not search sub objects.

**Parameters**

|             |                       |
|-------------|-----------------------|
| <i>name</i> | The name to look for. |
|-------------|-----------------------|

**Returns**

The type that the parser is now currently set to.

**Return values**

|                 |                                               |
|-----------------|-----------------------------------------------|
| <i>NOTFOUND</i> | If the an element with the name wasn't found. |
|-----------------|-----------------------------------------------|

**16.87.2.37 FindFullAtName()**

```
json_primitive_type ParsedJsonDataSet::FindFullAtName (
 const char * name) [inline]
```

Find the element in the data set with the given name and move the parser to that element. This searches a full name path, such as ob1.ob2.ob3.ob4.

**Parameters**

|             |                            |
|-------------|----------------------------|
| <i>name</i> | The full name to look for. |
|-------------|----------------------------|

**Returns**

The type that the parser is now currently set to.

**Return values**

|                 |                                               |
|-----------------|-----------------------------------------------|
| <i>NOTFOUND</i> | If the an element with the name wasn't found. |
|-----------------|-----------------------------------------------|

**16.87.2.38 FindFullName()**

```
json_primitive_type ParsedJsonDataSet::FindFullName (
 const char * name) [inline]
```

Find the element in the data set with the given name and move the parser to the next element. This searches a full name path, such as ob1.ob2.ob3.ob4.

**Parameters**

|             |                            |
|-------------|----------------------------|
| <i>name</i> | The full name to look for. |
|-------------|----------------------------|

**Returns**

The type that the parser is now currently set to.

**Return values**

|                 |                                                                                               |
|-----------------|-----------------------------------------------------------------------------------------------|
| <i>NOTFOUND</i> | If the an element with the name wasn't found, or there is no element after the named element. |
|-----------------|-----------------------------------------------------------------------------------------------|

**16.87.2.39 FindFullNameBoolean()**

```
bool ParsedJsonDataSet::FindFullNameBoolean (
 const char * name) [inline]
```

Find the boolean value of a given element.

**Parameters**

|             |                                       |
|-------------|---------------------------------------|
| <i>name</i> | The full name of the element to find. |
|-------------|---------------------------------------|

**Return values**

|              |                                                      |
|--------------|------------------------------------------------------|
| <i>true</i>  | If the element is of the TRUE_EL primitive type.     |
| <i>false</i> | If the element is not of the TRUE_EL primitive type. |

**16.87.2.40 FindFullNameNumber()**

```
double ParsedJsonDataSet::FindFullNameNumber (
 const char * name) [inline]
```

Find the number value of the element with the given name in the current object.

**Parameters**

|             |                                       |
|-------------|---------------------------------------|
| <i>name</i> | The full name of the element to find. |
|             | .                                     |

**Returns**

The number value of the element if found, otherwise a quiet nan.

**16.87.2.41 FindFullNamePermissiveBoolean()**

```
bool ParsedJsonDataSet::FindFullNamePermissiveBoolean (
 const char * name) [inline]
```

Find the permissive boolean value of a given element.

**Parameters**

|             |                                       |
|-------------|---------------------------------------|
| <i>name</i> | The full name of the element to find. |
|-------------|---------------------------------------|

**Return values**

|              |                                                                                              |
|--------------|----------------------------------------------------------------------------------------------|
| <i>true</i>  | If the current element a TRUE_EL primitive type, is "True", "true", or is a non-zero number. |
| <i>false</i> | If the current element is not a TRUE_EL primitive type, "True", "true", or is 0.             |

**16.87.2.42 FindFullNameString()**

```
const char * ParsedJsonDataSet::FindFullNameString (
 const char * name) [inline]
```

Find the string value of the element with the given name in the current object.

**Parameters**

|             |                                       |
|-------------|---------------------------------------|
| <i>name</i> | The full name of the element to find. |
|             | .                                     |

**Returns**

A pointer to the buffer if the string is found, or null otherwise.

**16.87.2.43 FindGlobalBoolean()**

```
bool ParsedJsonDataSet::FindGlobalBoolean (
 const char * name) [inline]
```

Find the boolean value of a given element. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.

## Parameters

|             |                                  |
|-------------|----------------------------------|
| <i>name</i> | The name of the element to find. |
|-------------|----------------------------------|

## Return values

|              |                                                      |
|--------------|------------------------------------------------------|
| <i>true</i>  | If the element is of the TRUE_EL primitive type.     |
| <i>false</i> | If the element is not of the TRUE_EL primitive type. |

**16.87.2.44 FindGlobalElementAfterName()**

```
json_primitive_type ParsedJsonDataSet::FindGlobalElementAfterName (
 const char * name) [inline]
```

Finds name in current object points at element after name. This only supports simple, single element names. It starts the search from the parser's current position, and if it doesn't find it, it will start the search over from the beginning.

## Parameters

|             |                       |
|-------------|-----------------------|
| <i>name</i> | The name to look for. |
|-------------|-----------------------|

## Returns

The type that the parser is now currently set to.

## Return values

|                 |                                               |
|-----------------|-----------------------------------------------|
| <i>NOTFOUND</i> | If the an element with the name wasn't found. |
|-----------------|-----------------------------------------------|

**16.87.2.45 FindGlobalNumber()**

```
double ParsedJsonDataSet::FindGlobalNumber (
 const char * name) [inline]
```

Find the number value of a given element. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.

## Parameters

|             |                                  |
|-------------|----------------------------------|
| <i>name</i> | The name of the element to find. |
|             | .                                |

## Returns

The number value of the element if found, otherwise a quiet nan.

**16.87.2.46 FindGlobalObject()**

```
bool ParsedJsonDataSet::FindGlobalObject (
 const char * name) [inline]
```

Find the OBJECT with the given name. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.

## Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>name</i> | The name of the OBJECT to find. |
|             | .                               |

## Return values

|              |                                                                                       |
|--------------|---------------------------------------------------------------------------------------|
| <i>true</i>  | If the OBJECT was found. The current position will be set to the start of the OBJECT. |
| <i>false</i> | If the OBJECT was not found.                                                          |

**16.87.2.47 FindGlobalPermissiveBoolean()**

```
bool ParsedJsonDataSet::FindGlobalPermissiveBoolean (
 const char * name) [inline]
```

Find the permissive boolean value of a given element. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.

## Parameters

|             |                                  |
|-------------|----------------------------------|
| <i>name</i> | The name of the element to find. |
|-------------|----------------------------------|

## Return values

|              |                                                                                              |
|--------------|----------------------------------------------------------------------------------------------|
| <i>true</i>  | If the current element a TRUE_EL primitive type, is "True", "true", or is a non-zero number. |
| <i>false</i> | If the current element is not a TRUE_EL primitive type, "True", "true", or is 0.             |

**16.87.2.48 FindGlobalString()**

```
const char * ParsedJsonDataSet::FindGlobalString (
 const char * name) [inline]
```

Find the string value of a given element. Starts at the current position and then starts again at the beginning of the data set if the element isn't found. This supports only simple, single element names.

## Parameters

|             |                                  |
|-------------|----------------------------------|
| <i>name</i> | The name of the element to find. |
|-------------|----------------------------------|

## Returns

A pointer to the buffer if the string is found, or null otherwise.

**16.87.2.49 FindNumber()**

```
double ParsedJsonDataSet::FindNumber (
 const char * name) [inline]
```

Find the number value of the element after the element with the given name.

## Parameters

|             |                                  |
|-------------|----------------------------------|
| <i>name</i> | The name of the element to find. |
|-------------|----------------------------------|

**Returns**

The number value of the element if found, otherwise a quiet nan.

**16.87.2.50 FindNumberInCurentObject()**

```
double ParsedJsonDataSet::FindNumberInCurentObject (
 const char * name) [inline]
```

Find the number value of the element with the given name in the current object. Does not search sub-objects.

**Parameters**

|             |                                  |
|-------------|----------------------------------|
| <i>name</i> | The name of the element to find. |
|             | .                                |

**Returns**

The number value of the element if found, otherwise a quiet nan.

**16.87.2.51 FindObject()**

```
bool ParsedJsonDataSet::FindObject (
 const char * name) [inline]
```

Find the OBJECT of the element after the element with the given name.

**Parameters**

|             |                                 |
|-------------|---------------------------------|
| <i>name</i> | The name of the OBJECT to find. |
|-------------|---------------------------------|

**Return values**

|              |                                                                                       |
|--------------|---------------------------------------------------------------------------------------|
| <i>true</i>  | If the OBJECT was found. The current position will be set to the start of the OBJECT. |
| <i>false</i> | If the OBJECT was not found.                                                          |

**16.87.2.52 FindObjectInCurentObject()**

```
bool ParsedJsonDataSet::FindObjectInCurentObject (
 const char * name) [inline]
```

Find the OBJECT of the element with the given name in the current OBJECT. Does not search sub-objects.

**Parameters**

|             |                                 |
|-------------|---------------------------------|
| <i>name</i> | The name of the OBJECT to find. |
|-------------|---------------------------------|

**Return values**

|              |                                                                                       |
|--------------|---------------------------------------------------------------------------------------|
| <i>true</i>  | If the OBJECT was found. The current position will be set to the start of the OBJECT. |
| <i>false</i> | If the OBJECT was not found.                                                          |

**16.87.2.53 FindPermissiveBoolean()**

```
bool ParsedJsonDataSet::FindPermissiveBoolean (
 const char * name) [inline]
```

Find the permissive boolean value of the element after the element with the provided name.

**Parameters**

|             |                                   |
|-------------|-----------------------------------|
| <i>name</i> | The name of element to search on. |
|-------------|-----------------------------------|

**Return values**

|              |                                                                                              |
|--------------|----------------------------------------------------------------------------------------------|
| <i>true</i>  | If the current element a TRUE_EL primitive type, is "True", "true", or is a non-zero number. |
| <i>false</i> | If the current element is not a TRUE_EL primitive type, "True", "true", or is 0.             |

**16.87.2.54 FindPermissiveBooleanInCurentObject()**

```
bool ParsedJsonDataSet::FindPermissiveBooleanInCurentObject (
 const char * name) [inline]
```

Find the permissive boolean value of the element with the given name in the current object. Does not search sub-objects.

**Parameters**

|             |                                  |
|-------------|----------------------------------|
| <i>name</i> | The name of the element to find. |
|-------------|----------------------------------|

**Return values**

|              |                                                                                              |
|--------------|----------------------------------------------------------------------------------------------|
| <i>true</i>  | If the current element a TRUE_EL primitive type, is "True", "true", or is a non-zero number. |
| <i>false</i> | If the current element is not a TRUE_EL primitive type, "True", "true", or is 0.             |

**16.87.2.55 FindString()**

```
const char * ParsedJsonDataSet::FindString (
 const char * name) [inline]
```

Find the string value of the element after the element with the given name.

**Parameters**

|             |                                  |
|-------------|----------------------------------|
| <i>name</i> | The name of the element to find. |
|-------------|----------------------------------|

**Returns**

A pointer to the buffer if the string is found, or null otherwise.

**16.87.2.56 FindStringInCurentObject()**

```
const char * ParsedJsonDataSet::FindStringInCurentObject (
 const char * name) [inline]
```

Find the string value of the element with the given name in the current object. Does not search sub-objects.

## Parameters

|             |                                  |
|-------------|----------------------------------|
| <i>name</i> | The name of the element to find. |
|             | •                                |

## Returns

A pointer to the buffer if the string is found, or null otherwise.

**16.87.2.57 GetCurrent()**

`json_primitive_type` ParsedJsonDataSet::GetCurrent ( ) [inline]

Get the element at the current position of the JSON data set.

## Returns

The current element of the JSON data set.

## Return values

|                  |                                                                        |
|------------------|------------------------------------------------------------------------|
| <i>UNDEFINED</i> | If there is an error in the parsing or if the parsing is not complete. |
| <i>EOF_EL</i>    | If it's the last element in the data set.                              |

**16.87.2.58 GetFirst()**

`json_primitive_type` ParsedJsonDataSet::GetFirst ( ) [inline]

Get the first element of the JSON data set.

## Returns

The first element of the JSON data set.

## Return values

|                  |                                                                        |
|------------------|------------------------------------------------------------------------|
| <i>UNDEFINED</i> | If there is an error in the parsing or if the parsing is not complete. |
| <i>EOF_EL</i>    | If it's the last element in the data set.                              |

**16.87.2.59 GetNext()**

`json_primitive_type` `ParsedJsonDataSet::GetNext ( ) [inline]`

Get the element at the next position of the JSON data set.

**Returns**

The next element of the JSON data set.

**Return values**

|                        |                                                                        |
|------------------------|------------------------------------------------------------------------|
| <code>UNDEFINED</code> | If there is an error in the parsing or if the parsing is not complete. |
| <code>EOF_EL</code>    | If it's the last element in the data set.                              |

**16.87.2.60 GetNextArray()**

`json_primitive_type` `ParsedJsonDataSet::GetNextArray ( )`

Iterates the current element of the JSON data set until it finds one of type `BEGIN_ARRAY`.

**Returns**

The next element with type `BEGIN_ARRAY` after the current position.

**Return values**

|                       |                                                                             |
|-----------------------|-----------------------------------------------------------------------------|
| <code>NOTFOUND</code> | If there is no <code>BEGIN_ARRAY</code> element after the current position. |

[GetNextNameInCurrentArray\(\)](#)

**16.87.2.61 GetNextBoolInCurrentArray()**

`json_primitive_type` `ParsedJsonDataSet::GetNextBoolInCurrentArray ( )`

Get the next element of type `TRUE_EL` that exists in the current `ARRAY` after the current position.

**Returns**

The next element with type `TRUE_EL` in the current `ARRAY` after the current position.

**Return values**

|                       |                                                                      |
|-----------------------|----------------------------------------------------------------------|
| <code>NOTFOUND</code> | If there is no <code>NAME</code> element after the current position. |
|-----------------------|----------------------------------------------------------------------|

### 16.87.2.62 GetNextName()

`json_primitive_type` `ParsedJsonDataSet::GetNextName ( ) [inline]`

Iterates the current element of the JSON data set until it finds one of type NAME.

Returns

The next element with type NAME after the current position.

Return values

|                       |                                                         |
|-----------------------|---------------------------------------------------------|
| <code>NOTFOUND</code> | If there is no NAME element after the current position. |
|-----------------------|---------------------------------------------------------|

See also

[GetNextNameInCurrentArray\(\)](#)

### 16.87.2.63 GetNextNameInCurrentArray()

`json_primitive_type` `ParsedJsonDataSet::GetNextNameInCurrentArray ( ) [inline]`

Get the next element of type NAME that exists in the current ARRAY after the current position.

Returns

The next element with type NAME in the current ARRAY after the current position.

Return values

|                       |                                                         |
|-----------------------|---------------------------------------------------------|
| <code>NOTFOUND</code> | If there is no NAME element after the current position. |
|-----------------------|---------------------------------------------------------|

### 16.87.2.64 GetNextNameInCurrentObject()

`json_primitive_type` `ParsedJsonDataSet::GetNextNameInCurrentObject ( ) [inline]`

Get the next element of type NAME that exists in the current OBJECT after the current position.

Returns

The next element with type NAME in the current OBJECT after the current position.

Return values

|                       |                                                         |
|-----------------------|---------------------------------------------------------|
| <code>NOTFOUND</code> | If there is no NAME element after the current position. |
|-----------------------|---------------------------------------------------------|

#### 16.87.2.65 GetNextNumberInCurrentArray()

`json_primitive_type` `ParsedJsonDataSet::GetNextNumberInCurrentArray ( )`

Get the next element of type NUMBER that exists in the current ARRAY after the current position.

Returns

The next element with type NUMBER in the current ARRAY after the current position.

Return values

|                 |                                                         |
|-----------------|---------------------------------------------------------|
| <i>NOTFOUND</i> | If there is no NAME element after the current position. |
|-----------------|---------------------------------------------------------|

See also

[CurrentNumber\(\)](#)

#### 16.87.2.66 GetNextObject()

`json_primitive_type` `ParsedJsonDataSet::GetNextObject ( )`

Get the next element of type name that exists in the current OBJECT after the current position.

Returns

The next element with type BEGIN\_OBJECT after the current position.

Return values

|                 |                                                                 |
|-----------------|-----------------------------------------------------------------|
| <i>NOTFOUND</i> | If there is no BEGIN_OBJECT element after the current position. |
|-----------------|-----------------------------------------------------------------|

[GetNextNameInCurrentArray\(\)](#)

#### 16.87.2.67 GetNextObjectInCurrentArray()

`json_primitive_type` `ParsedJsonDataSet::GetNextObjectInCurrentArray ( )`

Get the next element of type BEGIN\_OBJECT that exists in the current ARRAY after the current position.

Returns

The next element with type BEGIN\_OBJECT in the current ARRAY after the current position.

Return values

|                 |                                                                 |
|-----------------|-----------------------------------------------------------------|
| <i>NOTFOUND</i> | If there is no BEGIN_OBJECT element after the current position. |
|-----------------|-----------------------------------------------------------------|

See also

[GetNextName\(\)](#)

[GetNextNameInCurrentObject\(\)](#)

### 16.87.2.68 GetNextStringInCurrentArray()

`json_primitive_type` ParsedJsonDataSet::GetNextStringInCurrentArray ( )

Get the next element of type STRING that exists in the current ARRAY after the current position.

Returns

The next element with type STRING in the current ARRAY after the current position.

Return values

|                       |                                                         |
|-----------------------|---------------------------------------------------------|
| <code>NOTFOUND</code> | If there is no NAME element after the current position. |
|-----------------------|---------------------------------------------------------|

See also

[CurrentString\(\)](#)

### 16.87.2.69 GetParsePosition()

`JsonRef` ParsedJsonDataSet::GetParsePosition ( )

Gets the current parse position object for the JSON data set.

Returns

The current parse position object.

### 16.87.2.70 GetPrintSize()

```
int ParsedJsonDataSet::GetPrintSize (
 bool pretty = false) [inline]
```

Calculates how many characters the JSON data set would take to print.

Parameters

|                     |                                                                        |
|---------------------|------------------------------------------------------------------------|
| <code>pretty</code> | Whether indentation and new lines should be provided between elements. |
|---------------------|------------------------------------------------------------------------|

Returns

The number of characters needed to print the JSON data set.

### 16.87.2.71 GetRawCurrent()

`json_primitive_type` ParsedJsonDataSet::GetRawCurrent ( ) [inline]

Get the element at the current position of the JSON data set, including non-public types.

Returns

The current element of the JSON data set.

Return values

|                        |                                                                        |
|------------------------|------------------------------------------------------------------------|
| <code>UNDEFINED</code> | If there is an error in the parsing or if the parsing is not complete. |
| <code>EOF_EL</code>    | If it's the last element in the data set.                              |

**16.87.2.72 name()**

```
JsonRef ParsedJsonDataSet::name (
 const char * name) [inline]
```

Get a [JsonRef](#) representing any entity from a parent object by key name. Useful if more than one JSON object/element has the same name.

## Example

```
JsonRef userThree = myJsonRef.name("users")[3];
```

## Parameters

|              |                                       |
|--------------|---------------------------------------|
| <i>*name</i> | Pointer to name of the entity to find |
|--------------|---------------------------------------|

## Returns

The reference to the entity of type [JsonRef](#)

## See also

[ParsedJsonDataSet::operator\(\)\(\)](#), [ParsedJsonDataSet::object\(\)](#)

**16.87.2.73 object()**

```
JsonRef ParsedJsonDataSet::object (
 const char * name) [inline]
```

Get a [JsonRef](#) representing an object from a parent object by key name.

