- Consider implementing authentication for WebSocket endpoints
- Add error handling for memory allocation failures
- Implement rate limiting for DoS protection

12.57.4.1.7.2 Debugging Features

- Real-time message logging to stdout
- Connection status messages
- Socket close notifications

12.57.4.1.8 Error Handling

The application includes error handling:

- Automatic connection cleanup on socket errors
- Graceful handling of multiple connection attempts
- Resource management with proper file descriptor cleanup
- Timeout handling for network operations

12.57.5 HTTPS WebSocket Demo

12.57.5.1 SSL/TLS WebSocket Demo

A NetBurner application demonstrating secure and non-secure HTTP/HTTPS web server functionality with WebSocket support and SSL/TLS authentication.

12.57.5.1.1 Overview

This application showcases how to implement both secure (HTTPS) and non-secure (HTTP) access to web resources alongside WebSocket communication. The server provides different access levels based on connection security, demonstrating practical SSL/TLS authentication patterns.

12.57.5.1.2 Features

- **Dual Protocol Support:** Serves content over both HTTP (port 80) and HTTPS (port 443)
- **SSL/TLS WebSocket:** Secure WebSocket communication with authentication
- **Access Control:** Directory-based security with SSL-only restricted areas
- **Dynamic Content:** Server-side functions for generating dynamic links and content
- **Echo WebSocket:** Real-time bidirectional communication demonstration

12.57.5.1.3 Directory Structure

```
html/
  httpsdir/
    ssl.html          # HTTPS-only accessible content
  images/
    SSL-Good.gif      # Shown for secure connections
    SSL-Bad.gif       # Shown for non-secure connections
  index.html         # Main page (HTTP/HTTPS accessible)
  script.js          # Client-side JavaScript
```

12.57.5.1.4 Access Control

The application implements a three-tier access control system:

- **Level 0:** Public access (HTTP/HTTPS)
- **Level 1:** HTTPS-only access
- **Higher Levels:** Custom authentication (extensible)

12.57.5.1.4.1 Security Implementation

```
HTTP_ACCESS CheckHttpAccess(int sock, int access_level, HTTP_Request &Req)
```

This function overrides the system default to enforce SSL/TLS requirements:

- Level 0: Always accessible
- Level 1: Requires SSL connection, returns HTTP_FORBIDDEN for non-SSL
- Extensible for additional security levels

12.57.5.1.5 WebSocket Functionality

12.57.5.1.5.1 Echo WebSocket Endpoint

- **Endpoint:** `/echo*`
- **Functionality:** Echoes received messages back to sender
- **Protocol:** Supports both WS and WSS (secure WebSocket)

12.57.5.1.5.2 WebSocket Lifecycle

1. Connection established via `WSStart()` callback
2. Socket registered and semaphore posted
3. Main loop handles read/write operations
4. Automatic cleanup on connection errors

12.57.5.1.6 Dynamic Content Functions

12.57.5.1.6.1 SSL_Image()

Dynamically serves different images based on connection security:

- SSL connections: `SSL-Good.gif`
- Non-SSL connections: `SSL-Bad.gif`

12.57.5.1.6.2 HTTPS_Ref() / HTTP_Ref()

Generates protocol-specific URLs for navigation:

- Automatically detects host information
- Constructs proper HTTPS/HTTP links
- Supports both hostname and IP address formats

12.57.5.1.6.3 Host_Ref()

Provides the current host identifier (hostname or IP address)

12.57.5.1.7 Configuration Options

12.57.5.1.7.1 Default Configuration

```
StartHttps(); // Starts both HTTP (80) and HTTPS (443)
```

12.57.5.1.7.2 HTTPS-Only Configuration

```
StartHttps(443, 0); // HTTPS only, disables HTTP port
```

12.57.5.1.8 Network Requirements

- **DHCP:** Waits up to 5 seconds for network address assignment
- **Ports:**
 - HTTP: 80 (configurable/disableable)
 - HTTPS: 443 (configurable)
- **SSL/TLS:** Requires valid SSL certificate configuration

12.57.5.1.9 Main Application Flow

1. Initialization

- Network stack initialization
- System diagnostics enablement
- `DHCP` address acquisition

2. Server Startup

- HTTP/HTTPS web server activation
- WebSocket endpoint registration

3. Main Loop

- WebSocket connection monitoring
- Bidirectional data handling
- Error detection and cleanup
- Connection state management

12.57.5.1.10 Development Notes

12.57.5.1.10.1 Memory Management

- Uses `SMPoolPtr` for buffer management
- `ETHER_BUFFER_SIZE` defines maximum message size
- Automatic cleanup on connection errors

12.57.5.1.10.2 Concurrency

- Uses `OS_SEM` semaphore for WebSocket synchronization
- `select()` for non-blocking I/O operations
- Proper file descriptor management

12.57.5.1.10.3 Error Handling

- Connection error detection via `select()`
- Graceful socket closure
- Automatic reconnection support

12.57.5.1.11 Security Considerations

1. **SSL/TLS Configuration:** Ensure proper certificate installation
2. **Access Control:** Directory-based restrictions prevent unauthorized access
3. **Connection Validation:** All SSL connections verified before serving content
4. **Resource Protection:** Sensitive content isolated in `httpsdir/`

12.57.5.1.12 Usage Instructions

1. **Build and Deploy:** Compile with NetBurner development tools
2. **Network Setup:** Ensure device has network connectivity
3. **Access:** Navigate to device IP address via web browser
4. **Test Security:** Compare HTTP vs HTTPS access to different resources
5. **WebSocket:** Use JavaScript client to connect to echo endpoint

12.57.5.1.13 Troubleshooting

- **Connection Issues:** Check network configuration and [DHCP](#)
- **SSL Errors:** Verify certificate installation and validity
- **Access Denied:** Ensure proper file placement in directory structure
- **WebSocket Failures:** Monitor console output for connection status

12.58 WiFi Examples

Wifi Examples:

- [Wifi Config AP](#)
- [Configure AP with JSON](#)
- [Wifi Firmware Update](#)
- [Wifi Access Point](#)
- [Wifi Client](#)
- [Wifi Scan](#)

12.58.1 Wifi Config AP

12.58.1.1 NetBurner WiFi Configuration Access Point

12.58.1.1.1 Overview

This application configures a NetBurner device's WiFi interface as an access point, providing users with a convenient way to connect the device to local wireless networks. When no network credentials are stored, the device automatically starts a WiFi Access Point that hosts a webpage for network configuration.

12.58.1.1.2 Features

- **Automatic AP Mode:** Starts WiFi Access Point when no stored network credentials are found
- **Network Scanning:** Scans and displays available wireless networks
- **Web-based Configuration:** Provides a webpage interface for connecting to local networks
- **Interactive Console:** Command-line interface for manual WiFi management
- **Status Monitoring:** Real-time WiFi connection status and network information
- **Persistent Storage:** Saves WiFi credentials for automatic reconnection

12.58.1.1.3 Default Behavior

12.58.1.1.3.1 Access Point Configuration

- **Default SSID Format:** NB_<last 6 bytes of MAC address>
 - Example: NB_012345
- **Default IP Address:** 192.168.0.1
- **DHCP Range:** Starting from 192.168.0.2

12.58.1.1.3.2 Custom Branding

You can customize the access point SSID prefix by uncommenting and modifying this line in `main.cpp`:

```
extern const NB::SSID_t default_SSID_Prefix = { 4, "FOO_" };
```

This would create access point names like FOO_012345 instead of NB_012345.

12.58.1.1.4 Operation Modes

12.58.1.1.4.1 1. Configuration Mode (No Stored Credentials)

- Device starts as WiFi Access Point
- SSID and IP address printed to serial console
- Web interface accessible for network selection and credential entry
- User can scan for available networks and connect to desired network

12.58.1.1.4.2 2. Client Mode (Stored Credentials Found)

- Device automatically connects to previously configured network
- Normal operation with internet connectivity
- Web server runs on port 80

12.58.1.1.5 Interactive Commands

The application provides a console interface with the following commands:

Command	Function
C	Connect to WiFi network
D	Disconnect from current network
R	Reset stored WiFi SSID credentials
S	Scan for available networks
W	Display WiFi status and configuration
X	Reset WiFi module
Z	System reboot

12.58.1.1.6 Network Information Display

The status command (W) provides comprehensive information including:

12.58.1.1.6.1 Ethernet Interface

- Interface number
- IP address, netmask, gateway, DNS
- MAC address

12.58.1.1.6.2 WiFi Interface

- Interface number and IP configuration
- Connection status
- Current SSID and BSSID
- Signal strength (RSSI)
- Channel information
- Security type (Open, WEP, WPA, WPA2, WPS)
- Cipher type (None, TKIP, AES, Mixed)

12.58.1.1.6.3 Device Information

- Hardware revision
- WiFi firmware revision
- Stored configuration parameters

12.58.1.1.7 Security Support

The application supports various WiFi security protocols:

- **Open**: No security
- **WEP**: Wired Equivalent Privacy
- **WPA**: WiFi Protected Access
- **WPA2**: WiFi Protected Access 2
- **WPS**: WiFi Protected Setup

Cipher support includes:

- **TKIP**: Temporal Key Integrity Protocol
- **AES**: Advanced Encryption Standard
- **Mixed**: Both TKIP and AES

12.58.1.1.8 Technical Details

12.58.1.1.8.1 Initialization Sequence

1. Network stack initialization
2. HTTP server startup (port 80)
3. WiFi interface initialization and scanning
4. Check for stored credentials
5. Start Configuration AP or connect to stored network

12.58.1.1.8.2 Interface Management

- Uses SPI communication with WiFi module
- Automatic interface number assignment
- Dual-interface support (Ethernet + WiFi)

12.58.1.1.8.3 Memory Management

- Automatic scan result deallocation
- Pool-based buffer management for device information

12.58.1.1.9 Configuration Options

Several library defaults can be overridden by uncommenting variables in `main.cpp`:

```
// Custom DHCP lease start address
// const IPAddress configAP_LeaseStart(192, 168, 0, 2);

// Custom access point IP address
// const IPAddress configAP_IPAddr(192, 168, 0, 1);

// Custom SSID prefix for branding
// const NB::SSID_t default_SSID_Prefix = { 4, "FOO_" };
```

12.58.1.1.10 Usage Instructions

1. First Time Setup:

- Power on the device
- Look for the access point SSID printed on serial console
- Connect to the AP using a computer or smartphone
- Navigate to the device's IP address (typically 192.168.0.1)
- Select and configure your local WiFi network

2. Subsequent Boots:

- Device automatically connects to configured network
- Access device via its assigned IP address on local network

3. Manual Configuration:

- Use serial console commands for advanced configuration
- Reset credentials with 'R' command if needed
- Perform network scans with 'S' command

12.58.1.1.11 Development Notes

- Built for NetBurner embedded systems
- Requires NetBurner RTOS and WiFi libraries
- Designed for development kits with dual Ethernet/WiFi interfaces
- System diagnostics enabled (should be disabled for production)

12.58.2 Configure AP with JSON

12.58.2.1 WiFi Configuration Access Point with JSON

12.58.2.1.1 Overview

This NetBurner application configures the WiFi interface as an access point to provide users with a convenient way to connect to local wireless networks. The application creates a web-based configuration interface that allows users to scan for and connect to available WiFi networks.

Note

The difference from the previous ConfigAP example is that the list of networks is generated using JavaScript to parse a JSON object sent by the NetBurner which contains the access point scan results.

For the user's convenience, the device's SSID and WiFi Interface IP address are printed out the serial port. These can be used to access the device's webpage, which allows the user to connect to a local network.

12.58.2.1.2 Key Features

- **Automatic Access Point Creation:** If no network SSID is configured, the device automatically starts as a WiFi Access Point
- **Network Scanning:** Scan for and display available local wireless networks
- **Web-based Configuration:** User-friendly webpage for network selection and connection
- **JSON-based Communication:** JavaScript parsing of JSON objects containing scan results
- **Custom Branding Support:** Configurable SSID prefix for custom product branding
- **Serial Interface:** Command-line interface for manual WiFi operations

12.58.2.1.3 How It Works

12.58.2.1.3.1 Initial Startup

1. On boot, the application checks for a stored network SSID
2. If no SSID is found, it creates a WiFi Access Point
3. The access point SSID follows the format: NB_<last 6 bytes of MAC>
 - Example: NB_012345
4. The device's SSID and IP address are printed to the serial port

12.58.2.1.3.2 Configuration Process

1. Users connect to the NetBurner's access point using a WiFi-enabled device
2. Navigate to the device's webpage using the provided IP address
3. The webpage displays a list of available networks (generated via JavaScript)
4. Users select their desired network and enter credentials
5. The device connects to the selected network and stores the configuration

12.58.2.1.3.3 Custom Branding

To customize the access point SSID prefix, uncomment and modify this line in `main.cpp`:

```
extern const NB::SSID_t default_SSID_Prefix = { 4, "FOO_" };
```

12.58.2.1.4 Serial Commands

The application provides several serial commands for manual WiFi management:

- **C** - Connect to WiFi network
- **D** - Disconnect from current network
- **R** - Reset stored WiFi SSID
- **S** - Perform network scan
- **W** - Display WiFi status and configuration
- **X** - Reset WiFi module
- **Z** - System reboot

12.58.2.1.5 Technical Details

12.58.2.1.5.1 WiFi Security Support

The application supports multiple security protocols:

- Open (no security)
- WEP
- WPA
- WPA2
- WPS

12.58.2.1.5.2 Cipher Support

- None
- TKIP
- AES
- Mixed (TKIP/AES)

12.58.2.1.5.3 Network Information Display

When connected, the application displays:

- SSID (network name)
- BSSID (access point MAC address)
- Signal strength (RSSI)
- Channel
- Security type
- Cipher method
- IP configuration (address, mask, gateway, DNS)

12.58.2.1.6 Configuration Options

The application allows customization of default settings by uncommenting and modifying these variables:

```
// Default DHCP lease start address for AP mode
// extern const IPADDR4 configAP_LeaseStart(192, 168, 0, 2);

// Default IP address for AP mode
// extern const IPADDR4 configAP_IPAddr(192, 168, 0, 1);

// Custom SSID prefix for branding
// extern const NB::SSID_t default_SSID_Prefix = { 4, "FOO_" };
```

12.58.2.1.7 Usage Instructions

1. First Time Setup:

- Power on the NetBurner device
- Connect to the NB_XXXXXX access point
- Open a web browser and navigate to the device's IP address
- Select your WiFi network and enter credentials

2. Subsequent Startups:

- The device will automatically connect to the stored network
- If connection fails, it will revert to access point mode

3. Manual Configuration:

- Use serial commands for direct control
- Monitor connection status and network information

12.58.2.1.8 Development Notes

- The application uses SPI communication for WiFi operations
- Web server runs on default port 80
- System diagnostics are enabled (should be disabled for production)
- Configuration mirroring is enabled for debugging
- The application includes comprehensive error handling and status reporting

12.58.3 Wifi Firmware Update

12.58.3.1 WiFi Firmware Update Application

12.58.3.1.1 Overview

The NBWIFI-IN Firmware Update application is a C++ program designed to update the firmware on NetBurner WiFi modules. This application provides a simple interface to check current firmware information and perform firmware updates on compatible WiFi hardware.

12.58.3.1.2 Features

- **Firmware Information Display:** Shows current hardware and software revision numbers
- **Interactive Firmware Update:** User-prompted firmware update process
- **Network Stack Integration:** Built-in HTTP server and [DHCP](#) support
- **System Diagnostics:** Optional diagnostic capabilities for development
- **Error Handling:** Comprehensive error checking and status reporting

12.58.3.1.3 Application Flow

1. Initialization

- Initializes the network stack
- Enables system diagnostics
- Starts HTTP server on default port 80
- Waits for [DHCP](#) address assignment (5-second timeout)

2. WiFi Module Detection

- Attempts to initialize WiFi interface
- Sets SPI communication speed to 15 MHz
- Validates communication with WiFi module

3. Status Display

- Shows current hardware revision (major.minor)
- Shows current firmware revision (major.minor)

4. Firmware Update Process

- Waits for user input to begin update
- Performs firmware update using embedded firmware image
- Reports success or failure status
- Displays updated firmware information

12.58.3.1.4 Hardware Requirements

- NetBurner development board with WiFi capability
- Compatible WiFi module supporting firmware updates
- Proper SPI connections for WiFi communication

12.58.3.1.5 Key Components

12.58.3.1.5.1 WiFi Interface Management

- Automatic WiFi driver initialization
- SPI speed configuration (15 MHz)
- Module communication validation

12.58.3.1.5.2 Firmware Update Process

- Uses embedded firmware image (`nbWifiImage[]`)
- Validates image length (`nbWifiImageLen`)
- Provides real-time update status feedback

12.58.3.1.5.3 Network Services

- HTTP server for web-based management
- [DHCP](#) client for automatic IP configuration
- Network stack diagnostics

12.58.3.1.6 Error Handling

The application includes robust error handling:

- WiFi module communication failure detection
- Firmware update success/failure reporting
- Graceful degradation when WiFi module is unavailable

12.58.3.1.7 Usage

1. Compile and flash the application to your NetBurner device
2. Connect to the device via serial terminal
3. Wait for network initialization and WiFi module detection
4. Review the current firmware information displayed
5. Press any key when prompted to begin the firmware update
6. Wait for the update process to complete
7. Verify the new firmware information

12.58.3.1.8 Development Notes

- System diagnostics are enabled by default (consider disabling for production)
- The application runs an infinite loop after completion
- HTTP server remains active throughout the application lifecycle
- Serial output provides detailed status information

12.58.3.1.9 Troubleshooting

"Could not talk to Wifi module"**: Check physical connections, power supply, and ensure the WiFi module is properly seated and compatible.

Firmware update failure**: Verify the embedded firmware image is correct for your hardware revision and that the WiFi module supports firmware updates.

12.58.4 Wifi Access Point

12.58.4.1 WiFi Access Point Application

12.58.4.1.1 Overview

This application demonstrates how to configure a NetBurner device to operate as a WiFi Access Point (AP) with an integrated [DHCP](#) server. The application allows other devices to connect directly to the NetBurner module and automatically receive IP addresses.

12.58.4.1.2 Features

- WiFi Access Point mode operation
- Integrated **DHCP** server for automatic IP assignment
- Configurable network settings
- Client connection monitoring
- Serial interface for displaying connected clients

12.58.4.1.3 Default Configuration

The application uses the following default network settings:

- **Access Point SSID:** NetBurnerAP
- **Access Point Password:** password
- **WiFi Interface IP:** 192.168.3.1
- **Subnet Mask:** 255.255.255.0
- **DHCP Start Address:** 192.168.3.2
- **WiFi Channel:** 6 (802.11)

12.58.4.1.4 Network Setup

12.58.4.1.4.1 Recommended Configuration

For proper Access Point operation, configure your network settings as follows:

- WiFi Interface IP: 192.168.0.1 (or your preferred network)
- Subnet Mask: 255.255.255.0
- **DHCP** Start Address: 192.168.0.2

12.58.4.1.4.2 Configuration Methods

1. **IPSetup Tool:** Use the NetBurner IPSetup utility to configure:

- WiFi interface IP address and subnet mask
- SSID and password settings

2. **Code Modification:** Modify the default values in `main.cpp`:

```
IPADDR4 startAddr = AsciiToIp4("192.168.3.2"); // DHCP start address
IPADDR4 defaultWifiIPAddr = AsciiToIp4("192.168.3.1"); // AP IP address
```

12.58.4.1.5 How It Works

1. **Initialization:** The application initializes the system and waits for network activation
2. **WiFi AP Setup:** Configures the WiFi module in Access Point mode using SPI communication
3. **IP Configuration:** Sets up the WiFi interface with IP address and subnet mask
4. **DHCP Server:** Starts a **DHCP** server on the WiFi interface to assign IP addresses to connecting clients
5. **Monitoring:** Provides serial interface to display connected **DHCP** clients

12.58.4.1.6 Function Parameters

The `InitAP_SPI()` function accepts the following parameters:

- `SSID`: Network name (default from config if empty)
- `password`: Network password (8-64 characters, default from config if empty)
- `channel`: 802.11 channel (default: 6)
- `irqNum`: Interrupt number (default: 3)
- `moduleNum`: Module number (default: 1)
- `csNum`: Chip select number
- `connectorNum`: Connector number
- `gpioPinNum`: GPIO pin number
- `resetPinNum`: Reset pin number (default: 42)

12.58.4.1.7 Usage

1. **Compile and Deploy**: Build and flash the application to your NetBurner device
2. **Connect**: Use a WiFi-enabled device to connect to the NetBurnerAP network with password `password`
3. **Access**: The device will automatically receive an IP address via [DHCP](#)
4. **Monitor**: Press any key in the serial terminal to display connected clients
5. **Web Access**: Access the NetBurner web interface at the AP IP address (default: `192.168.3.1`)

12.58.4.1.8 Serial Interface

The application provides a simple serial interface:

- Press any key to display currently connected [DHCP](#) clients
- System diagnostics are enabled for debugging (should be disabled in production)

12.58.4.1.9 Error Handling

The application includes error handling for:

- WiFi initialization failures
- [DHCP](#) server startup failures
- Network configuration issues

If errors occur, the application will display error messages and enter an infinite loop for debugging.

12.58.4.1.10 Production Considerations

- **Security**: Change the default SSID and password before deployment
- **Diagnostics**: Disable `EnableSystemDiagnostics()` in production code
- **Network Planning**: Choose appropriate IP ranges that don't conflict with existing networks
- **Channel Selection**: Select an appropriate WiFi channel based on your environment

12.58.4.1.11 Troubleshooting

- **WiFi fails to initialize:** Check SPI connections and module configuration
- **DHCP server fails:** Verify IP configuration and ensure no conflicts
- **Clients can't connect:** Check SSID/password and WiFi channel settings
- **No IP assignment:** Verify **DHCP** start address is in the same subnet as the AP IP

12.58.5 Wifi Client

12.58.5.1 WiFi Client Application

12.58.5.1.1 Overview

This application demonstrates how to connect to a WiFi network using NetBurner's WiFi driver and access comprehensive status information about the connection. The application provides detailed monitoring capabilities for both Ethernet and WiFi network interfaces.

12.58.5.1.2 Features

- **WiFi Network Connection:** Automatically connects to a configured WiFi network using stored credentials
- **Network Scanning:** Scans and displays available WiFi networks
- **Status Monitoring:** Provides real-time status information including:
 - IP configuration (address, mask, gateway, DNS)
 - MAC addresses
 - Signal strength (RSSI)
 - Security protocols and cipher types
 - Connection status
 - Hardware and firmware versions
- **Interactive Interface:** Serial debug port menu for real-time status updates
- **Multi-Interface Support:** Displays both Ethernet and WiFi interface information

12.58.5.1.3 Hardware Compatibility

This application is designed for NetBurner platforms, with special considerations for:

- **5270 and 5234 processors:** Automatically enables spread spectrum mode to reduce radio interference
- **External Antenna Support:** Optimized for WiFi modules with external antennas

12.58.5.1.4 Security Protocols Supported

The application can identify and display the following security types:

- Open (no security)
- WEP
- WPA
- WPA2
- WPS

12.58.5.1.5 Cipher Support

Supported cipher types include:

- None
- TKIP
- AES
- Mixed (TKIP/AES)

12.58.5.1.6 Configuration

12.58.5.1.6.1 WiFi Credentials

The application uses stored configuration records for WiFi credentials:

- SSID and passphrase are loaded from the system configuration
- Total length of SSID and passphrase must not exceed 68 characters
- Credentials can be configured using IPSetup utility

12.58.5.1.6.2 SPI Interface Configuration

The WiFi module connects via SPI with the following default parameters:

- IRQ Number: 3
- Module Number: 1
- CS Number: Default
- Connector Number: Default
- GPIO Pin Number: Default
- Reset Pin Number: 42

12.58.5.1.7 Usage

1. **Startup:** The application automatically scans for available networks on startup
2. **Connection:** Attempts to connect using stored WiFi credentials
3. **Status Display:** Shows comprehensive network status information
4. **Interactive Mode:** Press any key to refresh and display current status

12.58.5.1.8 Output Information

12.58.5.1.8.1 Ethernet Interface

- IP Address, Subnet Mask, Gateway, DNS
- MAC Address

12.58.5.1.8.2 WiFi Interface

- Interface number and IP configuration
- SSID (Service Set Identifier) - network name
- BSSID (Basic Service Set Identifier) - Access Point MAC address
- Signal strength (RSSI)
- Channel information
- Security and cipher protocols
- Connection status
- Hardware and firmware revision information

12.58.5.1.9 Code Structure

12.58.5.1.9.1 Main Components

- **DisplaySecurity()**: Converts security protocol values to human-readable labels
- **DisplayCipher()**: Converts cipher type values to human-readable labels
- **DisplayWifiStatus()**: Comprehensive status information display
- **DisplayWifiConfigRecordParameters()**: Shows configured SSID and passphrase
- **UserMain()**: Primary application entry point and main loop

12.58.5.1.10 Troubleshooting

- If WiFi interface fails to initialize, check SPI connections and module power
- Ensure WiFi credentials are properly configured in system config records
- Verify antenna connections for optimal signal strength
- Check that the WiFi module is compatible with your NetBurner platform

12.58.6 Wifi Scan

12.58.6.1 WiFi Scan Application

12.58.6.1.1 Overview

This is a NetBurner WiFi scanning and management application that provides an interactive command-line interface for WiFi operations on embedded systems. The application demonstrates how to use the NetBurner WiFi driver to scan for access points, connect/disconnect from networks, and monitor connection status.

12.58.6.1.2 Features

- **WiFi Network Scanning**: Scan for available WiFi access points and display their details
- **Connection Management**: Connect to and disconnect from WiFi networks
- **Network Status Monitoring**: Display detailed WiFi and Ethernet interface information
- **Security Information**: Show security protocols (Open, WEP, WPA, WPA2, WPS) and cipher types
- **Interactive Menu System**: Serial command interface for real-time WiFi management
- **System Diagnostics**: Built-in diagnostic capabilities and system reset functions

12.58.6.1.3 Application Structure

12.58.6.1.3.1 Core Components

- **main.cpp**: Primary application file containing the WiFi management logic
- **ReadMe.txt**: Brief description indicating this is a WiFi scanning example

12.58.6.1.3.2 Key Functions

Network Scanning

- `DoSyncScan()`: Performs synchronous WiFi network scan and displays results
- `WifiInitScanAndShow_SPI()`: Initialize WiFi interface and perform initial scan

Status Display

- `DisplayWifiStatus()`: Shows comprehensive WiFi connection and interface information
- `DisplaySecurity()`: Converts security type codes to readable labels
- `DisplayCipher()`: Converts cipher type codes to readable labels
- `DisplayWifiConfigRecordParameters()`: Shows configured SSID and passphrase

Connection Management

- Connect/disconnect functionality through the NetBurner WiFi driver
- Interface number tracking and object management

12.58.6.1.4 Command Interface

The application provides an interactive serial menu with the following commands:

Command	Function
C	Connect to WiFi network
D	Disconnect from current WiFi network
S	Perform WiFi network scan
W	Display WiFi status and configuration
X	Reset WiFi module
Z	System reboot

12.58.6.1.5 Technical Details

12.58.6.1.5.1 Dependencies

- NetBurner HAL (Hardware Abstraction Layer)
- NetBurner WiFi driver libraries
- DSPI (Serial Peripheral Interface) support
- Standard C/C++ libraries

12.58.6.1.5.2 WiFi Security Support

- Open networks
- WEP encryption
- WPA/WPA2 security protocols
- WPS (WiFi Protected Setup)
- TKIP and AES cipher support

12.58.6.1.5.3 Network Information Displayed

- **Interface Details:** IP address, subnet mask, gateway, DNS servers
- **MAC Addresses:** Both Ethernet and WiFi interface MAC addresses
- **WiFi Specific:** SSID, BSSID, signal strength (RSSI), channel, security type
- **Device Information:** Hardware and firmware revision numbers

12.58.6.1.6 Usage

1. **Initialization:** The application automatically initializes the network stack and performs an initial WiFi scan on startup
2. **Web Server:** Starts an HTTP server on port 80 for additional functionality
3. **Interactive Control:** Use the serial interface to send commands for WiFi management
4. **Network Waiting:** Waits up to 5 seconds for [DHCP](#) address assignment

12.58.6.1.7 Configuration

The application reads WiFi configuration from stored settings including:

- Target SSID (network name)
- Passphrase/password
- Security settings

12.58.6.1.8 Error Handling

- Interface initialization validation
- Connection status verification
- Retry limit monitoring
- Graceful failure reporting

12.58.6.1.9 Notes

- The application is designed for development and testing purposes
- System diagnostics are enabled (should be disabled for production)
- Supports both Ethernet and WiFi interfaces simultaneously
- Uses C++ with NetBurner-specific namespaces and libraries

Deprecated List

Member [flexcan_clock_source_t](#)

Do not use the kFLEXCAN_ClkSrcOs. It has been superceded kFLEXCAN_ClkSrc0

Do not use the kFLEXCAN_ClkSrcPeri. It has been superceded kFLEXCAN_ClkSrc1

Member [flexcan_config_t](#)

Do not use the baudRate. It has been superceded bitRate

Do not use the baudRateFD. It has been superceded bitRateFD

Module [groupFtpServerCallback](#)

For NetBurner customers porting from the 2.x tools to 3.x: FTP_FAIL and FTP_OK were deprecated on Jan 16, 2008. These defines were removed and all server functions (denoted as FTPD) were modified to use FTPD_OK and FTPD_FAIL. This was necessary so that the FTP client and server header files could be used at the same time. If you have any errors in your application code, you can safely change all server functions from FTP_OK/FAIL to FTPD_OK/FAIL.

Chapter 14

NetBurner API

14.1 AES - Advanced Encryption Standard

Classes

- struct `aes_context`
AES context structure.

Functions

- void `aes_set_key` (`aes_context` *ctx, const unsigned char *key, int keysize)
AES key schedule.
- void `aes_encrypt` (`aes_context` *ctx, unsigned char input[16], unsigned char output[16])
AES block encryption (ECB mode)
- void `aes_decrypt` (`aes_context` *ctx, unsigned char input[16], unsigned char output[16])
AES block decryption (ECB mode)
- void `aes_cbc_encrypt` (`aes_context` *ctx, unsigned char iv[16], unsigned char *input, unsigned char *output, int len)
AES-CBC buffer encryption.
- void `aes_cbc_decrypt` (`aes_context` *ctx, unsigned char iv[16], unsigned char *input, unsigned char *output, int len)
AES-CBC buffer decryption.
- int `aes_self_test` (int verbose)
Checkup routine.

14.1.1 Detailed Description

```
#include< aes.h>
```

Function to implement the symmetric block cyper AES

14.1.2 Function Documentation

14.1.2.1 `aes_cbc_decrypt()`

```
void aes_cbc_decrypt (
    aes_context * ctx,
    unsigned char iv[16],
    unsigned char * input,
    unsigned char * output,
    int len)
#include <aes.h>
```

AES-CBC buffer decryption.

Parameters

<i>ctx</i>	AES context
<i>iv</i>	initialization vector (modified after use)
<i>input</i>	buffer holding the ciphertext
<i>output</i>	buffer holding the plaintext
<i>len</i>	length of the data to be decrypted

14.1.2.2 aes_cbc_encrypt()

```
void aes_cbc_encrypt (  
    aes_context * ctx,  
    unsigned char iv[16],  
    unsigned char * input,  
    unsigned char * output,  
    int len)
```

```
#include <aes.h>
```

AES-CBC buffer encryption.

Parameters

<i>ctx</i>	AES context
<i>iv</i>	initialization vector (modified after use)
<i>input</i>	buffer holding the plaintext
<i>output</i>	buffer holding the ciphertext
<i>len</i>	length of the data to be encrypted

14.1.2.3 aes_decrypt()

```
void aes_decrypt (  
    aes_context * ctx,  
    unsigned char input[16],  
    unsigned char output[16])
```

```
#include <aes.h>
```

AES block decryption (ECB mode)

Parameters

<i>ctx</i>	AES context
<i>input</i>	ciphertext block
<i>output</i>	plaintext block

14.1.2.4 aes_encrypt()

```
void aes_encrypt (  
    aes_context * ctx,  
    unsigned char input[16],  
    unsigned char output[16])
```

```
#include <aes.h>
```

AES block encryption (ECB mode)

Parameters

<i>ctx</i>	AES context

Parameters

<i>input</i>	plaintext block
<i>output</i>	ciphertext block

14.1.2.5 aes_self_test()

```
int aes_self_test (
    int verbose)
#include <aes.h>
Checkup routine.
```

Returns

0 if successful, or 1 if the test failed

14.1.2.6 aes_set_key()

```
void aes_set_key (
    aes_context * ctx,
    const unsigned char * key,
    int keysize)
#include <aes.h>
AES key schedule.
```

Parameters

<i>ctx</i>	AES context to be initialized
<i>key</i>	the secret key
<i>keysizes</i>	must be 128, 192 or 256

14.2 ARP - Address Resolution Protocol

Address Resolution Protocol implementation and cache management.

Classes

- struct [ARP](#)
Address Resolution Protocol packet structure.

Typedefs

- typedef [ARP](#) * [PARP](#)
Pointer to [ARP](#) packet structure.

Functions

- void [ShowArp](#) ()
Display the current [ARP](#) cache contents to the standard output.
- void [fShowArp](#) (FILE *fp)
Display the current [ARP](#) cache contents to a specified file stream.
- BOOL [GetArpMacFromIp](#) ([IPADDR4](#) ip, [MACADR](#) &ma)
Check if an IP address is in the [ARP](#) cache and retrieve its MAC address.
- void [sendGratuitousArp](#) (int interfaceNumber, [IPADDR4](#) ip)

- Send a Gratuitous [ARP](#) to announce interface presence and IP address.*

 - **BOOL [IsMyAddressUsedArpDetect](#)** (uint16_t timeout, int interface=0)

Detect if the interface's IP address is already in use on the network.
- **int [GetProperInterface4](#)** (IPADDR4 dst)

Get the appropriate network interface for routing to a destination IP.
- **void [processArp](#)** (PoolPtr p, PEFRAME pf)

Process incoming [ARP](#) packets (internal use only)
- **void [AddCheckArp](#)** (MACADR *ma, IPADDR4 ip, int ifnum)

Add or update [ARP](#) cache entry (internal use only)
- **void [DeleteArpFromIp](#)** (IPADDR4 ip)

Delete [ARP](#) cache entry by IP address (internal use only)
- **void [RouteOut](#)** (PEFRAME pf, IPADDR4 ip, PoolPtr p)

Route packet to destination (internal use only)
- **void [RouteOutVia](#)** (PEFRAME pf, IPADDR4 ipfrom, IPADDR4 ipto, PoolPtr p, int intf)

Route packet via specific interface (internal use only)
- **void [AgeArp](#)** ()

Age out old [ARP](#) cache entries (internal use only)
- **void [AddStaticArp](#)** (MACADR *ma, IPADDR4 ip, int ifnum)

Add static [ARP](#) entry (internal use only)
- **void [InitializeArp](#)** ()

Initialize [ARP](#) subsystem (internal use only)

Variables

- **beuint16_t [ARP::hard_Type](#)**
- Hardware type (1 for Ethernet)*
- **beuint16_t [ARP::prot_Type](#)**
- Protocol type (0x0800 for IPv4)*
- **uint8_t [ARP::hard_size](#)**
- Hardware address length (6 for MAC)*
- **uint8_t [ARP::prot_size](#)**
- Protocol address length (4 for IPv4)*
- **beuint16_t [ARP::op_code](#)**
- Operation: 1=Request, 2=Reply.*
- **MACADR [ARP::sender_phy](#)**
- Sender MAC address.*
- **IPADDR4 [ARP::sender_ip](#)**
- Sender IP address.*
- **MACADR [ARP::target_phy](#)**
- Target MAC address.*
- **IPADDR4 [ARP::target_ip](#)**
- Target IP address.*

14.2.1 Detailed Description

Address Resolution Protocol implementation and cache management.

```
#include< arp.h>
```

The Address Resolution Protocol ([ARP](#)) is a fundamental network protocol that maps Internet Protocol (IP) addresses to physical Media Access Control (MAC) addresses on local Ethernet networks. [ARP](#) enables devices to discover the hardware address of another device on the same network segment when only the IP address is known.

14.2.2 How ARP Works

When a device needs to communicate with another device on the local network:

1. **Cache Check:** First checks local [ARP](#) cache for existing IP-to-MAC mapping
2. **ARP Request:** If not found, broadcasts an [ARP](#) request to all devices
3. **ARP Reply:** Target device responds with its MAC address
4. **Cache Update:** Mapping is stored in local [ARP](#) cache for future use
5. **Communication:** Original packet is sent using the resolved MAC address

14.2.3 ARP Cache Management

NetBurner maintains an [ARP](#) cache that stores recently resolved IP-to-MAC address mappings. This cache:

- Reduces network traffic by avoiding repeated [ARP](#) requests
- Ages out entries after a timeout period
- Can be queried programmatically
- Supports static entries for critical devices

14.2.4 Function Categories

Function	Purpose	Use Case
ShowArp()	Display cache	Debugging, diagnostics
GetArpMacFromIp()	Query cache	Check if address is resolved
sendGratuitousArp()	Announce presence	After IP change or boot
IsMyAddressUsedArpDetect()	Detect conflicts	IP conflict detection

14.2.5 Example Usage

14.2.5.1 Querying the ARP Cache

```
#include <arp.h>

void checkDevicePresence(IPADDR4 deviceIP) {
    MACADDR mac;

    if (GetArpMacFromIp(deviceIP, mac)) {
        iprintf("Device found: ");
        iprintf("%02X:%02X:%02X:%02X:%02X:%02X\n",
            mac.ma[0], mac.ma[1], mac.ma[2],
            mac.ma[3], mac.ma[4], mac.ma[5]);
    } else {
        iprintf("Device not in ARP cache\n");
        // Optionally send a ping to trigger ARP resolution
    }
}
```

14.2.5.2 Displaying ARP Cache Contents

```
#include <arp.h>

void displayNetworkStatus() {
    iprintf("=== Current ARP Cache ===\n");
    ShowArp(); // Outputs to stdio serial port
    iprintf("=====\n");
}

void logArpToFile() {
    FILE *fp = fopen("arp.log", "a");
    if (fp != NULL) {
        fShowArp(fp); // Write to file
        fclose(fp);
    }
}
```

14.2.5.3 Sending Gratuitous ARP

```
#include <arp.h>
#include <netinterface.h>

void announceNewIPAddress(int interface, IPADDR4 newIP) {
    // Update interface IP address
    InterfaceBlock *ib = GetInterfaceBlock(interface);
    ib->ip4.cur_addr = newIP;

    // Announce new address to network
    sendGratuitousArp(interface, newIP);

    iprintf("Gratuitous ARP sent for new IP\n");
}

void UserMain(void *pd) {
    init();

    // Send gratuitous ARP after initialization
    IPADDR4 myIP = AsciiToIp4("192.168.1.100");
    sendGratuitousArp(GetFirstInterface(), myIP);

    // Rest of application...
}
```

14.2.5.4 IP Address Conflict Detection

```
#include <arp.h>

void checkIPConflict(int interface) {
    // Check if our IP is already in use (2 second timeout)
    if (IsMyAddressUsedArpDetect(2, interface)) {
        iprintf("ERROR: IP address conflict detected!\n");
        iprintf("Another device is using this IP address.\n");
        // Handle conflict (change IP, alert user, etc.)
    } else {
        iprintf("No IP conflict detected - address is available\n");
    }
}

void UserMain(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Check for IP conflicts after network initialization
    checkIPConflict(GetFirstInterface());

    // Continue with application...
}
```

14.2.5.5 Network Device Monitoring

```
#include <arp.h>
#include <icmp.h>

bool isDeviceReachable(IPADDR4 deviceIP) {
    MACADDR mac;

    // First check ARP cache
    if (GetArpMacFromIp(deviceIP, mac)) {
        return true; // Recently communicated with device
    }

    // Not in cache - send ping to trigger ARP
    Ping4(deviceIP, 1, 1); // 1 packet, 1 second timeout
    OSTimeDly(TICKS_PER_SECOND / 2); // Wait for ARP response

    // Check cache again
    return GetArpMacFromIp(deviceIP, mac);
}

void monitorCriticalDevices() {
    IPADDR4 plc = AsciiToIp4("192.168.1.50");
    IPADDR4 gateway = AsciiToIp4("192.168.1.1");

    if (!isDeviceReachable(plc)) {
        iprintf("WARNING: PLC not reachable!\n");
    }

    if (!isDeviceReachable(gateway)) {
        iprintf("WARNING: Gateway not reachable!\n");
    }
}
```

14.2.6 Best Practices

1. **Cache Checking:** Always check [GetArpMacFromIp\(\)](#) return value
2. **Gratuitous ARP:** Send after IP changes to update network caches
3. **Conflict Detection:** Use [IsMyAddressUsedArpDetect\(\)](#) during startup
4. **Triggering Resolution:** Send ping to force [ARP](#) resolution if needed
5. **Cache Monitoring:** Use [ShowArp\(\)](#) for debugging network issues

14.2.7 Troubleshooting

Device Not in Cache:

- Device may be offline or unreachable
- No recent communication with device
- Send ping or UDP packet to trigger [ARP](#) resolution

IP Address Conflict:

- Use [IsMyAddressUsedArpDetect\(\)](#) to verify
- Check for [DHCP](#) server issues
- Verify static IP configurations

Stale Cache Entries:

- Entries age out automatically
- Power cycle or reset may be needed for recovery
- Use gratuitous [ARP](#) to update remote caches

14.2.8 Important Notes

Note

[GetArpMacFromIp\(\)](#) only checks the cache - it does not send [ARP](#) requests. To force [ARP](#) resolution, send a ping or packet to the target first.

Gratuitous [ARP](#) should be sent whenever an interface IP address changes or during system initialization to ensure network-wide cache consistency.

[ARP](#) only works on the local network segment. Devices on different subnets require routing through a gateway.

Warning

IP address conflicts can cause serious network communication issues. Always use [IsMyAddressUsedArpDetect\(\)](#) when configuring static IPs.

The [ARP](#) cache has limited size. Entries are aged out over time to make room for new entries.

14.2.9 Protocol Specifications

- **RFC 826:** Address Resolution Protocol ([ARP](#)) specification
- **RFC 5227:** IPv4 Address Conflict Detection (ACD)
- **RFC 3927:** Dynamic Configuration of IPv4 Link-Local Addresses

See also

[groupICMP](#) For ICMP/Ping functionality

[groupNetInterface](#) For network interface management

[groupIPv4](#) For IPv4 address handling

14.2.10 Typedef Documentation

14.2.10.1 PARP

```
typedef ARP* PARP
```

```
#include <arp.h>
```

Pointer to [ARP](#) packet structure.

Convenience typedef for pointer to [ARP](#) structure. Used throughout the NetBurner stack for packet processing.

14.2.11 Function Documentation

14.2.11.1 fShowArp()

```
void fShowArp (
```

```
    FILE * fp)
```

```
#include <arp.h>
```

Display the current [ARP](#) cache contents to a specified file stream.

Similar to [ShowArp\(\)](#) but outputs to a specified FILE pointer instead of the standard output. This allows [ARP](#) cache contents to be written to:

- Log files on SD card or file system
- Network sockets
- Serial ports via fdopen()
- Any other FILE stream destination

Parameters

<i>fp</i>	Pointer to FILE stream for output. Must be a valid, open FILE pointer (from fopen(), fdopen(), etc.)

Precondition

fp must be a valid, open FILE pointer with write access

Postcondition

[ARP](#) cache contents are written to the specified FILE stream

Note

The FILE pointer must remain valid for the duration of the call

Does not close the FILE pointer - caller is responsible for fclose()

Output format is identical to [ShowArp\(\)](#)

Example: Logging to SD Card

```
#include <arp.h>

void logArpCache() {
    FILE *fp = fopen("SD:/arp_cache.log", "a");
    if (fp != NULL) {
        fprintf(fp, "\n=== ARP Cache at %lu seconds ===\n", Secs);
        fShowArp(fp);
        fprintf(fp, "=====\n");
        fclose(fp);
    } else {
        iprintf("ERROR: Could not open log file\n");
    }
}
```

Example: Sending via Network Socket

```

void sendArpCacheToClient(int clientFd) {
    FILE *fp = fdopen(clientFd, "w");
    if (fp != NULL) {
        fprintf(fp, "Current ARP Cache:\r\n");
        fprintf(fp, "=====\r\n");
        fShowArp(fp);
        fflush(fp);
        // Note: Don't fclose(fp) as it would close the socket
    }
}

```

Example: Multiple Output Destinations

```

void reportArpCache() {
    // Output to serial
    ShowArp();

    // Also log to file
    FILE *fp = fopen("SD:/network.log", "a");
    if (fp) {
        fShowArp(fp);
        fclose(fp);
    }

    // Also send to remote server
    int serverFd = connect4(serverIP, serverPort, 0);
    if (serverFd > 0) {
        FILE *netfp = fdopen(serverFd, "w");
        fShowArp(netfp);
        fflush(netfp);
        fclose(serverFd);
    }
}

```

Example: Custom Formatting Wrapper

```

void formattedArpReport(FILE *fp) {
    time_t now = time(NULL);
    fprintf(fp, "\n");
    fprintf(fp, "┌ ARP CACHE REPORT ────────────┐\n");
    fprintf(fp, "│ %s, ctime(&now); │\n");
    fprintf(fp, "└───────────────────────────┘\n");
    fShowArp(fp);
    fprintf(fp, "\n");
}

```

See also

[ShowArp\(\)](#) For output to standard stdio

[GetArpMacFromIp\(\)](#) To query specific [ARP](#) entries

14.2.11.2 GetArpMacFromIp()

```

BOOL GetArpMacFromIp (
    IPADDR4 ip,
    MACADDR & ma)
#include <arp.h>

```

Check if an IP address is in the [ARP](#) cache and retrieve its MAC address.

Queries the local [ARP](#) cache to determine if a mapping exists for the specified IP address. If found, the corresponding MAC address is returned via the reference parameter.

This function ONLY checks the cache - it does not send [ARP](#) requests over the network. If the entry is not in the cache, you may need to send a packet (such as a ping) to the target IP to trigger [ARP](#) resolution first.

Parameters

	<i>ip</i>	IP address to look up in the ARP cache
out	<i>ma</i>	Reference to MACADDR structure that will receive the MAC address if found. Only modified if the function returns TRUE.

Returns

TRUE if the IP address was found in the cache and MAC address retrieved

FALSE if the IP address is not in the cache

Precondition

ip must be a valid IPv4 address

Postcondition

If TRUE is returned, ma contains the resolved MAC address

If FALSE is returned, ma is unmodified

Note

This function does NOT send [ARP](#) requests - it only checks the cache

To force [ARP](#) resolution, send a ping or packet to the target first

Cache entries age out over time - a FALSE result doesn't mean the device is offline, just that it's not in the current cache

Example: Basic Cache Query

```
#include <arp.h>

void checkDevice(IPADDR4 deviceIP) {
    MACADR mac;

    if (GetArpMacFromIp(deviceIP, mac)) {
        iprintf("Device MAC: %02X:%02X:%02X:%02X:%02X\n",
            mac.ma[0], mac.ma[1], mac.ma[2],
            mac.ma[3], mac.ma[4], mac.ma[5]);
    } else {
        iprintf("Device not in ARP cache\n");
    }
}
```

Example: Forcing ARP Resolution

```
#include <arp.h>
#include <icmp.h>

bool getDeviceMAC(IPADDR4 ip, MACADR &mac) {
    // First check if already in cache
    if (GetArpMacFromIp(ip, mac)) {
        return true;
    }

    // Not in cache - send ping to trigger ARP
    iprintf("Resolving MAC for ");
    ShowIP(ip);
    iprintf("...\n");

    Ping4(ip, 1, 2); // 1 ping, 2 second timeout

    // Wait briefly for ARP resolution
    OSTimeDly(TICKS_PER_SECOND / 2);

    // Check cache again
    if (GetArpMacFromIp(ip, mac)) {
        iprintf("MAC resolved successfully\n");
        return true;
    }

    iprintf("Failed to resolve MAC - device may be offline\n");
    return false;
}
```

Example: Device Presence Detection

```

bool isDevicePresent(IPADDR4 ip) {
    MACADDR mac;
    return GetArpMacFromIp(ip, mac); // True if recently active
}

void monitorDevices() {
    IPADDR4 plc = AsciiToIp4("192.168.1.50");
    IPADDR4 hmi = AsciiToIp4("192.168.1.51");

    while (1) {
        if (!isDevicePresent(plc)) {
            iprintf("WARNING: PLC not responding\n");
        }
        if (!isDevicePresent(hmi)) {
            iprintf("WARNING: HMI not responding\n");
        }
        OSTimeDly(TICKS_PER_SECOND * 10);
    }
}

```

Example: MAC Address Filtering

```

bool isAuthorizedMAC(const MACADDR &mac) {
    // List of authorized MAC addresses
    static const MACADDR authorized[] = {
        {{0x00, 0x11, 0x22, 0x33, 0x44, 0x55}},
        {{0xAA, 0xBB, 0xCC, 0xDD, 0xEE, 0xFF}}
    };

    for (size_t i = 0; i < sizeof(authorized)/sizeof(authorized[0]); i++) {
        if (memcmp(&mac, &authorized[i], sizeof(MACADDR)) == 0) {
            return true;
        }
    }
    return false;
}

bool allowConnection(IPADDR4 clientIP) {
    MACADDR mac;

    if (GetArpMacFromIp(clientIP, mac)) {
        return isAuthorizedMAC(mac);
    }

    return false; // Not in cache - deny
}

```

See also

[ShowArp\(\)](#) To display all cached entries

[sendGratuitousArp\(\)](#) To announce device presence

[Ping4\(\)](#) To trigger [ARP](#) resolution

14.2.11.3 GetProperInterface4()

```

int GetProperInterface4 (
    IPADDR4 dst)
#include <arp.h>

```

Get the appropriate network interface for routing to a destination IP.

Determines which network interface should be used to reach a specific IPv4 destination address based on routing table and interface configuration.

Parameters

<i>dst</i>	Destination IPv4 address to route to

Returns

Interface number to use for routing to *dst*, or -1 if no route available

Note

This is primarily for internal stack use
Consider using [GetInterfaceBlock\(\)](#) for interface queries

14.2.11.4 IsMyAddressUsedArpDetect()

```
BOOL IsMyAddressUsedArpDetect (
    uint16_t timeout,
    int interface = 0)
#include <arp.h>
```

Detect if the interface's IP address is already in use on the network.

Performs ARP-based IP address conflict detection by sending [ARP](#) probes and listening for replies. This is used to detect if another device on the network is already using the interface's configured IP address.

This function is critical for:

- Validating static IP configurations
- Detecting duplicate IPs during startup
- Implementing IPv4 Link-Local addressing (169.254.x.x)
- Preventing IP conflicts in dynamic reconfiguration

Parameters

<i>timeout</i>	Maximum time to wait for replies, in seconds. Typical values are 1-5 seconds. Longer timeouts provide more reliable detection but delay startup.
<i>interface</i>	Network interface number to check (default = 0 for primary interface). Use GetFirstInterface() for the default interface.

Returns

TRUE if another device is already using this IP address (conflict detected)
FALSE if the IP address is available (no conflict)

Precondition

The interface must be initialized with a valid IP address
The network interface must be physically active (link up)

Postcondition

Function blocks for up to timeout seconds while probing

Note

This function blocks for the specified timeout period
Multiple [ARP](#) probes may be sent during the detection period
FALSE does not guarantee the IP is permanently available - conflicts can occur after this check completes

Warning

This function can take several seconds to complete. Do not call from time-critical code or ISRs.
A return value of FALSE does not prevent future conflicts. Another device may start using the IP after this check.

Example: Startup IP Conflict Check

```

#include <arp.h>

void UserMain(void *pd) {
    init();

    // Wait for network link
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Check for IP conflict (2 second timeout)
    iprintf("Checking for IP address conflicts...\n");

    if (IsMyAddressUsedArpDetect(2, GetFirstInterface())) {
        iprintf("ERROR: IP address conflict detected!\n");
        iprintf("Another device is using this IP address.\n");
        iprintf("Please reconfigure the IP address.\n");

        // Optionally change to different IP or halt
        while (1) {
            OSTimeDly(TICKS_PER_SECOND);
        }
    } else {
        iprintf("No IP conflict - address is available\n");
    }

    // Continue with application...
}

```

Example: Auto-Recovery from Conflict

```

bool findAvailableIP(int interface, IPADDR4 baseIP) {
    // Try up to 10 different IP addresses
    for (int offset = 0; offset < 10; offset++) {
        IPADDR4 testIP = baseIP + offset;

        // Temporarily configure this IP
        InterfaceBlock *ib = GetInterfaceBlock(interface);
        IPADDR4 oldIP = ib->ip4.cur_addr;
        ib->ip4.cur_addr = testIP;

        iprintf("Testing ");
        ShowIP(testIP);
        iprintf("...\n");

        // Check if available (1 second timeout for speed)
        if (!IsMyAddressUsedArpDetect(1, interface)) {
            iprintf("Available IP found: ");
            ShowIP(testIP);
            iprintf("\n");
            sendGratuitousArp(interface, testIP);
            return true;
        }

        // Restore old IP for next test
        ib->ip4.cur_addr = oldIP;
    }

    return false; // No available IP found
}

```

Example: Link-Local IP Assignment

```

#include <arp.h>
#include <stdlib.h>

IPADDR4 assignLinkLocalIP(int interface) {
    // Link-local range: 169.254.1.0 - 169.254.254.255
    IPADDR4 baseIP = AsciiToIp4("169.254.1.0");

    // Generate random host portion
    srand(Secs);

    for (int attempts = 0; attempts < 100; attempts++) {
        // Random address in link-local range
        int hostBits = (rand() % 254) + 1; // 1-254
        IPADDR4 testIP = baseIP + hostBits;

        // Configure interface
        InterfaceBlock *ib = GetInterfaceBlock(interface);
        ib->ip4.cur_addr = testIP;
        ib->ip4.cur_mask = AsciiToIp4("255.255.0.0");

        // Test for conflicts (2 second timeout)
        if (!IsMyAddressUsedArpDetect(2, interface)) {

```

```

        // No conflict - announce and return
        sendGratuitousArp(interface, testIP);
        return testIP;
    }

    // Conflict detected - try another address
    iprintf("Conflict on ");
    ShowIP(testIP);
    iprintf(" - trying another...\n");
}

return 0; // Failed to find available address
}

```

Example: Configuration Validation

```

bool validateStaticIPConfig(const char *ipStr) {
    IPADDR4 newIP = AsciiToIp4(ipStr);
    int iface = GetFirstInterface();

    // Temporarily set the new IP
    InterfaceBlock *ib = GetInterfaceBlock(iface);
    IPADDR4 oldIP = ib->ip4.cur_addr;
    ib->ip4.cur_addr = newIP;

    iprintf("Validating IP configuration: %s\n", ipStr);

    // Check for conflicts
    bool conflict = IsMyAddressUsedArpDetect(3, iface);

    if (conflict) {
        iprintf("ERROR: IP %s is already in use!\n", ipStr);
        // Restore old IP
        ib->ip4.cur_addr = oldIP;
        return false;
    } else {
        iprintf("IP %s is available\n", ipStr);
        // Keep new IP and announce it
        sendGratuitousArp(iface, newIP);
        return true;
    }
}

```

[InterfaceIP4\(\)](#) To get interface IP address

14.2.11.5 sendGratuitousArp()

```

void sendGratuitousArp (
    int interfaceNumber,
    IPADDR4 ip)
#include <arp.h>

```

Send a Gratuitous [ARP](#) to announce interface presence and IP address.

Sends a gratuitous [ARP](#) request/reply to inform all devices on the local network about this interface's IP-to-MAC address mapping. This updates the [ARP](#) caches of all devices on the network segment.

Gratuitous [ARP](#) should be sent whenever:

- The system boots up or an interface is initialized
- An IP address is changed or reconfigured
- Taking over an IP from another device (failover)
- After detecting and resolving an IP address conflict

Parameters

<i>interfaceNumber</i>	Network interface number (0 for primary interface, use GetFirstInterface() for the default interface)
<i>ip</i>	IP address to announce. Should be the interface's currently configured IP address. Must be a valid, non-zero IP address.

Precondition

The interface must be initialized and have a valid IP address
 interfaceNumber must be a valid interface number

Postcondition

Gratuitous [ARP](#) is broadcast on the specified interface
 Other devices on the network will update their [ARP](#) caches

Note

This is a broadcast - all devices on the network segment will receive and process the announcement
 It may take a few milliseconds for other devices to update their caches after receiving the gratuitous [ARP](#)

Warning

Do not send gratuitous [ARP](#) before the interface has a valid IP address - this will send an invalid announcement
 Excessive gratuitous [ARP](#) sending can cause unnecessary network traffic. Only send when needed, not continuously.

Example: Startup Announcement

```
#include <arp.h>
#include <netinterface.h>

void UserMain(void *pd) {
    init();

    // Wait for network to be active
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Announce our presence to the network
    int iface = GetFirstInterface();
    IPADDR4 myIP = InterfaceIP4(iface);
    sendGratuitousArp(iface, myIP);

    iprintf("Sent gratuitous ARP for ");
    ShowIP(myIP);
    iprintf("\n");

    // Continue with application...
}
```

Example: IP Address Change

```
#include <arp.h>
#include <netinterface.h>

void changeIPAddress(IPADDR4 newIP) {
    int iface = GetFirstInterface();

    // Update the interface IP
    InterfaceBlock *ib = GetInterfaceBlock(iface);
    ib->ip4.cur_addr = newIP;
    ib->ip4.cur_mask = AsciiToIp4("255.255.255.0");

    iprintf("IP address changed to ");
    ShowIP(newIP);
    iprintf("\n");

    // Announce new IP to network
    sendGratuitousArp(iface, newIP);

    iprintf("Gratuitous ARP sent - network caches updated\n");
}
```

Example: Failover Scenario

```

void takeOverBackupIP(IPADDR4 backupIP) {
    int iface = GetFirstInterface();

    iprintf("Taking over backup IP ");
    ShowIP(backupIP);
    iprintf("...\n");

    // Configure our interface with the backup IP
    InterfaceBlock *ib = GetInterfaceBlock(iface);
    ib->ip4.cur_addr = backupIP;

    // Immediately announce ownership of this IP
    sendGratuitousArp(iface, backupIP);

    // Send multiple times for reliability
    for (int i = 0; i < 3; i++) {
        OSTimeDly(TICKS_PER_SECOND / 10);
        sendGratuitousArp(iface, backupIP);
    }

    iprintf("Failover complete - now responding on backup IP\n");
}

```

Example: Post-Conflict Resolution

```

void resolveIPConflict() {
    int iface = GetFirstInterface();
    IPADDR4 currentIP = InterfaceIP4(iface);

    // Detected conflict - change to different IP
    IPADDR4 newIP = AsciiToIp4("192.168.1.101");

    InterfaceBlock *ib = GetInterfaceBlock(iface);
    ib->ip4.cur_addr = newIP;

    iprintf("IP conflict resolved - changed to ");
    ShowIP(newIP);
    iprintf("\n");

    // Announce new IP to network
    sendGratuitousArp(iface, newIP);
}

```

Example: Multi-Interface System

```

void announceAllInterfaces() {
    int numInterfaces = GetNumInterfaces();

    for (int i = 0; i < numInterfaces; i++) {
        IPADDR4 ifaceIP = InterfaceIP4(i);
        if (ifaceIP != 0) { // Valid IP configured
            sendGratuitousArp(i, ifaceIP);
            iprintf("Interface %d announced\n", i);
        }
    }
}

```

[GetArpMacFromIp\(\)](#) To query ARP cache

[InterfaceIP4\(\)](#) To get interface IP address

14.2.11.6 ShowArp()

```

void ShowArp ()
#include <arp.h>

```

Display the current [ARP](#) cache contents to the standard output.