## Example

```
JsonRef john = myJsonRef.object("users").object("john");
```

## Parameters

|              |                                       |
|--------------|---------------------------------------|
| <i>*name</i> | Pointer to name of the object to find |
|--------------|---------------------------------------|

## Returns

The reference to the object of type [JsonRef](#)

**16.87.2.74 operator()()**

```
JsonRef ParsedJsonDataSet::operator() (
 const char * name) [inline]
```

Get a [JsonRef](#) representing any entity from a parent object by key name. Shortcut for [JsonRef::name\(\)](#)

**Example**

```
JsonRef allUsers = myJsonRef("users");
```

**Parameters**

|              |                                       |
|--------------|---------------------------------------|
| <i>*name</i> | Pointer to name of the entity to find |
|--------------|---------------------------------------|

**Returns**

The reference to the entity of type [JsonRef](#)

**See also**

[ParsedJsonDataSet::name\(\)](#), [ParsedJsonDataSet::object\(\)](#)

**16.87.2.75 operator[]()**

```
JsonRef ParsedJsonDataSet::operator[] (
 int i) [inline]
```

Get a [JsonRef](#) from an array by numerical index.

**Example**

```
JsonRef userThree = myJsonRef("users")[3];
```

**Returns**

A [JsonRef](#) if array element is found

**16.87.2.76 PermissiveCurrentBool()**

```
bool ParsedJsonDataSet::PermissiveCurrentBool () [inline]
```

Returns true if the current element a TRUE\_EL primitive type, is "True", "true", or is a non-zero number.

**Return values**

|              |                                                                                              |
|--------------|----------------------------------------------------------------------------------------------|
| <i>true</i>  | If the current element a TRUE_EL primitive type, is "True", "true", or is a non-zero number. |
| <i>false</i> | If the current element does not meet the true condition..                                    |

**16.87.2.77 PrintObject()**

```
int ParsedJsonDataSet::PrintObject (
 bool pretty = false) [inline]
```

Prints the JSON data set to stdout.

**Parameters**

|               |                                                                  |
|---------------|------------------------------------------------------------------|
| <i>pretty</i> | Whether to show indentation and new lines between JSON elements. |
|---------------|------------------------------------------------------------------|

**16.87.2.78 PrintObjectToBuffer()**

```
int ParsedJsonDataSet::PrintObjectToBuffer (
 char * buffer,
 int maxlen,
 bool pretty = false) [inline]
```

Prints the JSON data set to a provided buffer.

#### Parameters

|               |                                                                        |
|---------------|------------------------------------------------------------------------|
| <i>buffer</i> | The buffer to print to.                                                |
| <i>maxlen</i> | The max length of the buffer.                                          |
| <i>pretty</i> | Whether indentation and new lines should be provided between elements. |

#### Returns

The number of characters printed.

#### 16.87.2.79 PrintObjectToFd()

```
int ParsedJsonDataSet::PrintObjectToFd (
 int fd,
 bool pretty = false) [inline]
```

Prints the JSON data set to a specified file descriptor.

#### Parameters

|               |                                                                        |
|---------------|------------------------------------------------------------------------|
| <i>fd</i>     | The file descriptor to print to.                                       |
| <i>pretty</i> | Whether indentation and new lines should be provided between elements. |

#### 16.87.2.80 PrintObjectToString()

```
int ParsedJsonDataSet::PrintObjectToString (
 NBString & s,
 bool pretty = false) [inline]
```

Prints the JSON data set to a [NBString](#) object.

#### Parameters

|               |                                                                        |
|---------------|------------------------------------------------------------------------|
| <i>s</i>      | The <a href="#">NBString</a> to print to.                              |
| <i>pretty</i> | Whether indentation and new lines should be provided between elements. |

#### 16.87.2.81 ReadFrom()

```
virtual int ParsedJsonDataSet::ReadFrom (
 int fd) [virtual]
```

Reads in data from the specified file descriptor and parses it into the JSON data set.

#### Parameters

|           |                                        |
|-----------|----------------------------------------|
| <i>fd</i> | The file descriptor to read data from. |
|-----------|----------------------------------------|

#### Returns

The number of bytes read

#### 16.87.2.82 ResetPosition()

```
void ParsedJsonDataSet::ResetPosition () [inline]
```

Resets the parser position to the beginning of the JSON data set.

## See also

[GetFirst\(\)](#)  
[GetNext\(\)](#)  
[GetCurrent\(\)](#)  
[SkipCurrentValue\(\)](#)

**16.87.2.83 SetParsePosition()**

```
JsonRef ParsedJsonDataSet::SetParsePosition (
 JsonRef pos)
```

Sets the current parse position object for the JSON data set.

## Parameters

|            |                                                                           |
|------------|---------------------------------------------------------------------------|
| <i>pos</i> | The <a href="#">JsonRef</a> that you want to set the current position to. |
|------------|---------------------------------------------------------------------------|

## Returns

The current parse ref position for the JSON data set.

**16.87.2.84 SkipCurrentValue()**

```
json_primitive_type ParsedJsonDataSet::SkipCurrentValue () [inline]
```

Skips over the current value, and get the next element. If called inside an ARRAY or OBJECT, it will walk to the end of the ARRAY or OBJECT and return the next element it finds. If it reaches the end of the ARRAY or OBJECT before it finds a value, it will return NOTFOUND.

## Returns

The next element.

## Return values

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| <i>NOTFOUND</i> | If there are no other elements after the current one. |
|-----------------|-------------------------------------------------------|

## See also

[GetFirst\(\)](#)  
[GetCurrent\(\)](#)  
[GetNext\(\)](#)  
[ResetPosition\(\)](#)  
[SkipCurrentValue\(\)](#)

**16.87.2.85 WriteData()**

```
virtual int ParsedJsonDataSet::WriteData (
 const unsigned char * pCopyFrom,
 int numBytes) [virtual]
```

Writes the passed in data to the JSON data set.

## Parameters

|                  |                         |
|------------------|-------------------------|
| <i>pCopyFrom</i> | What data to write.     |
| <i>numBytes</i>  | How many bytes to copy. |

**Returns**

The number of bytes written

*Check the security state of the cached URI object. Requires WEB\_CLIENT\_SSL\_SUPPORT be defined in [predef.h](#).*
- void **Invalidate** ()  
*Set the state of the cached URI object to invalid.*

### 16.88.1 Detailed Description

Parsed Uniform Resource Identifier Class (URI)

Web Client HTTP functions can pass a URL, which has to be parsed and use DNS to resolve if necessary. This class provides an object with the parsed and DNS results that can be used for future transactions. The intent of using this class is to cache the parsed results and dns lookup for communication to the same resource.

Enabling WEB\_CLIENT\_SSL\_SUPPORT in [predef.h](#) adds TLS support.

The maximum size of the cached URI, path and hose are 256 bytes each.

### 16.88.2 Constructor & Destructor Documentation

#### 16.88.2.1 ParsedURI()

```
ParsedURI::ParsedURI (
 const char * uri,
 uint16_t timeout = 20 * TICKS_PER_SECOND,
 bool skipLookup = false) [inline]
```

Constructor to create a new URI object.

## Parameters

|                   |                                    |
|-------------------|------------------------------------|
| <i>uri</i>        | Pointer to a URI.                  |
| <i>timeout</i>    | Number of sysem time tick to wait. |
| <i>skipLookup</i> | Skip URI lookup. Default is false. |

**16.88.3 Member Function Documentation****16.88.3.1 GetAddr()**

```
IPADDR ParsedURI::GetAddr () [inline]
```

Get the resolved host Address.

## Returns

The resolved host address.

**16.88.3.2 GetHost()**

```
const char * ParsedURI::GetHost () [inline]
```

Get the cached URI Host name.

## Returns

Pointer to the cached host name if the cached URI is valid, otherwise NULL.

**16.88.3.3 GetPath()**

```
const char * ParsedURI::GetPath () [inline]
```

Get the cached URI path.

## Returns

Pointer to the cached path string if the cached URI is valid, otherwise NULL.

**16.88.3.4 GetPort()**

```
uint16_t ParsedURI::GetPort () [inline]
```

Get the cached URI network port number.

## Returns

The cached URI port number if the cached URI is valid, otherwise 0.

**16.88.3.5 IsSecure()**

```
bool ParsedURI::IsSecure () [inline]
```

Check the security state of the cached URI object. Requires WEB\_CLIENT\_SSL\_SUPPORT be defined in [predef.h](#).

## Return values

|              |                        |
|--------------|------------------------|
| <i>true</i>  | Secure.                |
| <i>false</i> | URI object is invalid. |

**16.88.3.6 NewUri()**

```
void ParsedURI::NewUri (
```

```

 const char * uri,
 uint16_t timeout = 20 *TICKS_PER_SECOND,
 bool skipLookup = false)

```

Replace the existing (URI) object with new information.  
Update the existing URI with a new value.

#### Parameters

|                   |                                     |
|-------------------|-------------------------------------|
| <i>uri</i>        | Pointer to a URI string.            |
| <i>timeout</i>    | Number of sysem time ticks to wait. |
| <i>skipLookup</i> | Skip URI lookup. Default is false.  |

#### 16.88.3.7 valid()

```
bool ParsedURI::valid () const [inline]
```

Check to see if URI is valid.

#### Return values

|              |              |
|--------------|--------------|
| <i>true</i>  | if valid     |
| <i>false</i> | if not valid |

The documentation for this class was generated from the following file:

## 16.89.1 Detailed Description

GPIO Pin Class.

## 16.89.2 Member Enumeration Documentation

### 16.89.2.1 pin\_fn\_t [1/2]

enum **PinIO::pin\_fn\_t**

Enumerator

|            |               |
|------------|---------------|
| PIN_FN_IN  | Input.        |
| PIN_FN_OUT | Output.       |
| PIN_FN_IN  | Input.        |
| PIN_FN_OUT | Output.       |
| PIN_FN_A   | Peripheral A. |

## Enumerator

|          |               |
|----------|---------------|
| PIN_FN_B | Peripheral B. |
| PIN_FN_C | Peripheral C. |
| PIN_FN_D | Peripheral D. |

**16.89.2.2 pin\_fn\_t [2/2]**

```
enum PinIO::pin_fn_t
```

Pin Function modes to configure the managed pin(s).

## Enumerator

|            |               |
|------------|---------------|
| PIN_FN_IN  | Input.        |
| PIN_FN_OUT | Output.       |
| PIN_FN_IN  | Input.        |
| PIN_FN_OUT | Output.       |
| PIN_FN_A   | Peripheral A. |
| PIN_FN_B   | Peripheral B. |
| PIN_FN_C   | Peripheral C. |
| PIN_FN_D   | Peripheral D. |

**16.89.3 Constructor & Destructor Documentation****16.89.3.1 PinIO() [1/2]**

```
constexpr PinIO::PinIO (
 uint32_t port,
 uint32_t pin) [inline], [constexpr]
```

Construct a [PinIO](#) for a specific cpu pin.

## Parameters

|             |                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------|
| <i>port</i> | The zero-indexed numeric instance number of the desired Pio module. (PIOA=0, PIOB=1, PIOC=2, etc.)     |
| <i>pin</i>  | The zero-indexed pin number within the requested port that the new <a href="#">PinIO</a> is to manage. |

Example usage for pin 'PIOD\_24'

```
PinIO LED1(3, 24);
```

**16.89.3.2 PinIO() [2/2]**

```
constexpr PinIO::PinIO (
 const PinIO & rhs) [inline], [constexpr]
```

Construct a copy of another [PinIO](#).

## Parameters

|            |                                                   |
|------------|---------------------------------------------------|
| <i>rhs</i> | The <a href="#">PinIO</a> to construct a copy of. |
|------------|---------------------------------------------------|

## 16.89.4 Member Function Documentation

### 16.89.4.1 function()

```
void PinIO::function (
 pin_fn_t fn) const [inline]
```

Set the pin function for the managed pin(s).

#### Parameters

|           |                                                        |
|-----------|--------------------------------------------------------|
| <i>fn</i> | The pin function to be assigned to the managed pin(s). |
|-----------|--------------------------------------------------------|

### 16.89.4.2 getFn()

```
int8_t PinIO::getFn () [inline]
```

Get the pin function for the managed pin(s).

#### Returns

The pin function as a `pin_fn_t` of the managed pin(s). Returns -1 if pin is not an I/O (ex: GND, VCC)

### 16.89.4.3 multdrv()

```
void PinIO::multdrv (
 bool enable) const [inline]
```

Configure the multdrive/open-drain driver for the pin(s).

#### Parameters

|               |                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------|
| <i>enable</i> | True: configure the output driver as Open Drain. False: configure the output driver as Push-Pull. |
|---------------|---------------------------------------------------------------------------------------------------|

### 16.89.4.4 operator bool()

```
PinIO::operator bool () const [inline]
```

Read the line state of the pin(s).

#### Returns

The line state of the pin(s): true = High, false = Low

### 16.89.4.5 operator"!()

```
bool PinIO::operator! () const [inline]
```

Return the opposite of the *driven* value of the pin(s).

#### Returns

The opposite of the *driven* value of the pin(s).

### 16.89.4.6 operator=() [1/2]

```
bool PinIO::operator= (
 bool val) [inline]
```

Assign a driven value to the pin(s).

#### Parameters

|            |                                                                |
|------------|----------------------------------------------------------------|
| <i>val</i> | The value to be driven on the pin(s): true = High, false = Low |
|------------|----------------------------------------------------------------|

**Returns**

The driven value for the pin(s).

**16.89.4.7 operator=()** [2/2]

```
PinIO & PinIO::operator= (
 const PinIO & rhs) [inline]
```

Assign a driven value to the pin(s) based on the line state of another pin(s).

**Parameters**

|            |                                                           |
|------------|-----------------------------------------------------------|
| <i>rhs</i> | The pin(s) who's line state will be assigned to this pin. |
|------------|-----------------------------------------------------------|

**Returns**

A copy of the [PinIO](#) being assigned to.

**16.89.4.8 PullDown()**

```
void PinIO::PullDown (
 bool enable) const [inline]
```

Configure the pad Pull Down resistor for the pin(s).

**Parameters**

|               |                                                                   |
|---------------|-------------------------------------------------------------------|
| <i>enable</i> | True: enable the pad Pull Down. False: disable the pad Pull Down. |
|---------------|-------------------------------------------------------------------|

**16.89.4.9 PullUp()**

```
void PinIO::PullUp (
 bool enable) const [inline]
```

Configure the pad Pull Up resistor for the pin(s).

**Parameters**

|               |                                                               |
|---------------|---------------------------------------------------------------|
| <i>enable</i> | True: enable the pad Pull Up. False: disable the pad Pull Up. |
|---------------|---------------------------------------------------------------|

**16.89.4.10 read()**

```
bool PinIO::read () const [inline]
```

Configure the pin as an input then return the line state.

**Returns**

The line state of the pin(s).

**16.89.4.11 readBack()**

```
bool PinIO::readBack () const [inline]
```

Read the state of the pin(s) line state *without* changing the pin function or direction.

**Returns**

The line state of the pin(s).

**16.89.4.12 setFn()**

```
void PinIO::setFn (
 pin_fn_t fn) const [inline]
```

Set the pin function for the managed pin(s).

**Parameters**

|           |                                                        |
|-----------|--------------------------------------------------------|
| <i>fn</i> | The pin function to be assigned to the managed pin(s). |
|-----------|--------------------------------------------------------|

**16.89.4.13 setHighStrength()**

```
void PinIO::setHighStrength (
 bool bHighDrive) [inline]
```

Configure the drive strength of the output driver for the pin(s).

**Parameters**

|                   |                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>bHighDrive</i> | True: configure the output driver for High Drive strength. False: configure the output driver for Low Drive strength. |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|

**16.89.4.14 tgl()**

```
bool PinIO::tgl () const [inline]
```

Toggle the driven value for the pin(s).

**Returns**

The previously driven value for the pin(s).

**16.89.4.15 toggle()**

```
bool PinIO::toggle () const [inline]
```

Toggle the driven value for the pin(s).

**Returns**

The previously driven value for the pin(s).

The documentation for this class was generated from the following files:

- [coldfire/cpu/MCF5441X/include/cpu\\_pins.h](#)
- [cortex-m7/cpu/SAME70/include/cpu\\_pins.h](#)

**16.90 PinIOArray2 Class Reference**

```
#include <pins.h>
```

**16.90.1 Detailed Description**

The following class is created to assist in processor pin configuration and operation for GPIO and special functions. Each pin is defined by the system in the "\nurn\<Platform>\system" and "\nurn\<Platform>\include" directories for the specific platform you are using.

Examples: P1[5] = 1; Set pin P1-5 high P2[30] = 0; Set pin P2-30 low P1[5].hiz(); Set pin P1-5 to be a high impedance input BOOL bpinstate = P2[30]; Set the pin to be an input and read if ( !P2[30] ) iprintf( "The pin is low" );

The documentation for this class was generated from the following file:

- [MODM7AE70/include/pins.h](#)

## 16.91 PinIOArrayJ1 Class Reference

```
#include <pins.h>
```

### 16.91.1 Detailed Description

The following class is created to assist in processor pin configuration and operation for GPIO and special functions. Each pin is defined by the system in the "\nurn\<Platform>\system" and "\nurn\<Platform>\include" directories for the specific platform you are using.

Examples: P1[5] = 1; Set pin P1-5 high P2[30] = 0; Set pin P2-30 low P1[5].hiz(); Set pin P1-5 to be a high impedance input BOOL bpinstate = P2[30]; Set the pin to be an input and read if ( !P2[30] ) iprintf( "The pin is low" );

The documentation for this class was generated from the following file:

- SBE70LC/include/pins.h

## 16.92 PinIOJ1Array Class Reference

```
#include <pins.h>
```

### 16.92.1 Detailed Description

The following class is created to assist in processor pin configuration and operation for GPIO and special functions. Each pin is defined by the system in the "\Nburn\<Platform>\system" and "\Nburn\<Platform>\include" directories for the specific platform you are using.

Examples: J1[5] = 1; Set pin J1-5 high J2[30] = 0; Set pin J2-30 low J1[5].hiz(); Set pin J1-5 to be a high impedance input BOOL bpinstate = J2[30]; Set the pin to be an input and read if ( !J2[30] ) iprintf( "The pin is low" );

The documentation for this class was generated from the following file:

- MOD5441X/include/pins.h

## 16.93 PinVector< n > Class Template Reference

GPIO Pin Vector Class [PinVector](#) is a template instantiation of the [\\_PinVector](#) class, allowing for minimal storage requirements for potentially large vectors, without heavy code duplication due to template copies.

```
#include <cpu_pins.h>
```

Inherits [\\_PinVector](#).

### Public Member Functions

- [PinVector](#) ()  
*Bare constructor for a [PinVector](#), where the bit configurations will be made later.*
- [PinVector](#) ([PinIO](#) \*initpins, uint32\_t pinCount)  
*[PinVector](#) Constructor, where pin configurations will be made at the time of construction.*
- uint32\_t [operator=](#) (uint32\_t val)  
*Assign a value to the [PinVector](#) Bus.*

### Public Member Functions inherited from [\\_PinVector](#)

- uint32\_t [operator=](#) (uint32\_t val)  
*Assign a value to the [\\_PinVector](#) Bus.*
- [PinIO](#) [operator\[\]](#) (int idx)  
*Access the [PinIO](#) for a specific bit position in the [\\_PinVector](#).*
- void [config](#) (uint32\_t idx, [PinIO](#) cfg)  
*Set the [PinIO](#) that will be used for a given bit position in the [\\_PinVector](#).*
- void [config](#) ([PinIO](#) \*pinCfgs, uint32\_t count)

Configure the `_PinVector` based on an array of PinIOs. The index of the `PinIO` in the configuration array will determine the bit position within the `_PinVector` that that `PinIO` represents.