Displays all entries in the [ARP](#) cache to the stdio serial port (typically the debug serial port). Each entry shows the IP address, MAC address, interface number, and entry status.

This function is useful for debugging network connectivity issues, verifying [ARP](#) resolution, and monitoring which devices are in the cache.

Postcondition

ARP cache contents are written to stdio serial port

Note

Output format includes IP address, MAC address, interface, and flags

Output goes to the default stdio serial port (cannot be redirected)

For file or socket output, use [fShowArp\(\)](#) instead

Output Format Example:

IP Address	MAC Address	Iface	Flags
192.168.1.1	00:11:22:33:44:55	0	P
192.168.1.100	AA:BB:CC:DD:EE:FF	0	
192.168.1.50	12:34:56:78:9A:BC	0	S

Where flags may be:

- P: Permanent entry
- S: Static entry
- (blank): Dynamic entry

Example: Basic Debugging

```
void displayNetworkInfo() {
    iprintf("\n== Network ARP Cache ==\n");
    ShowArp();
    iprintf("=====\n\n");
}
```

Example: Periodic Cache Display

```
void monitorArpCache(void *pd) {
    while (1) {
        OSTimeDly(TICKS_PER_SECOND * 30); // Every 30 seconds
        iprintf("\n--- ARP Cache Update ---\n");
        ShowArp();
    }
}

void UserMain(void *pd) {
    init();
    OSSimpleTaskCreateName(monitorArpCache, MAIN_PRIO - 1, "ArpMonitor");
    // ...
}
```

Example: Troubleshooting Connectivity

```
void troubleshootConnection(IPADDR4 targetIP) {
    iprintf("Checking connection to ");
    ShowIP(targetIP);
    iprintf("\n");

    // Display current ARP cache
    ShowArp();

    // Try to ping device
    iprintf("\nSending ping...\n");
    Ping4(targetIP, 3, 2);

    // Display updated cache
    iprintf("\nUpdated ARP cache:\n");
    ShowArp();
}
```

14.2.12 Variable Documentation

14.2.12.1 hard_size

`uint8_t ARP::hard_size`

Hardware address length (6 for MAC)

Hardware address length (HLEN). For Ethernet (MAC) this is 6 bytes.

14.2.12.2 hard_Type

`beuint16_t ARP::hard_Type`

Hardware type (1 for Ethernet)

Hardware type (HTYPE). For Ethernet this is 1. Network byte order (big-endian).

14.2.12.3 op_code

`beuint16_t ARP::op_code`

Operation: 1=Request, 2=Reply.

Operation code. Network byte order (big-endian).

- 1 = [ARP](#) Request
- 2 = [ARP](#) Reply
- 3 = RARP Request
- 4 = RARP Reply

14.2.12.4 prot_size

`uint8_t ARP::prot_size`

Protocol address length (4 for IPv4)

Protocol address length (PLEN). For IPv4 this is 4 bytes.

14.2.12.5 prot_Type

`beuint16_t ARP::prot_Type`

Protocol type (0x0800 for IPv4)

Protocol type (PTYPE). For IPv4 this is 0x0800. Network byte order (big-endian).

14.2.12.6 sender_ip

`IPADDR4 ARP::sender_ip`

Sender IP address.

Sender protocol (IP) address. The IPv4 address of the device sending this [ARP](#) packet.

14.2.12.7 sender_phy

`MACADR ARP::sender_phy`

Sender MAC address.

Sender hardware (MAC) address. The MAC address of the device sending this [ARP](#) packet.

14.2.12.8 target_ip

`IPADDR4 ARP::target_ip`

Target IP address.

Target protocol (IP) address. The IPv4 address being queried (in requests) or resolved (in replies).

Note

This structure is packed to match exact network packet format

All multi-byte fields use network byte order (big-endian)

Do not change structure without careful consideration of network compatibility

Warning

Structure changes will break network protocol compatibility

Always add new fields at the end to maintain compatibility

Typical ARP Request Packet:

```

ARP request;
request.hard_Type = htons(1);           // Ethernet
request.prot_Type = htons(0x0800);      // IPv4
request.hard_size = 6;                  // MAC address length
request.prot_size = 4;                  // IPv4 address length
request.op_code = htons(1);             // ARP Request
// sender_phy = our MAC
// sender_ip = our IP
// target_phy = 00:00:00:00:00:00 (unknown)
// target_ip = IP we're looking for

```

See also

RFC 826 - Address Resolution Protocol specification

14.2.12.9 target_phy

`MACADDR ARP::target_phy`

Target MAC address.

Target hardware (MAC) address. In [ARP](#) requests this is typically all zeros. In replies, this contains the requested MAC address.

14.3 AT Commands

Functions for serial modem AT commands.

Macros

- `#define AT_COMMAND_REASON_START_AT (1)`
`AT_COMMAND_REASON_START_AT.`
- `#define AT_COMMAND_REASON_EXIT_AT (2)`
`AT_COMMAND_REASON_EXIT_AT.`
- `#define AT_COMMAND_REASON_NORMAL_COMMAND (3)`
`AT_COMMAND_REASON_NORMAL_COMMAND.`
- `#define AT_COMMAND_OK (1)`
`AT_COMMAND_OK.`
- `#define AT_COMMAND_EXIT (2)`
`AT_COMMAND_EXIT.`

Typedefs

- typedef int [ProcessATcommandFunc](#)(int uartnum, const char *pCommand, FILE *pResponseFile, int reason)
typedef for the AT command processing function

Functions

- void **EnableATCommands** (int port_number, [ProcessATcommandFunc](#) *pcmdf, int task_priority)
Enable AT command on the specific serial port, port must already be popen'd in interrupt mode.
- void **DisableATCommands** (int port_number)
Disable AT command.

14.3.1 Detailed Description

Functions for serial modem AT commands.

```
#include< atcommand.h>
```

14.3.2 Typedef Documentation

14.3.2.1 ProcessATcommandFunc

```
typedef int ProcessATcommandFunc(int uartnum, const char *pCommand, FILE *pResponseFile, int reason)
```

```
#include <atcommand.h>
```

typedef for the AT command processing function

Returns

AT_COMMAND_OK or AT_COMMAND_EXIT

14.4 Base64

Functions

- int [Base64Decode](#) (const char *input, uint8_t *outputbuf, const char *pEndMarker=NULL)
Decodes a null terminated Base64 string into bytes.
- int [Base64UrlDecode](#) (const char *input, uint8_t *outputbuf, const char *pEndMarker=NULL)
Decodes a null terminated Base64Url string into bytes.
- int [Base64Encode](#) (uint8_t *input, int inlen, char *outputbuf)
Encodes arbitrary binary bytes into Base64 string.
- int [Base64UrlEncode](#) (uint8_t *input, int inlen, char *outputbuf)
Encodes arbitrary binary bytes into Base64Url string.
- int [Base64StreamEncode](#) (int fd, uint8_t *input, int inlen, char *outBuf, int maxOutLen)
Encodes arbitrary binary bytes into Base64 string and writes them to a file descriptor.
- int [Base64UrlStreamEncode](#) (int fd, uint8_t *input, int inlen, char *outBuf, int maxOutLen)
Encodes arbitrary binary bytes into Base64Url string and writes them to a file descriptor.

14.4.1 Detailed Description

```
#include< base64.h>
```

Functions to encode/decode in Base64

14.4.2 Function Documentation

14.4.2.1 Base64Decode()

```
int Base64Decode (  
    const char * input,  
    uint8_t * outputbuf,  
    const char * pEndMarker = NULL)
```

```
#include <base64.h>
```

Decodes a null terminated Base64 string into bytes.

Notes:

- outputbuf should be at least the size of input divided by 4, rounded up
- Does not null terminate results

Parameters

<i>input</i>	Base64 string
<i>outputbuf</i>	Resulting decoded data
<i>pEndMarker</i>	Pointer to the end of the string (in the event it is not terminated by either a null char or a base64 terminator)

Returns

Number of bytes returned in outputbuf

See also

[Base64Encode\(\)](#)

[Base64UrlDecode\(\)](#)

14.4.2.2 Base64Encode()

```
int Base64Encode (  
    uint8_t * input,  
    int inlen,  
    char * outputbuf)
```

```
#include <base64.h>
```

Encodes arbitrary binary bytes into Base64 string.

Notes: Does not null terminate results but terminates with an '='

Parameters

<i>input</i>	Data
<i>inlen</i>	Length of data
<i>outputbuf</i>	Resulting encoded data

Returns

Number of bytes returned in outputbuf

See also

[Base64Decode\(\)](#)

[Base64StreamEncode\(\)](#)

[Base64UrlEncode\(\)](#)

14.4.2.3 Base64StreamEncode()

```
int Base64StreamEncode (  
    int fd,  
    uint8_t * input,  
    int inlen,  
    char * outBuf,  
    int maxOutLen)
```

```
#include <base64.h>
```

Encodes arbitrary binary bytes into Base64 string and writes them to a file descriptor.

Notes: Does not null terminate results but terminates with an '='

Parameters

<i>fd</i>	Target File Descriptor
<i>input</i>	Data to be encoded
<i>inlen</i>	Length of data
<i>outBuf</i>	Temporary buffer to accumulate encoded data
<i>maxOutLen</i>	Maximum buffer space to accumulate data

Returns

Number of bytes returned in outputbuf

See also

[Base64Encode](#)

[Base64UrlStreamEncode](#)

14.4.2.4 Base64UrlDecode()

```
int Base64UrlDecode (  
    const char * input,  
    uint8_t * outputbuf,  
    const char * pEndMarker = NULL)
```

```
#include <base64.h>
```

Decodes a null terminated Base64Url string into bytes.

Notes:

- outputbuf should be at least the size of input divided by 4, rounded up
- Does not null terminate results

Parameters

<i>input</i>	Base64Url string
<i>outputbuf</i>	Resulting decoded data
<i>pEndMarker</i>	Pointer to the end of the string (in the event it is not terminated by either a null char or a base64 terminator)

Returns

Number of bytes returned in outputbuf

See also

[Base64UrlEncode\(\)](#)

[Base64Decode\(\)](#)

14.4.2.5 Base64UrlEncode()

```
int Base64UrlEncode (
    uint8_t * input,
    int inlen,
    char * outputbuf)
```

```
#include <base64.h>
```

Encodes arbitrary binary bytes into Base64Url string.

Notes: Does not null terminate results but terminates with an '='

Parameters

<i>input</i>	Data
<i>inlen</i>	Length of data
<i>outputbuf</i>	Resulting encoded data

Returns

Number of bytes returned in outputbuf

See also

[Base64UrlDecode\(\)](#)

[Base64UrlStreamEncode\(\)](#)

14.4.2.6 Base64UrlStreamEncode()

```
int Base64UrlStreamEncode (
    int fd,
    uint8_t * input,
    int inlen,
    char * outBuf,
    int maxOutLen)
```

```
#include <base64.h>
```

Encodes arbitrary binary bytes into Base64Url string and writes them to a file descriptor.

Notes: Does not null terminate results but terminates with an '='

Parameters

<i>fd</i>	Target File Descriptor
<i>input</i>	Data to be encoded
<i>inlen</i>	Length of data
<i>outBuf</i>	Temporary buffer to accumulate encoded data
<i>maxOutLen</i>	Maximum buffer space to accumulate data

Returns

Number of bytes returned in outputbuf

14.5 Buffers - System Buffer Pool

Topics

- [Buffer Ownership States](#)
- [Buffer State Flags](#)

Classes

- struct [pool_buffer](#)
Main buffer structure for network and serial communication.
- class [buffer_list](#)
Doubly-linked list management for buffers.
- class [fifo_buffer_storage](#)
FIFO buffer storage using linked pool buffers.
- class [SMPoolPtr](#)
Smart pointer wrapper for automatic buffer management.

Functions

- [PoolPtr GetBuffer](#) ()
Allocate a software buffer for general use.
- [PoolPtr GetFastBuffer](#) ()
Allocate a software buffer, preferring the fast memory pool.
- void [FreeBuffer](#) ([PoolPtr](#) nbuf)
Free a buffer and return it to the unused pool.
- void [FreeBufferList](#) ([PoolPtr](#) nbuf)
Free a linked list of buffers.
- void [IncUsageCount](#) ([PoolPtr](#) pp)
Increment the usage count of a buffer.
- uint16_t [GetFreeCount](#) ()
Returns the number of free buffers in the system. Buffers are used for both serial and network interfaces.
- void [InitBuffers](#) ()
Initialize the buffer system.
- void [ShowBuffer](#) ([PoolPtr](#) p)
Display buffer contents and state information.

14.5.1 Detailed Description

```
#include< buffers.h>
```

Functions associated with the buffers allocated for use by network interfaces and serial ports. If a system runs out of buffers it will no longer be able to send or receive network data.

14.5.2 Function Documentation

14.5.2.1 FreeBuffer()

```
void FreeBuffer (
    PoolPtr nbuf)
#include <buffers.h>
```

Free a buffer and return it to the unused pool.

Decrements the buffer's usage count and returns it to the free pool when the count reaches zero. This allows safe sharing of buffers between multiple system components.

Parameters

<i>nbuf</i>	Buffer to free

See also

[GetBuffer\(\)](#), [IncUsageCount\(\)](#)

14.5.2.2 FreeBufferList()

```
void FreeBufferList (  
    PoolPtr nbuf)  
#include <buffers.h>
```

Free a linked list of buffers.

Frees a chain of buffers linked by their pNextFifo_EI pointers. Each buffer in the list will be returned to the unused pool.

Parameters

<i>nbuf</i>	First buffer in the linked list to free

See also

[FreeBuffer\(\)](#)

14.5.2.3 GetBuffer()

```
PoolPtr GetBuffer ()  
#include <buffers.h>
```

Allocate a software buffer for general use.

Allocates a buffer from the system buffer pool for use by application software. The buffer will be marked with ownership state BO_SOFTWARE.

Returns

Pointer to allocated buffer, or NULL if no buffers available

See also

[FreeBuffer\(\)](#), [GetFastBuffer\(\)](#)

14.5.2.4 GetFastBuffer()

```
PoolPtr GetFastBuffer ()  
#include <buffers.h>
```

Allocate a software buffer, preferring the fast memory pool.

Similar to [GetBuffer\(\)](#), but attempts to allocate from the fast buffer pool first before falling back to the standard pool. Fast buffers may provide better performance for time-critical operations.

Returns

Pointer to allocated buffer, or NULL if no buffers available

See also

[GetBuffer\(\)](#), [FreeBuffer\(\)](#)

14.5.2.5 GetFreeCount()

```
uint16_t GetFreeCount ()
#include <buffers.h>
```

Returns the number of free buffers in the system. Buffers are used for both serial and network interfaces.

This function returns the number of free pool buffers, which are used for network and serial communication. The maximum number of buffers is defined in `\nburn\nbrtos\include\constants.h`:

```
#define BUFFER_POOL_SIZE (128)
```

The size of each buffer is defined as:

```
#define ETHER_BUFFER_SIZE 1548
```

If the number of free buffers reaches zero, then no further network communication will be possible until some buffers are freed. This is a good function to use as a debug tool for detecting buffer leaks in your application.

Serial ports also use buffers, which are allocated in `constants.h`:

```
#define SERIAL_TX_BUFFERS (2)
```

```
#define SERIAL_RX_BUFFERS (2)
```

Each serial port buffer is equal in size to an Ethernet buffer.

Returns

The number of free buffers in the system.

14.5.2.6 IncUsageCount()

```
void IncUsageCount (
    PoolPtr pp)
#include <buffers.h>
```

Increment the usage count of a buffer.

Increases the reference count for shared buffer usage. The buffer will not be freed until `FreeBuffer()` is called once for each reference (usage count reaches zero).

Parameters

<i>pp</i>	Buffer to increment usage count

See also

[FreeBuffer\(\)](#)

14.5.2.7 InitBuffers()

```
void InitBuffers ()
#include <buffers.h>
```

Initialize the buffer system.

Sets up the buffer pools and free lists. This function is called during system initialization and should not be called by application code.

See also

[GetFreeCount\(\)](#)

14.5.2.8 ShowBuffer()

```
void ShowBuffer (
    PoolPtr p)
#include <buffers.h>
```

Display buffer contents and state information.

Prints detailed information about a buffer including its state, size, and data contents to stdout. Useful for debugging.

Parameters

<i>p</i>	Buffer to display

14.5.3 Buffer Ownership States

Macros

- **#define BO_UNUSED 0**
The buffer is free and available for allocation.
- **#define BO_SOFTWARE 1**
The buffer belongs to application software.
- **#define BO_PRX 2**
The buffer is assigned to receive function.
- **#define BO_PTXF 3**
The buffer is to be transmitted then freed.
- **#define BO_PTXS 4**
The buffer is to be transmitted then returned to software.

14.5.3.1 Detailed Description

```
#include< buffers.h>
```

Buffer ownership states define which system component currently owns a buffer as it moves through the network stack.

14.5.4 Buffer State Flags

Macros

- **#define BS_PHY_BCAST 1**
Physical layer broadcast packet.
- **#define BS_IP_BCAST 2**
Layer 3 (IP) broadcast packet.
- **#define BS_IP_LOCAL_NET 4**
Packet to/from local subnet.
- **#define BS_TCP_PUSH 8**
TCP PUSH flag was set on receive.
- **#define BS_PHY_802_3 0x10**
Packet requires 802.3 encapsulation.
- **#define BS_VLAN 0x20**
Packet requires VLAN tagging.
- **#define BS_DBG_LOG 0x80**
Debug log buffer - do not log operations.

14.5.4.1 Detailed Description

```
#include< buffers.h>
```

Buffer state flags provide additional networking context for packet processing.

14.6 CAN

Topics

- [FlexCAN SOMRT1061](#)
- [MOD5441x, NANO54415, SB800EX](#)
- [MODM7AE70](#)

14.6.1 Detailed Description

Controller Area Network (CAN) API for NetBurner Platforms

14.6.2 FlexCAN SOMRT1061

Classes

- [struct _flexcan_frame](#)
FlexCAN message frame structure.
- [struct _flexcan_timing_config](#)
FlexCAN protocol timing characteristic configuration structure.
- [struct _flexcan_config](#)
FlexCAN module configuration structure.
- [struct _flexcan_rx_mb_config](#)
FlexCAN Receive Message Buffer configuration structure.
- [struct _flexcan_rx_fifo_config](#)
FlexCAN Legacy Rx FIFO configuration structure.
- [struct _flexcan_mb_transfer](#)
FlexCAN Message Buffer transfer.
- [struct _flexcan_fifo_transfer](#)
FlexCAN Rx FIFO transfer.
- [struct _flexcan_handle](#)
FlexCAN handle structure.

Macros

- [#define FLEXCAN_ID_STD\(id\)](#) (((uint32_t)((uint32_t)(id)) << CAN_ID_STD_SHIFT)) & CAN_ID_STD_MASK)
FlexCAN frame length helper macro.
- [#define FLEXCAN_ID_EXT\(id\)](#)
- [#define FLEXCAN_RX_MB_STD_MASK\(id, rtr, ide\)](#)
FlexCAN Rx Message Buffer Mask helper macro.
- [#define FLEXCAN_RX_MB_EXT_MASK\(id, rtr, ide\)](#)
- [#define FLEXCAN_RX_FIFO_STD_MASK_TYPE_A\(id, rtr, ide\)](#)
FlexCAN Legacy Rx FIFO Mask helper macro.

- [#define FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_HIGH\(id\)](#) ((FLEXCAN_ID_EXT(id) & 0x1FE00000) << 3)

- `#define FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_MID_HIGH(id)`
- `#define FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_MID_LOW(id)`
- `#define FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_LOW(id) ((FLEXCAN_ID_EXT(id) & 0x1FE00000) >> 21)`
- `#define FLEXCAN_RX_FIFO_STD_FILTER_TYPE_A(id, rtr, ide) FLEXCAN_RX_FIFO_STD_MASK_TYPE_A(id, rtr, ide)`
FlexCAN Rx FIFO Filter helper macro.
- `#define FLEXCAN_RX_FIFO_STD_FILTER_TYPE_B_HIGH(id, rtr, ide)`
- `#define FLEXCAN_RX_FIFO_STD_FILTER_TYPE_B_LOW(id, rtr, ide)`
- `#define FLEXCAN_RX_FIFO_STD_FILTER_TYPE_C_HIGH(id)`
- `#define FLEXCAN_RX_FIFO_STD_FILTER_TYPE_C_MID_HIGH(id)`
- `#define FLEXCAN_RX_FIFO_STD_FILTER_TYPE_C_MID_LOW(id)`
- `#define FLEXCAN_RX_FIFO_STD_FILTER_TYPE_C_LOW(id)`
- `#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_A(id, rtr, ide) FLEXCAN_RX_FIFO_EXT_MASK_TYPE_A(id, rtr, ide)`
- `#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_B_HIGH(id, rtr, ide)`
- `#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_B_LOW(id, rtr, ide)`
- `#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_C_HIGH(id)`
- `#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_C_MID_HIGH(id)`
- `#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_C_MID_LOW(id)`
- `#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_C_LOW(id) FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_LOW(id)`
- `#define FLEXCAN_ERROR_AND_STATUS_INIT_FLAG`
FlexCAN interrupt/status flag helper macro.
- `#define FLEXCAN_MEMORY_ENHANCED_RX_FIFO_INIT_FLAG (0U)`
FlexCAN Enhanced Rx FIFO base address helper macro.
- `#define FLEXCAN_CALLBACK(x) void(x)(CAN_Type * base, flexcan_handle_t * handle, status_t status, uint32_t result, void *userData)`
FlexCAN transfer callback function.

Typedefs

- `typedef enum _flexcan_frame_format flexcan_frame_format_t`
FlexCAN frame format.
- `typedef enum _flexcan_frame_type flexcan_frame_type_t`
FlexCAN frame type.
- `typedef enum _flexcan_clock_source flexcan_clock_source_t`
FlexCAN clock source.
- `typedef enum _flexcan_wake_up_source flexcan_wake_up_source_t`
FlexCAN wake up source.
- `typedef enum _flexcan_rx_fifo_filter_type flexcan_rx_fifo_filter_type_t`
FlexCAN Rx Fifo Filter type.
- `typedef enum _flexcan_rx_fifo_priority flexcan_rx_fifo_priority_t`
FlexCAN Enhanced/Legacy Rx FIFO priority.
- `typedef struct _flexcan_frame flexcan_frame_t`
FlexCAN message frame structure.
- `typedef struct _flexcan_timing_config flexcan_timing_config_t`
FlexCAN protocol timing characteristic configuration structure.
- `typedef struct _flexcan_config flexcan_config_t`
FlexCAN module configuration structure.
- `typedef struct _flexcan_rx_mb_config flexcan_rx_mb_config_t`
FlexCAN Receive Message Buffer configuration structure.
- `typedef struct _flexcan_rx_fifo_config flexcan_rx_fifo_config_t`
FlexCAN Legacy Rx FIFO configuration structure.

- typedef struct `_flexcan_mb_transfer` `flexcan_mb_transfer_t`
FlexCAN Message Buffer transfer.
- typedef struct `_flexcan_fifo_transfer` `flexcan_fifo_transfer_t`
FlexCAN Rx FIFO transfer.
- typedef struct `_flexcan_handle` `flexcan_handle_t`
FlexCAN handle structure definition.

Enumerations

- enum {
`kStatus_FLEXCAN_TxBusy` = MAKE_STATUS(kStatusGroup_FLEXCAN, 0) , `kStatus_FLEXCAN_TxIdle` =
MAKE_STATUS(kStatusGroup_FLEXCAN, 1) , `kStatus_FLEXCAN_TxSwitchToRx` , `kStatus_FLEXCAN_RxBusy`
= MAKE_STATUS(kStatusGroup_FLEXCAN, 3) ,
`kStatus_FLEXCAN_RxIdle` = MAKE_STATUS(kStatusGroup_FLEXCAN, 4) , `kStatus_FLEXCAN_RxOverflow`
= MAKE_STATUS(kStatusGroup_FLEXCAN, 5) , `kStatus_FLEXCAN_RxFifoBusy` = MAKE_STATUS(k↵
StatusGroup_FLEXCAN, 6) , `kStatus_FLEXCAN_RxFifoIdle` = MAKE_STATUS(kStatusGroup_FLEXCAN, 7)
,
`kStatus_FLEXCAN_RxFifoOverflow` = MAKE_STATUS(kStatusGroup_FLEXCAN, 8) , `kStatus_FLEXCAN_RxFifoWarning`
= MAKE_STATUS(kStatusGroup_FLEXCAN, 9) , `kStatus_FLEXCAN_RxFifoDisabled` , `kStatus_FLEXCAN_ErrorStatus`
= MAKE_STATUS(kStatusGroup_FLEXCAN, 11) ,
`kStatus_FLEXCAN_WakeUp` = MAKE_STATUS(kStatusGroup_FLEXCAN, 12) , `kStatus_FLEXCAN_UnHandled`
= MAKE_STATUS(kStatusGroup_FLEXCAN, 13) , `kStatus_FLEXCAN_RxRemote` = MAKE_STATUS(k↵
StatusGroup_FLEXCAN, 14) }
FlexCAN transfer status.
- enum `_flexcan_frame_format` { `kFLEXCAN_FrameFormatStandard` = 0x0U , `kFLEXCAN_FrameFormatExtend`
= 0x1U }
FlexCAN frame format.
- enum `_flexcan_frame_type` { `kFLEXCAN_FrameTypeData` = 0x0U , `kFLEXCAN_FrameTypeRemote` = 0x1U
}
FlexCAN frame type.
- enum `_flexcan_clock_source` { `kFLEXCAN_ClkSrcOsc` = 0x0U , `kFLEXCAN_ClkSrcPeri` = 0x1U ,
`kFLEXCAN_ClkSrc0` = 0x0U , `kFLEXCAN_ClkSrc1` = 0x1U }
FlexCAN clock source.
- enum `_flexcan_wake_up_source` { `kFLEXCAN_WakeupSrcUnfiltered` = 0x0U , `kFLEXCAN_WakeupSrcFiltered`
= 0x1U }
FlexCAN wake up source.
- enum `_flexcan_rx_fifo_filter_type` { `kFLEXCAN_RxFifoFilterTypeA` = 0x0U , `kFLEXCAN_RxFifoFilterTypeB` ,
`kFLEXCAN_RxFifoFilterTypeC` , `kFLEXCAN_RxFifoFilterTypeD` = 0x3U }
FlexCAN Rx Fifo Filter type.
- enum `_flexcan_rx_fifo_priority` { `kFLEXCAN_RxFifoPrioLow` = 0x0U , `kFLEXCAN_RxFifoPrioHigh` = 0x1U }
FlexCAN Enhanced/Legacy Rx FIFO priority.
- enum `_flexcan_interrupt_enable` {
`kFLEXCAN_BusOffInterruptEnable` = CAN_CTRL1_BOFFMSK_MASK , `kFLEXCAN_ErrorInterruptEnable`
= CAN_CTRL1_ERRMSK_MASK , `kFLEXCAN_TxWarningInterruptEnable` = CAN_CTRL1_TWRNMSK_↵
MASK , `kFLEXCAN_RxWarningInterruptEnable` = CAN_CTRL1_RWRNMSK_MASK ,
`kFLEXCAN_WakeUpInterruptEnable` = CAN_MCR_WAKMSK_MASK }
FlexCAN interrupt enable enumerations.
- enum `_flexcan_flags` {
`kFLEXCAN_SynchFlag` = CAN_ESR1_SYNCH_MASK , `kFLEXCAN_TxWarningIntFlag` = CAN_ESR1_↵
TWRNINT_MASK , `kFLEXCAN_RxWarningIntFlag` = CAN_ESR1_RWRNINT_MASK , `kFLEXCAN_IdleFlag`
= CAN_ESR1_IDLE_MASK ,
`kFLEXCAN_FaultConfinementFlag` = CAN_ESR1_FLTCONF_MASK , `kFLEXCAN_TransmittingFlag` =
CAN_ESR1_TX_MASK , `kFLEXCAN_ReceivingFlag` = CAN_ESR1_RX_MASK , `kFLEXCAN_BusOffIntFlag`
= CAN_ESR1_BOFFINT_MASK ,
`kFLEXCAN_ErrorIntFlag` = CAN_ESR1_ERRINT_MASK , `kFLEXCAN_WakeUpIntFlag` = CAN_ESR1_↵
WAKINT_MASK , `kFLEXCAN_ErrorFlag` }

FlexCAN status flags.

- enum `_flexcan_error_flags` {
`kFLEXCAN_TxErrorWarningFlag` = `CAN_ESR1_TXWRN_MASK` , `kFLEXCAN_RxErrorWarningFlag` =
`CAN_ESR1_RXWRN_MASK` , `kFLEXCAN_StuffingError` = `CAN_ESR1_STFERR_MASK` , `kFLEXCAN_FormError`
= `CAN_ESR1_FRMERR_MASK` ,
`kFLEXCAN_CrcError` = `CAN_ESR1_CRCERR_MASK` , `kFLEXCAN_AckError` = `CAN_ESR1_ACKERR_`
`_MASK` , `kFLEXCAN_Bit0Error` = `CAN_ESR1_BIT0ERR_MASK` , `kFLEXCAN_Bit1Error` = `CAN_ESR1_`
`BIT1ERR_MASK` }

FlexCAN error status flags.

- enum { `kFLEXCAN_RxFifoOverflowFlag` = `CAN_IFLAG1_BUF7I_MASK` , `kFLEXCAN_RxFifoWarningFlag` =
`CAN_IFLAG1_BUF6I_MASK` , `kFLEXCAN_RxFifoFrameAvlFlag` = `CAN_IFLAG1_BUF5I_MASK` }

FlexCAN Legacy Rx FIFO status flags.

Initialization and deinitialization

- void `FLEXCAN_EnterFreezeMode` (`CAN_Type *base`)
Enter FlexCAN Freeze Mode.
- void `FLEXCAN_ExitFreezeMode` (`CAN_Type *base`)
Exit FlexCAN Freeze Mode.
- uint32_t `FLEXCAN_GetInstance` (`CAN_Type *base`)
Get the FlexCAN instance from peripheral base address.
- bool `FLEXCAN_CalculateImprovedTimingValues` (`CAN_Type *base`, uint32_t bitRate, uint32_t sourceClock_Hz, `flexcan_timing_config_t *pTimingConfig`)
Calculates the improved timing values by specific bit Rates for classical CAN.
- void `FLEXCAN_Init` (`CAN_Type *base`, const `flexcan_config_t *pConfig`, uint32_t sourceClock_Hz)
Initializes a FlexCAN instance.
- void `FLEXCAN_Deinit` (`CAN_Type *base`)
De-initializes a FlexCAN instance.
- void `FLEXCAN_GetDefaultConfig` (`flexcan_config_t *pConfig`)
Gets the default configuration structure.

Configuration.

- void `FLEXCAN_SetTimingConfig` (`CAN_Type *base`, const `flexcan_timing_config_t *pConfig`)
Sets the FlexCAN classical CAN protocol timing characteristic.
- status_t `FLEXCAN_SetBitRate` (`CAN_Type *base`, uint32_t sourceClock_Hz, uint32_t bitRate_Bps)
Set bit rate of FlexCAN classical CAN frame or CAN FD frame nominal phase.
- void `FLEXCAN_SetRxMbGlobalMask` (`CAN_Type *base`, uint32_t mask)
Sets the FlexCAN receive message buffer global mask.
- void `FLEXCAN_SetRxFifoGlobalMask` (`CAN_Type *base`, uint32_t mask)
Sets the FlexCAN receive FIFO global mask.
- void `FLEXCAN_SetRxIndividualMask` (`CAN_Type *base`, uint8_t maskIdx, uint32_t mask)
Sets the FlexCAN receive individual mask.
- void `FLEXCAN_SetTxMbConfig` (`CAN_Type *base`, uint8_t mbIdx, bool enable)
Configures a FlexCAN transmit message buffer.
- void `FLEXCAN_SetRxMbConfig` (`CAN_Type *base`, uint8_t mbIdx, const `flexcan_rx_mb_config_t *pRxMbConfig`, bool enable)
Configures a FlexCAN Receive Message Buffer.
- void `FLEXCAN_SetRxFifoConfig` (`CAN_Type *base`, const `flexcan_rx_fifo_config_t *pRxFifoConfig`, bool enable)
Configures the FlexCAN Legacy Rx FIFO.

Bus Operations

- status_t **FLEXCAN_WriteTxMb** (CAN_Type *base, uint8_t mbldx, const flexcan_frame_t *pTxFrame)
Writes a FlexCAN Message to the Transmit Message Buffer.
- status_t **FLEXCAN_ReadRxMb** (CAN_Type *base, uint8_t mbldx, flexcan_frame_t *pRxFrame)
Reads a FlexCAN Message from Receive Message Buffer.
- status_t **FLEXCAN_ReadRxFifo** (CAN_Type *base, flexcan_frame_t *pRxFrame)
Reads a FlexCAN Message from Legacy Rx FIFO.

Transactional

- status_t **FLEXCAN_TransferSendBlocking** (CAN_Type *base, uint8_t mbldx, flexcan_frame_t *pTxFrame)
Performs a polling send transaction on the CAN bus.
- status_t **FLEXCAN_TransferReceiveBlocking** (CAN_Type *base, uint8_t mbldx, flexcan_frame_t *pRxFrame)
Performs a polling receive transaction on the CAN bus.
- status_t **FLEXCAN_TransferReceiveFifoBlocking** (CAN_Type *base, flexcan_frame_t *pRxFrame)
Performs a polling receive transaction from Legacy Rx FIFO on the CAN bus.
- void **FLEXCAN_TransferCreateHandle** (CAN_Type *base, flexcan_handle_t *handle, flexcan_transfer_t callback_t callback, void *userData)
Initializes the FlexCAN handle.
- status_t **FLEXCAN_TransferSendNonBlocking** (CAN_Type *base, flexcan_handle_t *handle, flexcan_mb_transfer_t *pMbXfer)
Sends a message using IRQ.
- status_t **FLEXCAN_TransferReceiveNonBlocking** (CAN_Type *base, flexcan_handle_t *handle, flexcan_mb_transfer_t *pMbXfer)
Receives a message using IRQ.
- status_t **FLEXCAN_TransferReceiveFifoNonBlocking** (CAN_Type *base, flexcan_handle_t *handle, flexcan_fifo_transfer_t *pFifoXfer)
Receives a message from Rx FIFO using IRQ.
- status_t **FLEXCAN_TransferGetReceiveFifoCount** (CAN_Type *base, flexcan_handle_t *handle, size_t *count)
Gets the Legacy Rx Fifo transfer status during a interrupt non-blocking receive.
- uint32_t **FLEXCAN_GetTimeStamp** (flexcan_handle_t *handle, uint8_t mbldx)
Gets the detail index of Mailbox's Timestamp by handle.
- void **FLEXCAN_TransferAbortSend** (CAN_Type *base, flexcan_handle_t *handle, uint8_t mbldx)
Aborts the interrupt driven message send process.
- void **FLEXCAN_TransferAbortReceive** (CAN_Type *base, flexcan_handle_t *handle, uint8_t mbldx)
Aborts the interrupt driven message receive process.
- void **FLEXCAN_TransferAbortReceiveFifo** (CAN_Type *base, flexcan_handle_t *handle)
Aborts the interrupt driven message receive from Rx FIFO process.
- void **FLEXCAN_TransferHandleIRQ** (CAN_Type *base, flexcan_handle_t *handle)
FlexCAN IRQ handle function.

Driver version

- #define **FSL_FLEXCAN_DRIVER_VERSION** (MAKE_VERSION(2, 11, 6))
FlexCAN driver version.

14.6.2.1 Detailed Description

14.6.2.2 Macro Definition Documentation

14.6.2.2.1 FLEXCAN_CALLBACK

```
#define FLEXCAN_CALLBACK(
    x) void(x)(CAN_Type * base, flexcan_handle_t * handle, status_t status, uint32_t result, void *userData)
```

#include <fsl_flexcan.h>
FlexCAN transfer callback function.
The FlexCAN transfer callback returns a value from the underlying layer. If the status equals to kStatus_FLEXCAN_ErrorStatus, the result parameter is the Content of FlexCAN status register which can be used to get the working status(or error status) of FlexCAN module. If the status equals to other FlexCAN Message Buffer transfer status, the result is the index of Message Buffer that generate transfer event. If the status equals to other FlexCAN Message Buffer transfer status, the result is meaningless and should be Ignored.

14.6.2.2.2 FLEXCAN_ID_EXT

```
#define FLEXCAN_ID_EXT(
    id)
#include <fsl_flexcan.h>
```

Value:
(((uint32_t)((uint32_t)(id)) << CAN_ID_EXT_SHIFT)) & \
(CAN_ID_EXT_MASK | CAN_ID_STD_MASK))

Extend Frame ID helper macro.

14.6.2.2.3 FLEXCAN_ID_STD

```
#define FLEXCAN_ID_STD(
    id) (((uint32_t)((uint32_t)(id)) << CAN_ID_STD_SHIFT)) & CAN_ID_STD_MASK)
#include <fsl_flexcan.h>
```

FlexCAN frame length helper macro.
FlexCAN Frame ID helper macro. Standard Frame ID helper macro.

14.6.2.2.4 FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_A

```
#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_A(
    id,
    rtr,
    ide) FLEXCAN_RX_FIFO_EXT_MASK_TYPE_A(id, rtr, ide)
#include <fsl_flexcan.h>
```

Extend Rx FIFO Filter helper macro Type A helper macro.

14.6.2.2.5 FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_B_HIGH

```
#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_B_HIGH(
    id,
    rtr,
    ide)
#include <fsl_flexcan.h>
```

Value:
FLEXCAN_RX_FIFO_EXT_MASK_TYPE_B_HIGH(id, rtr, ide)

Extend Rx FIFO Filter helper macro Type B upper part helper macro.

14.6.2.2.6 FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_B_LOW

```
#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_B_LOW(
    id,
    rtr,
    ide)
```

```
#include <fsl_flexcan.h>
```

Value:

```
FLEXCAN_RX_FIFO_EXT_MASK_TYPE_B_LOW(          \
    id, rtr, ide)
```

Extend Rx FIFO Filter helper macro Type B lower part helper macro.

14.6.2.2.7 FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_C_HIGH

```
#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_C_HIGH(
    id)
```

```
#include <fsl_flexcan.h>
```

Value:

```
FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_HIGH(          \
    id)
```

Extend Rx FIFO Filter helper macro Type C upper part helper macro.

14.6.2.2.8 FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_C_LOW

```
#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_C_LOW(
    id) FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_LOW(id)
```

```
#include <fsl_flexcan.h>
```

Extend Rx FIFO Filter helper macro Type C lower part helper macro.

14.6.2.2.9 FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_C_MID_HIGH

```
#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_C_MID_HIGH(
    id)
```

```
#include <fsl_flexcan.h>
```

Value:

```
FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_MID_HIGH(      \
    id)
```

Extend Rx FIFO Filter helper macro Type C mid-upper part helper macro.

14.6.2.2.10 FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_C_MID_LOW

```
#define FLEXCAN_RX_FIFO_EXT_FILTER_TYPE_C_MID_LOW(
    id)
```

```
#include <fsl_flexcan.h>
```

Value:

```
FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_MID_LOW(      \
    id)
```

Extend Rx FIFO Filter helper macro Type C mid-lower part helper macro.

14.6.2.2.11 FLEXCAN_RX_FIFO_EXT_MASK_TYPE_A

```
#define FLEXCAN_RX_FIFO_EXT_MASK_TYPE_A(
    id,
    rtr,
    ide)
```

```
#include <fsl_flexcan.h>
```

Value:

```
((uint32_t)((uint32_t)(rtr) << 31) | (uint32_t)((uint32_t)(ide) << 30)) | \
(FLEXCAN_ID_EXT(id) << 1)
```

Extend Rx FIFO Mask helper macro Type A helper macro.

14.6.2.2.12 FLEXCAN_RX_FIFO_EXT_MASK_TYPE_B_HIGH

```
#define FLEXCAN_RX_FIFO_EXT_MASK_TYPE_B_HIGH(
    id,
    rtr,
    ide)
```

```
#include <fsl_flexcan.h>
```

Value:

```
(
    ((uint32_t)((uint32_t)(rtr) << 31) | (uint32_t)((uint32_t)(ide) << 30)) | \
    ((FLEXCAN_ID_EXT(id) & 0x1FFF8000)
     << 1))
\
```

Extend Rx FIFO Mask helper macro Type B upper part helper macro.

14.6.2.2.13 FLEXCAN_RX_FIFO_EXT_MASK_TYPE_B_LOW

```
#define FLEXCAN_RX_FIFO_EXT_MASK_TYPE_B_LOW(
    id,
    rtr,
    ide)
#include <fsl_flexcan.h>
```

Value:

```
((uint32_t)((uint32_t)(rtr) << 15) | (uint32_t)((uint32_t)(ide) << 14)) | \
((FLEXCAN_ID_EXT(id) & 0x1FFF8000) >>
15))
\
```

Extend Rx FIFO Mask helper macro Type B lower part helper macro.

14.6.2.2.14 FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_HIGH

```
#define FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_HIGH(
    id) ((FLEXCAN_ID_EXT(id) & 0x1FE00000) << 3)
#include <fsl_flexcan.h>
```

Extend Rx FIFO Mask helper macro Type C upper part helper macro.

14.6.2.2.15 FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_LOW

```
#define FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_LOW(
    id) ((FLEXCAN_ID_EXT(id) & 0x1FE00000) >> 21)
#include <fsl_flexcan.h>
```

Extend Rx FIFO Mask helper macro Type C lower part helper macro.

14.6.2.2.16 FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_MID_HIGH

```
#define FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_MID_HIGH(
    id)
#include <fsl_flexcan.h>
```

Value:

```
((FLEXCAN_ID_EXT(id) & 0x1FE00000) >>
5)
\
```

Extend Rx FIFO Mask helper macro Type C mid-upper part helper macro.

14.6.2.2.17 FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_MID_LOW

```
#define FLEXCAN_RX_FIFO_EXT_MASK_TYPE_C_MID_LOW(
    id)
#include <fsl_flexcan.h>
```

Value:

```
((FLEXCAN_ID_EXT(id) & 0x1FE00000) >>
13)
\
```

Extend Rx FIFO Mask helper macro Type C mid-lower part helper macro.

14.6.2.2.18 FLEXCAN_RX_FIFO_STD_FILTER_TYPE_A

```
#define FLEXCAN_RX_FIFO_STD_FILTER_TYPE_A(
    id,

Value:

```
((uint32_t)((uint32_t)(rtr) < 31) | (uint32_t)((uint32_t)(ide) < 30)) | \
FLEXCAN_ID_EXT(id)
```

Extend Rx Message Buffer Mask helper macro.

14.6.2.2.33 FLEXCAN_RX_MB_STD_MASK

```
#define FLEXCAN_RX_MB_STD_MASK(
```

```
    id,
```

```
    rtr,
```

```
    ide)
```

```
#include <fsl_flexcan.h>
```

Value:

```
((uint32_t)((uint32_t)(rtr) < 31) | (uint32_t)((uint32_t)(ide) < 30)) | \
FLEXCAN_ID_STD(id)
```

FlexCAN Rx Message Buffer Mask helper macro.

Standard Rx Message Buffer Mask helper macro.

14.6.2.3 Typedef Documentation

14.6.2.3.1 flexcan_clock_source_t

```
typedef enum _flexcan_clock_source flexcan_clock_source_t
```

```
#include <fsl_flexcan.h>
```

FlexCAN clock source.

Deprecated Do not use the kFLEXCAN_ClkSrcOs. It has been superceded kFLEXCAN_ClkSrc0
Do not use the kFLEXCAN_ClkSrcPeri. It has been superceded kFLEXCAN_ClkSrc1

14.6.2.3.2 flexcan_config_t

```
typedef struct _flexcan_config flexcan_config_t
```

```
#include <fsl_flexcan.h>
```

FlexCAN module configuration structure.

Deprecated Do not use the baudRate. It has been superceded bitRate
Do not use the baudRateFD. It has been superceded bitRateFD

14.6.2.3.3 flexcan_rx_fifo_priority_t

```
typedef enum _flexcan_rx_fifo_priority flexcan_rx_fifo_priority_t
```

```
#include <fsl_flexcan.h>
```

FlexCAN Enhanced/Legacy Rx FIFO priority.

The matching process starts from the Rx MB(or Enhanced/Legacy Rx FIFO) with higher priority. If no MB(or Enhanced/Legacy Rx FIFO filter) is satisfied, the matching process goes on with the Enhanced/Legacy Rx FIFO(or Rx MB) with lower priority.

14.6.2.3.4 flexcan_rx_mb_config_t

```
typedef struct _flexcan_rx_mb_config flexcan_rx_mb_config_t
#include <fsl_flexcan.h>
```

FlexCAN Receive Message Buffer configuration structure.

This structure is used as the parameter of [FLEXCAN_SetRxMbConfig\(\)](#) function. The [FLEXCAN_SetRxMbConfig\(\)](#) function is used to configure FlexCAN Receive Message Buffer. The function abort previous receiving process, clean the Message Buffer and activate the Rx Message Buffer using given Message Buffer setting.

14.6.2.4 Enumeration Type Documentation

14.6.2.4.1 anonymous enum

```
anonymous enum
#include <fsl_flexcan.h>
FlexCAN transfer status.
```

Enumerator

kStatus_FLEXCAN_TxBusy	Tx Message Buffer is Busy.
kStatus_FLEXCAN_TxIdle	Tx Message Buffer is Idle.
kStatus_FLEXCAN_TxSwitchToRx	Remote Message is send out and Message buffer changed to Receive one.
kStatus_FLEXCAN_RxBusy	Rx Message Buffer is Busy.
kStatus_FLEXCAN_RxIdle	Rx Message Buffer is Idle.
kStatus_FLEXCAN_RxOverflow	Rx Message Buffer is Overflowed.
kStatus_FLEXCAN_RxFifoBusy	Rx Message FIFO is Busy.
kStatus_FLEXCAN_RxFifoIdle	Rx Message FIFO is Idle.
kStatus_FLEXCAN_RxFifoOverflow	Rx Message FIFO is overflowed.
kStatus_FLEXCAN_RxFifoWarning	Rx Message FIFO is almost overflowed.
kStatus_FLEXCAN_RxFifoDisabled	Rx Message FIFO is disabled during reading.
kStatus_FLEXCAN_ErrorStatus	FlexCAN Module Error and Status.
kStatus_FLEXCAN_WakeUp	FlexCAN is waken up from STOP mode.
kStatus_FLEXCAN_UnHandled	UnHadled Interrupt asserted.
kStatus_FLEXCAN_RxRemote	Rx Remote Message Received in Mail box.

14.6.2.4.2 anonymous enum

```
anonymous enum
#include <fsl_flexcan.h>
FlexCAN Legacy Rx FIFO status flags.
```

The FlexCAN Legacy Rx FIFO Status enumerations are used to determine the status of the Rx FIFO. Because Rx FIFO occupy the MB0 ~ MB7 (Rx Fifo filter also occupies more Message Buffer space), Rx FIFO status flags are mapped to the corresponding Message Buffer status flags.

Enumerator

kFLEXCAN_RxFifoOverflowFlag	Rx FIFO overflow flag.
kFLEXCAN_RxFifoWarningFlag	Rx FIFO almost full flag.
kFLEXCAN_RxFifoFrameAvlFlag	Frames available in Rx FIFO flag.

14.6.2.4.3 _flexcan_clock_source

```
enum _flexcan_clock_source
#include <fsl_flexcan.h>
FlexCAN clock source.
```

Deprecated Do not use the kFLEXCAN_ClkSrcOs. It has been superceded kFLEXCAN_ClkSrc0
Do not use the kFLEXCAN_ClkSrcPeri. It has been superceded kFLEXCAN_ClkSrc1

Enumerator

kFLEXCAN_ClkSrcOsc	FlexCAN Protocol Engine clock from Oscillator.
kFLEXCAN_ClkSrcPeri	FlexCAN Protocol Engine clock from Peripheral Clock.
kFLEXCAN_ClkSrc0	FlexCAN Protocol Engine clock selected by user as SRC == 0.
kFLEXCAN_ClkSrc1	FlexCAN Protocol Engine clock selected by user as SRC == 1.

14.6.2.4.4 _flexcan_error_flags

```
enum _flexcan_error_flags
#include <fsl_flexcan.h>
FlexCAN error status flags.
```

The FlexCAN Error Status enumerations is used to report current error of the FlexCAN bus. This enumerations should be used with KFLEXCAN_ErrorFlag in [_flexcan_flags](#) enumerations to determine which error is generated.

Enumerator

kFLEXCAN_TxErrorWarningFlag	Tx Error Warning Status.
kFLEXCAN_RxErrorWarningFlag	Rx Error Warning Status.
kFLEXCAN_StuffingError	Stuffing Error.
kFLEXCAN_FormError	Form Error.
kFLEXCAN_CrcError	Cyclic Redundancy Check Error.
kFLEXCAN_AckError	Received no ACK on transmission.
kFLEXCAN_Bit0Error	Unable to send dominant bit.
kFLEXCAN_Bit1Error	Unable to send recessive bit.

14.6.2.4.5 _flexcan_flags

```
enum _flexcan_flags
#include <fsl_flexcan.h>
FlexCAN status flags.
```

This provides constants for the FlexCAN status flags for use in the FlexCAN functions.

Note

The CPU read action clears the bits corresponding to the FLEXCAN_ErrorFlag macro, therefore user need to read status flags and distinguish which error is occur using [_flexcan_error_flags](#) enumerations.

Enumerator

kFLEXCAN_SynchFlag	CAN Synchronization Status.
kFLEXCAN_TxWarningIntFlag	Tx Warning Interrupt Flag.
kFLEXCAN_RxWarningIntFlag	Rx Warning Interrupt Flag.
kFLEXCAN_IdleFlag	FlexCAN In IDLE Status.
kFLEXCAN_FaultConfinementFlag	FlexCAN Fault Confinement State.
kFLEXCAN_TransmittingFlag	FlexCAN In Transmission Status.
kFLEXCAN_ReceivingFlag	FlexCAN In Reception Status.
kFLEXCAN_BusOffIntFlag	Bus Off Interrupt Flag.
kFLEXCAN_ErrorIntFlag	CAN Error Interrupt Flag.
kFLEXCAN_WakeUpIntFlag	Self Wake-Up Interrupt Flag.

14.6.2.4.6 _flexcan_frame_format

```
enum _flexcan_frame_format
#include <fsl_flexcan.h>
FlexCAN frame format.
```

Enumerator

kFLEXCAN_FrameFormatStandard	Standard frame format attribute.
kFLEXCAN_FrameFormatExtend	Extend frame format attribute.

14.6.2.4.7 _flexcan_frame_type

```
enum _flexcan_frame_type
#include <fsl_flexcan.h>
FlexCAN frame type.
```

Enumerator

kFLEXCAN_FrameTypeData	Data frame type attribute.
kFLEXCAN_FrameTypeRemote	Remote frame type attribute.

14.6.2.4.8 _flexcan_interrupt_enable

```
enum _flexcan_interrupt_enable
#include <fsl_flexcan.h>
FlexCAN interrupt enable enumerations.
This provides constants for the FlexCAN interrupt enable enumerations for use in the FlexCAN functions.
```

Note

FlexCAN Message Buffers and Legacy Rx FIFO interrupts not included in.

Enumerator

kFLEXCAN_BusOffInterruptEnable	Bus Off interrupt, use bit 15.
kFLEXCAN_ErrorInterruptEnable	CAN Error interrupt, use bit 14.
kFLEXCAN_TxWarningInterruptEnable	Tx Warning interrupt, use bit 11.
kFLEXCAN_RxWarningInterruptEnable	Rx Warning interrupt, use bit 10.
kFLEXCAN_WakeUpInterruptEnable	Self Wake Up interrupt, use bit 26.

14.6.2.4.9 _flexcan_rx_fifo_filter_type

```
enum _flexcan_rx_fifo_filter_type
#include <fsl_flexcan.h>
FlexCAN Rx Fifo Filter type.
```

Enumerator

kFLEXCAN_RxFifoFilterTypeA	One full ID (standard and extended) per ID Filter element.
kFLEXCAN_RxFifoFilterTypeB	Two full standard IDs or two partial 14-bit ID slices per ID Filter Table element.
kFLEXCAN_RxFifoFilterTypeC	Four partial 8-bit Standard or extended ID slices per ID Filter Table element.
kFLEXCAN_RxFifoFilterTypeD	All frames rejected.

14.6.2.4.10 _flexcan_rx_fifo_priority

```
enum _flexcan_rx_fifo_priority
#include <fsl_flexcan.h>
```

FlexCAN Enhanced/Legacy Rx FIFO priority.

The matching process starts from the Rx MB(or Enhanced/Legacy Rx FIFO) with higher priority. If no MB(or Enhanced/Legacy Rx FIFO filter) is satisfied, the matching process goes on with the Enhanced/Legacy Rx FIFO(or Rx MB) with lower priority.

Enumerator

kFLEXCAN_RxFifoPrioLow	Matching process start from Rx Message Buffer first.
kFLEXCAN_RxFifoPrioHigh	Matching process start from Enhanced/Legacy Rx FIFO first.

14.6.2.4.11 _flexcan_wake_up_source

```
enum _flexcan_wake_up_source
#include <fsl_flexcan.h>
```

FlexCAN wake up source.

Enumerator

kFLEXCAN_WakeupSrcUnfiltered	FlexCAN uses unfiltered Rx input to detect edge.
kFLEXCAN_WakeupSrcFiltered	FlexCAN uses filtered Rx input to detect edge.

14.6.2.5 Function Documentation

14.6.2.5.1 FLEXCAN_CalculateImprovedTimingValues()

```
bool FLEXCAN_CalculateImprovedTimingValues (
    CAN_Type * base,
    uint32_t bitRate,
    uint32_t sourceClock_Hz,
    flexcan_timing_config_t * pTimingConfig)
#include <fsl_flexcan.h>
```

Calculates the improved timing values by specific bit Rates for classical CAN.

This function use to calculates the Classical CAN timing values according to the given bit rate. The Calculated timing values will be set in CTRL1/CBT/ENCBT register. The calculation is based on the recommendation of the CiA 301 v4.2.0 and previous version document.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>bitRate</i>	The classical CAN speed in bps defined by user, should be less than or equal to 1Mbps.
<i>sourceClock_Hz</i>	The Source clock frequency in Hz.
<i>pTimingConfig</i>	Pointer to the FlexCAN timing configuration structure.

Returns

TRUE if timing configuration found, FALSE if failed to find configuration.

14.6.2.5.2 FLEXCAN_Deinit()

```
void FLEXCAN_Deinit (  
    CAN_Type * base)  
#include <fsl_flexcan.h>
```

De-initializes a FlexCAN instance.

This function disables the FlexCAN module clock and sets all register values to the reset value.

Parameters

<i>base</i>	FlexCAN peripheral base address.

14.6.2.5.3 FLEXCAN_EnterFreezeMode()

```
void FLEXCAN_EnterFreezeMode (
    CAN_Type * base)
#include <fsl_flexcan.h>
```

Enter FlexCAN Freeze Mode.

This function makes the FlexCAN work under Freeze Mode.

Parameters

<i>base</i>	FlexCAN peripheral base address.

14.6.2.5.4 FLEXCAN_ExitFreezeMode()

```
void FLEXCAN_ExitFreezeMode (
    CAN_Type * base)
#include <fsl_flexcan.h>
```

Exit FlexCAN Freeze Mode.

This function makes the FlexCAN leave Freeze Mode.

Parameters

<i>base</i>	FlexCAN peripheral base address.

14.6.2.5.5 FLEXCAN_GetDefaultConfig()

```
void FLEXCAN_GetDefaultConfig (
    flexcan_config_t * pConfig)
#include <fsl_flexcan.h>
```

Gets the default configuration structure.

This function initializes the FlexCAN configuration structure to default values. The default values are as follows. flexcanConfig->clkSrc = kFLEXCAN_ClkSrc0; flexcanConfig->bitRate = 1000000U; flexcanConfig->bitRateFD = 2000000U; flexcanConfig->maxMbNum = 16; flexcanConfig->enableLoopBack = false; flexcanConfig->enableSelfWakeup = false; flexcanConfig->enableIndividMask = false; flexcanConfig->disableSelfReception = false; flexcanConfig->enableListenOnlyMode = false; flexcanConfig->enableDoze = false; flexcanConfig->enableMemoryErrorControl = true; flexcanConfig->enableNonCorrectableErrorEnterFreeze = true; flexcanConfig.timingConfig = timingConfig;

Parameters

<i>pConfig</i>	Pointer to the FlexCAN configuration structure.

14.6.2.5.6 FLEXCAN_GetInstance()

```
uint32_t FLEXCAN_GetInstance (
    CAN_Type * base)
#include <fsl_flexcan.h>
```

Get the FlexCAN instance from peripheral base address.

Parameters

<i>base</i>	FlexCAN peripheral base address.

Returns

FlexCAN instance.

14.6.2.5.7 FLEXCAN_GetTimeStamp()

```
uint32_t FLEXCAN_GetTimeStamp (
    flexcan_handle_t * handle,
    uint8_t mbIdx)
#include <fsl_flexcan.h>
```

Gets the detail index of Mailbox's Timestamp by handle.

Then function can only be used when calling non-blocking Data transfer (TX/RX) API, After TX/RX data transfer done (User can get the status by handler's callback function), we can get the detail index of Mailbox's timestamp by handle, Detail non-blocking data transfer API (TX/RX) contain. -FLEXCAN_TransferSendNonBlocking -FLEXCAN_TransferFDSendNonBlocking -FLEXCAN_TransferReceiveNonBlocking -FLEXCAN_TransferFDReceiveNonBlocking -FLEXCAN_TransferReceiveFifoNonBlocking

Parameters

<i>handle</i>	FlexCAN handle pointer.
<i>mbIdx</i>	The FlexCAN Message Buffer index.

Return values

<i>the</i>	index of mailbox 's timestamp stored in the handle.

14.6.2.5.8 FLEXCAN_Init()

```
void FLEXCAN_Init (
    CAN_Type * base,
    const flexcan_config_t * pConfig,
    uint32_t sourceClock_Hz)
#include <fsl_flexcan.h>
```

Initializes a FlexCAN instance.

This function initializes the FlexCAN module with user-defined settings. This example shows how to set up the flexcan_config_t parameters and how to call the FLEXCAN_Init function by passing in these parameters.