- `operator uint32_t () const`

Read the line state of the `_PinVector` bus.

### 16.93.1 Detailed Description

```
template<uint8_t n>
class PinVector< n >
```

GPIO Pin Vector Class `PinVector` is a template instantiation of the `_PinVector` class, allowing for minimal storage requirements for potentially large vectors, without heavy code duplication due to template copies.

#### Parameters

|                                  |                                                                                                                  |
|----------------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>PinVector::pinStore</code> | pinStore is the actual storage allocation for large <code>PinVector</code> 's <code>PinIO</code> configurations. |
|----------------------------------|------------------------------------------------------------------------------------------------------------------|

### 16.93.2 Constructor & Destructor Documentation

#### 16.93.2.1 PinVector()

```
template<uint8_t n>
PinVector< n >::PinVector (
 PinIO * initpins,
 uint32_t pinCount) [inline]
```

`PinVector` Constructor, where pin configurations will be made at the time of construction.

#### Parameters

|                       |                                                                          |
|-----------------------|--------------------------------------------------------------------------|
| <code>initpins</code> | The array of PinIOs to be used to configure the <code>PinVector</code> . |
| <code>pinCount</code> | The number of PinIOs in the configuration array to be used.              |

### 16.93.3 Member Function Documentation

#### 16.93.3.1 operator=()

```
template<uint8_t n>
uint32_t PinVector< n >::operator= (
 uint32_t val) [inline]
```

Assign a value to the `PinVector` Bus.

#### Parameters

|                  |                                 |
|------------------|---------------------------------|
| <code>val</code> | The value to assign to the bus. |
|------------------|---------------------------------|

#### Returns

The value driven on the bus.

The documentation for this class was generated from the following file:

- [cortex-m7/cpu/SAME70/include/cpu\\_pins.h](#)

## 16.94 PsudeoHeader Struct Reference

UDP IPv4 Pseudo-header segment (bits 0 through 95)

```
#include <ip.h>
```

**Public Attributes**

- **beuint16\_t proto**  
*Protocol (UDP 0x11)*
- **beuint16\_t len**  
*UDP header and data.*
- **IPADDR4 srcip**  
*Source IP address.*
- **IPADDR4 dstip**  
*Destination IP address.*

**16.94.1 Detailed Description**

UDP IPv4 Pseudo-header segment (bits 0 through 95)

**WARNING:**

This structure has the elements in a different order than usually defined. The IPChecksum is order invariant on 16 bit values. The structure is this way so it can MAP over a section of UDP and TCP IP packets without messing them up. Don't change the order.

The documentation for this struct was generated from the following file:

- [ip.h](#)

**16.95 QSPI\_Record Struct Reference**

This struct contains the major variables/configurations used for a QSPI transfer.

```
#include <qspi.h>
```

**Public Attributes**

- volatile uint8\_t \* **pQSPIRxbuf**  
*This pointer is used to track the locations in memory where data will be read from the peripheral.*
- volatile uint8\_t \* **pQSPITxbuf**  
*This pointer is used to track the locations in memory where data will be written to the peripheral.*
- uint8\_t **BitsPerQueue**  
*This is the number of bits per transfer, (value = 8 - 32).*
- uint32\_t **QSPI\_SizeLeft**  
*This is the number of bytes left in the transfer.*
- uint16\_t **Command\_Mask**  
*This is a partial configuration for the queue's command reg.*
- **OS\_SEM** \* **QSPI\_Sem**  
*This is a pointer to an external semaphore provided by [QSPIStart\(\)](#).*

**16.95.1 Detailed Description**

This struct contains the major variables/configurations used for a QSPI transfer.

The documentation for this struct was generated from the following file:

- [qspi.h](#)

**16.96 SerialConfigServlet Class Reference**

Class to run serial configurator.

```
#include <config_server_serial.h>
```

Inherits servlet.

### 16.96.1 Detailed Description

Class to run serial configurator.

The documentation for this class was generated from the following file:

- `config_server_serial.h`

## 16.97 SerialRecord Struct Reference

```
#include <serialrecord.h>
```

### Public Member Functions

- void [AssignUartNumber](#) (void)

- void [OpenListenPort](#) (void)
- void [ProcessWriteNetworkData](#) (void)
- void [ProcessWriteSerialData](#) (void)
- void [ProcessSerialError](#) (void)
- void [ProcessListenError](#) (void)
- void [ProcessNetworkError](#) (void)
- void [GetCurrentChannelStatus](#) (char \*buffer)

### 16.97.1 Detailed Description

Class Definition (struct is class with all members public)

### 16.97.2 Member Function Documentation

#### 16.97.2.1 AssignUartNumber()

```
void SerialRecord::AssignUartNumber (
 void)
```

Methods

Assign physical UART number to PortRecord array index member

#### 16.97.2.2 CloseListenPort()

```
void SerialRecord::CloseListenPort (
 void)
```

Close the listening port

#### 16.97.2.3 GetCurrentChannelStatus()

```
void SerialRecord::GetCurrentChannelStatus (
 char * buffer)
```

" Connected to IP xx.xx.xx.xx " Listening on port xx " UDP mode with learned send-to IP Address : xx.xx.xx.xx "  
UDP mode send to Address : xx.xx.xx.xx " Idle

#### 16.97.2.4 MakeTcpConnection()

```
void SerialRecord::MakeTcpConnection (
 void)
```

Initiate a TCP connection

#### 16.97.2.5 MakeUdpConnection()

```
void SerialRecord::MakeUdpConnection (
 void)
```

Initiate a UDP connection

#### 16.97.2.6 OkToListen()

```
bool SerialRecord::OkToListen (
 void)
```

Check if conditions are right to establish a listening port

#### 16.97.2.7 OpenListenPort()

```
void SerialRecord::OpenListenPort (
 void)
```

Open the listening port

#### 16.97.2.8 OpenSerialPort()

```
void SerialRecord::OpenSerialPort (
 void)
```

Open a serial port

#### 16.97.2.9 ProcessAccept()

```
void SerialRecord::ProcessAccept (
 void)
```

Called when connections are waiting to be accepted

#### 16.97.2.10 ProcessListenError()

```
void SerialRecord::ProcessListenError (
 void)
```

Process listening errors

#### 16.97.2.11 ProcessNetworkError()

```
void SerialRecord::ProcessNetworkError (
 void)
```

Process network errors

#### 16.97.2.12 ProcessReadNetworkData()

```
void SerialRecord::ProcessReadNetworkData (
 void)
```

Called when data is received on the network port side

#### 16.97.2.13 ProcessSerialError()

```
void SerialRecord::ProcessSerialError (
 void)
```

Process serial errors

#### 16.97.2.14 ProcessSpecialFrameTCPReadSerialData()

```
void SerialRecord::ProcessSpecialFrameTCPReadSerialData (
 void)
```

Called to initiate an outgoing TCP connection when data is received on the serial data port side (this version for TCP packet customization logic)

#### 16.97.2.15 ProcessSpecialFrameWriteNetworkData()

```
void SerialRecord::ProcessSpecialFrameWriteNetworkData (
 void)
```

Called when write space has just opened up on network port (this version for TCP packet customization logic)

#### 16.97.2.16 ProcessSpecialFrameWriteTimeout()

```
void SerialRecord::ProcessSpecialFrameWriteTimeout (
 void)
```

Time-out function used with TCP packet customization logic - waits for a given time to accumulate serial characters before flushing them out the network side

#### 16.97.2.17 ProcessTCPReadSerialData()

```
void SerialRecord::ProcessTCPReadSerialData (
 void)
```

Called to initiate an outgoing TCP connection when data is received on the serial data port side

#### 16.97.2.18 ProcessTimeouts()

```
void SerialRecord::ProcessTimeouts (
 void)
```

Test all of the communication time-outs Periodically check for live connection at a user-specified interval by sending an empty packet to the target device.

Wait at least two seconds for ACK to return after sending keep-alive packet. Target is lost if ACK was not the last packet received.

#### 16.97.2.19 ProcessWriteNetworkData()

```
void SerialRecord::ProcessWriteNetworkData (
 void)
```

Called when write space has just opened up on network port

#### 16.97.2.20 ProcessWriteSerialData()

```
void SerialRecord::ProcessWriteSerialData (
 void)
```

Called when write space has just opened up serial port

The documentation for this struct was generated from the following files:

- serialrecord.h
- serialrecord.cpp

## 16.98 DHCP::Server Class Reference

[DHCP Server](#) class Requires a lease allocator to be added in order to function.

```
#include <dhcpcd.h>
```

### 16.98.1 Detailed Description

[DHCP Server](#) class Requires a lease allocator to be added in order to function. The documentation for this class was generated from the following file:

- [dhcpcd.h](#)

## 16.99 DHCP::SingleAllocator Class Reference

Stripped down allocator Fails to conform to many standard behaviors, but shows the basics of what needs to be implemented.

```
#include <dhcpcd.h>
```

Inherits [DHCP::LeaseAllocator](#).

### 16.99.1 Detailed Description

Stripped down allocator Fails to conform to many standard behaviors, but shows the basics of what needs to be implemented.

The documentation for this class was generated from the following file:

### 16.100.1 Detailed Description

The Single-Bit SPI mode QSPI Peripheral Class.  
Class definition for SPI module objects

### 16.100.2 Constructor & Destructor Documentation

#### 16.100.2.1 SPI\_QSPI() [1/2]

```
SPI_QSPI::SPI_QSPI (
 uint8_t QuadSPIModule = DEFAULT_QUADSPI_MODULE)
```

Create a SPI object.

This constructor will create the object, but will *not* initialize the SPI module. You must call the [Init\(\)](#) member function to initialize.

#### Parameters

|                      |                                                                 |
|----------------------|-----------------------------------------------------------------|
| <i>QuadSPIModule</i> | QSPI module number (0). The SAME70 only has one QuadSPI module. |
|----------------------|-----------------------------------------------------------------|

#### 16.100.2.2 SPI\_QSPI() [2/2]

```
SPI_QSPI::SPI_QSPI (
 uint8_t QuadSPIModule,
 uint32_t baudRateInBps,
 uint8_t transferSizeInBits = 8,
 uint8_t peripheralChipSelects = 0x00,
 uint8_t chipSelectPolarity = 0x0F,
 uint8_t clockPolarity = 0,
 uint8_t clockPhase = 1,
 BOOL doutHiz = TRUE,
```

```
uint8_t csToClockDelay = 0,
uint8_t delayAfterTransfer = 0)
```

Create a SPI object and Initialize with parameters.

Creates a SPI object and initializes the SPI module. You do not need to call the `Init()` member function.

- If configured for 8 bits per transfer then the data must be `uint8_t` aligned
- If configured for > than 8 bits per transfer then the data must be `uint16_t` aligned

#### Parameters

|                              |                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>QuadSPIModule</i>         | QSPI module number (0). The SAME70 has only one QuadSPI module                                                              |
| <i>baudRateInBps</i>         | Maximum baud rate requested                                                                                                 |
| <i>transferSizeInBits</i>    | Number of bits per transfer: 8-bit up to 16-bit transfer sizes are valid                                                    |
| <i>peripheralChipSelects</i> | SPI chip selects to use for transfer. Only one chip select is available to the QuadSPI peripheral on pin P2[48].            |
| <i>chipSelectPolarity</i>    | 0 = inactive logic level low, 1 = high                                                                                      |
| <i>clockPolarity</i>         | 0 = inactive logic level low, 1 = high                                                                                      |
| <i>clockPhase</i>            | 0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge. |
| <i>doutHiz</i>               | Data output high impedance between transfers                                                                                |
| <i>csToClockDelay</i>        | Delay from chip select to valid clock (default is 0). When 0, the delay is half the clock period.                           |
| <i>delayAfterTransfer</i>    | When 0, no delay between consecutive transfers is inserted and the clock keeps its duty cycle over the character transfers. |

### 16.100.3 Member Function Documentation

#### 16.100.3.1 Init()

```
virtual uint8_t SPI_QSPI::Init (
 uint32_t baudRateInBps = 2000000,
 uint8_t transferSizeInBits = 8,
 uint8_t peripheralChipSelects = 0x00,
 uint8_t chipSelectPolarity = 0x0F,
 uint8_t clockPolarity = 0,
 uint8_t clockPhase = 1,
 BOOL doutHiz = TRUE,
 uint8_t csToClockDelay = 0,
 uint8_t delayAfterTransfer = 0) [override], [virtual]
```

Initialize an existing SPI object.

- If configured for 8 bits per transfer then the data must be `uint8_t` aligned
- If configured for > than 8 bits per transfer then the data must be `uint16_t` aligned

#### Parameters

|                              |                                                                                                                  |
|------------------------------|------------------------------------------------------------------------------------------------------------------|
| <i>baudRateInBps</i>         | Maximum baud rate requested                                                                                      |
| <i>transferSizeInBits</i>    | Number of bits per transfer: 8-bit up to 16-bit transfer sizes are valid                                         |
| <i>peripheralChipSelects</i> | SPI chip selects to use for transfer. Only one chip select is available to the QuadSPI peripheral on pin P2[48]. |
| <i>chipSelectPolarity</i>    | 0 = inactive logic level low, 1 = high                                                                           |
| <i>clockPolarity</i>         | 0 = inactive logic level low, 1 = high                                                                           |

## Parameters

|                           |                                                                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>clockPhase</i>         | 0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge. |
| <i>doutHiz</i>            | Data output high impedance between transfers                                                                                |
| <i>csToClockDelay</i>     | Delay from chip select to valid clock (default is 0). When 0, the delay is half the clock period.                           |
| <i>delayAfterTransfer</i> | When 0, no delay between consecutive transfers is inserted and the clock keeps its duty cycle over the character transfers. |

## Returns

The current state of the SPI bus [dspState](#)

Reimplemented from [SPIModule](#).

**16.100.3.2 Rx()**

```
uint8_t SPI_QSPI::Rx (
 uint8_t * receiveBufferPtr,
 uint32_t byteCount,
 int csReturnToInactive = DEASSERT_AFTER_LAST) [inline], [virtual]
```

Convenience function for unidirectional receive.

## Parameters

|                           |                                                  |
|---------------------------|--------------------------------------------------|
| <i>receiveBufferPtr</i>   | Pointer to the buffer to write the received data |
| <i>byteCount</i>          | Number of bytes to transmit                      |
| <i>csReturnToInactive</i> | Chip select state                                |

## Returns

The current state of the SPI bus [dspState](#)

Reimplemented from [SPIModule](#).

**16.100.3.3 SetBusSpeed()**

```
virtual uint32_t SPI_QSPI::SetBusSpeed (
 uint32_t maxSpeed) [override], [virtual]
```

Set the SPI bus speed Will attempt to set the desired bus speed. It may be different based on the available system characteristics.

## Parameters

|                 |                               |
|-----------------|-------------------------------|
| <i>maxSpeed</i> | The maximum desired bus speed |
|-----------------|-------------------------------|

## Returns

The actual bus speed

Reimplemented from [SPIModule](#).

**16.100.3.4 SetCS()**

```
virtual bool SPI_QSPI::SetCS (
 uint8_t CS) [inline], [override], [virtual]
```

Set the chip select configuration for the SPI object's bus transactions.

Single-bit SPI mode for the QuadSPI peripheral only supports one chip select. This function is defined for compatibility between SPI drivers.

#### Parameters

|    |                                              |
|----|----------------------------------------------|
| CS | The QuadSPI module has only one chip select. |
|----|----------------------------------------------|

#### Returns

true if successful, false if SPI is currently active

Reimplemented from [SPIModule](#).

#### 16.100.3.5 Start()

```
virtual uint8_t SPI_QSPI::Start (
 uint8_t * transmitBufferPtr,
 volatile uint8_t * receiveBufferPtr,
 uint32_t byteCount,
 int csReturnToInactive = DEASSERT_AFTER_LAST) [override], [virtual]
```

Start a SPI transfer.

- If configured for 8 bits per transfer then the data must be uint8\_t aligned
- If configured for > than 8 bits per transfer then the data must be uint16\_t aligned
- If either RX or TX pointer is assigned 'null' then that communication direction will not occur.

#### Parameters

|                           |                                                       |
|---------------------------|-------------------------------------------------------|
| <i>transmitBufferPtr</i>  | Pointer to the buffer containing the data to transmit |
| <i>receiveBufferPtr</i>   | Pointer to the buffer to store the received data      |
| <i>byteCount</i>          | Number of bytes to transmit                           |
| <i>csReturnToInactive</i> | Chip select state <a href="#">dspIChipSelectMode</a>  |

#### Returns

The current state of the SPI bus [dspIState](#)

Reimplemented from [SPIModule](#).

#### 16.100.3.6 Tx()

```
virtual uint8_t SPI_QSPI::Tx (
 uint8_t * transmitBufferPtr,
 uint32_t byteCount,
 int csReturnToInactive = DEASSERT_AFTER_LAST) [inline], [override], [virtual]
```

Convenience function for unidirectional transmit.

#### Parameters

|                           |                                                       |
|---------------------------|-------------------------------------------------------|
| <i>transmitBufferPtr</i>  | Pointer to the buffer containing the data to transmit |
| <i>byteCount</i>          | Number of bytes to transmit                           |
| <i>csReturnToInactive</i> | Chip select state                                     |

## Returns

The current state of the SPI bus [dspiParam](#)

Reimplemented from [SPIModule](#).

The documentation for this class was generated from the following file:

- [quadspi.h](#)

## 16.101 SPI\_USART Class Reference

### 16.101.1 Detailed Description

USART in SPI mode Peripheral Module Class.  
Class definition for SPI module objects

### 16.101.2 Constructor & Destructor Documentation

#### 16.101.2.1 SPI\_USART() [1/2]

```
SPI_USART::SPI_USART (
 uint8_t USARTModule)
```

Create a SPI object.

This constructor will create the object, but will *not* initialize the SPI module. You must call the [Init\(\)](#) member function to initialize.

#### Parameters

|                    |                            |
|--------------------|----------------------------|
| <i>USARTModule</i> | SPI module number (0 or 1) |
|--------------------|----------------------------|

#### 16.101.2.2 SPI\_USART() [2/2]

```
SPI_USART::SPI_USART (
 uint8_t USARTModule,
 uint32_t baudRateInBps,
 uint8_t transferSizeInBits = 8,
 uint8_t peripheralChipSelects = 0x00,
 uint8_t chipSelectPolarity = 0x0F,
 uint8_t clockPolarity = 0,
 uint8_t clockPhase = 1,
 BOOL doutHiz = TRUE,
 uint8_t csToClockDelay = 0,
 uint8_t delayAfterTransfer = 0)
```

Create a SPI object and Initialize with parameters.

Creates a SPI object and initializes the SPI module. You do not need to call the [Init\(\)](#) member function.

#### Parameters

|                              |                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>USARTModule</i>           | USART module number (0 or 1)                                                                                                |
| <i>baudRateInBps</i>         | Maximum baud rate requested                                                                                                 |
| <i>transferSizeInBits</i>    | Number of bits per transfer: 8, 16 or 32                                                                                    |
| <i>peripheralChipSelects</i> | SPI chip selects to use for transfer                                                                                        |
| <i>chipSelectPolarity</i>    | 0 = inactive logic level low, 1 = high                                                                                      |
| <i>clockPolarity</i>         | 0 = inactive logic level low, 1 = high                                                                                      |
| <i>clockPhase</i>            | 0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge. |

## Parameters

|                           |                                                                   |
|---------------------------|-------------------------------------------------------------------|
| <i>doutHiz</i>            | Data output high impedance between transfers                      |
| <i>csToClockDelay</i>     | This option is not supported by the USART peripheral in SPI mode. |
| <i>delayAfterTransfer</i> | This option is not supported by the USART peripheral in SPI mode. |

### 16.101.3 Member Function Documentation

#### 16.101.3.1 Init()

```
virtual uint8_t SPI_USART::Init (
 uint32_t baudRateInBps = 2000000,
 uint8_t transferSizeInBits = 8,
 uint8_t peripheralChipSelects = 0x00,
 uint8_t chipSelectPolarity = 0x0F,
 uint8_t clockPolarity = 0,
 uint8_t clockPhase = 1,
 BOOL doutHiz = TRUE,
 uint8_t csToClockDelay = 0,
 uint8_t delayAfterTransfer = 0) [override], [virtual]
```

Initialize an existing SPI object.

## Parameters

|                              |                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>baudRateInBps</i>         | Maximum baud rate requested                                                                                                 |
| <i>transferSizeInBits</i>    | Number of bits per transfer: 8, 16 or 32                                                                                    |
| <i>peripheralChipSelects</i> | SPI chip selects to use for transfer                                                                                        |
| <i>chipSelectPolarity</i>    | 0 = inactive logic level low, 1 = high                                                                                      |
| <i>clockPolarity</i>         | 0 = inactive logic level low, 1 = high                                                                                      |
| <i>clockPhase</i>            | 0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge. |
| <i>doutHiz</i>               | Data output high impedance between transfers                                                                                |
| <i>csToClockDelay</i>        | This option is not supported by the USART peripheral in SPI mode.                                                           |
| <i>delayAfterTransfer</i>    | This option is not supported by the USART peripheral in SPI mode.                                                           |

## Returns

The current state of the SPI bus [dspState](#)

Reimplemented from [SPIModule](#).

#### 16.101.3.2 Rx()

```
uint8_t SPI_USART::Rx (
 uint8_t * receiveBufferPtr,
 uint32_t byteCount,
 int csReturnToInactive = DEASSERT_AFTER_LAST) [inline], [virtual]
```

Convenience function for unidirectional receive.

## Parameters

|                           |                                                  |
|---------------------------|--------------------------------------------------|
| <i>receiveBufferPtr</i>   | Pointer to the buffer to write the received data |
| <i>byteCount</i>          | Number of bytes to transmit                      |
| <i>csReturnToInactive</i> | Chip select state                                |

**Returns**

The current state of the SPI bus [dspiParam](#)

Reimplemented from [SPIModule](#).

**16.101.3.3 SetBusSpeed()**

```
virtual uint32_t SPI_USART::SetBusSpeed (
 uint32_t maxSpeed) [override], [virtual]
```

Set the SPI bus speed Will attempt to set the desired bus speed. It may be different based on the available system characteristics.

**Parameters**

|                 |                               |
|-----------------|-------------------------------|
| <i>maxSpeed</i> | The maximum desired bus speed |
|-----------------|-------------------------------|

**Returns**

The actual bus speed

Reimplemented from [SPIModule](#).

**16.101.3.4 SetCS()**

```
virtual bool SPI_USART::SetCS (
 uint8_t CS) [inline], [override], [virtual]
```

Set the chip select configuration for the SPI object's bus transactions.

**Parameters**

|           |                            |
|-----------|----------------------------|
| <i>CS</i> | Chip select to set, 0 - 3. |
|-----------|----------------------------|

**Returns**

true if successful, false if SPI is currently active

Reimplemented from [SPIModule](#).

**16.101.3.5 Start()**

```
virtual uint8_t SPI_USART::Start (
 uint8_t * transmitBufferPtr,
 volatile uint8_t * receiveBufferPtr,
 uint32_t byteCount,
 int csReturnToInactive = DEASSERT_AFTER_LAST) [override], [virtual]
```

Start a SPI transfer.

- If configured for 8 bits per transfer then the data must be uint8\_t aligned
- If configured for > than 8 bits per transfer then the data must be uint16\_t aligned
- If configured for > than 16 bits per transfer then the data must be uint32\_t aligned
- If either RX or TX pointer is assigned 'null' then that communication direction will not occur.

**Parameters**

|                           |                                                       |
|---------------------------|-------------------------------------------------------|
| <i>transmitBufferPtr</i>  | Pointer to the buffer containing the data to transmit |
| <i>receiveBufferPtr</i>   | Pointer to the buffer to store the received data      |
| <i>byteCount</i>          | Number of bytes to transmit                           |
| <i>csReturnToInactive</i> | Chip select state                                     |

**Returns**

The current state of the SPI bus [dspiParam](#)

Reimplemented from [SPIModule](#).

**16.101.3.6 Tx()**

```
virtual uint8_t SPI_USART::Tx (
 uint8_t * transmitBufferPtr,
 uint32_t byteCount,
 int csReturnToInactive = DEASSERT_AFTER_LAST) [inline], [override], [virtual]
```

Convenience function for unidirectional transmit.

**Parameters**

|                           |                                                       |
|---------------------------|-------------------------------------------------------|
| <i>transmitBufferPtr</i>  | Pointer to the buffer containing the data to transmit |
| <i>byteCount</i>          | Number of bytes to transmit                           |
| <i>csReturnToInactive</i> | Chip select state                                     |

**Returns**

The current state of the SPI bus [dspiParam](#)

Reimplemented from [SPIModule](#).

The documentation for this class was generated from the following file:

- [usart.h](#)

**16.102 SPIModule Class Reference**

SPI Peripheral Module Class.

## 16.102.1 Detailed Description

SPI Peripheral Module Class.

Class definition for SPI module objects

## 16.102.2 Constructor & Destructor Documentation

### 16.102.2.1 [SPIModule\(\)](#) [1/2]

```
SPIModule::SPIModule (
 uint8_t SPIModule)
```

Create a SPI object.

This constructor will create the object, but will *not* initialize the SPI module. You must call the [Init\(\)](#) member function to initialize.

#### Parameters

|                           |                            |
|---------------------------|----------------------------|
| <a href="#">SPIModule</a> | SPI module number (0 or 1) |
|---------------------------|----------------------------|

### 16.102.2.2 [SPIModule\(\)](#) [2/2]

```
SPIModule::SPIModule (
 uint8_t SPIModule,
 uint32_t baudRateInBps,
 uint8_t transferSizeInBits = 8,
 uint8_t peripheralChipSelects = 0x00,
 uint8_t chipSelectPolarity = 0x0F,
 uint8_t clockPolarity = 0,
 uint8_t clockPhase = 1,
 BOOL doutHiz = TRUE,
 uint8_t csToClockDelay = 0,
 uint8_t delayAfterTransfer = 0)
```

Create a SPI object and Initialize with parameters.

Creates a SPI object and initializes the SPI module. You do not need to call the [Init\(\)](#) member function.

#### Parameters

|                           |                            |
|---------------------------|----------------------------|
| <a href="#">SPIModule</a> | SPI module number (0 or 1) |
|---------------------------|----------------------------|

## Parameters

|                              |                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>baudRateInBps</i>         | Maximum baud rate requested                                                                                                 |
| <i>transferSizeInBits</i>    | Number of bits per transfer: 8, 16 or 32                                                                                    |
| <i>peripheralChipSelects</i> | SPI chip selects to use for transfer <a href="#">spiChipSelect</a>                                                          |
| <i>chipSelectPolarity</i>    | Parameter not supported on the MODM7AE70. Chip select asserts with logic level low. <a href="#">spiChipSelectPolarity</a>   |
| <i>clockPolarity</i>         | 0 = inactive logic level low, 1 = high                                                                                      |
| <i>clockPhase</i>            | 0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge. |
| <i>doutHiz</i>               | Data output high impedance between transfers                                                                                |
| <i>csToClockDelay</i>        | Delay from chip select to valid clock (default is 0)                                                                        |
| <i>delayAfterTransfer</i>    | Chip select mode <a href="#">dspChipSelectMode</a>                                                                          |

### 16.102.3 Member Function Documentation

#### 16.102.3.1 ClrSem()

```
virtual bool SPIModule::ClrSem () [inline], [virtual]
```

Clear a semaphore registration.

## Returns

true if the clear was successful, false if a SPI transaction is in progress

#### 16.102.3.2 Done() [1/2]

```
virtual bool SPIModule::Done () [inline], [virtual]
```

Function to check SPI status.

Called as a class method on a specific SPI object. For example: MySpi.Done()

## Returns

true if SPI is finished, false if active

#### 16.102.3.3 Done() [2/2]

```
static BOOL SPIModule::Done (
 uint8_t SPIModule) [static]
```

Static function to check SPI status.

Is called as a class wide static method. For example: SPIModule::Done(0)

## Parameters

|                           |                                    |
|---------------------------|------------------------------------|
| <a href="#">SPIModule</a> | The SPI module to check, 0, 1 or 2 |
|---------------------------|------------------------------------|

## Returns

true if SPI is finished, false if active

#### 16.102.3.4 GetActualBaudrate()

```
virtual uint32_t SPIModule::GetActualBaudrate () [inline], [virtual]
```

Returns the active baud rate.

The baud rate will be set to the value specified when the SPI module is initialized. If that value is not possible, the next lowest baud rate will be chosen.

**Returns**

The actual SPI module baud rate

**16.102.3.5 GetSem()**

```
virtual OS_SEM * SPIModule::GetSem () [inline], [virtual]
```

Obtain a pointer to the SPI finished semaphore.

**Returns**

A pointer to the semaphore

**16.102.3.6 Init()**

```
virtual uint8_t SPIModule::Init (
 uint32_t baudRateInBps = 2000000,
 uint8_t transferSizeInBits = 8,
 uint8_t peripheralChipSelects = 0x00,
 uint8_t chipSelectPolarity = 0x0F,
 uint8_t clockPolarity = 0,
 uint8_t clockPhase = 1,
 BOOL doutHiz = TRUE,
 uint8_t csToClockDelay = 0,
 uint8_t delayAfterTransfer = 0) [virtual]
```

Initialize an existing SPI object.

**Parameters**

|                              |                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>baudRateInBps</i>         | Maximum baud rate requested                                                                                                 |
| <i>transferSizeInBits</i>    | Number of bits per transfer: 8, 16 or 32                                                                                    |
| <i>peripheralChipSelects</i> | SPI chip selects to use for transfer <a href="#">spiChipSelect</a>                                                          |
| <i>chipSelectPolarity</i>    | Parameter not supported on the MODM7AE70. Chip select asserts with logic level low. <a href="#">spiChipSelectPolarity</a>   |
| <i>clockPolarity</i>         | 0 = inactive logic level low, 1 = high                                                                                      |
| <i>clockPhase</i>            | 0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge. |
| <i>doutHiz</i>               | Data output high impedance between transfers                                                                                |
| <i>csToClockDelay</i>        | Delay from chip select to valid clock (default is 0)                                                                        |
| <i>delayAfterTransfer</i>    | Chip select mode <a href="#">dspIChipSelectMode</a>                                                                         |

**Returns**

The current state of the SPI bus [dspIState](#)

Reimplemented in [SPI\\_QSPI](#), and [SPI\\_USART](#).

**16.102.3.7 RegisterSem()**

```
virtual bool SPIModule::RegisterSem (
 OS_SEM * finishedSem) [virtual]
```

Register a semaphore for the SPI module.

The SPI module will post to this semaphore when a transaction is complete

**Parameters**

|                    |                          |
|--------------------|--------------------------|
| <i>finishedSem</i> | Pointer to the semaphore |
|--------------------|--------------------------|

**Returns**

true if the registration was successful, false if a SPI transaction is in progress

**16.102.3.8 Rx()**

```
virtual uint8_t SPIModule::Rx (
 uint8_t * receiveBufferPtr,
 uint32_t byteCount,
 int csReturnToInactive = DEASSERT_AFTER_LAST) [inline], [virtual]
```

Convenience function for unidirectional receive.

**Parameters**

|                           |                                              |
|---------------------------|----------------------------------------------|
| <i>*receiveBufferPtr</i>  | Pointer to the buffer to store incoming data |
| <i>byteCount</i>          | Number of bytes to transmit                  |
| <i>csReturnToInactive</i> | Chip select state                            |

**Returns**

The current state of the SPI bus [dspiParam](#)

Reimplemented in [SPI\\_QSPI](#), and [SPI\\_USART](#).

**16.102.3.9 SetBusSpeed()**

```
virtual uint32_t SPIModule::SetBusSpeed (
 uint32_t maxSpeed) [virtual]
```

Set the SPI bus speed Will attempt to set the desired bus speed. It may be different based on the available system characteristics.

**Parameters**

|                 |                               |
|-----------------|-------------------------------|
| <i>maxSpeed</i> | The maximum desired bus speed |
|-----------------|-------------------------------|

**Returns**

The actual bus speed

Reimplemented in [SPI\\_QSPI](#), and [SPI\\_USART](#).

**16.102.3.10 SetCS()**

```
virtual bool SPIModule::SetCS (
 uint8_t CS) [inline], [virtual]
```

Set the chip select configuration for the SPI object's bus transactions.

**Parameters**

|           |                            |
|-----------|----------------------------|
| <i>CS</i> | Chip select to set, 0 - 3. |
|-----------|----------------------------|

**Returns**

true if successful, false if SPI is currently active

Reimplemented in [SPI\\_QSPI](#), and [SPI\\_USART](#).

**16.102.3.11 Start()**

```
virtual uint8_t SPIModule::Start (
 uint8_t * transmitBufferPtr,
 volatile uint8_t * receiveBufferPtr,
 uint32_t byteCount,
 int csReturnToInactive = DEASSERT_AFTER_LAST) [virtual]
```

Start a SPI transfer.

- If configured for 8 bits per transfer then the data must be uint8\_t aligned
- If configured for > than 8 bits per transfer then the data must be uint16\_t aligned
- If configured for > than 16 bits per transfer then the data must be uint32\_t aligned
- If either RX or TX pointer is assigned 'null' then that communication direction will not occur.
- If DSPI\_Finished points to a semaphore, then the DSPI will POST to it when the transfer is complete.
- The semaphore is optional, but it can increase efficiency.

**Parameters**

|                           |                                                       |
|---------------------------|-------------------------------------------------------|
| <i>transmitBufferPtr</i>  | Pointer to the buffer containing the data to transmit |
| <i>receiveBufferPtr</i>   | Pointer to the buffer to store the received data      |
| <i>byteCount</i>          | Number of bytes to transmit                           |
| <i>csReturnToInactive</i> | Chip select state                                     |

**Returns**

The current state of the SPI bus [dspState](#)

Reimplemented in [SPI\\_QSPI](#), and [SPI\\_USART](#).

**16.102.3.12 Tx()**

```
virtual uint8_t SPIModule::Tx (
 uint8_t * transmitBufferPtr,
 uint32_t byteCount,
 int csReturnToInactive = DEASSERT_AFTER_LAST) [inline], [virtual]
```

Convenience function for unidirectional transmit.

**Parameters**

|                           |                                                       |
|---------------------------|-------------------------------------------------------|
| <i>*transmitBufferPtr</i> | Pointer to the buffer containing the data to transmit |
| <i>byteCount</i>          | Number of bytes to transmit                           |
| <i>csReturnToInactive</i> | Chip select state                                     |

**Returns**

The current state of the SPI bus [dspState](#)

Reimplemented in [SPI\\_QSPI](#), and [SPI\\_USART](#).

## 16.103 SSC\_cfg\_t Struct Reference

Configuration structure for the SSC driver. Passed to the initialize function to configure the hardware.

```
#include <ssc_i2s.h>
```

### Public Attributes

- uint16\_t [clkDiv](#) {150}
- [SSC\\_rxtx\\_cfg\\_t rx](#)
- [SSC\\_rxtx\\_cfg\\_t tx](#)

### 16.103.1 Detailed Description

Configuration structure for the SSC driver. Passed to the initialize function to configure the hardware.

### 16.103.2 Member Data Documentation

#### 16.103.2.1 clkDiv

```
SSC_cfg_t::clkDiv {150}
```

The divider value for the peripheral clock used to generate the bit clock when CLK\_SRC\_MCK is selected.

#### 16.103.2.2 rx

```
SSC_cfg_t::rx
```

The receive configuration.

#### 16.103.2.3 tx

```
SSC_cfg_t::tx
```

The transmit configuration.

The documentation for this struct was generated from the following file:

- [ssc\\_i2s.h](#)

## 16.104 SSC\_rxtx\_cfg\_t Struct Reference

Configuration structure for a given direction (rx or tx) of the SSC module. Passed to the initialize function to configure the hardware.

```
#include <ssc_i2s.h>
```

### Public Attributes

- bool [enable](#) {false}
- uint8\_t [period](#) {64}
- uint8\_t [startDly](#) {1}
- startCond\_t [startCond](#) {START\_FRAME\_EDGE}
- clkGate\_t [clkGate](#) {CLK\_GATE\_CONTINUOUS}
- dataValid\_t [dataValid](#) {DATA\_VALID\_RISING}
- clkOut\_t [clkOut](#) {CLK\_OUT\_INPUT}
- clkSrc\_t [clkSrc](#) {CLK\_SRC\_RK}
- uint8\_t [syncLen](#) {0}
- frameEdge\_t [syncEdge](#) {FRAME\_SYNC\_FALLING}
- bool [syncDataEnabled](#) {false}
- frameSyncOut\_t [syncOut](#) {FRAME\_SYNC\_INPUT}

- uint8\_t `wordsPerFrame` {1}
- bitOrder\_t `bitOrder` {MOST\_SIG\_FIRST}
- bool `lineIdleState` {1}
- uint8\_t `bitsPerWord` {24}
- bufferDepletionBehavior\_t `depletionBehavior` {DEPLETED\_PAUSE}

### 16.104.1 Detailed Description

Configuration structure for a given direction (rx or tx) of the SSC module. Passed to the initialize function to configure the hardware.

### 16.104.2 Member Data Documentation

#### 16.104.2.1 bitOrder

```
SSC_rxtx_cfg_t::bitOrder {MOST_SIG_FIRST}
```

The bit order of transitions.

#### 16.104.2.2 bitsPerWord

```
SSC_rxtx_cfg_t::bitsPerWord {24}
```

The bit width of words to be transferred.

#### 16.104.2.3 clkGate

```
SSC_rxtx_cfg_t::clkGate {CLK_GATE_CONTINUOUS}
```

The clock gating condition for this channel.

#### 16.104.2.4 clkOut

```
SSC_rxtx_cfg_t::clkOut {CLK_OUT_INPUT}
```

The clock out condition for this channel.

#### 16.104.2.5 clkSrc

```
SSC_rxtx_cfg_t::clkSrc {CLK_SRC_RK}
```

The clock source for this channel.

#### 16.104.2.6 dataValid

```
SSC_rxtx_cfg_t::dataValid {DATA_VALID_RISING}
```

The data valid condition for this channel.