```
flexcan_config_t flexcanConfig;
flexcanConfig.clkSrc      = kFLEXCAN_ClkSrc0;
flexcanConfig.bitRate     = 1000000U;
flexcanConfig.maxMbNum    = 16;
flexcanConfig.enableLoopBack = false;
flexcanConfig.enableSelfWakeup = false;
flexcanConfig.enableIndividMask = false;
flexcanConfig.enableDoze     = false;
flexcanConfig.disableSelfReception = false;
flexcanConfig.enableListenOnlyMode = false;
flexcanConfig.timingConfig  = timingConfig;
FLEXCAN_Init(CAN0, &flexcanConfig, 40000000UL);
```

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>pConfig</i>	Pointer to the user-defined configuration structure.
<i>sourceClock_Hz</i>	FlexCAN Protocol Engine clock source frequency in Hz.

14.6.2.5.9 FLEXCAN_ReadRxFifo()

```
status_t FLEXCAN_ReadRxFifo (
    CAN_Type * base,
    flexcan_frame_t * pRxFrame)
```

```
#include <fsl_flexcan.h>
```

Reads a FlexCAN Message from Legacy Rx FIFO.

This function reads a CAN message from the FlexCAN Legacy Rx FIFO.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>pRxFrame</i>	Pointer to CAN message frame structure for reception.

Return values

<i>kStatus_Success</i>	- Read Message from Rx FIFO successfully.
<i>kStatus_Fail</i>	- Rx FIFO is not enabled.

14.6.2.5.10 FLEXCAN_ReadRxMb()

```
status_t FLEXCAN_ReadRxMb (
    CAN_Type * base,
    uint8_t mbIdx,
    flexcan_frame_t * pRxFrame)
```

```
#include <fsl_flexcan.h>
```

Reads a FlexCAN Message from Receive Message Buffer.

This function reads a CAN message from a specified Receive Message Buffer. The function fills a receive CAN message frame structure with just received data and activates the Message Buffer again. The function returns immediately.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>mbIdx</i>	The FlexCAN Message Buffer index.
<i>pRxFrame</i>	Pointer to CAN message frame structure for reception.

Return values

<i>kStatus_Success</i>	- Rx Message Buffer is full and has been read successfully.
<i>kStatus_FLEXCAN_RxOverflow</i>	- Rx Message Buffer is already overflowed and has been read successfully.
<i>kStatus_Fail</i>	- Rx Message Buffer is empty.

14.6.2.5.11 FLEXCAN_SetBitRate()

```
status_t FLEXCAN_SetBitRate (
    CAN_Type * base,
    uint32_t sourceClock_Hz,
    uint32_t bitRate_Bps)
```

```
#include <fsl_flexcan.h>
```

Set bit rate of FlexCAN classical CAN frame or CAN FD frame nominal phase.

This function set the bit rate of classical CAN frame or CAN FD frame nominal phase base on [FLEXCAN_CalculateImprovedTimingValue](#) API calculated timing values.

Note

Calling [FLEXCAN_SetBitRate\(\)](#) overrides the bit rate set in [FLEXCAN_Init\(\)](#).

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>sourceClock_Hz</i>	Source Clock in Hz.
<i>bitRate_Bps</i>	Bit rate in Bps.

Returns

kStatus_Success - Set CAN baud rate (only Nominal phase) successfully.

14.6.2.5.12 FLEXCAN_SetRxFifoConfig()

```
void FLEXCAN_SetRxFifoConfig (
    CAN_Type * base,
    const flexcan_rx_fifo_config_t * pRxFifoConfig,
    bool enable)
```

```
#include <fsl_flexcan.h>
```

Configures the FlexCAN Legacy Rx FIFO.

This function configures the FlexCAN Rx FIFO with given configuration.

Note

Legacy Rx FIFO only can receive classic CAN message.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>pRxFifoConfig</i>	Pointer to the FlexCAN Legacy Rx FIFO configuration structure. Can be NULL when enable parameter is false.
<i>enable</i>	Enable/disable Legacy Rx FIFO. • true: Enable Legacy Rx FIFO. • false: Disable Legacy Rx FIFO.

14.6.2.5.13 FLEXCAN_SetRxFifoGlobalMask()

```
void FLEXCAN_SetRxFifoGlobalMask (
    CAN_Type * base,
    uint32_t mask)
```

```
#include <fsl_flexcan.h>
```

Sets the FlexCAN receive FIFO global mask.

This function sets the global mask for FlexCAN FIFO in a matching process.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>mask</i>	Rx Fifo Global Mask value.

14.6.2.5.14 FLEXCAN_SetRxIndividualMask()

```
void FLEXCAN_SetRxIndividualMask (
    CAN_Type * base,
    uint8_t maskIdx,
    uint32_t mask)
#include <fsl_flexcan.h>
```

Sets the FlexCAN receive individual mask.

This function sets the individual mask for the FlexCAN matching process. The configuration is only effective when the Rx individual mask is enabled in the [FLEXCAN_Init\(\)](#). If the Rx FIFO is disabled, the individual mask is applied to the corresponding Message Buffer. If the Rx FIFO is enabled, the individual mask for Rx FIFO occupied Message Buffer is applied to the Rx Filter with the same index. Note that only the first 32 individual masks can be used as the Rx FIFO filter mask.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>maskIdx</i>	The Index of individual Mask.
<i>mask</i>	Rx Individual Mask value.

14.6.2.5.15 FLEXCAN_SetRxMbConfig()

```
void FLEXCAN_SetRxMbConfig (
    CAN_Type * base,
    uint8_t mbIdx,
    const flexcan_rx_mb_config_t * pRxMbConfig,
    bool enable)
#include <fsl_flexcan.h>
```

Configures a FlexCAN Receive Message Buffer.

This function cleans a FlexCAN build-in Message Buffer and configures it as a Receive Message Buffer.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>mbIdx</i>	The Message Buffer index.
<i>pRxMbConfig</i>	Pointer to the FlexCAN Message Buffer configuration structure.
<i>enable</i>	Enable/disable Rx Message Buffer. • true: Enable Rx Message Buffer. • false: Disable Rx Message Buffer.

14.6.2.5.16 FLEXCAN_SetRxMbGlobalMask()

```
void FLEXCAN_SetRxMbGlobalMask (
    CAN_Type * base,
    uint32_t mask)
#include <fsl_flexcan.h>
```

Sets the FlexCAN receive message buffer global mask.

This function sets the global mask for the FlexCAN message buffer in a matching process. The configuration is only effective when the Rx individual mask is disabled in the [FLEXCAN_Init\(\)](#).

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>mask</i>	Rx Message Buffer Global Mask value.

14.6.2.5.17 FLEXCAN_SetTimingConfig()

```
void FLEXCAN_SetTimingConfig (
    CAN_Type * base,
    const flexcan_timing_config_t * pConfig)
```

```
#include <fsl_flexcan.h>
```

Sets the FlexCAN classical CAN protocol timing characteristic.

This function gives user settings to classical CAN or CAN FD nominal phase timing characteristic. The function is for an experienced user. For less experienced users, call the [FLEXCAN_SetBitRate\(\)](#) instead.

Note

Calling [FLEXCAN_SetTimingConfig\(\)](#) overrides the bit rate set in [FLEXCAN_Init\(\)](#) or [FLEXCAN_SetBitRate\(\)](#).

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>pConfig</i>	Pointer to the timing configuration structure.

14.6.2.5.18 FLEXCAN_SetTxMbConfig()

```
void FLEXCAN_SetTxMbConfig (
    CAN_Type * base,
    uint8_t mbIdx,
    bool enable)
```

```
#include <fsl_flexcan.h>
```

Configures a FlexCAN transmit message buffer.

This function aborts the previous transmission, cleans the Message Buffer, and configures it as a Transmit Message Buffer.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>mbIdx</i>	The Message Buffer index.
<i>enable</i>	Enable/disable Tx Message Buffer. • true: Enable Tx Message Buffer. • false: Disable Tx Message Buffer.

14.6.2.5.19 FLEXCAN_TransferAbortReceive()

```
void FLEXCAN_TransferAbortReceive (
    CAN_Type * base,
    flexcan_handle_t * handle,
    uint8_t mbIdx)
```

```
#include <fsl_flexcan.h>
```

Aborts the interrupt driven message receive process.

This function aborts the interrupt driven message receive process.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>handle</i>	FlexCAN handle pointer.
<i>mbIdx</i>	The FlexCAN Message Buffer index.

14.6.2.5.20 FLEXCAN_TransferAbortReceiveFifo()

```
void FLEXCAN_TransferAbortReceiveFifo (
    CAN_Type * base,
    flexcan_handle_t * handle)
```

```
#include <fsl_flexcan.h>
```

Aborts the interrupt driven message receive from Rx FIFO process.

This function aborts the interrupt driven message receive from Rx FIFO process.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>handle</i>	FlexCAN handle pointer.

14.6.2.5.21 FLEXCAN_TransferAbortSend()

```
void FLEXCAN_TransferAbortSend (
    CAN_Type * base,
    flexcan_handle_t * handle,
    uint8_t mbIdx)
```

```
#include <fsl_flexcan.h>
```

Aborts the interrupt driven message send process.

This function aborts the interrupt driven message send process.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>handle</i>	FlexCAN handle pointer.
<i>mbIdx</i>	The FlexCAN Message Buffer index.

14.6.2.5.22 FLEXCAN_TransferCreateHandle()

```
void FLEXCAN_TransferCreateHandle (
    CAN_Type * base,
    flexcan_handle_t * handle,
    flexcan_transfer_callback_t callback,
    void * userData)
```

```
#include <fsl_flexcan.h>
```

Initializes the FlexCAN handle.

This function initializes the FlexCAN handle, which can be used for other FlexCAN transactional APIs. Usually, for a specified FlexCAN instance, call this API once to get the initialized handle.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>handle</i>	FlexCAN handle pointer.
<i>callback</i>	The callback function.
<i>userData</i>	The parameter of the callback function.

14.6.2.5.23 FLEXCAN_TransferGetReceiveFifoCount()

```
status_t FLEXCAN_TransferGetReceiveFifoCount (
    CAN_Type * base,
    flexcan_handle_t * handle,
    size_t * count)
```

```
#include <fsl_flexcan.h>
```

Gets the Legacy Rx Fifo transfer status during a interrupt non-blocking receive.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>handle</i>	FlexCAN handle pointer.
<i>count</i>	Number of CAN messages receive so far by the non-blocking transaction.

Return values

<i>kStatus_InvalidArgument</i>	count is Invalid.
<i>kStatus_Success</i>	Successfully return the count.

14.6.2.5.24 FLEXCAN_TransferHandleIRQ()

```
void FLEXCAN_TransferHandleIRQ (
    CAN_Type * base,
    flexcan_handle_t * handle)
```

```
#include <fsl_flexcan.h>
```

FlexCAN IRQ handle function.

This function handles the FlexCAN Error, the Message Buffer, and the Rx FIFO IRQ request.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>handle</i>	FlexCAN handle pointer.

14.6.2.5.25 FLEXCAN_TransferReceiveBlocking()

```
status_t FLEXCAN_TransferReceiveBlocking (
    CAN_Type * base,
    uint8_t mbIdx,
    flexcan_frame_t * pRxFrame)
```

```
#include <fsl_flexcan.h>
```

Performs a polling receive transaction on the CAN bus.

Note

A transfer handle does not need to be created before calling this API.

Parameters

<i>base</i>	FlexCAN peripheral base pointer.
<i>mbIdx</i>	The FlexCAN Message Buffer index.
<i>pRxFrame</i>	Pointer to CAN message frame structure for reception.

Return values

<i>kStatus_Success</i>	- Rx Message Buffer is full and has been read successfully.
<i>kStatus_FLEXCAN_RxOverflow</i>	- Rx Message Buffer is already overflowed and has been read successfully.
<i>kStatus_Fail</i>	- Rx Message Buffer is empty.

14.6.2.5.26 FLEXCAN_TransferReceiveFifoBlocking()

```
status_t FLEXCAN_TransferReceiveFifoBlocking (
    CAN_Type * base,
    flexcan_frame_t * pRxFrame)
```

```
#include <fsl_flexcan.h>
```

Performs a polling receive transaction from Legacy Rx FIFO on the CAN bus.

Note

A transfer handle does not need to be created before calling this API.

Parameters

<i>base</i>	FlexCAN peripheral base pointer.
<i>pRxFrame</i>	Pointer to CAN message frame structure for reception.

Return values

<i>kStatus_Success</i>	- Read Message from Rx FIFO successfully.
<i>kStatus_Fail</i>	- Rx FIFO is not enabled.

14.6.2.5.27 FLEXCAN_TransferReceiveFifoNonBlocking()

```
status_t FLEXCAN_TransferReceiveFifoNonBlocking (
    CAN_Type * base,
    flexcan_handle_t * handle,
    flexcan_fifo_transfer_t * pFifoXfer)
```

```
#include <fsl_flexcan.h>
```

Receives a message from Rx FIFO using IRQ.

This function receives a message using IRQ. This is a non-blocking function, which returns right away. When all messages have been received, the receive callback function is called.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>handle</i>	FlexCAN handle pointer.
<i>pFifoXfer</i>	FlexCAN Rx FIFO transfer structure. See the flexcan_fifo_transfer_t .

Return values

<i>kStatus_Success</i>	- Start Rx FIFO receiving process successfully.
<i>kStatus_FLEXCAN_RxFifoBusy</i>	- Rx FIFO is currently in use.

14.6.2.5.28 FLEXCAN_TransferReceiveNonBlocking()

```
status_t FLEXCAN_TransferReceiveNonBlocking (
    CAN_Type * base,
    flexcan_handle_t * handle,
    flexcan_mb_transfer_t * pMbXfer)
```

```
#include <fsl_flexcan.h>
```

Receives a message using IRQ.

This function receives a message using IRQ. This is non-blocking function, which returns right away. When the message has been received, the receive callback function is called.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>handle</i>	FlexCAN handle pointer.
<i>pMbXfer</i>	FlexCAN Message Buffer transfer structure. See the flexcan_mb_transfer_t .

Return values

<i>kStatus_Success</i>	- Start Rx Message Buffer receiving process successfully.
<i>kStatus_FLEXCAN_RxBusy</i>	- Rx Message Buffer is in use.

14.6.2.5.29 FLEXCAN_TransferSendBlocking()

```
status_t FLEXCAN_TransferSendBlocking (
    CAN_Type * base,
    uint8_t mbIdx,
    flexcan_frame_t * pTxFrame)
```

```
#include <fsl_flexcan.h>
```

Performs a polling send transaction on the CAN bus.

Note

A transfer handle does not need to be created before calling this API.

Parameters

<i>base</i>	FlexCAN peripheral base pointer.
<i>mbIdx</i>	The FlexCAN Message Buffer index.
<i>pTxFrame</i>	Pointer to CAN message frame to be sent.

Return values

<i>kStatus_Success</i>	- Write Tx Message Buffer Successfully.
<i>kStatus_Fail</i>	- Tx Message Buffer is currently in use.

14.6.2.5.30 FLEXCAN_TransferSendNonBlocking()

```
status_t FLEXCAN_TransferSendNonBlocking (
    CAN_Type * base,
    flexcan_handle_t * handle,
    flexcan_mb_transfer_t * pMbXfer)
```

```
#include <fsl_flexcan.h>
```

Sends a message using IRQ.

This function sends a message using IRQ. This is a non-blocking function, which returns right away. When messages have been sent out, the send callback function is called.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>handle</i>	FlexCAN handle pointer.
<i>pMbXfer</i>	FlexCAN Message Buffer transfer structure. See the flexcan_mb_transfer_t .

Return values

<i>kStatus_Success</i>	Start Tx Message Buffer sending process successfully.
<i>kStatus_Fail</i>	Write Tx Message Buffer failed.
<i>kStatus_FLEXCAN_TxBusy</i>	Tx Message Buffer is in use.

14.6.2.5.31 FLEXCAN_WriteTxMb()

```
status_t FLEXCAN_WriteTxMb (
    CAN_Type * base,
    uint8_t mbIdx,
    const flexcan_frame_t * pTxFrame)
```

```
#include <fsl_flexcan.h>
```

Writes a FlexCAN Message to the Transmit Message Buffer.

This function writes a CAN Message to the specified Transmit Message Buffer and changes the Message Buffer state to start CAN Message transmit. After that the function returns immediately.

Parameters

<i>base</i>	FlexCAN peripheral base address.
<i>mbIdx</i>	The FlexCAN Message Buffer index.
<i>pTxFrame</i>	Pointer to CAN message frame to be sent.

Return values

<i>kStatus_Success</i>	- Write Tx Message Buffer Successfully.
<i>kStatus_Fail</i>	- Tx Message Buffer is currently in use.

14.6.3 MOD5441x, NANO54415, SB800EX

Classes

- class [canMCF5441x::CanRxMessage](#)
Class to hold received CAN messages.

14.6.3.1 Detailed Description

- `#include< multican.h>`

Control Area Network (CAN) for ColdFire MCF5441x platforms including MOD54415, MOD54417, NANO54415 and SB800EX.

14.6.4 MODM7AE70

Topics

- [MCAN Driver Internals](#)

Classes

- class [mcanMODM7AE70::mcan_module](#)
MCAN Module Class.
- class [mcanMODM7AE70::mcan_config](#)

MCAN configuration structure.

- class [mcanMODM7AE70::CanRxMessage](#)

Class to hold received CAN messages.

MCAN Constants

- const uint32_t **mcanMODM7AE70::CONF_MCAN_RX_FIFO_0_NUM** = 32
Range: 1..64.
- const uint32_t **mcanMODM7AE70::CONF_MCAN_RX_FIFO_1_NUM** = 1
Range: 1..64.
- const uint32_t **mcanMODM7AE70::CONF_MCAN_RX_BUFFER_NUM** = 1
Range: 1..64.
- const uint32_t **mcanMODM7AE70::CONF_MCAN_TX_BUFFER_NUM** = 8
Range: 1..16.
- const uint32_t **mcanMODM7AE70::CONF_MCAN_TX_FIFO_QUEUE_NUM** = 1
Range: 1..16.
- const uint32_t **mcanMODM7AE70::CONF_MCAN_TX_EVENT_FIFO** = 8
Range: 1..32.
- const uint32_t **mcanMODM7AE70::CONF_MCAN_RX_STANDARD_ID_FILTER_NUM** = 32
Range: 1..128.
- const uint32_t **mcanMODM7AE70::CONF_MCAN_RX_EXTENDED_ID_FILTER_NUM** = 32
Range: 1..64.
- #define **CAN_DATA_STORE_SIZE** (512)
Receive OS_FIFO Buffer Size.

Helper Macros

- #define **CAN_EXTENDED_ID_BIT** (0x20000000)
The single bit used by this API to indicate an extended ID.
- #define **ExtToNbId**(id) (id | CAN_EXTENDED_ID_BIT)
Convert an ID to an extended ID.
- #define **NormToNbId**(id) (id & 0x7ff)
Convert a normal ID in the range of 0 to 2048 to the range of 0 to 1024.
- #define **IsNbIdExt**(id) ((id & CAN_EXTENDED_ID_BIT) != 0)
Check for an extended MCAN ID.
- #define **NbToExtId**(id) (id & 0x1FFFFFFF)
Remove the API extended flage from the ID.
- #define **NbToNormId**(id) (id & 0x7FF)
Shift a Normal ID so it has a value from 0 to 1023.

14.6.4.1 Detailed Description

```
#include< mcan.h>
```

Control Area Network (MCAN) Low Level Driver for MODM7AE70

The Controller Area Network (MCAN) performs communication according to ISO 11898-1:2015 and to Bosch CANFD specification. Additional transceiver hardware is required for connection to the physical layer. All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN core to the Message RAM, as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN core, as well as providing transmit status information.

Acceptance filtering is implemented by a combination of up to 128 filter elements, where each element can be configured as a range, as a bit mask, or as a dedicated ID filter.

There are two types of CAN identifiers that define different formats of the message frame, with the main difference being the identifier length. The two CAN protocol versions are:

- Version 2.0A, Normal or Standard CAN, supporting messages with 11-bit identifiers.
- Version 2.0B, Extended CAN, supporting messages with 29-bit identifiers consisting of an 11-bit base identifier for compatibility with Version 2.0A and an 18-bit extension identifier.

Note

Detailed information on the MCAN operation and features is located in the Microchip SAME70 Family Data Sheet located in your \nburn\docs\Microchip folder, chapter 49.

14.6.4.2 Macro Definition Documentation

14.6.4.2.1 IsNBIdExt

```
#define IsNBIdExt(  
    id) ( (id & CAN_EXTENDED_ID_BIT) !=0)
```

#include <mcan.h>
Check for an extended MCAN ID.
Returns non zero if the ID is an extended ID

14.6.4.2.2 NbToNormId

```
#define NbToNormId(  
    id) (id & 0x7FF)
```

#include <mcan.h>
Shift a Normal ID so it has a value from 0 to 1023.
Some CAN systems will treat normal ID's as an integer from 0 to 2048. Other systems may treat normal ID's as 28 bit values where the bottom 17 bits are zero. This macro will convert the NetBurner normal ID format to the 0 to 2048 format.

14.6.4.3 MCAN Driver Internals

Module Setting

- enum `mcan_timeout_mode` { `MCAN_TIMEOUT_CONTINUOUS` = `MCAN_TOCC_TOS_CONTINUOUS` , `MCAN_TIMEOUT_TX_EVEN_FIFO` = `MCAN_TOCC_TOS_TX_EV_TIMEOUT` , `MCAN_TIMEOUT_RX_FIFO_0` = `MCAN_TOCC_TOS_RX0_EV_TIMEOUT` , `MCAN_TIMEOUT_RX_FIFO_1` = `MCAN_TOCC_TOS_RX1_EV_TIMEOUT` }
- *Can time out modes.*

```

Can module interrupt source.

14.6.4.3.1 Detailed Description

```
#include< mcan_internal.h>
```

This driver for Atmel® | SMART SAM devices provides an low level interface for the configuration and management of the device's Control Area Network functionality.

Note

Since "The Control Area Network (CAN) performs communication according to ISO 11898-1 (Bosch CAN specification 2.0 part A,B) and to Bosch CAN FD specification V1.0", the driver is focus on the MAC layer and try to offer the APIs which can be used by upper application layer.

For storage of Rx/Tx messages and for storage of the filter configuration, a message RAM is needed to the CAN module. In this driver, the message RAM is static allocated, the related setting is defined and can be changed in the module configuration file "conf_mcan.h".

The following peripherals are used by this module:

- CAN (Control Area Network)

The following devices can use this module:

- SAMV71

The outline of this documentation is as follows:

- [Prerequisites](#)
- [Module Overview](#)
- [Special Considerations](#)
- [Extra Information](#)
- [Examples](#)
- [API Overview](#)

14.6.4.3.2 Prerequisites

There are no prerequisites for this module.

14.6.4.3.3 Module Overview

This driver provides an interface for the Control Area Network Controller functions on the device.

14.6.4.3.4 Special Considerations

There are no special considerations for this module.

14.6.4.3.5 Extra Information

For extra information see asfdoc_sam_mcan_extra. This includes:

- asfdoc_sam_mcan_extra_acronyms
- asfdoc_sam_mcan_extra_dependencies
- asfdoc_sam_mcan_extra_errata
- asfdoc_sam_mcan_extra_history

14.6.4.3.6 Examples

For a list of examples related to this driver, see asfdoc_sam_mcan_exqsg.

14.6.4.3.7 API Overview

14.6.4.3.8 Enumeration Type Documentation

14.6.4.3.8.1 mcan_interrupt_source

```
enum mcan_interrupt_source
#include <mcan_internal.h>
Can module interrupt source.
Enum for the interrupt source.
```

Enumerator

MCAN_RX_FIFO_0_NEW_MESSAGE	Rx FIFO 0 New Message Interrupt Enable.
MCAN_RX_FIFO_0_WATERMARK	Rx FIFO 0 Watermark Reached Interrupt Enable.
MCAN_RX_FIFO_0_FULL	Rx FIFO 0 Full Interrupt Enable.
MCAN_RX_FIFO_0_LOST_MESSAGE	Rx FIFO 0 Message Lost Interrupt Enable.
MCAN_RX_FIFO_1_NEW_MESSAGE	Rx FIFO 1 New Message Interrupt Enable.
MCAN_RX_FIFO_1_WATERMARK	Rx FIFO 1 Watermark Reached Interrupt Enable.
MCAN_RX_FIFO_1_FULL	Rx FIFO 1 Full Interrupt Enable.
MCAN_RX_FIFO_1_MESSAGE_LOST	Rx FIFO 1 Message Lost Interrupt Enable.
MCAN_RX_HIGH_PRIORITY_MESSAGE	High Priority Message Interrupt Enable.
MCAN_TIMESTAMP_COMPLETE	Transmission Completed Interrupt Enable.
MCAN_TX_CANCELLATION_FINISH	Transmission Cancellation Finished Interrupt Enable.
MCAN_TX_FIFO_EMPTY	Tx FIFO Empty Interrupt Enable.
MCAN_TX_EVENT_FIFO_NEW_ENTRY	Tx Event FIFO New Entry Interrupt Enable.
MCAN_TX_EVENT_FIFO_WATERMARK	Tx Event FIFO Watermark Reached Interrupt Enable.
MCAN_TX_EVENT_FIFO_FULL	Tx Event FIFO Full Interrupt Enable.
MCAN_TX_EVENT_FIFO_ELEMENT_LOST	Tx Event FIFO Element Lost Interrupt Enable.
MCAN_TIMESTAMP_WRAPAROUND	Timestamp Wraparound Interrupt Enable.
MCAN_MESSAGE_RAM_ACCESS_FAILURE	Message RAM Access Failure Interrupt Enable.
MCAN_TIMEOUT_OCCURRED	Timeout Occurred Interrupt Enable.
MCAN_RX_BUFFER_NEW_MESSAGE	Message stored to Dedicated Rx Buffer Interrupt Enable.
MCAN_ERROR_LOGGING_OVERFLOW	Error Logging Overflow Interrupt Enable.
MCAN_ERROR_PASSIVE	Error Passive Interrupt Enable.
MCAN_WARNING_STATUS	Warning Status Interrupt Enable.
MCAN_BUS_OFF	Bus_Off Status Interrupt Enable.
MCAN_WATCHDOG	Watchdog Interrupt Enable.
MCAN_CRC_ERROR	CRC Error Interrupt Enable
MCAN_BIT_ERROR	Bit Error Interrupt Enable.
MCAN_ACKNOWLEDGE_ERROR	Acknowledge Error Interrupt Enable .
MCAN_FORMAT_ERROR	Format Error Interrupt Enable
MCAN_STUFF_ERROR	Stuff Error Interrupt Enable

14.6.4.3.8.2 mcan_nonmatching_frames_action

```
enum mcan_nonmatching_frames_action
#include <mcan_internal.h>
```

Can non-matching frames action.

Enumerator

MCAN_NONMATCHING_FRAMES_FIFO_0	Accept in Rx FIFO 0.
MCAN_NONMATCHING_FRAMES_FIFO_1	Accept in Rx FIFO 1.
MCAN_NONMATCHING_FRAMES_REJECT	Reject.

14.6.4.3.8.3 mcan_timeout_mode

```
enum mcan_timeout_mode
#include <mcan_internal.h>
Can time out modes.
```

Enumerator

MCAN_TIMEOUT_CONTINUES	Continuous operation.
MCAN_TIMEOUT_TX_EVEN_FIFO	Timeout controlled by TX Event FIFO.
MCAN_TIMEOUT_RX_FIFO_0	Timeout controlled by Rx FIFO 0.
MCAN_TIMEOUT_RX_FIFO_1	Timeout controlled by Rx FIFO 1.

14.7 Command Processor

Topics

- [Command Processor Disconnect Causes](#)
- [Command Processor Listen Channels](#)
- [Command Processor Response Codes](#)

Functions

- int [CmdStartCommandProcessor](#) (int priority)
Start the command processor.
- int [CmdAddCommandFd](#) (int fd, bool require_auth, bool time_out_conn, bool local_echo=true)
Add an established FD connection to the list of fd's managed by the command processor.
- int [CmdRemoveCommandFd](#) (int fd)
Remove an established FD (either a TCP session, a serial connection, or an SSH session).
- int [CmdListenOnTcpPort](#) (uint16_t port, int do_telnet_processing, int max_connections)
Start listening for a connection over TCP.
- int [CmdListenQuietOnTcpPort](#) (uint16_t port, int do_telnet_processing, int max_connections)
Start listening for a connection over TCP, but without the siggnon or password.
- int [CmdListenOnSshPort](#) (uint16_t port, int max_connections)
Start listening for a connection over SSH.
- int [CmdListenQuietOnSshPort](#) (uint16_t port, int max_connections)
Start listening for a connection over SSH, but without the siggnon or password.
- int [CmdStopListeningOnTcpPort](#) (uint16_t port)
Stop Listening for connections on the specified port. Also closes all open connections that were based on that port.
- int [CmdStopListeningOnSshPort](#) (uint16_t port)
Stop Listening for connections on the specified port. Also closes all open connections that were based on that port.
- void [SendToAll](#) (const char *buffer, int len, bool include_serial_ports)
Send a message to all connected sockets, excluding "Listening sockets".

Variables

- `int(* CmdAuthenticateFunc )(const char *name, const char *passwd)`
External Authentication function CALLBACK for TCP connections, used to verify username and password. If this function pointer is not NULL then each new Telnet session will be asked to authenticate.
- `int(* CmdAuthenticateSshFunc )(const char *name, const char *authVal, AuthType authType)`
External Authentication function CALLBACK for SSH connections, used to verify username and password. If this function pointer is not NULL then each new SSH session will be asked to authenticate. If this function pointer is NULL, it tries to use CmdAuthenticateFunc instead.
- `int(* CmdCmd_func )(const char *command, FILE *fRespondto, void *pData)`
The command processing callback function for handling string commands.
- `int(* CmdChar_func )(char command, FILE *fRespondto, void *pData)`
The command processing callback function for handling single character commands. If this is implemented does not do echo or line editing this is the responsibility of the application programmer.
- `void (* CmdConnect_func )(FILE *fRespondto)`
Connect callback function. If this function is not NULL, then the system will call this function every time a new session is started.
- `void(* CmdPrompt_func )(FILE *fRespondto, void *pData)`
Prompt callback function. If this function is not NULL, then the system will call this function every time a new prompt line needs to be displayed.
- `void(* CmdDisConnect_func )(FILE *fRespondto, int cause, void *pData)`
Dis-Connect callback function, if this function is not NULL then the system will call this function every time a session is terminated.
- `int CmdIdleTimeout`
- `const char * Cmdlogin_prompt`
If this is defined, then it will be sent to the socket on connection before Authentication is tried.