#### 16.104.2.7 depletionBehavior

```
SSC_rxtx_cfg_t::depletionBehavior {DEPLETED_PAUSE}
```

The depletion behavior that should be used for driver DMA transfers.

#### 16.104.2.8 enable

```
SSC_rxtx_cfg_t::enable {false}
```

Whether this direction should be enabled.

#### 16.104.2.9 lineIdleState

```
SSC_rxtx_cfg_t::lineIdleState {1}
```

The state the line should be driven to when not transmitting a word.

**16.104.2.10 period**

```
SSC_rxtx_cfg_t::period {64}
```

The period of each frame, in terms of the bit clock.

**16.104.2.11 startCond**

```
SSC_rxtx_cfg_t::startCond {START_FRAME_EDGE}
```

The starting condition for this channel.

**16.104.2.12 startDly**

```
SSC_rxtx_cfg_t::startDly {1}
```

How many bit periods should data be delayed by at the start of the frame.

**16.104.2.13 syncDataEnabled**

```
SSC_rxtx_cfg_t::syncDataEnabled {false}
```

Whether synchronizing data is used.

**16.104.2.14 syncEdge**

```
SSC_rxtx_cfg_t::syncEdge {FRAME_SYNC_FALLING}
```

The frame sync edge defining frame start.

**16.104.2.15 syncLen**

```
SSC_rxtx_cfg_t::syncLen {0}
```

The bit length of the synchronization data (when used).

**16.104.2.16 syncOut**

```
SSC_rxtx_cfg_t::syncOut {FRAME_SYNC_INPUT}
```

The frame sync output configuration.

**16.104.2.17 wordsPerFrame**

```
SSC_rxtx_cfg_t::wordsPerFrame {1}
```

Number of words contained in a frame.

The documentation for this struct was generated from the following file:

- `ssc_i2s.h`

**16.105 SSCctx\_t Class Reference**

```
#include <ssc_i2s.h>
```

**Public Member Functions**

*Registers a callback for when a receive buffer is finished.*

### 16.105.1 Detailed Description

SSCctx\_t is a driver for the Synchronous Serial Controller. It operates on a buffer level, where buffers are handed to the system and either transmitted or filled with received data as appropriate.

### 16.105.2 Member Function Documentation

#### 16.105.2.1 getCurrentConfig()

```
int SSCctx_t::getCurrentConfig (
 SSC_cfg_t & cfg)
```

Fills in the config object with the current active configuration.

##### Parameters

|     |     |                                       |
|-----|-----|---------------------------------------|
| out | cfg | The configuration object to populate. |
|-----|-----|---------------------------------------|

##### Returns

Negative on failure.

#### 16.105.2.2 getState()

```
ctxState_t SSCctx_t::getState ()
```

Returns the current driver state.

##### Returns

The current driver state.

#### 16.105.2.3 Init()

```
int SSCctx_t::Init (
 const SSC_cfg_t & cfg)
```

Initializes the SSC hardware and driver context.

##### Parameters

|    |     |                           |
|----|-----|---------------------------|
| in | cfg | The configuration to use. |
|----|-----|---------------------------|

##### Returns

Negative on failure.

#### 16.105.2.4 ReadyReceiveBuffer()

```
int SSCctx_t::ReadyReceiveBuffer (
 void * buffer,
```

```
uint32_t bufferLen,
bool waitIfNeeded)
```

Hands off a buffer to be written to by the SSC driver.

#### Parameters

|                     |                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------|
| <i>buffer</i>       | A pointer to the buffer to be written to.                                                                   |
| <i>bufferLen</i>    | The length of the buffer to be written. (Must be multiples of 1, 2, or 4 bytes depending on word bit width) |
| <i>waitIfNeeded</i> | Whether the driver should wait for space to receive or fail immediately upon exhausting the queue depth.    |

#### Returns

Negative on failure.

#### 16.105.2.5 TransmitBuffer()

```
int SSCCtx_t::TransmitBuffer (
void * buffer,
uint32_t bufferLen,
bool waitIfNeeded)
```

Hands off a buffer to be transmitted by the SSC driver.

#### Parameters

|                     |                                                                                                              |
|---------------------|--------------------------------------------------------------------------------------------------------------|
| <i>buffer</i>       | A pointer to the buffer to be transmit.                                                                      |
| <i>bufferLen</i>    | The length of the buffer to be transmit. (Must be multiples of 1, 2, or 4 bytes depending on word bit width) |
| <i>waitIfNeeded</i> | Whether the driver should wait for space to transmit or fail immediately upon exhausting the queue depth.    |

#### Returns

Negative on failure.

The documentation for this class was generated from the following files:

- ssc\_i2s.h
- ssc\_i2s.cpp

## 16.106 Stopwatch Class Reference

Stopwatch for timing events.

```
#include <stopwatch.h>
```

#### Public Member Functions

- [StopWatch](#) (int timer\_number=[FIRST\\_UNUSED\\_TIMER](#))  
*Create a stopwatch object.*
- void [Start](#) ()  
*Start the stopwatch.*
- void [Clear](#) ()  
*Clear the stopwatch count.*
- unsigned long long [Stop](#) ()

Stop the [StopWatch](#).

- unsigned long long [GetTime](#) ()

Get the [StopWatch](#) time.

- double [CountResolution](#) ()

Returns the value of one [StopWatch](#) tick time.

- double [Convert](#) (unsigned long long)

Convert a time or interval from an unsigned long long to double floatl.

## 16.106.1 Detailed Description

Stopwatch for timing events.

## 16.106.2 Constructor & Destructor Documentation

### 16.106.2.1 Stopwatch()

```
StopWatch::StopWatch (
 int timer_number = FIRST_UNUSED_TIMER)
```

Create a stopwatch object.

The timer number can be ignored on platforms that have a permanently allocated timer for the RTOS and CPU frequency.

#### Parameters

|                     |                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------|
| <i>timer_number</i> | Optional. Specifies the timer to use. If no timer is specified, the first unused timer will be selected. |
|---------------------|----------------------------------------------------------------------------------------------------------|

## 16.106.3 Member Function Documentation

### 16.106.3.1 Clear()

```
void StopWatch::Clear ()
```

Clear the stopwatch count.

Clear the [StopWatch](#) count

### 16.106.3.2 Convert()

```
double StopWatch::Convert (
 unsigned long long)
```

Convert a time or interval from an unsigned long long to double floatl.

#### Return values

|                |                                 |
|----------------|---------------------------------|
| <i>Elapsed</i> | time as a floating point number |
|----------------|---------------------------------|

### 16.106.3.3 CountResolution()

```
double StopWatch::CountResolution ()
```

Returns the value of one [StopWatch](#) tick time.

#### Return values

|            |                             |
|------------|-----------------------------|
| <i>The</i> | value of one stopwatch tick |
|------------|-----------------------------|

### 16.106.3.4 GetTime()

```
unsigned long long Stopwatch::GetTime ()
```

Get the [StopWatch](#) time.

#### Return values

|                |                                               |
|----------------|-----------------------------------------------|
| <i>Elapsed</i> | time. Will work even if stopwatch is running. |
|----------------|-----------------------------------------------|

### 16.106.3.5 Start()

```
void Stopwatch::Start ()
```

Start the stopwatch.

Start the [StopWatch](#) timer

### 16.106.3.6 Stop()

```
unsigned long long Stopwatch::Stop ()
```

Stop the [StopWatch](#).

#### Return values

|                |      |
|----------------|------|
| <i>Elapsed</i> | time |
|----------------|------|

The documentation for this class was generated from the following file:

- [stopwatch.h](#)

## 16.107 TEMPL\_Q< T > Struct Template Reference

A convenience wrapper around [OS\\_Q](#).

```
#include <nbrtos.h>
```

### 16.107.1 Detailed Description

```
template<typename T>
```

```
struct TEMPL_Q< T >
```

A convenience wrapper around [OS\\_Q](#).

The documentation for this struct was generated from the following file:

- [nbrtos.h](#)

## 16.108 TickTimeout Class Reference

[TickTimeout](#) objects are used to facilitate sequential function calls with timeout parameters that need to be indexed from an initial start time, and to prevent TimeTick rollover errors.

```
#include <nbrtos.h>
```

### Public Member Functions

- [TickTimeout](#) (uint32\_t timeout)  
*Create and initialize the Timeout.*
- uint32\_t [val](#) () const  
*Get the timeout duration to be passed to a function utilizing timeout ticks.*
- bool [expired](#) () const

*Determine whether the timeout duration has elapsed.*

- `operator bool` ( ) const  
*Use the Timeout as a boolean (such as in a branch condition).*
- void `SetUntil` (uint32\_t when)  
*Set the TimeTick value to expire.*

## Friends

- void `OSTimeWaitUntil` (uint32\_t systemTickValue)  
*Delay the task until the specified value of the system timer tick. The number of system ticks per second is defined by the constant: `TICKS_PER_SECOND` in `<nburn_install>/nbrtos/include/constants.h`. The default value is 20 ticks per second.*

## 16.108.1 Detailed Description

`TickTimeout` objects are used to facilitate sequential function calls with timeout parameters that need to indexed from an initial start time, and to prevent TimeTick rollover errors.

## 16.108.2 Constructor & Destructor Documentation

### 16.108.2.1 TickTimeout()

```
TickTimeout::TickTimeout (
 uint32_t timeout) [inline]
```

Create and initialize the Timeout.

#### Parameters

|                |                                                                                                                       |
|----------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>timeout</i> | The maximum allowed time duration in ticks. <b>Note:</b> The maximum delay that can be used is <code>INT32_MAX</code> |
|----------------|-----------------------------------------------------------------------------------------------------------------------|

## 16.108.3 Member Function Documentation

### 16.108.3.1 expired()

```
bool TickTimeout::expired () const [inline]
```

Determine whether the timeout duration has elapsed.

#### Return values

|              |                             |
|--------------|-----------------------------|
| <i>true</i>  | The timeout has expired     |
| <i>false</i> | The timeout has not expired |

### 16.108.3.2 operator bool()

```
TickTimeout::operator bool () const [inline]
```

Use the Timeout as a boolean (such as in a branch condition).

Since the intention is to be used for while() loop or in a precondition check, the boolean value represents whether the duration is still valid and has not expired. **As a result this is the opposite behavior of the `expired()` method.**

#### Return values

|              |                                     |
|--------------|-------------------------------------|
| <i>true</i>  | The Timeout duration is still valid |
| <i>false</i> | The Timeout duration is expired     |

### 16.108.3.3 SetUntil()

```
void TickTimeout::SetUntil (
 uint32_t when) [inline]
```

Set the TimeTick value to expire.

#### Parameters

|             |                                   |
|-------------|-----------------------------------|
| <i>when</i> | TimeTick value in which to expire |
|-------------|-----------------------------------|

### 16.108.3.4 val()

```
uint32_t TickTimeout::val () const [inline]
```

Get the timeout duration to be passed to a function utilizing timeout ticks.

#### Returns

The timeout duration in TimeTicks

## 16.108.4 Friends And Related Symbol Documentation

### 16.108.4.1 OSTimeWaitUntil

```
void OSTimeWaitUntil (
 uint32_t systemTickValue) [friend]
```

Delay the task until the specified value of the system timer tick. The number of system ticks per second is defined by the constant: `TICKS_PER_SECOND` in `<nburn_install>/nrtos/include/constants.h`. The default value is 20 ticks per second.

#### Parameters

|                        |                                        |
|------------------------|----------------------------------------|
| <i>systemTickValue</i> | The system time tick value to wait for |
|------------------------|----------------------------------------|

```
uint32_t Now = TimeTick;
while(1)
{
 Now += 60 * TICKS_PER_SECOND;
 OSTimeWaitUntil(Now);
 // Do whatever every 60 seconds, no mater how long this takes to run the interval will have a consistant
 spacing
}
```

## 16.109 UDPPacket Class Reference

UDP Packet Class.

```
#include <udp.h>
```

#### Public Member Functions

- [UDPPacket](#) ([OS\\_FIFO](#) \*pFifo, [TickTimeout](#) timeout)
 

*Constructor to create a UDP Packet object from a UDP FIFO entry.*
- [UDPPacket](#) (int sock)
 

*Constructor to create a UDP Packet object from an open UDP socket.*
- [UDPPacket](#) (PoolPtr p)

- Constructor to create a UDP packet from a system pool buffer.*

  - [UDPPacket](#) ([UDPPacket](#) &pkt)
- Constructor to create a new UDP packet from an existing UDP packet.*

  - [~UDPPacket](#) ()
- UDP packet object destructor. Frees any associated memory.*

  - void [SetSourcePort](#) (uint16\_t port)
- Set the source port number of a UDP Packet object.*

  - uint16\_t [GetSourcePort](#) (void) const
- Get the source port number of a UDP Packet object.*

  - [MACADR](#) [GetMacSource](#) ()
- Get the source MAC address a UDP Packet object.*

  - [IPADDR](#) [GetSourceAddress](#) (void)
- Get the source IP address a UDP Packet object.*

  - [IPADDR](#) [GetDestinationAddress](#) (void)
- Get the destination IP address a UDP Packet object.*

  - bool [blsIPv6](#) ()
- Check if the IPADDR holds an IPv6 IP address.*

  - void [SetDestinationPort](#) (uint16\_t port)
- Set the destination port number of a UDP Packet object.*

  - uint16\_t [GetDestinationPort](#) (void) const
- Get the destination port number of a UDP Packet object.*

  - uint16\_t [GetPacketId](#) (void)
- Get UDP packet ID.*

  - uint8\_t [GetDataBuffer](#) (bool bReAllocateIfNeeded=false)
- Get a pointer to the UDP Packet object's data buffer.*

  - void [SetDataSize](#) (uint16\_t numBytes)
- Set the UDP Packet data size.*

  - uint16\_t [GetDataSize](#) (void) const
- Get the UDP Packet object data size.*

  - void [AddData](#) (uint8\_t pData, uint16\_t len)
- Add a number of data bytes to a UDP Packet object.*

  - void [AddData](#) (PCSTR pData)
- Add data to a UDP Packet object as a NULL terminated ASCII string.*

  - void [AddDataWord](#) (uint16\_t w)
- Add a 16-bit unsigned integer to a UDP Packet object.*

  - void [AddDataByte](#) (uint8\_t b)
- Add an 8-bit unsigned integer to a UDP Packet object.*

  - BOOL [Validate](#) (void)
- Verify a received UDP packet is valid.*

  - void [ResetData](#) (void)
- Set the data size of a UDP Packet object to 0.*

  - void [SendAndKeep](#) (const [IPADDR](#) &to, uint8\_t ttl=0)
- Make a copy of a UDP Packet and send it. The original packet will remain intact.*

  - void [Send](#) (const [IPADDR](#) &to, uint8\_t ttl=0)
- Send the UDP Packet and free the pool buffer.*

  - void [SendAndKeepViaInterfaceNum](#) (const [IPADDR](#) &to, int interface, uint8\_t ttl=0)
- Make a copy of a UDP Packet and send it using the specified network interface. The original packet will remain intact.*

  - void [SendViaInterfaceNum](#) (const [IPADDR](#) &to, int interface, uint8\_t ttl=0)
- Send the UDP Packet using the specified network interface and free the pool buffer.*

  - void [SendAndKeepViaAddr](#) (const [IPADDR](#) &to, const [IPADDR](#) &from\_ip, uint8\_t ttl=0)

Make a copy of a UDP Packet and send it through the network interface specified by the `from_ip` IP address parameter. If more than one interface has the same IP address, the lower interface number will be used. The original packet will remain intact.

- void [SendViaIfAddr](#) (const [IPADDR](#) &to, const [IPADDR](#) &from\_ip, uint8\_t ttl=0)

Send a UDP packet through the network interface specified by the `from_ip` IP address parameter. If more than one interface has the same IP address, the lower interface number will be used. The UDP pool buffer will be freed.

## 16.109.1 Detailed Description

UDP Packet Class.

This class holds PoolBuffers and treats them as UDP Packets. The process for sending a UDP packet is as follows:

```
UDPPacket myUdpPacket; // Create a UDPPacket object

myUdpPacket.SetSourcePort(123); // Set the source port number
myUdpPacket.SetDestinationPort(456); // Set destination port number
```

Data can be put in the packet two ways:

1. Obtain a pointer to the object's data buffer and copy the data in. Be certain to set the data length.
 

```
uint16_t len = sprintf(myUdpPacket.GetDataBuffer(), "Using sprintf() to copy data at time = %ld",
TickCount);
myUdpPacket.SetDataSize(len);
```
2. Copy the data directly to the packet buffer:
 

```
AddData("This is the data to add"); // Add a constant ASCII null terminated string
AddData(pData, len); // Add with a pointer to the data and the data length
```

When the UDP packet has been configured it can be sent two ways:

1. Send and keep the packet and keep the constructed pool buffer: `SendAndKeep(IPADDR destinationIP);`. You must free the buffer manually.
2. Send and automatically free the pool buffer (recommended and more efficient): `Send(IPADDR4 destinationIP);`

There are many UDP examples, and we recommend reviewing them to determine the best method to use for your application.

## 16.109.2 Constructor & Destructor Documentation

### 16.109.2.1 UDPPacket() [1/4]

```
UDPPacket::UDPPacket (
 OS_FIFO * pFifo,
 TickTimeout timeout)
```

Constructor to create a UDP Packet object from a UDP FIFO entry.

UDP packets are received in a [OS\\_FIFO](#). This constructor create a UDP packet from the next entry in the FIFO, which also removes the entry from the FIFO. If there is not a packet in the FIFO, this constructor will block until one is available, or the specified timeout occurs. If a timeout occurs, an invalid UDP packet will be created. The [UDP Validate\(\)](#) function must always be called after this constructor to verify a valid UDP packet has been created.

Parameters

|                |                                              |
|----------------|----------------------------------------------|
| <i>pFifo</i>   | Pointer to an <a href="#">OS_FIFO</a> object |
| <i>timeout</i> | Timeout in system Time Ticks                 |

See also

[UDPPacket\(int sock\)](#), [UDPPacket\( PoolPtr p \)](#)

### 16.109.2.2 UDPPacket() [2/4]

```
UDPPacket::UDPPacket (
 int sock)
```

Constructor to create a UDP Packet object from an open UDP socket.

This constructor will block until a UDP packet is received. It is useful for situations such as a [select\(\)](#) call that will block on a UDP file descriptor until a packet is received. After the [select\(\)](#) returns, this constructor can be used to create the packet.

#### Parameters

|             |                 |
|-------------|-----------------|
| <i>sock</i> | Open UDP socket |
|-------------|-----------------|

#### See also

[UDPPacket\( OS\\_FIFO \\*pFifo, uint32\\_t timeout \)](#), [UDPPacket\( PoolPtr p \)](#)

### 16.109.2.3 UDPPacket() [3/4]

```
UDPPacket::UDPPacket (
 PoolPtr p)
```

Constructor to create a UDP packet from a system pool buffer.

This constructor can be used in unique situations in which an application is operating directly on the system pool buffers. This is a rare situation.

#### Parameters

|          |                          |
|----------|--------------------------|
| <i>p</i> | Pointer to a pool buffer |
|----------|--------------------------|

#### See also

[UDPPacket\( OS\\_FIFO \\*pFifo, uint32\\_t timeout \)](#), [UDPPacket\(int sock\)](#)

### 16.109.2.4 UDPPacket() [4/4]

```
UDPPacket::UDPPacket (
 UDPPacket & pkt)
```

Constructor to create a new UDP packet from an existing UDP packet.

The UDP packet passed in the argument will be destroyed.

#### Parameters

|            |                   |
|------------|-------------------|
| <i>pkt</i> | UDP packet object |
|------------|-------------------|

#### See also

[UDPPacket\( OS\\_FIFO \\*pFifo, uint32\\_t timeout \)](#), [UDPPacket\(int sock\)](#)

### 16.109.2.5 ~UDPPacket()

```
UDPPacket::~UDPPacket ()
```

UDP packet object destructor. Frees any associated memory.

See also

[UDPPacket\( OS\\_FIFO \\*pFifo, uint32\\_t timeout \)](#), [UDPPacket\(int sock\)](#), [UDPPacket\( PoolPtr p \)](#)

## 16.109.3 Member Function Documentation

### 16.109.3.1 AddData() [1/2]

```
void UDPPacket::AddData (
 PCSTR pData)
```

Add data to a UDP Packet object as a NULL terminated ASCII string.

Parameters

|              |                                       |
|--------------|---------------------------------------|
| <i>pData</i> | Pointer to the null terminated string |
|--------------|---------------------------------------|

See also

[AddDataByte\(\)](#), [AddDataWord\(\)](#)

### 16.109.3.2 AddData() [2/2]

```
void UDPPacket::AddData (
 uint8_t pData,
 uint16_t len)
```

Add a number of data bytes to a UDP Packet object.

Parameters

|              |                            |
|--------------|----------------------------|
| <i>pData</i> | Pointer to the data to add |
| <i>len</i>   | Number of bytes            |

See also

[AddDataByte\(\)](#), [AddDataWord\(\)](#)

### 16.109.3.3 AddDataByte()

```
void UDPPacket::AddDataByte (
 uint8_t b)
```

Add an 8-bit unsigned integer to a UDP Packet object.

Parameters

|          |                        |
|----------|------------------------|
| <i>b</i> | 8-bit unsigned integer |
|----------|------------------------|

See also

[AddDataWord\(\)](#), [AddData\(\)](#)

### 16.109.3.4 AddDataWord()

```
void UDPPacket::AddDataWord (
 uint16_t w)
```

Add a 16-bit unsigned integer to a UDP Packet object.

## Parameters

|          |                         |
|----------|-------------------------|
| <i>w</i> | 16 bit unsigned integer |
|----------|-------------------------|

## See also

[AddDataByte\(\)](#), [AddData\(\)](#)

**16.109.3.5 bIsIPv6()**

```
bool UDPPacket::bIsIPv6 () [inline]
```

Check if the IPADDR holds an IPv6 IP address.

## Returns

true if the IP address is an IPv6 address

**16.109.3.6 GetDataBuffer()**

```
point8_t UDPPacket::GetDataBuffer (
 bool bReAllocateIfNeeded = false)
```

Get a pointer to the UDP Packet object's data buffer.

## Returns

Pointer to the data buffer

**16.109.3.7 GetDataSize()**

```
uint16_t UDPPacket::GetDataSize (
 void) const
```

Get the UDP Packet object data size.

## Returns

The data size as number of bytes

## See also

[SetDataSize\(\)](#)

**16.109.3.8 GetDestinationAddress()**

```
IPADDR UDPPacket::GetDestinationAddress (
 void) [inline]
```

Get the destination IP address a UDP Packet object.

## Returns

The destination IP address

**16.109.3.9 GetDestinationPort()**

```
uint16_t UDPPacket::GetDestinationPort (
 void) const
```

Get the destination port number of a UDP Packet object.

## Returns

The destination port number

## See also

[SetDestinationPort\(\)](#)

**16.109.3.10 GetMacSource()**

```
MACADDR UDPPacket::GetMacSource ()
```

Get the source MAC address a UDP Packet object.

**Returns**

The source MAC address

**16.109.3.11 GetPacketId()**

```
uint16_t UDPPacket::GetPacketId (
 void)
```

Get UDP packet ID.

**Returns**

The UDP packet ID

**16.109.3.12 GetSourceAddress()**

```
IPADDR UDPPacket::GetSourceAddress (
 void) [inline]
```

Get the source IP address a UDP Packet object.

**Returns**

The source IP address

**16.109.3.13 GetSourcePort()**

```
uint16_t UDPPacket::GetSourcePort (
 void) const
```

Get the source port number of a UDP Packet object.

**Returns**

The source port number

**See also**

[SetSourcePort\(\)](#)

**16.109.3.14 Send()**

```
void UDPPacket::Send (
 const IPADDR & to,
 uint8_t ttl = 0) [inline]
```

Send the UDP Packet and free the pool buffer.

**Parameters**

|            |                                                            |
|------------|------------------------------------------------------------|
| <i>to</i>  | Destination IP address                                     |
| <i>ttl</i> | Optional. If not specified the system default will be used |

**See also**

[SendAndKeep\(\)](#), [SendViaInterfaceNum\(\)](#), [SendViaIAddr\(\)](#)

**16.109.3.15 SendAndKeep()**

```
void UDPPacket::SendAndKeep (
 const IPADDR & to,
 uint8_t ttl = 0) [inline]
```

Make a copy of a UDP Packet and send it. The original packet will remain intact.

**Parameters**

|            |                                                            |
|------------|------------------------------------------------------------|
| <i>to</i>  | Destination IP address                                     |
| <i>ttl</i> | Optional. If not specified the system default will be used |

**See also**

[Send\(\)](#), [SendViaInterfaceNum\(\)](#), [SendAndKeepViaIfAddr\(\)](#)

**16.109.3.16 SendAndKeepViaIfAddr()**

```
void UDPPacket::SendAndKeepViaIfAddr (
 const IPADDR & to,
 const IPADDR & from_ip,
 uint8_t ttl = 0) [inline]
```

Make a copy of a UDP Packet and send it through the network interface specified by the `from_ip` IP address parameter. If more than one interface has the same IP address, the lower interface number will be used. The original packet will remain intact.

**Parameters**

|                      |                                                                  |
|----------------------|------------------------------------------------------------------|
| <i>to</i>            | Destination IP address                                           |
| <i>from↔<br/>_ip</i> | IP address to identify the local network interface as the source |
| <i>ttl</i>           | Optional. If not specified the system default will be used       |

**See also**

[Send\(\)](#), [SendViaInterfaceNum\(\)](#)

**16.109.3.17 SendAndKeepViaInterfaceNum()**

```
void UDPPacket::SendAndKeepViaInterfaceNum (
 const IPADDR & to,
 int interface,
 uint8_t ttl = 0) [inline]
```

Make a copy of a UDP Packet and send it using the specified network interface. The original packet will remain intact.

**Parameters**

|                  |                                                            |
|------------------|------------------------------------------------------------|
| <i>to</i>        | Destination IP address                                     |
| <i>interface</i> | Interface number                                           |
| <i>ttl</i>       | Optional. If not specified the system default will be used |

**See also**

[Send\(\)](#), [SendAndKeep\(\)](#), [SendViaInterfaceNum\(\)](#), [SendAndKeepViaIfAddr\(\)](#)

**16.109.3.18 SendViaIfAddr()**

```
void UDPPacket::SendViaIfAddr (
 const IPADDR & to,
 const IPADDR & from_ip,
 uint8_t ttl = 0) [inline]
```

Send a UDP packet through the network interface specified by the `from_ip` IP address parameter. If more than one interface has the same IP address, the lower interface number will be used. The UDP pool buffer will be freed.

**Parameters**

|                       |                                                                  |
|-----------------------|------------------------------------------------------------------|
| <i>to</i>             | Destination IP address                                           |
| <i>from_↔<br/>_ip</i> | IP address to identify the local network interface as the source |
| <i>ttl</i>            | Optional. If not specified the system default will be used       |

**See also**

[Send\(\)](#), [SendAndKeep\(\)](#), [SendAndKeepViaIfAddr\(\)](#)

**16.109.3.19 SendViaInterfaceNum()**

```
void UDPPacket::SendViaInterfaceNum (
 const IPADDR & to,
 int interface,
 uint8_t ttl = 0) [inline]
```

Send the UDP Packet using the specified network interface and free the pool buffer.

**Parameters**

|                  |                                                            |
|------------------|------------------------------------------------------------|
| <i>to</i>        | Destination IP address                                     |
| <i>interface</i> | Interface number                                           |
| <i>ttl</i>       | Optional. If not specified the system default will be used |

**See also**

**16.109.3.20 SetDataSize()**

```
void UDPPacket::SetDataSize (
 uint16_t numBytes)
```

Set the UDP Packet data size.

**Parameters**

|                 |                              |
|-----------------|------------------------------|
| <i>numBytes</i> | Data size as number of bytes |
|-----------------|------------------------------|

**See also**

[GetDataSize\(\)](#)

**16.109.3.21 SetDestinationPort()**

```
void UDPPacket::SetDestinationPort (
 uint16_t port)
```

Set the destination port number of a UDP Packet object.

#### Parameters

|             |                         |
|-------------|-------------------------|
| <i>port</i> | Destination port number |
|-------------|-------------------------|

#### See also

[GetDestinationPort\(\)](#)

#### 16.109.3.22 SetSourcePort()

```
void UDPPacket::SetSourcePort (
 uint16_t port)
```

Set the source port number of a UDP Packet object.

#### Parameters

|             |                    |
|-------------|--------------------|
| <i>port</i> | Source port number |
|-------------|--------------------|

#### See also

[GetSourcePort\(\)](#)

#### 16.109.3.23 Validate()

```
BOOL UDPPacket::Validate (
 void)
```

Verify a received UDP packet is valid.

Verifies a received UDP packet has data and validates the checksum. This function should be called anytime a UDP packet is received.

#### Returns

true if packet is valid, otherwise false

The documentation for this class was generated from the following file:

- [udp.h](#)

## 16.110 UDPPKT Struct Reference

Internal UDP Header.

```
#include <ip.h>
```

#### Public Attributes

- **beuint16\_t srcPort**  
*Source port number.*
- **beuint16\_t dstPort**  
*Destination port number.*
- **beuint16\_t UdpLen**  
*Datagram length including header.*
- **uint16\_t UdpCSum**  
*Checksum (zero in IPv4) Do not make big endian, see IPPKT.*
- **uint8\_t DATA []**

### 16.110.1 Detailed Description

Internal UDP Header.

### 16.110.2 Member Data Documentation

#### 16.110.2.1 DATA

```
uint8_t UDPPKT::DATA[]
```

The data field is actually as long as the packet

The documentation for this struct was generated from the following file:

## 16.111 UniqueIdentifier Class Reference

Get the 128-bit Unique Identifier.

```
#include <bsp.h>
```

### Public Member Functions

- const uint8\_t \* [GetUniqueIdentifier](#) ()  
*Will attempt to read the Unique Identifier from flash memory.*
- [UniqueIdentifier](#) ()  
*Create a [UniqueIdentifier](#) object and read the Unique Identifier from flash memory.*
- const uint8\_t \* [GetBuffer](#) ()  
*Get a pointer to the buffer containing the uniqueID.*
- void [Print](#) ()  
*Print the 128-bit UniqueID in hex to serial.*
- const uint8\_t \* [GetUniqueIdentifier](#) ()  
*Will attempt to read the Unique Identifier from flash memory.*
- [UniqueIdentifier](#) ()  
*Create a [UniqueIdentifier](#) object and read the Unique Identifier from flash memory.*
- const uint8\_t \* [GetBuffer](#) ()  
*Get a pointer to the buffer containing the uniqueID.*
- void [Print](#) ()  
*Print the 128-bit UniqueID in hex to serial.*

### 16.111.1 Detailed Description

Get the 128-bit Unique Identifier.

Each MODM7AE70 is programmed with a 128-bit unique identifier in flash memory. This class exposes functions to get the 128-bit unique ID in a 16-byte array of type uint8\_t.

Each SBE70LC is programmed with a 128-bit unique identifier in flash memory. This class exposes functions to get the 128-bit unique ID in a 16-byte array of type uint8\_t.

### 16.111.2 Member Function Documentation

#### 16.111.2.1 GetBuffer() [1/2]

```
const uint8_t * UniqueIdentifier::GetBuffer () [inline]
```

Get a pointer to the buffer containing the uniqueID.

#### Returns

A pointer to the buffer containing the uniqueID.

**16.111.2.2 GetBuffer()** [2/2]

```
const uint8_t * UniqueIdentifier::GetBuffer () [inline]
```

Get a pointer to the buffer containing the uniqueID.

**Returns**

A pointer to the buffer containing the uniqueID.

**16.111.2.3 GetUniqueIdentifier()** [1/2]

```
const uint8_t * UniqueIdentifier::GetUniqueIdentifier ()
```

Will attempt to read the Unique Identifier from flash memory.

**Returns**

If successful, returns a pointer to the buffer containing the uniqueID. Otherwise, returns a nullptr.

**16.111.2.4 GetUniqueIdentifier()** [2/2]

```
const uint8_t * UniqueIdentifier::GetUniqueIdentifier ()
```

Will attempt to read the Unique Identifier from flash memory.

**Returns**

If successful, returns a pointer to the buffer containing the uniqueID. Otherwise, returns a nullptr.

The documentation for this class was generated from the following files:

- [MODM7AE70/include/bsp.h](#)
- [SBE70LC/include/bsp.h](#)

## 16.112 UserAuthManager Class Reference

The user authorization manager class allows application developers the ability to manage user authorization records. The can be loaded and saved to any storage space, including the config system or UserParams. Authorization values are hashed before being saved. Validation compares both the hash as well as the authorization type. Adding, updating, and removing records will automatically call the user devined save functions. For usage, please see the example found in `examples/SSH/sshServerUserAuth`.

```
#include <UserAuthManager.h>
```

**Public Member Functions**

- **UserAuthManager** ()  
*Default constructor.*
- **~UserAuthManager** ()  
*Default destructor.*
- bool **Init** ([SaveAuthRecordsFn](#) svRcFn, [LoadAuthRecordsFn](#) ldRcFn)  
*Initialization function. Must be called before use.*
- bool **UserExists** (const [NBString](#) &userName)  
*Determines if a user record exists.*
- [AuthResponse](#) **AddUserAuth** (const [NBString](#) &userName, const [NBString](#) &auth, [AuthType](#) authType)  
*Attempts to add a user authorization record. This will automatically call the save record function if the user is added.*
- [AuthResponse](#) **CheckUserAuth** (const [NBString](#) &userName, const [NBString](#) &auth, [AuthType](#) authType)  
*Checks the for a user and compares the authorization value to what is stored.*
- [AuthResponse](#) **CheckUserAuth** (const [NBString](#) &userName, byte \*auth, [AuthType](#) authType)  
*Checks the for a user and compares the authorization value to what is stored.*

- **AuthResponse UpdateUserAuth** (const `NBString` &userName, const `NBString` &newAuth, `AuthType` auth↔  
Type)  
*Updates a user authorization record with the information provided. This function will automatically save all user records if the changes are successful.*
- **AuthResponse RemoveUserAuth** (const `NBString` &userName)  
*Remove a user authorization record. This function will automatically save all user records if the removal is successful.*
- **AuthResponse CheckUserAuthLevel** (const `NBString` &userName, `uint32_t` authLevel, bool hasAll=true)  
*Checks the user against the specific authLevel.*
- **AuthResponse SetUserAuthLevel** (const `NBString` &userName, `uint32_t` authLevel)  
*This adds the authorization levels passed in to the user's current authorization level.*
- **AuthResponse ClrUserAuthLevel** (const `NBString` &userName, `uint32_t` authLevel)  
*Clears the authorization for the specified user.*
- void **ListUsers** ()  
*Lists the users currently in the User Authorization Record system, along with their saved authorization type and level.*
- int **GetMaxAuthRecords** ()  
*Gets the maximum number of authorization records available to the system. This can be changed with the macro `MAX_AUTH_RECORDS`.*

### 16.112.1 Detailed Description

The user authorization manager class allows application developers the ability to manage user authorization records. The can be loaded and saved to any storage space, including the config system or UserParams. Authorization values are hashed before being saved. Validation compares both the hash as well as the authorization type. Adding, updating, and removing records will automatically call the user devined save functions. For usage, please see the example found in `examples/SSH/sshServerUserAuth`.

### 16.112.2 Member Function Documentation

#### 16.112.2.1 AddUserAuth()

```
AuthResponse UserAuthManager::AddUserAuth (
 const NBString & userName,
 const NBString & auth,
 AuthType authType)
```

Attempts to add a user authorization record. This will automatically call the save record function if the user is added.

#### Parameters

|                       |                                                    |
|-----------------------|----------------------------------------------------|
| <code>userName</code> | The username to add.                               |
| <code>auth</code>     | The authorization value to hash and store.         |
| <code>authType</code> | The authorization type of the authorization value. |

#### Return values

|                            |                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------|
| <code>eAuthSuccess</code>  | If the user was successfully added.                                                             |
| <code>!eAuthSuccess</code> | If the user was not added successfully. The AuthResponse error code returned will indicate why. |

#### 16.112.2.2 CheckUserAuth() [1/2]

```
AuthResponse UserAuthManager::CheckUserAuth (
 const NBString & userName,
 byte * auth,
 AuthType authType)
```

Checks the for a user and compares the authorization value to what is stored.

## Parameters

|                 |                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------|
| <i>userName</i> | The username to check against.                                                                                      |
| <i>auth</i>     | The authorization value to compare as hashed value. This will be compared directly to what is stored in the record. |
| <i>authType</i> | The authorization type of the authorization value.                                                                  |

## Return values

|                      |                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>eAuthSuccess</i>  | If the user exists and the authorization value matches what was stored                                                    |
| <i>!eAuthSuccess</i> | If the user does not exist or the authorization comparison fails. The AuthResponse error code returned will indicate why. |

**16.112.2.3 CheckUserAuth() [2/2]**

```
AuthResponse UserAuthManager::CheckUserAuth (
 const NBString & userName,
 const NBString & auth,
 AuthType authType)
```

Checks the for a user and compares the authorization value to what is stored.

## Parameters

|                 |                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------|
| <i>userName</i> | The username to check against.                                                                           |
| <i>auth</i>     | The authorization value to compare as a plain string. This value will be hashed before getting compared. |
| <i>authType</i> | The authorization type of the authorization value.                                                       |

## Return values

|                      |                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>eAuthSuccess</i>  | If the user exists and the authorization value matches what was stored                                                    |
| <i>!eAuthSuccess</i> | If the user does not exist or the authorization comparison fails. The AuthResponse error code returned will indicate why. |

**16.112.2.4 CheckUserAuthLevel()**

```
AuthResponse UserAuthManager::CheckUserAuthLevel (
 const NBString & userName,
 uint32_t authLevel,
 bool hasAll = true)
```

Checks the user against the specific authLevel.

## Parameters

|                  |                                                                                                                                                                                                                                            |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>userName</i>  | The username to check.                                                                                                                                                                                                                     |
| <i>authLevel</i> | The authorization level to check against. This check compares the bits passed in against the bits set on the user's authLevel.                                                                                                             |
| <i>hasAll</i>    | Used to establish the conditions for the check to pass. If hasAll is true, then every bit passed in must be set on the user's authLevel for the check to pass. If hasAll is false, then only one bit needs to match for the check to pass. |

## Return values

|                      |                                                                      |
|----------------------|----------------------------------------------------------------------|
| <i>eAuthSuccess</i>  | If the check passed and the user has the proper authorization level. |
| <i>leAuthSuccess</i> | If the user does not have the proper authorization level.            |

**16.112.2.5 ClrUserAuthLevel()**

```
AuthResponse UserAuthManager::ClrUserAuthLevel (
 const NBString & userName,
 uint32_t authLevel)
```

Clears the authorization for the specified user.