14.7.1 Detailed Description

```
#include< command.h>
```

This is NetBurner's Command Processor Library. It operates as a task and reads input one line at a time from multiple sources. When it has gathered a whole line, it sends it to a command processor that is defined by the user.

14.7.2 Function Documentation

14.7.2.1 CmdAddCommandFd()

```
int CmdAddCommandFd (
    int fd,
    bool require_auth,
    bool time_out_conn,
    bool local_echo = true)
#include <command.h>
```

Add an established FD connection to the list of fd's managed by the command processor.

Parameters

<i>fd</i>	The file descriptor.
<i>require_auth</i>	Do we Authenticate the connection on this FD?
<i>time_out_conn</i>	Do we time out the connection on this FD?
<i>local_echo</i>	Do we provide a local echo for this FD (default is true)?

Return values

<i>CMD_OK</i>	Command processor task started properly.
<i>CMD_FAIL</i>	Command processor task failed to start.
<i>CMD_TO_MANY_FDS</i>	Too many file descriptors are currently in use.

14.7.2.2 CmdListenOnSshPort()

```
int CmdListenOnSshPort (
    uint16_t port,
    int max_connections)
#include <command.h>
Start listening for a connection over SSH.
```

Parameters

<i>port</i>	The port number to listen on.
<i>max_connections</i>	What are the max number of connections we should allow on this port?

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_TO_MANY_FDS</i>	Too many file descriptors are currently in use.
<i>CMD_FAILED_SSH_KEY_GEN</i>	Unable to generate the key needed for SSH communication.

14.7.2.3 CmdListenOnTcpPort()

```
int CmdListenOnTcpPort (
    uint16_t port,
    int do_telnet_processing,
    int max_connections)
#include <command.h>
Start listening for a connection over TCP.
```

Parameters

<i>port</i>	The port number to listen on.
<i>do_telnet_processing</i>	Should we treat the port as telnet and process telnet negotiations?
<i>max_connections</i>	What are the max number of connections we should allow on this port?

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_TO_MANY_FDS</i>	Too many file descriptors are currently in use.

14.7.2.4 CmdListenQuietOnSshPort()

```
int CmdListenQuietOnSshPort (
    uint16_t port,
    int max_connections)
#include <command.h>
Start listening for a connection over SSH, but without the siggnon or password.
```

Parameters

<i>port</i>	The port number to listen on.
<i>max_connections</i>	What are the max number of connections we should allow on this port?

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_TO_MANY_FDS</i>	Too many file descriptors are currently in use.
<i>CMD_FAILED_SSH_KEY_GEN</i>	Unable to generate the key needed for SSH communication.

14.7.2.5 CmdListenQuietOnTcpPort()

```
int CmdListenQuietOnTcpPort (
    uint16_t port,
    int do_telnet_processing,
    int max_connections)
```

```
#include <command.h>
```

Start listening for a connection over TCP, but without the siggnon or password.

Parameters

<i>port</i>	The port number to listen on.
<i>do_telnet_processing</i>	Should we treat the port as telnet and process telnet negotiations?
<i>max_connections</i>	What are the max number of connections we should allow on this port?

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_TO_MANY_FDS</i>	Too many file descriptors are currently in use.

14.7.2.6 CmdRemoveCommandFd()

```
int CmdRemoveCommandFd (
    int fd)
```

```
#include <command.h>
```

Remove an established FD (either a TCP session, a serial connection, or an SSH session).

Parameters

<i>fd</i>	The file descriptor to remove.

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_FAIL</i>	Failed to remove the file descriptor.

14.7.2.7 CmdStartCommandProcessor()

```
int CmdStartCommandProcessor (
    int priority)
#include <command.h>
Start the command processor.
```

Parameters

<i>priority</i>	The NBRTOS task priority to run at.

Return values

<i>CMD_OK</i>	Command processor task started properly.
<i>CMD_FAIL</i>	Command processor task failed to start.

14.7.2.8 CmdStopListeningOnSshPort()

```
int CmdStopListeningOnSshPort (
    uint16_t port)
```

```
#include <command.h>
```

Stop Listening for connections on the specified port. Also closes all open connections that were based on that port.

Parameters

<i>port</i>	The port number to listen on.

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_FAIL</i>	Port requested wasn't listening for a connection.

14.7.2.9 CmdStopListeningOnTcpPort()

```
int CmdStopListeningOnTcpPort (
    uint16_t port)
```

```
#include <command.h>
```

Stop Listening for connections on the specified port. Also closes all open connections that were based on that port.

Parameters

<i>port</i>	The port number to listen on.

Return values

<i>CMD_OK</i>	Successfully removed the file descriptor.
<i>CMD_FAIL</i>	Port requested wasn't listening for a connection.

14.7.2.10 SendToAll()

```
void SendToAll (
    const char * buffer,
    int len,
    bool include_serial_ports)
```

```
#include <command.h>
```

Send a message to all connected sockets, excluding "Listening sockets".

Parameters

<i>buffer</i>	A buffer holding the message to send.
<i>len</i>	The length of the buffer to send.
<i>include_serial_ports</i>	Also send to serial ports?

14.7.3 Variable Documentation

14.7.3.1 CmdAuthenticateFunc

```
int(* CmdAuthenticateFunc) (const char *name, const char *passwd) (
    const char * name,
    const char * passwd) [extern]
```

```
#include <command.h>
```

External Authentication function CALLBACK for TCP connections, used to verify username and password. If this function pointer is not NULL then each new Telnet session will be asked to authenticate.

Parameters

<i>name</i>	The user name trying to authenticate.
<i>passwd</i>	The password provided for the user.

Return values

<i>CMD_OK</i>	If the authentication was successful.
<i>CMD_CLOSE</i>	If the authentication was not successful.

14.7.3.2 CmdAuthenticateSshFunc

```
int(* CmdAuthenticateSshFunc) (const char *name, const char *authVal, AuthType authType) (
    const char * name,
    const char * authVal,
    AuthType authType) [extern]
```

```
#include <command.h>
```

External Authentication function CALLBACK for SSH connections, used to verify username and password. If this function pointer is not NULL then each new SSH session will be asked to authenticate. If this function pointer is NULL, it tries to use CmdAuthenticateFunc instead.

Parameters

<i>name</i>	The user name trying to authenticate.
<i>authVal</i>	The authorization value provided for the user.
<i>authType</i>	The type of authorization value passed in.

Return values

<i>CMD_OK</i>	If the authentication was successful.
<i>CMD_CLOSE</i>	If the authentication was not successful.

14.7.3.3 CmdChar_func

```
int (* CmdChar_func) (char command, FILE *fRespondto, void *pData) (
    char command,
    FILE * fRespondto,
    void * pData) [extern]
```

```
#include <command.h>
```

The command processing callback function for handling single character commands. If this is implemented does not do echo or line editing this is the responsibility of the application programmer.

Parameters

<i>command</i>	The single command character.
<i>fRespondto</i>	The FILE * all responses should be set to (use fprintf).
<i>pData</i>	Any data that is associated from the session. This is returned by CmdConnect_func.

Return values

<i>CMD_OK</i>	If the command was okay.
<i>CMD_CLOSE</i>	If the command causes the session to terminate (Close).

See also

[CmdCmd_func](#)

[CmdConnect_func](#)

14.7.3.4 CmdCmd_func

```
int (* CmdCmd_func) (const char *command, FILE *fRespondto, void *pData) (
    const char * command,
    FILE * fRespondto,
    void * pData) [extern]
```

```
#include <command.h>
```

The command processing callback function for handling string commands.

Parameters

<i>command</i>	A pointer to the null terminated ASCII text of the command.
<i>fRespondto</i>	The FILE * all responses should be set to (use fprintf).
<i>pData</i>	Any data that is associated from the session and is returned by CmdConnect_func.

Return values

<i>CMD_OK</i>	If the command was okay.
<i>CMD_CLOSE</i>	If the command causes the session to terminate (Close).

See also

[CmdChar_func](#)

[CmdConnect_func](#)

14.7.3.5 CmdConnect_func

```
void (* CmdConnect_func) (FILE *fRespondto) (
    FILE * fRespondto) [extern]
```

```
#include <command.h>
```

Connect callback function. If this function is not NULL, then the system will call this function every time a new session is started.

Parameters

<i>fRespondto</i>	The FILE * all responses should be set to (use fprintf).

Return values

<i>Returns</i>	an arbitrary void* data item to be associated with the session. This data item is the same pData item used in other callback functions such as CmdPrompt_func.

See also

[CmdCmd_func](#)

[CmdChar_func](#)

14.7.3.6 CmdDisconnect_func

```
void(* CmdDisconnect_func) (FILE *fRespondto, int cause, void *pData) (
    FILE * fRespondto,
    int cause,
    void * pData) [extern]
```

```
#include <command.h>
```

Dis-Connect callback function, if this function is not NULL then the system will call this function every time a session is terminated.

Parameters

<i>fRespondto</i>	The FILE * all responses should be set to (use fprintf).
<i>cause</i>	Why it disconnected. Can be any value from Command Processor Disconnect Causes .
<i>pData</i>	Any data that is associated from the session. This is returned by CmdConnect_func.

See also

[CmdConnect_func](#)

14.7.3.7 CmdIdleTimeout

```
int CmdIdleTimeout [extern]
#include <command.h>
```

User defined value that specifies the number of seconds a connection is idle before it is terminated due to inactivity.

14.7.3.8 CmdPrompt_func

```
void(* CmdPrompt_func) (FILE *fRespondto, void *pData) (
    FILE * fRespondto,
    void * pData) [extern]
```

```
#include <command.h>
```

Prompt callback function. If this function is not NULL, then the system will call this function every time a new prompt line needs to be displayed.

Parameters

<i>fRespondto</i>	The FILE * all responses should be set to (use fprintf).
<i>pData</i>	Any data that is associated from the session. This is returned by CmdConnect_func.

[CmdConnect_func](#)

14.7.4 Command Processor Disconnect Causes

Macros

- #define **CMD_DIS_CAUSE_TIMEOUT** (1)
Connection timed out.
- #define **CMD_DIS_CAUSE_CLOSED** (2)
Connection closed.
- #define **CMD_DIS_SOCKET_CLOSED** (3)
Socket closed. Don't send a response for this case.
- #define **CMD_DIS_AUTH_FAILED** (4)
Authorization failed. Don't send a response for this case.

14.7.4.1 Detailed Description

Possible causes given for disconnects.

14.7.5 Command Processor Listen Channels

Enumerations

- enum [ListenOn](#) : int8_t { [eListenOnTcp](#) = 1 , [eListenOnSsh](#) = 2 }
- The various remote channels that the command processor can listen to.*

14.7.5.1 Detailed Description

14.7.5.2 Enumeration Type Documentation

14.7.5.2.1 ListenOn

```
enum ListenOn : int8_t
#include <command.h>
```

The various remote channels that the command processor can listen to.

Enumerator

eListenOnTcp	Listen on TCP.
eListenOnSsh	Listen on SSH.

14.7.6 Command Processor Response Codes

Macros

- #define **CMD_OK** (0)
Function was executed properly.
- #define **CMD_CLOSE** (1)
Connection closed.
- #define **CMD_FAIL** (2)

- General function failed.*
- #define **CMD_AUTH_FAIL** (3)
Authorization failed.
- #define **CMD_TO_MANY_FDS** (4)
Too many file descriptors currently in use.
- #define **CMD_FAILED_SSH_KEY_GEN** (5)
Unable to correctly generate key needed for SSH connections.

14.7.6.1 Detailed Description

Valid return codes that can be returned by the NetBurner Command Processor functions.

14.8 Configuration System

Configuration System Variables.

Topics

- [Configuration Network Objects](#)
- [Configuration Server](#)
- [Configuration Time Objects](#)
- [Configuration Variables](#)

Configuration System Variables.

14.8.1 Detailed Description

Configuration System Variables.

```
#include< config_fs_bulkstore.h>
```

```
#include< config_obj.h>
```

14.8.2 Configuration Network Objects

Classes

- class [config_localname](#)
Configure device network name.
- class [CUR_IPADDR4](#)
- class [I4Record](#)
- class [Dynamic_IPADDR](#)
Dynamic_IPADDR.
- class [I6Record](#)

14.8.2.1 Detailed Description

```
#include< config_netobj.h>
```

14.8.3 Configuration Server

Classes

- class [WebConfigServlet](#)
Class to run web configurator.

Functions

- void [EnableConfigMirror](#) ()
Enable the configuration mirror.
- void [SaveConfigToStorage](#) ()
Write all pending data to flash memory.
- size_t [ConfigSize](#) ()
Returns the number of bytes currently in use by configuration flash.
- size_t [ConfigMaxSize](#) ()
Returns the number of bytes available in configuration flash.

14.8.3.1 Detailed Description

```
#include< config_server.h>
```

The configuration server manages the configuration variables, which can be used internally, or optionally presented on a configuration server web page. Please refer to the configuration object section for more details.

There is a default factory web interface that is normally running on the device as a user interface to set configuration options. Enabling the Configuration Mirror provides a method to replace the factory interface with your own custom interface. The is an easy way to use your company brand on the device.

Any time a configuration variable is modified, it is marked as pending. Modified values will not be written to flash memory until a call to [SaveConfigToStorage\(\)](#) is executed. Note that if a user clicks on the Update button on the configuration web page, values will be written to flash.

14.8.3.2 Function Documentation

14.8.3.2.1 ConfigMaxSize()

```
size_t ConfigMaxSize ()
#include <config_server.h>
```

Returns the number of bytes available in configuration flash.

Returns

The maximum number of bytes available. This function is implemented in hal.cpp

14.8.3.2.2 ConfigSize()

```
size_t ConfigSize ()
#include <config_server.h>
```

Returns the number of bytes currently in use by configuration flash.

Returns

Number of bytes in use

14.8.3.2.3 EnableConfigMirror()

```
void EnableConfigMirror ()
#include <config_server.h>
```

Enable the configuration mirror.

When enabled, the application configuration web interface will replace the default system web interface. In this way you can easily customize and brand the configuration web interface for your company.

Note

This is an empty function. To enable the config mirror, it needs to be called within the application code, which in turn forces the function to be linked during compilation. The linking is what enables the config mirror.

14.8.3.2.4 SaveConfigToStorage()

```
void SaveConfigToStorage ()
```

```
#include <config_server.h>
```

Write all pending data to flash memory.

Checks the pending flag of all configuration system objects and writes updates to flash memory

14.8.4 Configuration Time Objects**Classes**

- class [config_time_t](#)
Class to hold time configuration.

14.8.4.1 Detailed Description

```
#include< config_time.h>
```

14.8.5 Configuration Variables

Configuration System Variables.

Topics

- [Configuration Variable Flags](#)

Classes

- class [config_obj](#)
Base class used to create configuration objects.
- class [config_value](#)
Base class used to create a configuration value.
- class [config_uint](#)
Unsigned 32-bit Integer Configuration Variable.
- class [config_int](#)
Signed 32-bit Integer Configuration Variable.
- class [config_double](#)
Double Float Configuration Variable.
- class [config_bool](#)
Boolean Configuration Variable.
- class [config_string](#)
String Configuration Variable.
- class [config_pass](#)
Password string Configuration Variable.
- class [config_IPADDR4](#)
Configuration Variable for [IPADDR4](#) (IPv4) object types.
- class [config_IPADDR](#)
Configuration Variable for [IPADDR](#) (IPv6) object type.

- class [config_MACADR](#)
Configuration Variable for [MACADR](#) object type.
- class [config_chooser](#)
Chooser Configuration Variable - Select From a List of Items.
- class [config_int_limit](#)
A [config_int](#) with minimum and/or maximum values Attempting to set a value lower than the minimum or greater than the maximum will fail with an error both programmatically and in the Config Web UI.
- class [config_uint_limit](#)
A [config_uint](#) with minimum and/or maximum values Attempting to set a value lower than the minimum or greater than the maximum will fail with an error both programmatically and in the Config Web UI.
- class [config_double_limit](#)
A [config_double](#) with minimum and/or maximum values Attempting to set a value lower than the minimum or greater than the maximum will fail with an error both programmatically and in the Config Web UI.
- class [config_string_limit](#)
A [config_string](#) with minimum and/or maximum lengths Attempting to set a value shorter than the minimum or longer than the maximum will fail with an error both programmatically and in the Config Web UI.
- class [config_pass_limit](#)
A [config_pass](#) with minimum and/or maximum lengths Attempting to set a value shorter than the minimum or longer than the maximum will fail with an error both programmatically and in the Config Web UI.

Functions

- void **SaveConfigToStorage** ()
Save configuration to flash storage.
- void **OverrideConfig** ()
Create this function to override config settings.

14.8.5.1 Detailed Description

Configuration System Variables.

```
#include< config_obj.h>
```

Configuration variable objects are part of the NetBurner 3.x configuration system. The use of configuration objects facilitates a much easier method to create and store non-volatile information for both system configuration and for user application configuration and storage. They use a JSON interface so the information can be easily downloaded to save a configuration, or uploaded to configure the entire device at one time, such as in production bring-up. This includes system configuration such as IP addresses, and also any settings specific to your application.

The JSON value types include: integer, unsigned integer, float, boolean and string. There are also objects for IPv4 IP, IPv6 IP, MAC addresses, passwords, and selection lists options. In JSON everything is represented as a string, so there are object member functions to convert between values. These functions make use of the [NBString](#) class. For customers using the 2.x tools, the User Parameter flash sector method is still available, but we do recommend converting to the new configuration system. In 3.x you have the ability to access the data through a web configuration page and also through JSON, but you can certainly choose not to use those features and treat the configuration system as internal storage, and any configuration can be done through your application just as with the 2.x tool set.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

14.8.5.2 Function Documentation

14.8.5.2.1 OverrideConfig()

```
void OverrideConfig ()
#include <config_obj.h>
```

Create this function to override config settings.

This function exists as a weak reference. So you just need to create it and then force set any config variables you want to control. This will be called after config is loaded before any config is used by anything. It will also be called when anyone calls `revert` on the config system.

14.8.5.3 Configuration Variable Flags

Variables

- `const uint32_t fConfigValueLeaf = 0x01`
Value is a leaf.
- `const uint32_t fConfigReadOnly = 0x02`
Variable is read-only.
- `const uint32_t fConfigModified = 0x04`
Variable has been modified, but not yet saved.
- `const uint32_t fConfigHidden = 0x08`
Not visible to configuration web server display.
- `const uint32_t fConfigNoSave = 0x10`
Do not save to flash memory when save functions are called.
- `const uint32_t fConfigNoObscure = 0x20`
Do not obscure the value.
- `const uint32_t fConfigNeedReboot = 0x40`
System reboot required for changes to take effect.
- `const uint32_t fConfigNoReload = 0x80`
Disable reloading value from flash during a call to `ReloadFromFlash`.
- `const uint32_t fConfigDetached = 0x100`
Disable reloading value from flash during a call to `ReloadFromFlash`.
- `const uint32_t fConfigIsDefault = 0x200`
Value is unchanged from the default, i.e. was never set.
- `const uint32_t fMaskDoingSave = 0x40000000`
We're currently executing a config save to non-volatile storage.

14.8.5.3.1 Detailed Description

Specifies the characteristics of a configuration variable, such as read-only, hidden, etc.

14.9 Constants (constants.h)

NetBurner System Constants.

Macros

- `#define TICK_IRQ_LEVEL (5)`
System clock IRQ level.
- `#define SERIAL_IRQ_LEVEL (3)`
- `#define SERIAL_VECTOR_BASE (64)`
- `#define TICKS_PER_SECOND (20)`
System clock ticks per second.
- `#define OS_MAX_TASKS (32)`
Max number of system tasks.
- `#define OS_MAX_PRIOS (64)`

Maximum number of system priorities (NBRTOS limit: 256)

- **#define SSH_TASK_PRIORITY** (56)
ief SSH server must be lower than main for progress displays

Ethernet buffer defines

OS Maximum Interrupt Level

OS_MAX_IRQ_MASK - Optional, Maximum IRQ level that the RTOS is allowed to mask. RTOS objects may not be used in ISRs above this level.

- **#define ETHER_BUFFER_SIZE** (1548)
- **#define ETH_MAX_PAYLOAD** (1500)
- **#define ETH_MAX_SIZE** (1522)
- **#define ETH_MIN_SIZE** (46)
- **#define IP_HEADER_SIZE** (20)
- **#define UDP_HEADER_SIZE** (8)
- **#define MAX_UDPDATA** (ETH_MAX_PAYLOAD - (IP_HEADER_SIZE + UDP_HEADER_SIZE))
- **#define SERIAL_TX_BUFFERS** (2)
ETHERN_BUFFER_SIZE = bytes of serial TX fifo.
- **#define SERIAL_RX_BUFFERS** (2)
ETHERN_BUFFER_SIZE = bytes of serial RX fifo.
- **#define stdin_buffer_size** (200)

System task priorities

Restating the NBRTOS RTOS Library document (NBRTosLibrary.pdf) Lowest priority is OS_MAX_PRIOS-1, 1 is the highest. There can only be one task at each priority level. Idle task is created at priority 63.

UserMain is created at priority 10. It is recommended and is supported by examples and default projects that a call to OSChangePrio(MAIN_PRIO); be made to lower the priority to the range recommended for the main application. Factory applications use priorities 46 through 56.

Netburner Runtime library support and driver tasks use 36 through 45.

Care should be taken in use of priorities it can affect reliability and performance.

- **#define MAIN_PRIO** (50)
Recommend UserMain priority.

Runtime library driver and support task priorities

- **#define USB_HW_PRIO** (45)
- **#define PPP_PRIO** (44)
- **#define SECURITY_TASK_PRIO** (43)
- **#define WIFI_STATION_TASK_PRIO** (42)
- **#define WIFI_TASK_PRIO** (41)

- `#define CONFIG_SERVER_PRIO` (40)
- `#define HTTP_PRIO` (39)
- `#define ETHER_SEND_PRIO` (38)
- `#define MQTT_TASK_PRIO` ([MAIN_PRIO](#)-1)

14.9.1 Detailed Description

NetBurner System Constants.

```
#include< constants.h>
```

14.9.2 Macro Definition Documentation

14.9.2.1 TICKS_PER_SECOND

```
#define TICKS_PER_SECOND (20)
```

```
#include <constants.h>
```

System clock ticks per second.

PLEASE READ THIS BEFORE MODIFYING TICKS_PER_SECOND

Before you change this value understand what changing it does. Making it faster only slows things down. It does not speed up task switches, If only changes the granularity of time delays and timeouts. Task switches happen much much faster than the tick interval. They happen as soon as one task blocks or an interrupt /or task causes a higher priority task to be unblocked. The Time tick has NOTHING to do with task switches.

If you change it to the maximum 200 you have increased the RTOS overhead by a factor of 10 and have actually slowed your system.

14.10 DHCP

Topics

- [DHCP Server](#)
- [DHCPv4 Client](#)
- [DHCPv6 Client](#)

14.10.1 Detailed Description

[DHCP](#) Client functions. Refer to DHCPv4 or DHCPv6 documents for IPv4 or IPv6.

The [DHCP](#) client services are automatically controlled by the configuration option when the [init\(\)](#) function is called in an application. Options are:

- [DHCP](#)
- [DHCP](#) with Static Fallback
- Static

You may also create your own [DHCP](#) objects.

14.10.2 DHCP Server

Namespaces

- namespace [DHCP](#)
[DHCP](#) Namespace.

Macros

- `#define DHCP_SERV_MAX_INTF (4)`
- `#define DHCP_OFFER_DURATION (2 * TICKS\_PER\_SECOND)`
- `#define DHCP_SERV_MAX_HOSTNAME_LEN (32)`
- `#define LEASE_POOL_SIZE 150`
- `#define DHCPD_STARTING_ADDRESS 0xC0A80184`

Functions

- bool [AddStandardDHCPServer](#) (int intf=0, [IPADDR4](#) startAddr=[IPADDR4::NullIP\(\)](#))
Starts a standard allocator [DHCP](#) server.

14.10.2.1 Detailed Description

```
#include< dhcpd.h>
```

Adding a [DHCP](#) server will enable your NetBurner device to serve IPv4 addresses. This can be useful in circumstances such as direct connections between 2 devices.

14.10.2.2 Function Documentation

14.10.2.2.1 AddStandardDHCPServer()

```
bool AddStandardDHCPServer (
    int intf = 0,
    IPADDR4 startAddr = IPADDR4::NullIP\(\))
```

```
#include <dhcpd.h>
```

Starts a standard allocator [DHCP](#) server.

Also checks for existing [DHCP](#) servers on the specified network interface.

Parameters

<i>intf</i>	The interface to use. If no parameter is specified the default value is 0 which will use the first system interface.
<i>startAddr</i>	The starting IP address. If no parameter is specified the default range of 192.168.1.100 to 192.168.1.249 will be used.

Return values

<i>true</i>	Success
<i>false</i>	A server already exists or error starting the server

14.10.3 DHCPv4 Client

Topics

- [DHCP State](#)

Classes

- class [DhcpObject](#)
DHCP client class.

Functions

- `int32_t GetInterfaceDHCPState (int interface=0)`
Returns current state of the [DHCP](#) lease, with optional interface parameter.
- `int32_t WaitForDHCPInterface (int interface=0, uint16_t TicksToWait=10 * TICKS\_PER\_SECOND)`
Wait until a [DHCP](#) lease is obtained, or the timeout occurs.

14.10.3.1 Detailed Description

```
#include< dhcpclient.h>
```

14.10.3.2 Function Documentation

14.10.3.2.1 GetInterfaceDHCPState()

```
int32_t GetInterfaceDHCPState (
    int interface = 0)
#include <dhcpclient.h>
```

Returns current state of the [DHCP](#) lease, with optional interface parameter.

The [DhcpObject::GetDHCPState\(\)](#) function is a member function of the [DHCP](#) client class.

Returns

[DHCP State](#)

See also

[DhcpObject::GetDHCPState](#)

14.10.3.2.2 WaitForDHCPInterface()

```
int32_t WaitForDHCPInterface (
    int interface = 0,
    uint16_t TicksToWait = 10 * TICKS\_PER\_SECOND)
#include <dhcpclient.h>
```

Wait until a [DHCP](#) lease is obtained, or the timeout occurs.

Parameters

<i>interface</i>	The network interface to wait on.
<i>TicksToWait</i>	The number of system Time Ticks to wait. The TICKS_PER_SECOND constant can be used to more easily specify a number of seconds. If not specified, the default timeout is 10 seconds.

Returns

[DHCP State](#)

See also

[DhcpObject::GetDHCPState](#)

14.10.3.3 DHCP State

Macros

- **#define SDHCP_NOTSTARTED 0**
The System has not been initialized.
- **#define SDHCP_DISCOVER 1**
The system is discovering the [DHCP](#) servers.
- **#define SDHCP_OFFER 2**
The system has responded to an OFFER.
- **#define SDHCP_ACK 3**
The System has Acknowledged the OFFER.
- **#define SDHCP_INIT 4**
The System is reinitializing.
- **#define SDHCP_CMPL 5**
The System has obtained a valid [DHCP](#) lease.
- **#define SDHCP_RENEW 6**
The System is in the process of renewing.
- **#define SDHCP_REBIND 7**
The System has failed the Renew and is trying to Rebind.
- **#define SDHCP_RELEASE 8**
The System is trying to release the Lease.
- **#define SBOOTP_TRANSMITTING 9**
Trying BOOTP.
- **#define SBOOTP_DONE 10**
BOOTP complete.
- **#define SDHCP_FAILED 11**
[DHCP](#) attempt failed - could not obtain a [DHCP](#) lease.

14.10.3.3.1 Detailed Description

14.10.4 DHCPv6 Client

Functions

- void [InitIPv6](#) (int ifc=0)
- void [ShowAllV6Info](#) ()
- void [StartDHCPv6_Solicit](#) (int ifnum=-1)
Manually starts the DHCPv6 Client in Full Solicitation mode.
- void [StartDHCPv6_InfoReq](#) (int ifnum=-1)
Manually starts the DHCPv6 Client in Full Solicitation mode.
- void [StartDHCPv6](#) (int ifnum=-1)
Manually starts the DHCPv6 Client in Information Request mode.
- bool [AddStaticIPv6Address](#) (const [IPADDR6](#) &ip, int ifnum=-1)
Add a static IPv6 address to an interface.
- bool [RemoveStaticIPv6Address](#) (const [IPADDR6](#) &ip, int ifnum=-1)
Add a static IPv6 address to an interface.

14.10.4.1 Detailed Description

```
#include< ipv6_intf.h>
```

14.10.4.2 Function Documentation

14.10.4.2.1 AddStaticIPv6Address()

```
bool AddStaticIPv6Address (
    const IPADDR6 & ip,
    int ifnum = -1)
#include <ipv6_intf.h>
Add a static IPv6 address to an interface.
```

Parameters

<i>ip</i>	The IP address to add.
<i>ifnum</i>	The desired IPv6Interface to operate on. A negative value will use the first interface.