## Parameters

|                  |                                   |
|------------------|-----------------------------------|
| <i>userName</i>  | The username to check.            |
| <i>authLevel</i> | The authorization level to clear. |

## Return values

|                      |                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------|
| <i>eAuthSuccess</i>  | If the specified authorization level was successfully cleared and saved.                                           |
| <i>leAuthSuccess</i> | If the authorization level could not be cleared and saved. The AuthResponse error code returned will indicate why. |

**16.112.2.6 Init()**

```
bool UserAuthManager::Init (
 SaveAuthRecordsFn svRcFn,
 LoadAuthRecordsFn ldRcFn)
```

Initialization function. Must be called before use.

## Parameters

|               |                                                                                                                         |
|---------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>svRcFn</i> | The user defined function that will save authorization records.                                                         |
| <i>ldRcFn</i> | The user defined function that will load the authorization records from storage. Called inside <a href="#">init()</a> . |

## Return values

|             |                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------|
| <i>true</i> | If successfully initialized, and the users are properly loaded.                                           |
| <i>!0</i>   | If there was an error initializing the object, or the users were not successfully loaded. Error code will |

**16.112.2.7 RemoveUserAuth()**

```
AuthResponse UserAuthManager::RemoveUserAuth (
 const NBString & userName)
```

Remove a user authorization record. This function will automatically save all user records if the removal is successful.

## Parameters

|                 |                         |
|-----------------|-------------------------|
| <i>userName</i> | The username to remove. |
|-----------------|-------------------------|

## Return values

|                      |                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------|
| <i>eAuthSuccess</i>  | If the user record was successfully removed.                                                     |
| <i>leAuthSuccess</i> | If the user record could not be removed. The AuthResponse error code returned will indicate why. |

**16.112.2.8 SetUserAuthLevel()**

```
AuthResponse UserAuthManager::SetUserAuthLevel (
 const NSString & userName,
 uint32_t authLevel)
```

This adds the authorization levels passed in to the user's current authorization level.

## Parameters

|                  |                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>userName</i>  | The username to check.                                                                                                         |
| <i>authLevel</i> | The authorization level to check against. This check compares the bits passed in against the bits set on the user's authLevel. |

## Return values

|                      |                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>eAuthSuccess</i>  | If the the user authorization level was properly set and saved.                                                       |
| <i>leAuthSuccess</i> | If the user's authorization level could not be set and saved. The AuthResponse error code returned will indicate why. |

**16.112.2.9 UpdateUserAuth()**

```
AuthResponse UserAuthManager::UpdateUserAuth (
 const NSString & userName,
 const NSString & newAuth,
 AuthType authType)
```

Updates a user authorization record with the information provided. This function will automatically save all user records if the changes are successful.

## Parameters

|                 |                                                    |
|-----------------|----------------------------------------------------|
| <i>userName</i> | The username to check against.                     |
| <i>newAuth</i>  | The new authorization value to assign to the user. |
| <i>authType</i> | The authorization type of the authorization value. |

## Return values

|                      |                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------|
| <i>eAuthSuccess</i>  | If the user record was successfully updated.                                                     |
| <i>leAuthSuccess</i> | If the user record could not be updated. The AuthResponse error code returned will indicate why. |

**16.112.2.10 UserExists()**

```
bool UserAuthManager::UserExists (
 const NSString & userName)
```

Determines if a user record exists.

## Parameters

|                       |                        |
|-----------------------|------------------------|
| <code>userName</code> | The username to check. |
|-----------------------|------------------------|

## Return values

|                    |                             |
|--------------------|-----------------------------|
| <code>true</code>  | If the user exists.         |
| <code>false</code> | If the user does not exist. |

The documentation for this class was generated from the following file:

## 16.113 UserAuthRecord Struct Reference

A stored record of a user's authorization credentials. The value is hashed when saved so it can't be read directly. User's can currently only have one authorization record per user name.

```
#include <UserAuthManager.h>
```

### Public Attributes

- [NBString m\\_userName](#)  
*The username for the record. This value must be unique across all records.*
- `uint8_t m_authHash [WC_SHA256_DIGEST_SIZE]`  
*The hashed representation of the authentication value.*
- [AuthType m\\_authType](#)  
*The type of authentication hashes. Currently supported are keys and passwords.*
- `uint32_t m_authLevel`

### 16.113.1 Detailed Description

A stored record of a user's authorization credentials. The value is hashed when saved so it can't be read directly. User's can currently only have one authorization record per user name.

### 16.113.2 Member Data Documentation

#### 16.113.2.1 m\_authLevel

```
uint32_t UserAuthRecord::m_authLevel
```

The authorization level granted to this user. This is treated as a bit field, and authorization checks look for specific bits being set.

The documentation for this struct was generated from the following file:

- [UserAuthManager.h](#)

## 16.114 USERCritObj Class Reference

User critical section object class.

```
#include <nbrtos.h>
```

### 16.114.1 Detailed Description

User critical section object class.

The documentation for this class was generated from the following file:

- [nbrtos.h](#)

## 16.115 WebConfigServlet Class Reference

Class to run web configurator.

```
#include <config_server.h>
```

Inherits servlet.

### 16.115.1 Detailed Description

Class to run web configurator.

The documentation for this class was generated from the following file:

- [config\\_server.h](#)

## 16.116 wifi\_init Struct Reference

```
#include <wifiDriver.h>
```

### 16.116.1 Detailed Description

This structure is used as a WiFi initialization structure for defining pins, IRQ, and type of WiFi module being used with a specific bus type. the GetDriver function pointer must be defined to one of the supported WiFi module option's static driver function. The options are GetNewWicedSPIDriver(), GetNewWicedSerialDriver(), or GetNewWicedWilcDriver(). Default WiFiInit structures are defined using macros for each of the NBWIFI development kit options. If the user is using pin/IRQ settings that differ from the default values, the user must either define their own wifiInit structure in their project or pass in the custom values to the WiFi initialization functions as parameters.

The documentation for this struct was generated from the following file:

- [wifiDriver.h](#)

## 16.117 WifInterface Class Reference

WiFi Interface clas.

```
#include <nbWifiApi.h>
```

### 16.117.1 Detailed Description

WiFi Interface clas.

The documentation for this class was generated from the following file:

- [nbWifiApi.h](#)

## 16.118 WireIntf Class Reference

Wire Interface Class for I2C.

```
#include <i2c.h>
```

### Public Member Functions

- void **begin** ()
 

*Initialize the [WireIntf](#) driver object as a master with a bus speed of 100 kHz. This normally only needs to be called once.*
- uint32\_t **requestFrom** (uint8\_t addr, uint32\_t len, bool stop=true)
 

*Request a number of bytes from a slave device. The bytes can then be retrieved from the slave device with the [read\(\)](#) and [available\(\)](#) functions.*
- void **beginTransmission** (uint8\_t addr)
 

*Begin a transmission to a [I2C](#) slave device at the provided address. Bytes can be queued for transmission with the [write\(\)](#) functions, and are transmitted by calling [endTransmission\(\)](#).*

- void `endTransmission` (bool stop=true)  
Transmits the bytes of data queued by using the `write()` functions, and ends a transmission to a slave device that was started using `beginTransmission()`.
- `uint32_t write` (`uint8_t dat`)  
Queues bytes of data to be transmitted to the slave device. This function can be called after a call to `beginTransmission()`. The data will not be transmitted on the I2C bus until a call to `endTransmission()` or `flush()` is performed.
- `uint32_t write` (`char *str`)  
Queues bytes of data to be transmitted to the slave device. This function can be called after a call to `beginTransmission()`. The data will not be transmitted on the I2C bus until a call to `endTransmission()` or `flush()` is performed.
- `uint32_t write` (`uint8_t *buf`, `uint32_t len`)  
Queues bytes of data to be transmitted to the slave device. This function can be called after a call to `beginTransmission()`. The data will not be transmitted on the I2C bus until a call to `endTransmission()` or `flush()` is performed.
- `uint32_t available` ()  
Get the number of bytes available to be read from the slave device with `read()`. This function can be called after a call to `requestFrom()`.
- `uint8_t read` ()  
Reads a byte of data that was transmitted from a slave I2C device after a call to `requestFrom()`.
- void `flush` (bool blssueStop=false)  
Force the data that were queued to be transmitted using the `write()` functions to be transmitted on the I2C bus.

### 16.118.1 Detailed Description

Wire Interface Class for I2C.

For I2C communication, you can choose the `WireIntf` class, or the `I2C` class. The `WireIntf` class is simpler to use, while the `I2C` class provides more low level control.

Note that the system automatically instantiates `I2C` and `WireIntf` objects for each of the I2C peripheral modules. The `WireIntf` objects can be accessed with: `Wire`, `Wire1` and `Wire2`. The `I2C` objects can be accesses with `I2C[0]`, `I2C[1]` and `I2C[2]`.

### 16.118.2 Member Function Documentation

#### 16.118.2.1 available()

```
uint32_t WireIntf::available ()
```

Get the number of bytes available to be read from the slave device with `read()`. This function can be called after a call to `requestFrom()`.

#### Returns

The number of bytes available for reading from the slave device.

#### 16.118.2.2 beginTransmission()

```
void WireIntf::beginTransmission (
 uint8_t addr)
```

Begin a transmission to a I2C slave device at the provided address. Bytes can be queued for transmission with the `write()` functions, and are transmitted by calling `endTransmission()`.

#### Parameters

|                   |                                                |
|-------------------|------------------------------------------------|
| <code>addr</code> | the address of the device to transmit data to. |
|-------------------|------------------------------------------------|

**16.118.2.3 endTransmission()**

```
void WireIntf::endTransmission (
 bool stop = true)
```

Transmits the bytes of data queued by using the [write\(\)](#) functions, and ends a transmission to a slave device that was started using [beginTransaction\(\)](#).

**Parameters**

|             |                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>stop</i> | If true, sends a stop message after the request, releasing the <a href="#">I2C</a> bus. If false, the driver will send a restart request, keeping the connection alive. This prevents other <a href="#">I2C</a> master devices from transmitting between messages. This allows one master to transmit multiple transmissions uninterrupted. |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**16.118.2.4 flush()**

```
void WireIntf::flush (
 bool bIssueStop = false)
```

Force the data that were queued to be transmitted using the [write\(\)](#) functions to be transmitted on the [I2C](#) bus. If you need to know exactly when a transaction will occur, call [flush\(\)](#). If accessing a register, be sure to write all address bytes before the call.

**Parameters**

|                   |                                                                                                                                                                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>bIssueStop</i> | If true, sends a stop message after the request, releasing the <a href="#">I2C</a> bus. If false, the driver will send a restart request, keeping the connection alive. This prevents other <a href="#">I2C</a> master devices from transmitting between messages. This allows one master to transmit multiple transmissions uninterrupted. |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**16.118.2.5 read()**

```
uint8_t WireIntf::read ()
```

Reads a byte of data that was transmitted from a slave [I2C](#) device after a call to [requestFrom\(\)](#).

**Returns**

The byte of data received from the slave [I2C](#) device.

**16.118.2.6 requestFrom()**

```
uint32_t WireIntf::requestFrom (
 uint8_t addr,
 uint32_t len,
 bool stop = true)
```

Request a number of bytes from a slave device. The bytes can then be retrieved from the slave device with the [read\(\)](#) and [available\(\)](#) functions.

**Parameters**

|             |                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>addr</i> | the address of the slave to request data from.                                                                                                                                                                                                                                                                                              |
| <i>len</i>  | the number of bytes to request from the slave.                                                                                                                                                                                                                                                                                              |
| <i>stop</i> | If true, sends a stop message after the request, releasing the <a href="#">I2C</a> bus. If false, the driver will send a restart request, keeping the connection alive. This prevents other <a href="#">I2C</a> master devices from transmitting between messages. This allows one master to transmit multiple transmissions uninterrupted. |

**Returns**

The number of bytes returned from the slave [I2C](#) device.

**16.118.2.7 write() [1/3]**

```
uint32_t WireIntf::write (
 char * str)
```

Queues bytes of data to be transmitted to the slave device. This function can be called after a call to [beginTransmission\(\)](#). The data will not be transmitted on the [I2C](#) bus until a call to [endTransmission\(\)](#) or [flush\(\)](#) is performed.

**Parameters**

|            |                                                                                |
|------------|--------------------------------------------------------------------------------|
| <i>str</i> | A string to send as a series of bytes to the <a href="#">I2C</a> slave device. |
|------------|--------------------------------------------------------------------------------|

**Returns**

The number of of bytes written to the transmit queue buffer.

**16.118.2.8 write() [2/3]**

```
uint32_t WireIntf::write (
 uint8_t * buf,
 uint32_t len)
```

Queues bytes of data to be transmitted to the slave device. This function can be called after a call to [beginTransmission\(\)](#). The data will not be transmitted on the [I2C](#) bus until a call to [endTransmission\(\)](#) or [flush\(\)](#) is performed.

**Parameters**

|            |                                                                            |
|------------|----------------------------------------------------------------------------|
| <i>buf</i> | An array of data to send as bytes to the <a href="#">I2C</a> slave device. |
| <i>len</i> | The number of bytes to be written from the <i>buf</i> parameter.           |

**Returns**

The number of of bytes written to the transmit queue buffer.

**16.118.2.9 write() [3/3]**

```
uint32_t WireIntf::write (
 uint8_t dat)
```

Queues bytes of data to be transmitted to the slave device. This function can be called after a call to [beginTransmission\(\)](#). The data will not be transmitted on the [I2C](#) bus until a call to [endTransmission\(\)](#) or [flush\(\)](#) is performed.

**Parameters**

|            |                                                                           |
|------------|---------------------------------------------------------------------------|
| <i>dat</i> | A byte of data to be transmitted to the <a href="#">I2C</a> slave device. |
|------------|---------------------------------------------------------------------------|

**Returns**

The number of of bytes written to the transmit queue buffer.

*Registers a callback for when a receive buffer is finished.*

### 16.119.1 Detailed Description

[WM8904](#) is a driver for the [WM8904](#) Audio Codec.

## 16.119.2 Constructor & Destructor Documentation

### 16.119.2.1 WM8904()

```
WM8904::WM8904 (
 I2C & module)
```

The constructor for the [WM8904](#) context.

#### Parameters

|               |                                                                                     |
|---------------|-------------------------------------------------------------------------------------|
| <i>module</i> | A reference to the <a href="#">I2C</a> module to be used for configuring the codec. |
|---------------|-------------------------------------------------------------------------------------|

## 16.119.3 Member Function Documentation

### 16.119.3.1 GetMicGain()

```
uint8_t WM8904::GetMicGain (
 AudioChSelect_t channel)
```

Get the microphone gain of the selected input channel.

#### Parameters

|                |                          |
|----------------|--------------------------|
| <i>channel</i> | Input Channel to select. |
|----------------|--------------------------|

#### Returns

Gain the channel is set to.

### 16.119.3.2 GetVolume()

```
uint8_t WM8904::GetVolume (
 AudioOutSelect_t out,
 AudioChSelect_t channel)
```

Get the volume of the selected audio output and channel.

#### Parameters

|                |                           |
|----------------|---------------------------|
| <i>out</i>     | Audio Output to select.   |
| <i>channel</i> | Output Channel to select. |

#### Returns

Volume the channel is set to.

### 16.119.3.3 Init()

```
void WM8904::Init (
 const cfg_t & cfg,
 const SSC_cfg_t & ssc_cfg)
```

Configures and initializes both the driver and the codec.

#### Parameters

|                |                                      |
|----------------|--------------------------------------|
| <i>cfg</i>     | The driver configuration to use.     |
| <i>ssc_cfg</i> | The SSC driver configuration to use. |

**16.119.3.4 Mute()**

```
void WM8904::Mute (
 AudioOutSelect_t out,
 AudioChSelect_t channel,
 bool mute)
```

Mute or unmute the selected audio output and channel.

**Parameters**

|                |                                     |
|----------------|-------------------------------------|
| <i>out</i>     | Audio Output to select.             |
| <i>channel</i> | Output Channel to select.           |
| <i>mute</i>    | Whether the channel is to be muted. |

**16.119.3.5 MuteMic()**

```
void WM8904::MuteMic (
 AudioChSelect_t channel,
 bool mute)
```

Mute or unmute the selected input channel.

**Parameters**

|                |                                     |
|----------------|-------------------------------------|
| <i>channel</i> | Input Channel to select.            |
| <i>mute</i>    | Whether the channel is to be muted. |

**16.119.3.6 ReadReg()**

```
uint16_t WM8904::ReadReg (
 Reg::RegAddr_t reg)
```

Read a register on the [WM8904](#).

**Parameters**

|            |                    |
|------------|--------------------|
| <i>reg</i> | Register to write. |
|------------|--------------------|

**Returns**

Data read.

**16.119.3.7 ReadyReceiveBuffer()**

```
int WM8904::ReadyReceiveBuffer (
 void * buffer,
 uint32_t bufferLen,
 bool waitIfNeeded)
```

Hands off a buffer to be written to by the codec.

**Parameters**

|                     |                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------|
| <i>buffer</i>       | A pointer to the buffer to be written to.                                                                   |
| <i>bufferLen</i>    | The length of the buffer to be written. (Must be multiples of 1, 2, or 4 bytes depending on word bit width) |
| <i>waitIfNeeded</i> | Whether the driver should wait for space to receive or fail immediately upon exhausting the queue depth.    |

**Returns**

Negative on failure.

**16.119.3.8 SendCmd()**

```
void WM8904::SendCmd (
 Reg::cmd_t cmd)
```

Execute codec Command. A command is: a register to write, a value to write, and a delay of time required for command execution.

**Parameters**

|            |                    |
|------------|--------------------|
| <i>cmd</i> | Command to execute |
|------------|--------------------|

**16.119.3.9 SendCmdList()**

```
void WM8904::SendCmdList (
 Reg::cmd_t * cmds,
 uint32_t len)
```

Execute an array of codec Commands. A command is: a register to write, a value to write, and a delay of time required for command execution.

**Parameters**

|             |                                |
|-------------|--------------------------------|
| <i>cmds</i> | Commands to execute            |
| <i>len</i>  | Number of commands to execute. |

**16.119.3.10 SetMicGain()**

```
void WM8904::SetMicGain (
 WM8904::AudioChSelect_t channel,
 uint8_t gain)
```

Set the microphone gain of the selected input channel.

**Parameters**

|                |                          |
|----------------|--------------------------|
| <i>channel</i> | Input Channel to select. |
| <i>gain</i>    | Gain to set channel to.  |

**16.119.3.11 SetVolume()**

```
void WM8904::SetVolume (
 WM8904::AudioOutSelect_t out,
 WM8904::AudioChSelect_t channel,
 uint8_t volume)
```

Set the volume of the selected audio output and channel.

**Parameters**

|                |                           |
|----------------|---------------------------|
| <i>out</i>     | Audio Output to select.   |
| <i>channel</i> | Output Channel to select. |
| <i>volume</i>  | Volume to set channel to. |

**16.119.3.12 TransmitBuffer()**

```
int WM8904::TransmitBuffer (
 void * buffer,
 uint32_t bufferLen,
 bool waitIfNeeded)
```

Hands off a buffer to be transmitted to the codec.