Return values

<i>true</i>	IP address successfully added
<i>false</i>	Error

See also

[RemoveStaticIPv6Address\(\)](#)

14.10.4.2.2 InitIPv6()

```
void InitIPv6 (
    int ifc = 0)
#include <ipv6_intf.h>
```

14.10.4.2.3 RemoveStaticIPv6Address()

```
bool RemoveStaticIPv6Address (
    const IPADDR6 & ip,
    int ifnum = -1)
#include <ipv6_intf.h>
Add a static IPv6 address to an interface.
```

Parameters

<i>ip</i>	The IP address to remove.
<i>ifnum</i>	The desired IPv6Interface to operate on. A negative value will use the first interface.

Return values

<i>true</i>	IP address successfully removed
<i>false</i>	Error

See also

[AddStaticIPv6Address\(\)](#)

14.10.4.2.4 ShowAllV6Info()

```
void ShowAllV6Info ()
#include <ipv6_intf.h>
```

14.10.4.2.5 StartDHCPv6()

```
void StartDHCPv6 (
    int ifnum = -1) [inline]
#include <ipv6_intf.h>
```

Manually starts the DHCPv6 Client in Information Request mode.

Parameters

<i>ifnum</i>	The desired IPv6Interface to operate on. A negative value indicates all interfaces

See also

[StartDHCPv6_Solicit\(\)](#)

14.10.4.2.6 StartDHCPv6_InfoReq()

```
void StartDHCPv6_InfoReq (
    int ifnum = -1)
#include <ipv6_intf.h>
```

Manually starts the DHCPv6 Client in Full Solicitation mode.

Parameters

<i>ifnum</i>	The desired IPv6Interface to operate on. A negative value indicates all interfaces

14.10.4.2.7 StartDHCPv6_Solicit()

```
void StartDHCPv6_Solicit (
    int ifnum = -1)
#include <ipv6_intf.h>
```

Manually starts the DHCPv6 Client in Full Solicitation mode.

Parameters

<i>ifnum</i>	The desired IPv6Interface to operate on. A negative value indicates all interfaces

See also

[StartDHCPv6\(\)](#)

14.11 DNS - Domain Name System**Topics**

- [DNS Record Types](#)
- [DNS Return Codes](#)

Functions

- bool [IsNameIPAddress](#) (const char *name)
Determine if the name is a valid IP Address and does not need to be looked up.
- int [fd_dns_part1](#) (const char *name, const [IPADDR](#) &dns_server, uint16_t TYPE=[DNS_A](#), uint16_t TYPE2=0, int ifn=-1)
Open a UDP socket and initiate a DNS lookup.
- bool [fd_dns_processresult](#) (int fd, const char *name, [IPADDR](#) &addr_out, uint16_t TYPE=[DNS_A](#), uint16_t TYPE2=[DNS_AAAA](#), uint32_t *ttl=0)
Process any responses on the UDP socket opened for DNS.
- int [fd_outstanding_Responses](#) (int fd)
Check to see if there are any outstanding DNS requests.
- bool [AnyDNSInterFaceActive](#) ()
Determine if we have an active DNS route; DNS server is set for an active interface.
- int [GetHostByName](#) (const char *name, [IPADDR](#) *plpaddr, const [IPADDR](#) &dns_server, const TickTimeout tout, uint16_t TYPE1=[DNS_A](#), uint16_t TYPE2=[extra_dns_t](#), uint32_t *ttl=NULL)
Get the IP address associated with the specified domain name.
- int [GetHostByNameVialfNum](#) (const char *name, [IPADDR](#) *plpaddr, const [IPADDR](#) &dns_server, int ifn, const TickTimeout &tout, uint16_t TYPE1=[DNS_A](#), uint16_t TYPE2=[extra_dns_t](#), uint32_t *ttl=NULL)
Get the IP address associated with the specified domain name on a specific interface.
- bool [CheckDnsCache](#) (const char *name, [IPADDR](#) &ia, uint32_t *ttl, uint16_t rtype)
Check the DNS cache for a stored response.

14.11.1 Detailed Description

```
#include< dns.h>
```

The current DNS system is agnostic about the use of [IPADDR](#), [IPADDR6](#) or [IPADDR4](#). The capability of C++ is such that you pass in any of those types and the compiler will select the correct function for that type. This is a change from tools versions 3.4.0 and earlier in which explicit IPv4 and IPv6 functions were used.

Note

While we are pointing out the automatic functionality in this DNS API, the same is true for most functions, structures and classes throughout the NetBurner API libraries.

The DNS system can be accessed as a blocking or synchronous operation with: [GetHostByName\(\)](#). If you want to do asynchronous non-blocking lookups, please refer to the functions:

- [fd_dns_part1\(\)](#)
- [fd_dns_processresult\(\)](#)

14.11.2 Function Documentation

14.11.2.1 AnyDNSInterFaceActive()

```
bool AnyDNSInterFaceActive ()
#include <dns.h>
```

Determine if we have an active DNS route; DNS server is set for an active interface.

Returns

true if active DNS is available somewhere

See also

[GetHostByName\(\)](#)
[InterfaceLinkActive\(int interface\);](#)

14.11.2.2 CheckDnsCache()

```
bool CheckDnsCache (
    const char * name,
    IPADDR & ia,
    uint32_t * ttl,
    uint16_t rtype)
#include <dns.h>
Check the DNS cache for a stored response.
```

Parameters

<i>*name</i>	Pointer to domain name to resolve
<i>ia</i>	Variable of type IPADDR to store resultant IP address
<i>ttl</i>	Optional pointer to return variable for TimeToLive value for DNS record
<i>rtype</i>	Request type: DNS Record Types

Returns

true if the cache had a valid answer for this query

14.11.2.3 fd_dns_part1()

```
int fd_dns_part1 (
    const char * name,
    const IPADDR & dns_server,
    uint16_t TYPE = DNS_A,
    uint16_t TYPE2 = 0,
    int ifn = -1)
#include <dns.h>
Open a UDP socket and initiate a DNS lookup.
This socket can be put in a select and used for asynchronous DNS lookups. Opens a UDP receive FD and sends
DNS queries.
```

Parameters

<i>name</i>	Pointer to domain name to resolve
<i>dns_server</i>	Reference to the DNS server to use. Pass INADDR_ANY to use the DNS server associated with the interface.
<i>TYPE</i>	Optional DNS record type. If no type is specified the default is IPv4 DNS_A
<i>TYPE2</i>	Optional 2nd DNS record type. If no type is specified the default is no look up
<i>ifn</i>	Which interface to use -1 uses the default active DNS interface

Returns

fd The file descriptor of the udp socket. [DNS Return Codes](#)

See also

[fd_dns_processresult\(\)](#), [fd_outstanding_Responses\(\)](#), [GetHostByName\(\)](#),

14.11.2.4 fd_dns_processresult()

```
bool fd_dns_processresult (
    int fd,
    const char * name,
```

```

    IPADDR & addr_out,
    uint16_t TYPE = DNS_A,
    uint16_t TYPE2 = DNS_AAAA,
    uint32_t * ttl = 0)

```

```
#include <dns.h>
```

Process any responses on the UDP socket opened for DNS.

This should only be called when the socket has data, otherwise it will block.

Parameters

<i>fd</i>	The file descriptor opened with <code>fd_dns_part1</code>
<i>name</i>	Pointer to domain name to resolve
<i>addr_out</i>	Reference to IPADDR variable to hold the result
<i>TYPE</i>	DNS record type. If no type is specified the default is IPv4 DNS_A
<i>TYPE2</i>	2nd DNS record type. If no type is specified the default is no look up
<i>ttl</i>	Optional pointer to return variable for TimeToLive value for DNS record

Returns

true if resolution was successful

See also

[fd_dns_part1\(\)](#), [fd_outstanding_Responses\(\)](#), [GetHostByName\(\)](#),

14.11.2.5 fd_outstanding_Responses()

```

int fd_outstanding_Responses (
    int fd)

```

```
#include <dns.h>
```

Check to see if there are any outstanding DNS requests.

If this returns 0 then all DNS responses have been processed and one can assume there is no such name.

Parameters

<i>fd</i>	The file descriptor opened with <code>fd_dns_part1</code>

Returns

The number of outstanding DNS requests that have not been answered.

See also

[fd_dns_part1\(\)](#), [fd_dns_processresult\(\)](#), [GetHostByName\(\)](#),

14.11.2.6 GetHostByName()

```

int GetHostByName (
    const char * name,
    IPADDR * pIpaddr,
    const IPADDR & dns_server,
    const TickTimeout tout,
    uint16_t TYPE1 = DNS_A,
    uint16_t TYPE2 = extra_dns_t,
    uint32_t * ttl = NULL) [inline]
#include <dns.h>

```

Get the IP address associated with the specified domain name.

Calling [GetHostByName\(\)](#) in dual stack mode will automatically call the correct IPv4 or IPv6 function.

The function will attempt to retrieve record type 1 first. If successful the function returns. If the attempt using type 1 fails, the function will attempt to get a record using the type 2 parameter. For example, let's say you wish your code to use IPv6, but it's OK to fall back to IPv4. You can set type 1 to DNS_AAAA and type2 to DNS_A.

Parameters

<i>*name</i>	Pointer to domain name to resolve
<i>*pIpaddr</i>	Pointer to variable of type IPADDR (or IPADDR4) to store resultant IP address.
<i>&dns_server</i>	Specified the DNS server to use. Pass INADDR_ANY to use the DNS server associated with the interface.
<i>tout</i>	Number of time ticks to wait of type TickTimeout
<i>TYPE1</i>	Optional record type. If not specified will default to IPv4 DNS_A
<i>TYPE2</i>	Optional record type. If not specified will default to IPv6 DNS_AAAA
<i>tTl</i>	Optional pointer to return variable for TimeToLive value for DNS record

Returns

[DNS Return Codes](#)

See also

[GetHostByName4\(\)](#)

[GetHostByName6\(\)](#)

14.11.2.7 GetHostByNameViaIfNum()

```
int GetHostByNameViaIfNum (
    const char * name,
    IPADDR * pIpaddr,
    const IPADDR & dns_server,
    int ifn,
    const TickTimeout & tout,
    uint16_t TYPE1 = DNS_A,
    uint16_t TYPE2 = extra_dns_t,
    uint32_t * ttl = NULL) [inline]

#include <dns.h>
```

Get the IP address associated with the specified domain name on a specific interface.

Calling [GetHostByName\(\)](#) in dual stack mode will automatically call the correct IPv4 or IPv6 function.

The function will attempt to retrieve record type 1 first. If successful the function returns. If the attempt using type 1 fails, the function will attempt to get a record using the type 2 parameter. For example, let's say you wish your code to use IPv6, but it's OK to fall back to IPv4. You can set type 1 to DNS_AAAA and type2 to DNS_A.

Parameters

<i>*name</i>	Pointer to domain name to resolve
<i>*pIpaddr</i>	Pointer to variable of type IPADDR to store resultant IP address
<i>&dns_server</i>	Specified the DNS server to use. Pass INADDR_ANY to use the DNS server associated with the interface.
<i>tout</i>	A reference to the number of time ticks to wait of type TickTimeout
<i>TYPE1</i>	Optional record type. If not specified will default to IPv4 DNS_A
<i>TYPE2</i>	Optional record type. If not specified will default to IPv6 DNS_AAAA
<i>ifn</i>	Interface number
<i>ttl</i>	Optional pointer to return variable for TimeToLive value for DNS record

Returns[DNS Return Codes](#)**See also**[GetHostByName4VialfNum\(\)](#)[GetHostByNameVialfNum\(\)](#)**14.11.2.8 IsNameIPAddress()**

```
bool IsNameIPAddress (
    const char * name)
```

```
#include <dns.h>
```

Determine if the name is a valid IP Address and does not need to be looked up.

Parameters

<i>*name</i>	Pointer to domain name to check

Returns

true If it is a valid IP address

See also[GetHostByName\(\)](#), [GetHostByName4VialfNum\(\)](#), [GetHostByName6\(\)](#)**14.11.3 DNS Record Types****Macros**

- **#define DNS_A 1**
32-bit IPv4 address
- **#define DNS_CNAME 5**
Canonical name record.
- **#define DNS_MB 7**
Mailing list subscriber list.
- **#define DNS_MG 8**
Mailing list subscriber list.
- **#define DNS_MX 15**
Mail exchange record.
- **#define DNS_AAAA 28**
128-bit IPv6 address

14.11.3.1 Detailed Description

DNS record types from RFC1035

14.11.4 DNS Return Codes**Macros**

- **#define DNS_OK (0)**
Success.
- **#define DNS_TIMEOUT (1)**
Request timed out.
- **#define DNS_NOSUCHNAME (2)**
Name not found.
- **#define DNS_ERR (3)**
Other error.

14.11.4.1 Detailed Description

14.12 Device Interrupts

Macros

- #define **DEVICE_INTERRUPT_MAXIMUM** (8)
Fixed interrupt sources.

Typedefs

- typedef enum [_DeviceInterruptTrigger](#) **DeviceInterruptTrigger**
DeviceSetupIsr interrupt trigger.
- typedef void **DeviceIsrFn**()
ISR function.

Enumerations

- enum [_DeviceInterruptTrigger](#) {
 [InterruptTriggerNone](#) , [InterruptTriggerSensitive](#) , [InterruptTriggerRisingEdge](#) , [InterruptTriggerFallingEdge](#) ,
 [InterruptTriggerBothEdge](#) }
DeviceSetupIsr interrupt trigger.

Functions

- BOOL [DevicesValid](#) (int irq)
Verify availability and support for device. (Only verifies IRQ is valid)
- BOOL [DeviceSetupIsr](#) (int irq, [DeviceInterruptTrigger](#) trigger, DeviceIsrFnPtr isrPtr)
Set interrupt controller and attach function to interrupt.
- void [DeviceAckInterrupt](#) (int irq)
Acknowledge interrupt.
- void [DeviceDisableInterrupt](#) (int irq)
Disable interrupt.
- void [DeviceEnableInterrupt](#) (int irq)
Enable interrupt.
- OS_SEM * [DeviceGetQspiSem](#) (void)
Acquire QSPI semaphore for sharing access to SPI devices.
- OS_SEM * [DeviceGetI2cSem](#) (void)
Acquire I2C semaphore for sharing access to I2C devices.

14.12.1 Detailed Description

```
#include< device.h>
```

14.12.2 Enumeration Type Documentation

14.12.2.1 _DeviceInterruptTrigger

```
enum \_DeviceInterruptTrigger
#include <device.h>
DeviceSetupIsr interrupt trigger.
```

Enumerator

InterruptTriggerNone	No interrupt level.
InterruptTriggerSensitive	Trigger-sensitive interrupt.
InterruptTriggerRisingEdge	Rising edge triggered interrupt.
InterruptTriggerFallingEdge	Falling edge triggered interrupt.
InterruptTriggerBothEdge	Both rising and falling edge triggered.

14.12.3 Function Documentation**14.12.3.1 DeviceAckInterrupt()**

```
void DeviceAckInterrupt (
    int irq)
#include <device.h>
Acknowledge interrupt.
```

Parameters

<i>irq</i>	Fixed level interrupt source

14.12.3.2 DeviceDisableInterrupt()

```
void DeviceDisableInterrupt (
    int irq)
#include <device.h>
Disable interrupt.
```

Parameters

<i>irq</i>	Fixed level interrupt source

14.12.3.3 DeviceEnableInterrupt()

```
void DeviceEnableInterrupt (
    int irq)
#include <device.h>
Enable interrupt.
```

Parameters

<i>irq</i>	Fixed level interrupt source

14.12.3.4 DeviceGetI2cSem()

```
OS_SEM * DeviceGetI2cSem (
    void )
#include <device.h>
Acquire I2C semaphore for sharing access to I2C devices.
```

Returns

Semaphore

Return values

<i>NULL</i>	for non-existent device

14.12.3.5 DeviceGetQspiSem()

```
OS_SEM * DeviceGetQspiSem (
    void )
```

```
#include <device.h>
```

Acquire QSPI semaphore for sharing access to SPI devices.

Returns

Semaphore

Return values

<i>NULL</i>	for non-existent device

14.12.3.6 DeviceIsValid()

```
BOOL DeviceIsValid (
    int irq)
```

```
#include <device.h>
```

Verify availability and support for device. (Only verifies IRQ is valid)

Parameters

<i>irq</i>	Fixed level interrupt source

Return values

<i>TRUE</i>	Support and available on module
<i>FALSE</i>	Option not supported

14.12.3.7 DeviceSetupIsr()

```
BOOL DeviceSetupIsr (
    int irq,
    DeviceInterruptTrigger trigger,
    DeviceIsrFnPtr isrPtr)
```

```
#include <device.h>
```

Set interrupt controller and attach function to interrupt.

Parameters

<i>irq</i>	Fixed level interrupt source
<i>trigger</i>	Triggering edge level
<i>isrPtr</i>	ISR function

Return values

<i>TRUE</i>	Set
<i>FALSE</i>	Not valid interrupt source

14.13 Diagnostics (DIAG)

Classes

- class [DiagItemClass](#)
Base class for all diagnostic items.
- class [DiagCallBack](#)
Callback-based diagnostic item that calls a custom function to generate diagnostic content.
- class [DiagVarMon](#)
Monitor and report the value of numeric variables.
- class [DiagStrMon](#)
Monitor and report string values.
- class [DiagPtrMon](#)
Monitor and report pointer values.

Typedefs

- typedef void [diagcallback](#)(int sock)
Callback function type for custom diagnostic reports.

Functions

- bool [SendDiagReport](#) (const char *pUrl, const char *pUser=0, const char *pPass=0)
Send the complete diagnostic report to an external URL via HTTP POST.
- bool [SendDiagReport](#) ([ParsedURI](#) &uri, const char *pUser=0, const char *pPass=0)
Send the complete diagnostic report to an external URL via HTTP POST.
- void [InitPlatformDiag](#) ()
Initialize platform-specific diagnostics.

14.13.1 Detailed Description

```
#include< diagnostics.h>
```

The functions in this header are used to add diagnostic reports to the diagnostics tab under the config page when [diagnostics.h](#) is included and [EnableSystemDiagnostics\(\)](#) is called.

The resulting JSON blob can be accessed directly (replace 10.1.1.100 with your IP or dns name) <http://10.1.1.100:20034/DIAG>

You can also access subgroups directly from the diagnostics: <http://10.1.1.100:20034/DIAG/Buffers> or <http://10.1.1.100:20034/DIAG/Tasks>

Examples

If I have a `uint32_t` called `myVar` I want to monitor:

```
DiagVarMon MyVarMon("MyVarName", myVar);
```

If I have char buffer holding the name of the current mode:

```
DiagStrMon MyStrMon("CurMode", cur_mode);
```

If I want to output a complex JSON object for a custom report, I can write a routine that outputs this object to an fd:

```
void MyCustomReport(int fd);
DiagCallBack MyReporter("MyReportName", MyCustomReport);
```

14.13.2 Typedef Documentation

14.13.2.1 diagcallback

```
typedef void diagcallback(int sock)
#include <diagnostics.h>
```

Callback function type for custom diagnostic reports.

This function type is used to create custom diagnostic output functions that can be called when the diagnostic system needs to output data for a specific diagnostic item.

Parameters

<i>sock</i>	File descriptor to write diagnostic output to

14.13.3 Function Documentation

14.13.3.1 InitPlatformDiag()

```
void InitPlatformDiag ()
#include <diagnostics.h>
```

Initialize platform-specific diagnostics.

This function is called by [EnableSystemDiagnostics\(\)](#) to allow platforms to register their own diagnostic items. The default implementation is weak-linked and does nothing. Platforms can override this by providing their own implementation without weak linkage.

14.13.3.2 SendDiagReport() [1/2]

```
bool SendDiagReport (
    const char * pUrl,
    const char * pUser = 0,
    const char * pPass = 0)
#include <diagnostics.h>
```

Send the complete diagnostic report to an external URL via HTTP POST.

This function collects all diagnostic data and sends it as a JSON payload via HTTP POST to the specified URL. This is useful for remote monitoring and logging of device diagnostics.

Parameters

<i>pUrl</i>	Target URL to send the diagnostic data to
<i>pUser</i>	Optional username for HTTP authentication
<i>pPass</i>	Optional password for HTTP authentication

Returns

true if the report was sent successfully, false otherwise

See also

[SendDiagReport\(ParsedURI&, const char*, const char*\)](#)

14.13.3.3 SendDiagReport() [2/2]

```
bool SendDiagReport (
    ParsedURI & uri,
    const char * pUser = 0,
    const char * pPass = 0)
#include <diagnostics.h>
```

Send the complete diagnostic report to an external URL via HTTP POST.

This function collects all diagnostic data and sends it as a JSON payload via HTTP POST to the specified URL using a [ParsedURI](#) object.

Parameters

<i>uri</i>	ParsedURI object containing the target URL
<i>pUser</i>	Optional username for HTTP authentication
<i>pPass</i>	Optional password for HTTP authentication

Returns

true if the report was sent successfully, false otherwise

See also

[SendDiagReport\(const char*, const char*, const char*\)](#)

14.14 EFFS - Embedded Flash File System

Topics

- [EFFS-STD Flash File System](#)

The Standard Embedded Flash File System, EFFS-STD
`#include< fsf.h>`

- [FAT File System](#)

The FAT32 Embedded Flash File System for Flash Cards, EFFS-FAT
`#include< api_f.h>`

14.14.1 Detailed Description

Two Embedded Flash File Systems are supported:

- FAT32 File System (EFFS-FAT), a FAT32 file system used on external flash memory cards and ram drives.
- Standard File System (EFFS-STD), a power-fail safe file system that resides in the flash on the module.

14.14.2 EFFS-STD Flash File System

The Standard Embedded Flash File System, EFFS-STD
`#include< fsf.h>`

Topics

- [STD File System Seek Codes](#)

Macros

- `#define fs\_getfreespace(drivenum, space) fsm_getfreespace(drivenum, space)`
Provides information about the drive space usage.
- `#define fs\_mkdir(dirname) fsm_mkdir(dirname)`
Makes a new directory.
- `#define fs\_chdir(dirname) fsm_chdir(dirname)`
Change the directory.
- `#define fs\_rmdir(dirname) fsm_rmdir(dirname)`
Removes a directory.
- `#define fs\_delete(filename) fsm_delete(filename)`
Deletes a file.

- `#define fs_findfirst(filename, find) fsm_findfirst(filename, find)`
Find the first file or subdirectory in a specified directory.
- `#define fs_findnext(find) fsm_findnext(find)`
Finds the next file or subdirectory in a specified directory after a previous call to `fs_findfirst()` or `fs_findnext()`.
- `#define fs_open(filename, mode) fsm_open(filename, mode)`
Opens a file in the file system.
- `#define fs_close(filehandle) fsm_close(filehandle)`
Closes an opened file.
- `#define fs_write(buf, size, size_st, filehandle) fsm_write(buf, size, size_st, filehandle)`
Write data to the file at the current position.
- `#define fs_read(buf, size, size_st, filehandle) fsm_read(buf, size, size_st, filehandle)`
Read data from the current position in a file.
- `#define fs_seek(filehandle, offset, whence) fsm_seek(filehandle, offset, whence)`
Move the stream position of an open file.
- `#define fs_eof(filehandle) fsm_eof(filehandle)`
Check whether the current position in the open target file is the end of the file.
- `#define fs_rewind(filehandle) fsm_rewind(filehandle)`
Sets the file position in the open target file to the start of the file.
- `#define fs_settimedate(filename, ctime, cdate) fsm_settimedate(filename, ctime, cdate)`
Set the time and date of a file or directory.
- `#define fs_gettimedate(filename, pctime, pdate) fsm_gettimedate(filename, pctime, pdate)`
Get the time and date of a file or directory.

14.14.2.1 Detailed Description

The Standard Embedded Flash File System, EFFS-STD

```
#include< fsf.h>
```

14.14.2.2 Macro Definition Documentation

14.14.2.2.1 fs_chdir

```
#define fs_chdir(  
    dirname) fsm_chdir(dirname)  
#include <fsf.h>  
Change the directory.
```

Parameters

<i>dirname</i>	The directory to change to.

Return values

<i>FS_NOERR</i>	If able to change to the directory
<i>IFS_NOERR</i>	If unable to change to the directory

See also

[fs_mkdir\(\)](#)

[fs_rmdir\(\)](#)

14.14.2.2.2 fs_close

```
#define fs_close(  
    filehandle) fsm_close(filehandle)
```

```
#include <fsf.h>
```

Closes an opened file.

Parameters

<i>filehandle</i>	A handle to the file to close.

Return values

<i>FS_NOERR</i>	If able to close the file
<i>IFS_NOERR</i>	If unable to close the file

14.14.2.2.3 fs_delete

```
#define fs_delete(  
    filename) fsm_delete(filename)
```

```
#include <fsf.h>
```

Deletes a file.

A read-only or open file cannot be deleted.

Parameters

<i>filename</i>	The name of the file to be deleted.

Return values

<i>FS_NOERR</i>	If able to delete the file
<i>IFS_NOERR</i>	If unable to delete the file

14.14.2.2.4 fs_eof

```
#define fs_eof(  
    filehandle) fsm_eof(filehandle)
```

```
#include <fsf.h>
```

Check whether the current position in the open target file is the end of the file.

Parameters

<i>filehandle</i>	A handle to the file to check.

Return values

<i>0</i>	Nothing at the end of the file
<i>!0</i>	The end of the file, or an error

14.14.2.2.5 fs_findfirst

```
#define fs_findfirst(  
    filename,  
    find) fsm_findfirst(filename, find)  
#include <fsf.h>
```

Find the first file or subdirectory in a specified directory.

Note: If this is called with "*" and this is not the root directory, the first entry found will be ".", which is the current directory.

Parameters

<i>filename</i>	The name of the file to find.
<i>find</i>	Where to store the found information.

Return values

<i>FS_NOERR</i>	If the file was found
<i>IFS_NOERR</i>	If the file wasn't found or there are errors

See also

[fs_findnext\(\)](#)

14.14.2.2.6 fs_findnext

```
#define fs_findnext(  
    find) fsm_findnext(find)  
#include <fsf.h>
```

Finds the next file or subdirectory in a specified directory after a previous call to [fs_findfirst\(\)](#) or [fs_findnext\(\)](#).

Note: If this is called with "*" and this is not the root directory, the first entry found will be ".", which is the current directory.

Parameters

<i>find</i>	Where to store the found information.

Return values

<i>FS_NOERR</i>	If the file was found
<i>IFS_NOERR</i>	If the file wasn't found or there are errors

See also

[fs_findfirst\(\)](#)

14.14.2.2.7 fs_getfreespace

```
#define fs_getfreespace(  
    drivenum,  
    space) fsm_getfreespace(drivenum, space)  
#include <fsf.h>
```

Provides information about the drive space usage.

Parameters

<i>drivenum</i>	The drive number to get space usage for.
<i>space</i>	The structure to store the usage information in.

Return values

<i>FS_NOERR</i>	If able to get the drive space usage
<i>IFS_NOERR</i>	If unable to get the drive space usage

14.14.2.2.8 fs_gettimedate

```
#define fs_gettimedate(  
    filename,  
    pctime,  
    pcdte) fsm_gettimedate(filename, pctime, pcdte)
```

```
#include <fsf.h>
```

Get the time and date of a file or directory.

Parameters

<i>filename</i>	The name of the file or directory to modify.
<i>pctime</i>	A pointer to store the creation time of the file or directory.
<i>pcdate</i>	A pointer to store the creation date of the file or directory.

Return values

<i>FS_NOERR</i>	If able to get time and date
<i>IFS_NOERR</i>	If unable to get time and date

14.14.2.2.9 fs_mkdir

```
#define fs_mkdir(  
    dirname) fsm_mkdir(dirname)
```

```
#include <fsf.h>
```

Makes a new directory.

Parameters

<i>dirname</i>	The name to use for the new directory.

Return values

<i>FS_NOERR</i>	If able to make the directory
<i>IFS_NOERR</i>	If unable to make the directory

See also

[fs_chdir\(\)](#)

[fs_rmdir\(\)](#)

14.14.2.2.10 fs_open

```
#define fs_open(
    filename,
    mode) fsm_open(filename, mode)
#include <fsf.h>
Opens a file in the file system.
```

Parameters

<i>filename</i>	The name of the file to open.
<i>mode</i>	The mode to open the file in. The following options are available: "r": Reading. The stream is positioned at the beginning of the file. "r+": Reading and writing. The stream is positioned at the beginning of the file. "w": Truncate file to 0 length or create for writing. The stream is positioned at the beginning of the file. "w+": Reading and writing. Create if it doesn't exist, or truncate if it does. The stream is positioned at the beginning of the file. "a": Append, and create if it doesn't exist. The stream is positioned at the end of the file. "a+": Reading and appending, and create if it doesn't exist. The stream is positioned at the end of the file.

Return values

<i>FS_FILE*</i>	Pointer to the file if it could be opened
<i>0</i>	If it a file could not be opened

See also

[fs_close\(\)](#)

14.14.2.2.11 fs_read

```
#define fs_read(
    buf,
    size,
    size_st,
    filehandle) fsm_read(buf, size, size_st, filehandle)
#include <fsf.h>
Read data from the current position in a file.
```

Parameters

<i>buf</i>	A pointer where the data should be read.
<i>size</i>	The size of the items to be read.
<i>size_st</i>	The number of items to be read.
<i>filehandle</i>	A handle to the file to read to.

Returns

The number of items read.

14.14.2.2.12 fs_rewind

```
#define fs_rewind(  
    filehandle) fsm_rewind(filehandle)  
#include <fsf.h>  
Sets the file position in the open target file to the start of the file.
```

Parameters

<i>filehandle</i>	A handle to the file operate on.

Return values

<i>FS_NOERR</i>	If successful
<i>IFS_NOERR</i>	If there was an error

14.14.2.2.13 fs_rmdir

```
#define fs_rmdir(  
    dirname) fsm_rmdir(dirname)  
#include <fsf.h>  
Removes a directory.  
Note: The target directory must be empty, otherwise an error code is returned.
```

Parameters

<i>dirname</i>	The name of the directory to remove.