**Parameters**

|                     |                                                                                                              |
|---------------------|--------------------------------------------------------------------------------------------------------------|
| <i>buffer</i>       | A pointer to the buffer to be transmit.                                                                      |
| <i>bufferLen</i>    | The length of the buffer to be transmit. (Must be multiples of 1, 2, or 4 bytes depending on word bit width) |
| <i>waitIfNeeded</i> | Whether the driver should wait for space to transmit or fail immediately upon exhausting the queue depth.    |

**Returns**

Negative on failure.

**16.119.3.13 UpdateCmd()**

```
void WM8904::UpdateCmd (
 Reg::cmd_t cmd,
 uint16_t updateMask)
```

Execute a codec Command to update a register. A command is: a register to write, a value to write, and a delay of time required for command execution.

**Parameters**

|                   |                                                              |
|-------------------|--------------------------------------------------------------|
| <i>cmd</i>        | Command to execute                                           |
| <i>updateMask</i> | A Positive bit mask of bits to update in the target register |

**16.119.3.14 WriteReg()**

```
void WM8904::WriteReg (
 Reg::RegAddr_t reg,
 uint16_t dat)
```

Write a register on the [WM8904](#).

**Parameters**

|            |                    |
|------------|--------------------|
| <i>reg</i> | Register to write. |
| <i>dat</i> | Data to write.     |

```

**Classes**

- struct [dspiDMAStruct](#)
- struct [dspiDriverStruct](#)  
Major variables/configurations used for a DSPI transfer.
- class [DSPIModule](#)  
*DSPIModule* is a SPI communications driver. It is an object based driver, which allows for low overhead multiplexing between peripherals with different bus configurations.

**Macros**

- #define [DEFAULT\\_DSPI\\_MODULE](#) 1
- #define [DSPI\\_MODULE\\_COUNT](#) 4

**DSPI state**

- #define [DSPI\\_OK](#) (0)
- #define [DSPI\\_BUSY](#) (1)
- #define [DSPI\\_ERROR](#) (2)

**MCR Register masks**

- #define [MCR\\_MASTER\\_INIT](#) 0x80000C01
- #define [MCR\\_HALT\\_BIT](#) 0x00000001
- #define [MCR\\_DIS\\_TXF](#) 0x00002000
- #define [MCR\\_DIS\\_RXF](#) 0x00001000
- #define [MCR\\_CLR\\_FIFOS](#) 0x00000C00

**CTAR Register masks**

- #define [CTAR\\_CLOCK\\_POLARITY](#) 0x04000000
- #define [CTAR\\_CLOCK\\_PHASE](#) 0x02000000
- #define [CTAR\\_FRAME\\_16BIT](#) 0x78000000
- #define [CTAR\\_FRAME\\_4BIT](#) 0x18000000

**SR Register masks**

- #define [SR\\_EOQF\\_MASK](#) 0x10000000
- #define [SR\\_CLR\\_FLAGS](#) 0x8A0A0000

**RSER (Interrupt/DMA enable) Register masks**

- #define [RSER\\_EOQF\\_IRQ\\_ONLY](#) ~0x8B0B0000
- #define [RSER\\_DMA\\_IRQ\\_ONLY](#) 0x03030000

### Classes

- class [SPIModule](#)  
*SPI Peripheral Module Class.*

### Macros

#### DSPI Bus State

- #define **DSPI\_OK** ( 0 )  
*DSPI OK.*
- #define **DSPI\_BUSY** ( 1 )  
*DSPI Busy.*
- #define **DSPI\_ERROR** ( 2 )  
*DSPI Error.*

#### DSPI Peripheral Module

- #define **DEFAULT\_DSPI\_MODULE** 0  
*Default DSPI module.*
- #define **DSPI\_MODULE\_COUNT** 1  
*Number of modules: 0, 1.*

### Enumerations

- enum [csReturnType](#) { [DEASSERT\\_NEVER](#) = 0 , [DEASSERT\\_AFTER\\_LAST](#) = 1 , [DEASSERT\\_EVERY\\_TRANSFER](#) = 2 }
- Chip select deassertion modes. Used to determine when the driver should deassert chip selects during SPI transfer.*
- enum [spiChipSelect](#) { [CHIP\\_SELECT\\_0](#) = 0 , [CHIP\\_SELECT\\_1](#) = 1 , [CHIP\\_SELECT\\_2](#) = 2 , [CHIP\\_SELECT\\_3](#) = 3 , [CHIP\\_SELECT\\_DISABLED](#) = 0xFF }
- Chip select number.*
- enum [spiChipSelectPolarity](#) { [CS\\_ASSERT\\_LOW](#) = 0 , [CS\\_ASSERT\\_HIGH](#) = 1 }
- Chip select polarity.*

### Functions

- [uint8\\_t DSPIInit](#) ([uint8\\_t SPIModule=DEFAULT\\_DSPI\\_MODULE](#), [uint32\\_t Baudrate=2000000](#), [uint8\\_t QueueBitSize=8](#), [uint8\\_t CS=0x00](#), [uint8\\_t CSPol=0x0F](#), [uint8\\_t ClkPolarity=0](#), [uint8\\_t ClkPhase=1](#), [BOOL DoutHiz=TRUE](#), [uint8\\_t QCD=0](#), [uint8\\_t DTL=0](#))  
*Initialize a DSPI module.*
- [uint8\\_t DSPIStart](#) ([uint8\\_t SPIModule](#), [puint8\\_t transmitBufferPtr](#), [volatile uint8\\_t \\*receiveBufferPtr](#), [uint32\\_t byteCount](#), [OS\\_SEM \\*finishedSem=NULL](#), [uint8\\_t enableDMA=TRUE](#), [int csReturnToInactive=DEASSERT\\_AFTER\\_LAST](#))  
*Start a DSPI transfer.*
- [BOOL DSPIDone](#) ([uint8\\_t SPIModule=DEFAULT\\_DSPI\\_MODULE](#))  
*Check SPI status.*
- [uint8\\_t QSPIInit](#) ([uint32\\_t baudRateInBps=2000000](#), [uint8\\_t transferSizeInBits=8](#), [uint8\\_t peripheralChipSelects=0x0F](#), [uint8\\_t chipSelectPolarity=1](#), [uint8\\_t clockPolarity=0](#), [uint8\\_t clockPhase=1](#), [BOOL doutHiz=TRUE](#), [uint8\\_t csToClockDelay=0](#), [uint8\\_t delayAfterTransfer=0](#))

*Compatibility function for previous drivers. Initialize SPI module.*

- `uint8_t QSPISstart` (`uint8_t transmitBufferPtr`, `volatile uint8_t *receiveBufferPtr`, `uint32_t byteCount`, `OS_SEM *finishedSem=NULL`)

*Compatibility function for previous drivers. Start a SPI transfer.*

- `BOOL QSPIdone` ()

*Compatibility function for previous drivers. Check SPI status.*

## 17.9.1 Detailed Description

NetBurner DMA SPI (DSPI) API for ARM SAME70 (MODM7AE70, SBE70LC)

## 17.10 cortex-m7/cpu/SAME70/include/dspi.h

00147 /*****
00148
00149 A special note about CAN identifiers
00150
00151 *****/
00152 Can identifiers come in two flavors, Normal (11 bits) and Extended. (29 bits)
00153 In this software API we always refer to can identifiers as 32 bit uint32_tS.
00154 A 32 bit uint32_t is bigger than either Identifier.
00155
00156 A Normal identifier will always have bits 0 to 17 as zero
00157
00158 An extended identifier can have bits 0 to 17 low. So extended identifiers
00159 that are received will have bit 29 set to 1. Any ID input into the
00160 system will be treated as extended if bit 29 is set or if bits
00161 0 to 17 are not zero.
00162
00163 The following MACROS can help work with this ID scheme.
00164 */
00165
00166 /* The single bit used by this API to indicate an extended ID */
00167 #define CAN_EXTENDED_ID_BIT (0x20000000)
00168
00169 /* This macro takes an id and returns an ID that is guaranteed
00170 to be treated as an extended ID by the system
00171 Make an id that is extended from either extended or normal */
00172 #define ExtToNbId(id) (id | CAN_EXTENDED_ID_BIT)
00173
00174 /*Make Normal Id make an ID set from a normal id in the range 0 to 2048 */
00175 #define NormToNbId(id) ((id & 0x7ff) << 18)
00176
00177 /* Is the ID extended ? returns non zero if the id passed in was an extended ID */
00178 #define IsNBIdExt(id) ((id & (CAN_EXTENDED_ID_BIT | 0x3FFFF)) != 0)
00179
00180 /* Strip the extra flag remove the API extended flage from the ID*/
00181 #define NbToExtId(id) (id & 0x1FFFFFFF)
00182
00183 /* Shift a Normal ID so it has value 0 to 1023
00184 Some CAN systems will treat normal ID's as an integer from 0 to 2048
00185 Other systems may treat normal ID's as 28 bit values where the bottom 17 bits are zero
00186 This MACRO will convert our Normal ID format into the 0 to 2048 format.*/
00187 #define NbToNormId(id) ((id >> 18) & 0x7FFF)
00188
00189 /* Initialize the CAN system
00190 parameters:
00191
00192 bit_rate is the bitrate to run the CAN system at.
00193 The system will get as close as possible, but 1000000, 500000, 250000 and 125000 are
00194 the only values that are known to work.
00195
00196 Global_Mask is the mask used to mask received ID's a bit =0 is don't care, 1= care.

```

```

00197
00198 irq_level The interrupt level you want the CAN system to operate at.
00199
00200 Returns
00201 CAN_OK on success.
00202 CAN_RATE_FAIL if the bit rate could not be set withing 1.5%
00203 CAN_ALREADYOPEN if the CAN system is already running. You must call CanShutDown first.
00204 */

00213 /* The CAN system has 16 available channels this tells how many are currently in use */
00214 int MultiCanFreeCanChannels(int moduleNum);
00215
00216 /* This tells if a specific channel is currently free */
00217 BOOL MultiCanIsChannelFree(int moduleNum, int channel);
00218
00219 /* RegisterCanRx Fifo and RegisterCanSpecialRx Fifo
00220 Tell the CAN system to start listening for a specific CAN ID.
00221 Any incoming CAN frames that match the id as set by the appropriate mask will
00222 be placed into the fifo.
00223
00224 Parameters:
00225 uint32_t id The identifier to match on received frames. This is modified by
00226 the global mask, or in the case of the RegisterCanSpecial
00227 the passed in mask.
00228
00229 uint32_t spl_mask Only used by RegisterCanSpecialRx Fifo. There are only
00230 two channels available for use with the special mask
00231 so use this call sparingly and only if really needed.
00232
00233 OSFifo * pFifo The Fifo used to communicate between the CAN subsystem and
00234 the CanRxMessageClass. This FIFO must be initialized before use.
00235 The same fifo can be passed to multiple receive registration functions.
00236
00237 int channel The Channel to place the receive request. A value of -1 allows the system to
00238 select an unused channel.
00239
00240 Returns
00241 Any value >=0 the channel this request is assigned to. This value must be stored to
00242 later call UnRegisterCanFifo.
00243 CAN_CHANNEL_USED If the channel is used or there are no free channels.
00244 */

00259
00260 /* Send a message
00261 Parameters:
00262 uint32_t id The Identifier to send. See the earlier discussion of identifiers.
00263 and the identifier macros.
00264
00265 uint8_t * data A pointer to the data to send
00266
00267 uint8_t len The length of the Data must be <=8.
00268
00269 uint16_t timeout How long to wait for confirmation it sent.
00270 0 = wait forever.
00271 0xFFFF = don't wait at all.
00272
00273 int channel The channel to use. A value of -1
00274 will allow the system to pick and unused channel.
00275
00276 Returns
00277 CAN_OK If the message was sent
00278 CAN_CHANNEL_USED Can't send because the channel was already in use or no channels available.
00279 CAN_TIMEOUT Did not send in the time allotted
00280 */
00281 int MultiCanSendMessage(int moduleNum, uint32_t id, uint8_t *data, uint8_t len, uint16_t timeout, int
00282 channel = -1);

```

```

00282

00284 Can can be configured to send messages in response to memessage requests.
00285 The next three functions handle that functionality */
00286
00287 /* Set RTRMessage
00288 This sets up a message to be sent in response to an incoming message that matches the
00289 RTR message id. The system will continue to respond with this message forever.
00290
00291 Parameters:
00292 uint32_t id. The id to respond to and the id responded with.
00293 uint8_t * data The data to respond with
00294 uint8_t len The length of the responding data.
00295 int channel The channel to use, or -1 to let the system pic one.
00296
00297 Returns:
00298 value >0 the channel assigned to this tsk or the channel requested.
00299 CAN_CHANNEL_USED if the channel is already used or no free channels are available.
00300 */
00301 int MultiCanSetRTRMessage(int moduleNum, uint32_t id, uint8_t *data, uint8_t len, int channel = -1);
00302
00303 /*ReplaceRTRMessage
00304 Replace the outgoing message in an RTR channel already set up
00305 with a call to SetRTRMessage. Use of this function can
00306 cause a brief instant (a few uSec.) when no message response would be sent
00307 to an incoming request. If this is unacceptable register two identical RTR
00308 messages and change them in sequence.
00309
00310 Parameters:
00311 int channel The channel value returned from the SetRTRMessage call
00312 uint8_t * data the data to send.
00313 uint8_t len the length of the data.
00314
00315 Returns
00316 CAN_OK if the replacement succeeded.
00317 CAN_CHANNEL_NOT_USED if the passed in channel was not set up for RTR messages
00318
00319 */

### Macros

#### Multichannel I2C Return Values

*Function return values*

- #define **I2C\_OK** (0)  
*Last instruction terminated correctly.*
- #define **I2C\_NEXT\_WRITE\_OK** (1)  
*I2C bus is OK for a write.*
- #define **I2C\_NEXT\_READ\_OK** (2)  
*I2C bus is OK for a read.*
- #define **I2C\_MASTER\_OK** (3)  
*I2C finished transmission but still owns but (need to stop or restart)*
- #define **I2C\_TIMEOUT** (4)  
*A timeout occurred while trying communicate on I2C bus.*
- #define **I2C\_BUS\_NOT\_AVAIL** (5)  
*A timeout occurred while trying gain I2C bus control.*
- #define **I2C\_NOT\_READY** (6)  
*A read or write was attempted before I2C ready or during a slave transmission.*
- #define **I2C\_LOST\_ARB** (7)  
*Lost arbitration during start.*
- #define **I2C\_LOST\_ARB\_ADD** (8)  
*Lost arbitration and then winner addressed our slave address.*
- #define **I2C\_NO\_LINK\_RX\_ACK** (9)  
*We are in Master TX mode and received no ACK from slave device, possibly during start.*

#### Multichannel I2C Macros

*I2C Macros*

- #define **I2C\_SR\_BUSY** (((0x20 & I2C\_SR) == 0x20))  
*Bus is busy (bit 5 of I2SR)*
- #define **I2C\_CR\_SLAVE** (((0x20 & I2C\_CR) == 0x00))  
*Bus set as slave (bit 5 of I2CR)*
- #define **I2C\_SR\_ARB\_LOST** (((0x10 & I2C\_SR) == 0x10))  
*Bus arbitration was lost (bit 4 of I2SR)*
- #define **I2C\_SR\_ADRES\_AS\_SLAVE** (((0x40 & I2C\_SR) == 0x40))  
*Addressed as a slave (bit 6 of I2SR)*
- #define **I2C\_SR\_SLAVE\_TX** (((0x04 & I2C\_SR) == 0x04))

- *State of read/write bit of the received address command (bit 2 of I2SR)*
- #define **I2C\_CR\_TX** (((0x10 & I2C\_CR) == 0x10))  
*Configured for transmit (bit 4 of I2CR)*
- #define **I2C\_SR\_RX\_ACK** (((0x01 & I2C\_SR) == 0x00))  
*Received a RX ACK after last transmit (bit 0 of I2SR)*
- #define **I2C\_CR\_RX\_ACK** (((0x08 & I2C\_CR) == 0x00))  
*Configured to RX Ack.*
- #define **I2C\_SET\_NO\_ACK** ((I2C\_CR |= 0x08))  
*Configure I2C module not to send a RX ACK (bit 3 of I2CR)*
- #define **I2C\_SET\_ACK** ((I2C\_CR &= 0xF7))  
*Configure I2C module to send a RX ACK (bit 3 of I2CR)*
- #define **I2C\_SET\_TX** ((I2C\_CR |= 0x10))  
*Configure I2C module to be in TX mode (bit 4 of I2CR)*
- #define **I2C\_SET\_RX** ((I2C\_CR &= 0xEF))  
*Configure I2C module to be in RX mode (bit 4 of I2CR)*
- #define **I2C\_SET\_REPEAT\_START** ((I2C\_CR |= 0x04))  
*Configure I2C to send a repeated start signal.*
- #define **I2C\_CLR\_ARB\_LOST** ((I2C\_SR &= 0xEF))  
*Clear Arbitration lost error condition.*

## Functions

- void **MultiChannel\_I2CInit** (int moduleNum=DEFAULT\_I2C\_MODULE, uint8\_t slave\_Addr=0x08, uint8\_t freqdiv=0x3C)  
*Initialize the I2C peripheral module.*
- uint8\_t **MultiChannel\_I2CSendBuf** (int moduleNum, uint8\_t addr, uint8\_t buf, int num, bool stop=true)  
*Send a buffer of bytes to an I2C device.*
- uint8\_t **MultiChannel\_I2CReadBuf** (int moduleNum, uint8\_t addr, uint8\_t buf, int num, bool stop=true)  
*Read a number of bytes from an I2C device and store in the specified buffer.*
- void **I2CMultiChannelResetPeripheral** (int moduleNum)  
*Reset the specified I2C peripheral module.*
- uint8\_t **MultiChannel\_I2CRestart** (int moduleNum, uint8\_t addr, bool Read\_Not\_Write, uint32\_t ticks\_to\_wait=I2C\_RX\_TX\_TIMEOUT)  
*Restart communication with a I2C device.*
- uint8\_t **MultiChannel\_I2CStart** (int moduleNum, uint8\_t addr, bool Read\_Not\_Write, uint32\_t ticks\_to\_wait=I2C\_START\_TIMEOUT)  
*Send an I2C start to an I2C device to begin communication.*
- uint8\_t **MultiChannel\_I2CStop** (int moduleNum=DEFAULT\_I2C\_MODULE, uint32\_t ticks\_to\_wait=I2C\_RX\_TX\_TIMEOUT)  
*Issue an I2C stop terminate communication with an I2C device and release the bus.*
- uint8\_t **MultiChannel\_I2CSend** (int moduleNum, uint8\_t val, uint32\_t ticks\_to\_wait=I2C\_RX\_TX\_TIMEOUT)  
*Send a single byte on the I2C bus.*
- uint8\_t **MultiChannel\_I2CRead** (int moduleNum, uint8\_t val, uint32\_t ticks\_to\_wait=I2C\_RX\_TX\_TIMEOUT)  
*Read a single byte from the I2C bus.*

### 17.21.1 Detailed Description

NetBurner I2C API for MOD5441x and NANO54415.

## 17.22 multichanneli2c.h

00004
00005 /*-----
```

```

00006 NetBurner I2C Multi-Master I2C Driver.
00007 Multi-Master I2C will enable operation as a master device on the I2C bus when
00008 actively seeking to communicate. When idle, the NetBurner will act as a slave
00009 device so other I2C masters can use the bus.
00010
00011 Note: If your NetBurner device is the only master on the I2C bus, you may
00012 choose to use the Master-Only I2C driver to conserve system resources