Return values

<i>FS_NOERR</i>	If able to get the drive space usage
<i>IFS_NOERR</i>	If unable to get the drive space usage

See also

[fs_chdir\(\)](#)
[fs_mkdir\(\)](#)

14.14.2.2.14 fs_seek

```
#define fs_seek(  
    filehandle,  
    offset,  
    whence) fsm_seek(filehandle, offset, whence)  
#include <fsf.h>  
Move the stream position of an open file.
```

Parameters

<i>filehandle</i>	A handle to the file to move the position of.
<i>offset</i>	The relative byte position according to whence.
<i>whence</i>	Where to calculate the offset from. Can be a value from fSeekCodeGroup.

Return values

<i>FS_NOERR</i>	If the seek operation was successful
<i>IFS_NOERR</i>	If there was an error

14.14.2.2.15 fs_settimedate

```
#define fs_settimedate(
    filename,
    ctime,
    cdate) fsm_settimedate(filename, ctime, cdate)
```

```
#include <fsf.h>
```

Set the time and date of a file or directory.

Parameters

<i>filename</i>	The name of the file or directory to modify.
<i>ctime</i>	The creation time of the file or directory.
<i>cdate</i>	The creation date of the file or directory.

Return values

<i>FS_NOERR</i>	If able to set time and date
<i>IFS_NOERR</i>	If unable to set time and date

14.14.2.2.16 fs_write

```
#define fs_write(
    buf,
    size,
    size_st,
    filehandle) fsm_write(buf, size, size_st, filehandle)
```

```
#include <fsf.h>
```

Write data to the file at the current position.

Parameters

<i>buf</i>	A pointer to the data to write.
<i>size</i>	The size of the items to write.
<i>size_st</i>	The number of items to write.
<i>filehandle</i>	A handle to the file to write to.

Returns

The number of items written.

14.14.2.3 STD File System Seek Codes

Macros

- **#define FS_SEEK_SET 0**
Beginning of file.
- **#define FS_SEEK_CUR 1**
Current position of the file pointer.
- **#define FS_SEEK_END 2**
End of file.

14.14.2.3.1 Detailed Description

```
#include< fsf.h>
```

The codes used when calling `f_seek()`.

14.14.3 FAT File System

The FAT32 Embedded Flash File System for Flash Cards, EFFS-FAT

```
#include< api_f.h>
```

Topics

- [FAT File System Seek Codes](#)

Macros

- `#define f_delvolume(drvnumber) fm_delvolume(drvnumber)`
Un-mounts a flash card.
- `#define f_getfreespace(drivenum, pspace) fm_getfreespace(drivenum, pspace)`
Provides information about the drive space usage.
- `#define f_chdir(dirname) fm_chdir(dirname)`
Change the directory.
- `#define f_mkdir(dirname) fm_mkdir(dirname)`
Makes a new directory.
- `#define f_rmdir(dirname) fm_rmdir(dirname)`
Removes a directory.
- `#define f_findfirst(filename, find) fm_findfirst(filename, find)`
Find the first file or subdirectory in a specified directory.
- `#define f_findnext(find) fm_findnext(find)`
Finds the next file or subdirectory in a specified directory after a previous call to `f_findfirst()` or `f_findnext()`.
- `#define f_close(filehandle) fm_close(filehandle)`
Closes an opened file.
- `#define f_open(filename, mode) fm_open(filename, mode)`
Opens a file in the file system.
- `#define f_read(buf, size, size_st, filehandle) fm_read(buf, size, size_st, filehandle)`
Read data from the current position in a file.
- `#define f_write(buf, size, size_st, filehandle) fm_write(buf, size, size_st, filehandle)`
Write data to the file at the current position.
- `#define f_seek(filehandle, offset, whence) fm_seek(filehandle, offset, whence)`
Move the stream position of an open file.
- `#define f_rewind(filehandle) fm_rewind(filehandle)`
Sets the file position in the open target file to the start of the file.
- `#define f_eof(filehandle) fm_eof(filehandle)`
Check whether the current position in the open target file is the end of the file.
- `#define f_gettimedate(filename, pctime, pctime) fm_gettimedate(filename, pctime, pctime)`
Get the time and date of a file or directory.
- `#define f_settimedate(filename, ctime, cdate) fm_settimedate(filename, ctime, cdate)`
Set the time and date of a file or directory.
- `#define f_delete(filename) fm_delete(filename)`
Deletes a file.

Functions

- int [f_enterFS](#) (void)
Adds a new task priority to the task list used by the file system.
- void [f_releaseFS](#) (void)
Removes a task priority from the task list used by the file system.

14.14.3.1 Detailed Description

The FAT32 Embedded Flash File System for Flash Cards, EFFS-FAT
`#include < api_f.h>`

14.14.3.2 Macro Definition Documentation

14.14.3.2.1 [f_chdir](#)

```
#define f_chdir(  
    dirname) fm_chdir(dirname)  
#include <api_f.h>  
Change the directory.
```

Parameters

<i>dirname</i>	The directory to change to.

Return values

<i>F_NO_ERROR</i>	If able to change to the directory
<i>!F_NO_ERROR</i>	If unable to change to the directory

See also

[f_mkdir\(\)](#)
[f_rmdir\(\)](#)

14.14.3.2.2 [f_close](#)

```
#define f_close(  
    filehandle) fm_close(filehandle)  
#include <api_f.h>  
Closes an opened file.
```

Parameters

<i>filehandle</i>	A handle to the file to close.

Return values

<i>F_NO_ERROR</i>	If able to close the file
<i>!F_NO_ERROR</i>	If unable to close the file

14.14.3.2.3 f_delete

```
#define f_delete(  
    filename) fm_delete(filename)
```

```
#include <api_f.h>
```

Deletes a file.

A read-only or open file cannot be deleted.

Parameters

<i>filename</i>	The name of the file to be deleted.

Return values

<i>F_NO_ERROR</i>	If able to delete the file
<i>!F_NO_ERROR</i>	If unable to delete the file

14.14.3.2.4 f_delvolume

```
#define f_delvolume(  
    drvnumber) fm_delvolume(drvnumber)
```

```
#include <api_f.h>
```

Un-mounts a flash card.

Parameters

<i>drvnumber</i>	The drive to be un-mount.

14.14.3.2.5 f_eof

```
#define f_eof(  
    filehandle) fm_eof(filehandle)
```

```
#include <api_f.h>
```

Check whether the current position in the open target file is the end of the file.

Parameters

<i>filehandle</i>	A handle to the file to check.

Return values

<i>0</i>	Nothing at the end of the file
<i>!0</i>	The end of the file, or an error

14.14.3.2.6 f_findfirst

```
#define f_findfirst(  
    filename,  
    find) fm_findfirst(filename, find)
```

```
#include <api_f.h>
```

Find the first file or subdirectory in a specified directory.

Note: If this is called with "*. *" and this is not the root directory, the first entry found will be ".", which is the current directory.

Parameters

<i>filename</i>	The name of the file to find.
<i>find</i>	Where to store the found information.

Return values

<i>F_NO_ERROR</i>	If the file was found
<i>!F_NO_ERROR</i>	If the file wasn't found or there are errors

See also

[f_findnext\(\)](#)**14.14.3.2.7 f_findnext**

```
#define f_findnext(  
    find) fm_findnext(find)  
#include <api_f.h>
```

Finds the next file or subdirectory in a specified directory after a previous call to [f_findfirst\(\)](#) or [f_findnext\(\)](#).

Note: If this is called with " *.* " and this is not the root directory, the first entry found will be ".", which is the current directory.

Parameters

<i>find</i>	Where to store the found information.

Return values

<i>F_NO_ERROR</i>	If the file was found
<i>!F_NO_ERROR</i>	If the file wasn't found or there are errors

See also

[f_findfirst\(\)](#)**14.14.3.2.8 f_getfreespace**

```
#define f_getfreespace(  
    drivenum,  
    pspace) fm_getfreespace(drivenum, pspace)  
#include <api_f.h>
```

Provides information about the drive space usage.

Parameters

<i>drivenum</i>	The drive number to get space usage for.
<i>pspace</i>	The structure to store the usage information in.

Return values

<i>F_NO_ERROR</i>	If able to get the drive space usage
<i>!F_NO_ERROR</i>	If unable to get the drive space usage

14.14.3.2.9 f_gettimedate

```
#define f_gettimedate(
    filename,
    pctime,
    pctime) fm_gettimedate(filename, pctime, pctime)
#include <api_f.h>
```

Get the time and date of a file or directory.

Parameters

	<i>filename</i>	The name of the file or directory to modify.
out	<i>pctime</i>	A pointer to store the creation time of the file or directory.
out	<i>pctime</i>	A pointer to store the creation date of the file or directory.

Return values

<i>F_NO_ERROR</i>	If able to get time and date
<i>IF_NO_ERROR</i>	If unable to get time and date

14.14.3.2.10 f_mkdir

```
#define f_mkdir(
    dirname) fm_mkdir(dirname)
#include <api_f.h>
```

Makes a new directory.

Parameters

<i>dirname</i>	The name to use for the new directory.

Return values

<i>F_NO_ERROR</i>	If able to make the directory
<i>IF_NO_ERROR</i>	If unable to make the directory

See also

[f_chdir\(\)](#)

[f_rmdir\(\)](#)

14.14.3.2.11 f_open

```
#define f_open(
    filename,
    mode) fm_open(filename, mode)
#include <api_f.h>
```

Opens a file in the file system.

Parameters

<i>filename</i>	The name of the file to open.

Parameters

<i>mode</i>	The mode to open the file in. The following options are available: • "r": Reading. The stream is positioned at the beginning of the file. • "r+": Reading and writing. The stream is positioned at the beginning of the file. • "w": Truncate file to 0 length or create for writing. The stream is positioned at the beginning of the file. • "w+": Reading and writing. Create if it doesn't exist, or truncate if it does. The stream is positioned at the beginning of the file. • "a": Append, and create if it doesn't exist. The stream is positioned at the end of the file. • "a+": Reading and appending, and create if it doesn't exist. The stream is positioned at the end of the file.

Return values

<i>F_FILE*</i>	Pointer to the file if it could be opened
<i>0</i>	If it a file could not be opened

See also

[f_close\(\)](#)**14.14.3.2.12 f_read**

```
#define f_read(  
    buf,  
    size,  
    size_st,  
    filehandle) fm_read(buf, size, size_st, filehandle)  
#include <api_f.h>  
Read data from the current position in a file.
```

Parameters

<i>buf</i>	A pointer where the data should be read.
<i>size</i>	The size of the items to be read.
<i>size_st</i>	The number of items to be read.
<i>filehandle</i>	A handle to the file to read to.

Returns

The number of items read.

14.14.3.2.13 f_rewind

```
#define f_rewind(  
    filehandle) fm_rewind(filehandle)  
#include <api_f.h>  
Sets the file position in the open target file to the start of the file.
```

Parameters

<i>filehandle</i>	A handle to the file operate on.

Return values

<i>F_NO_ERROR</i>	If successful
<i>!F_NO_ERROR</i>	If there was an error

14.14.3.2.14 f_rmdir

```
#define f_rmdir(  
    dirname) fm_rmdir(dirname)  
#include <api_f.h>
```

Removes a directory.

Note: The target directory must be empty, otherwise an error code is returned.

Parameters

<i>dirname</i>	The name of the directory to remove.

Return values

<i>F_NO_ERROR</i>	If able to remove the directory
<i>!F_NO_ERROR</i>	If unable to remove the directory

See also

[f_chdir\(\)](#)

[f_mkdir\(\)](#)

14.14.3.2.15 f_seek

```
#define f_seek(  
    filehandle,  
    offset,  
    whence) fm_seek(filehandle, offset, whence)  
#include <api_f.h>
```

Move the stream position of an open file.

Parameters

<i>filehandle</i>	A handle to the file to move the position of.
<i>offset</i>	The relative byte position according to whence.
<i>whence</i>	Where to calculate the offset from. Can be a value from FAT File System Seek Codes .

Return values

<i>F_NO_ERROR</i>	If the seek operation was successful
<i>!F_NO_ERROR</i>	If there was an error

14.14.3.2.16 f_settimedate

```
#define f_settimedate(
    filename,
    ctime,
    cdate) fm_settimedate(filename, ctime, cdate)
```

```
#include <api_f.h>
```

Set the time and date of a file or directory.

Parameters

<i>filename</i>	The name of the file or directory to modify.
<i>ctime</i>	The creation time of the file or directory.
<i>cdate</i>	The creation date of the file or directory.

Return values

<i>F_NO_ERROR</i>	If able to set time and date
<i>!F_NO_ERROR</i>	If unable to set time and date

14.14.3.2.17 f_write

```
#define f_write(
    buf,
    size,
    size_st,
    filehandle) fm_write(buf, size, size_st, filehandle)
```

```
#include <api_f.h>
```

Write data to the file at the current position.

Parameters

<i>buf</i>	A pointer to the data to write.
<i>size</i>	The size of the items to write.
<i>size_st</i>	The number of items to write.
<i>filehandle</i>	A handle to the file to write to.

Returns

The number of items written.

14.14.3.3 Function Documentation

14.14.3.3.1 f_enterFS()

```
int f_enterFS (
    void ) [extern]
```

```
#include <api_f.h>
```

Adds a new task priority to the task list used by the file system.

This function needs to be called when a new task wants to use the file system, before any other calls to other file system functions. Up to 10 tasks can be assigned to use the file system at any given time.

Note: The task priority level is associated with the task list, not the task itself. This means that a task switched priority levels and still wants to use the file system, it will need to be called again.

Return values

0	If successful

<i>!O</i>	If there were errors

See also

[f_releaseFS\(\)](#)

14.14.3.3.2 f_releaseFS()

```
void f_releaseFS (
    void ) [extern]
#include <api_f.h>
```

Removes a task priority from the task list used by the file system.

When a task no longer needs to use the file system, or prior to task changing priorities, this should be called. In the case of a task changing priorities, if access to the file system is still desired, another call to [f_enterFS\(\)](#) should be made.

[f_releaseFS\(\)](#)

14.14.3.4 FAT File System Seek Codes

Macros

- `#define F_SEEK_SET FN_SEEK_SET`
Beginning of file.
- `#define F_SEEK_END FN_SEEK_END`
End of file.
- `#define F_SEEK_CUR FN_SEEK_CUR`
Current position of the file pointer.

14.14.3.4.1 Detailed Description

```
#include< api_f.h>
```

The codes used when calling [f_seek\(\)](#).

14.15 Ethernet

Topics

- [Ethernet I/O Counters](#)

Classes

- struct [_EthernetFrameHeader](#)
Ethernet Type II Frame Header.

Macros

- `#define NO_AUTOMATIC_2ND_ETHERNET` extern const bool bAutomatic2ndEther = false;
Disable automatic initialization of second Ethernet interface.

Typedefs

- typedef struct [_EthernetFrameHeader](#) **EthernetFrameHeader**
Ethernet Type II Frame Header.

Functions

- void [AddEthernetInterfaces](#) ()
Add an Ethernet interface.
- void [ManualEthernetConfig](#) (int interface, BOOL speed100Mbit, BOOL fullDuplex, BOOL autoNegotiate)
Manually configure Ethernet speed and duplex settings.
- void [DisablePHY](#) (int ifn)
Disable the specified Ethernet PHY.
- void [EnablePHY](#) (int ifn)
Enable the specified Ethernet PHY.

Ethernet Interface Types

EtherType Field (Ethernet Version II)

- #define **ETHERNET_ETHERTYPE_IPV4** (uint16_t)(0x0800)
Internet Protocol, Version 4 (IPv4)
- #define **ETHERNET_ETHERTYPE_ARP** (uint16_t)(0x0806)
Address Resolution Protocol ([ARP](#))
- #define **ETHERNET_ETHERTYPE_IPV6** (uint16_t)(0x86DD)
Internet Protocol, Version 6 (IPv6)
- #define **ETHERNET_ETHERTYPE_AARP** (uint16_t)(0x80F3)
AppleTalk Address Resolution Prot. (AARP)
- #define **ETHERNET_ETHERTYPE_IPX** (uint16_t)(0x8137)
Novell Internet Packet Exchange (IPX) (alt.)
- #define **ETHERNET_ETHERTYPE_EAPOL** (uint16_t)(0x888E)
Extensible Authorization Protocol (EAP) over LAN.
- #define **ETHERNET_ETHERTYPE_VLAN** (uint16_t)(0x8100)
Virtual Private Network (VLAN)

14.15.1 Detailed Description

```
#include< ethernet.h>
```

Functions to add, configure and disable Ethernet interfaces

14.15.2 Macro Definition Documentation

14.15.2.1 NO_AUTOMATIC_2ND_ETHERNET

```
#define NO_AUTOMATIC_2ND_ETHERNET extern const bool bAutomatic2ndEther = false;
#include <ethernet.h>
```

Disable automatic initialization of second Ethernet interface.

Include this macro in UserMain to prevent automatic system addition and initialization of the second Ethernet interface on dual Ethernet devices.

14.15.3 Function Documentation

14.15.3.1 AddEthernetInterfaces()

```
void AddEthernetInterfaces ()
#include <ethernet.h>
```

Add an Ethernet interface.

The default system behavior is all Ethernet interfaces will automatically be added and initialized. Interface numbers range from 1 to (MAX_INTERFACES - 1)

14.15.3.2 DisablePHY()

```
void DisablePHY (
    int ifn)
#include <ethernet.h>
Disable the specified Ethernet PHY.
Typically used for low power mode.
```

Parameters

<i>ifn</i>	Interface number to disable

See also

[EnablePHY](#)

14.15.3.3 EnablePHY()

```
void EnablePHY (
    int ifn)
#include <ethernet.h>
Disable the specified Ethernet PHY.
Enable an Ethernet PHY previously disabled by DisablePHY\(\)
```

Parameters

<i>ifn</i>	Interface number to enable

See also

[DisablePHY\(\)](#)

14.15.3.4 ManualEthernetConfig()

```
void ManualEthernetConfig (
    int interface,
    BOOL speed100Mbit,
    BOOL fullDuplex,
    BOOL autoNegotiate)
#include <ethernet.h>
```

Manually configure Ethernet speed and duplex settings.

The default setting to establish an Ethernet link is autonegotiate. This function can be used to disable autonegotiate and set the Ethernet link speed and duplex.

Warning

With autonegotiate disabled, the other Ethernet host must also be configured manually with the same settings. If the other host is set to autonegotiate, the link will have undefined behavior and data loss.

Parameters

<i>interface</i>	The network interface to modify. The first interface number is 1
<i>speed100Mbit</i>	True = 100Mbps, False = 10Mbps
<i>fullDuplex</i>	True = full duplex, False = half duplex
<i>autoNegotiate</i>	True = enabled, False = disabled. If enabled, will override manual settings.

14.15.4 Ethernet I/O Counters

Data counters kept by the TCP/IP system

- volatile uint32_t **frames_tx**
"tx:%u", "tx:%d",
- volatile uint32_t **frames_rx**
"rx:%u", "rx:%d",
- volatile uint32_t **frames_tx_err**

14.15.4.1 Detailed Description

```
#include< counters.h>
```

14.16 Extra File Descriptors

Functions

- int [GetExtraFD](#) (void *extra_data, struct IoExpandStruct *pFuncs)
Returns a file descriptor for the structure passed as the IoExpandStruct. [FreeExtraFd\(\)](#) will release the fd back to the pool of available fds.
- IoExpandStruct * [GetIoExpandStruct](#) (int fd)
Returns the pointer to the IoExpandStruct associated with the file descriptor.
- void * [GetExtraData](#) (int fd)
Returns the extra structure value from IoExpandStruct associated with the file descriptor.
- void [FreeExtraFd](#) (int fd)
Free a file descriptor and associated resources.
- int [GetFreeExtraFDCount](#) ()
Returns the number of free file descriptors.
- int [GetFreeSocketCount](#) (void)
Returns the number of free sockets.

14.16.1 Detailed Description

```
#include< iointernal.h>
```

The NetBurner environment integrates the RTOS, TCP/IP stack, and other peripherals with a file I/O system based on file descriptors. A file descriptor can be described as a handle to a network socket, serial port, system peripheral, or any other object that can be read or written to. Most of the API functions pass a file descriptor as a parameter to such an object. These function are available if you wish to use the file descriptor system capabilities for your own application purposes. Please refer to the File Descriptor section in the Programmers Guide.

14.16.2 Function Documentation

14.16.2.1 FreeExtraFd()

```
void FreeExtraFd (
    int fd)
#include <iointernal.h>
Free a file descriptor and associated resources.
```

Parameters

<i>fd</i>	File descriptor

14.16.2.2 GetExtraData()

```
void * GetExtraData (
    int fd)
#include <iointernal.h>
Returns the extra structure value from IoExpandStruct associated with the file descriptor.
```

Parameters

<i>fd</i>	File descriptor

Return values

<i>Value</i>	of the extra member of the structure

14.16.2.3 GetExtraFD()

```
int GetExtraFD (
    void * extra_data,
    struct IoExpandStruct * pFuncs)
#include <iointernal.h>
```

Returns a file descriptor for the structure passed as the `IoExpandStruct`. [FreeExtraFd\(\)](#) will release the fd back to the pool of available fds.

Parameters

<i>extra_data</i>	The optional extra_data void pointer can be used to pass data into the file descriptor
<i>*pFuncs</i>	Structure containing callback functions for such things as read, write, close, and the extra_data variable

Return values

<i>Value</i>	greater than 0, representing the file descriptor on success
<i>-1</i>	on failure

14.16.2.4 GetFreeExtraFDCount()

```
int GetFreeExtraFDCount ()
#include <iointernal.h>
```

Returns the number of free file descriptors.

Return values

<i>Number</i>	of free extra file descriptors

14.16.2.5 GetFreeSocketCount()

```
int GetFreeSocketCount (
    void )
#include <iointernal.h>
```

Returns the number of free sockets.

Return values

<i>Number</i>	of free sockets

14.16.2.6 GetIoExpandStruct()

```
IoExpandStruct * GetIoExpandStruct (  
    int fd)
```

```
#include <iointernal.h>
```

Returns the pointer to the `IoExpandStruct` associated with the file descriptor.

Parameters

<i>fd</i>	File descriptor

Return values

<i>Pointer</i>	to the the <code>IoExpandStruct</code> associated with the file descriptor.

14.17 FTP Client

Functions

- int [FTP_InitializeSession](#) (IPADDR4 server_address, uint16_t port, PCSTR UserName, PCSTR Password, uint32_t time_out)
Initialize a FTP session with a FTP server.
- int [FTP_CloseSession](#) (int session)
Close a FTP session.
- int [FTPGetDir](#) (int ftp_Session, char *dir_buf, int nbytes, uint16_t timeout)
Get the current working directory.
- int [FTPSetDir](#) (int ftp_Session, const char *new_dir, uint16_t timeout)
Set the current working directory.
- int [FTPDeleteDir](#) (int ftp_Session, const char *dir_to_delete, uint16_t timeout)
Delete a directory.
- int [FTPMakeDir](#) (int ftp_Session, const char *dir_to_make, uint16_t timeout)
Create a new directory.
- int [FTPUpDir](#) (int ftp_Session, uint16_t timeout)
Move up one directory level.
- int [FTPDeleteFile](#) (int ftp_Session, const char *file_name, uint16_t timeout)
Delete a file.
- int [FTPRenameFile](#) (int ftp_Session, const char *old_file_name, const char *new_file_name, uint16_t time-out)
Rename a file.
- int [FTPSendFile](#) (int ftp_Session, const char *full_file_name, BOOL bBinaryMode, uint16_t timeout)
Initialize the process to send a file to s FTP server.
- int [FTPGetFile](#) (int ftp_Session, const char *full_file_name, BOOL bBinaryMode, uint16_t timeout)
Initialize the process to get a file from a FTP server.
- int [FTPGetList](#) (int ftp_Session, const char *full_dir_name, uint16_t timeout)
Initialize the process to receive a directory listing from a FTP server.
- int [FTPGetFileNames](#) (int ftp_Session, const char *full_dir_name, uint16_t timeout)
Initialize the process to receive just the file names in a directory from a FTP server.
- int [FTPRawCommand](#) (int ftp_Session, const char *cmd, char *cmd_buf, int nbytes, uint16_t timeout)
Send a FTP command to the FTP server.
- int [FTPGetCommandResult](#) (int ftp_Session, char *cmd_buf, int nbytes, uint16_t timeout)
Returns the result of the last FTP operation.
- int [FTPRawStreamCommand](#) (int ftp_Session, const char *cmd, int *pResult, char *cmd_buf, int nbytes, uint16_t timeout)
Send a command and receive a response over a stream connection.
- void [FTPActiveMode](#) (int ftp_Session)
Set mode to active.
- void [FTPPassiveMode](#) (int ftp_Session)
Set mode to passive.

FTP Client Return Codes

- `#define FTP_OK (0)`
OK.
- `#define FTP_TIMEOUT (-1)`
Timeout.
- `#define FTP_PASSWORDERROR (-2)`
Password error.
- `#define FTP_CONNECTFAIL (-3)`
Connection failed.
- `#define FTP_COMMANDFAIL (-4)`
Command failed.
- `#define FTP_COMMANDERROR (-4)`
Command error.
- `#define FTP_BADSESSION (-5)`
Bad session.
- `#define FTP_NETWORKERROR (-6)`
Network error.

14.17.1 Detailed Description

```
#include< ftp.h>
```

The NetBurner FTP Client Group

14.17.2 Function Documentation**14.17.2.1 FTP_CloseSession()**

```
int FTP_CloseSession (
    int session)
```

```
#include <ftp.h>
```

Close a FTP session.

Parameters

<i>session</i>	FTP session number to close

Returns

[ftpClientReturnCodes](#)

See also

[FTP_InitializeSession\(\)](#)

14.17.2.2 FTP_InitializeSession()

```
int FTP_InitializeSession (
    IPADDR4 server_address,
    uint16_t port,
    PCSTR UserName,
    PCSTR Password,
    uint32_t time_out)
```

```
#include <ftp.h>
```

Initialize a FTP session with a FTP server.

Open a connection to a FTP server and log in with the specified username and password. The session number returned from this call can be used with the file and directory functions.

Parameters

<i>server_address</i>	The IP address of the FTP server
<i>port</i>	The listen port number of the FTP server. Typically 21.
<i>UserName</i>	Log-in username
<i>Password</i>	Log-in password
<i>time_out</i>	Timeout in system Time Ticks

Returns

A value greater than 0 is a FTP session handle, otherwise [ftpClientReturnCodes](#)

See also

[FTP_CloseSession\(\)](#)

14.17.2.3 FTPActiveMode()

```
void FTPActiveMode (
    int ftp_Session)
#include <ftp.h>
Set mode to active.
```

Parameters

<i>ftp_Session</i>	FTP session number

14.17.2.4 FTPDeleteDir()

```
int FTPDeleteDir (
    int ftp_Session,
    const char * dir_to_delete,
    uint16_t timeout)
#include <ftp.h>
Delete a directory.
```

Parameters

<i>ftp_Session</i>	FTP session number
<i>dir_to_delete</i>	Directory to delete
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.17.2.5 FTPDeleteFile()

```
int FTPDeleteFile (
    int ftp_Session,
    const char * file_name,
    uint16_t timeout)
#include <ftp.h>
Delete a file.
```

Parameters

<i>ftp_Session</i>	FTP session number
<i>file_name</i>	Name of file to delete
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.17.2.6 FTPGetCommandResult()

```
int FTPGetCommandResult (
    int ftp_Session,
    char * cmd_buf,
    int nbytes,
    uint16_t timeout)
```

```
#include <ftp.h>
```

Returns the result of the last FTP operation.

Queries the FTP server for the last FTP operation status.

Must be called after the following functions are used:

- [FTPGetList\(\)](#)
- [FTPFileNames\(\)](#)
- [FTPGetFile\(\)](#)
- [FTPSendFile\(\)](#)

Parameters

<i>ftp_Session</i>	FTP session number
<i>cmd_buf</i>	The buffer to hold the ASCII FTP server response. See FTP Server return codes for details.
<i>nbytes</i>	The maximum number of bytes cmd_buf can hold
<i>timeout</i>	Timeout in system Time Ticks

Returns

The FTP server response number on success, otherwise [ftpClientReturnCodes](#)

14.17.2.7 FTPGetDir()

```
int FTPGetDir (
    int ftp_Session,
    char * dir_buf,
    int nbytes,
    uint16_t timeout)
```

```
#include <ftp.h>
```

Get the current working directory.

Parameters

<i>ftp_Session</i>	FTP session number
<i>dir_buf</i>	The buffer to copy the directory information into
<i>nbytes</i>	Maximum number of bytes in the dir_buf
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.17.2.8 FTPGetFile()

```
int FTPGetFile (
    int ftp_Session,
    const char * full_file_name,
    BOOL bBinaryMode,
    uint16_t timeout)
```

```
#include <ftp.h>
```

Initialize the process to get a file from a FTP server.

This function opens a TCP connection to a FTP server so that a file may be read. it will return a file descriptor that can then be used to read the file data using file I/O functions such as: [read\(\)](#) and [ReadWithTimeout\(\)](#).

IMPORTANT After reading the file data you must do 2 things:

- The TCP connection must be closed with the [close\(\)](#) function.
- [FTPGetCommandResult\(\)](#) must be called to check the result of the operation.

Parameters

<i>ftp_Session</i>	FTP session number
<i>full_file_name</i>	Full file name being read, including the path
<i>bBinaryMode</i>	True = read file as binary data, False = read file as ASCII data
<i>timeout</i>	Timeout in system Time Ticks

Returns

TCP file descriptor if greater than 0, otherwise [ftpClientReturnCodes](#)

```
int fd = FTPGetFile(ftp, "testfile.txt", FALSE, 5 * TICKS_PER_SECOND);    // Send file in ASCII mode

if (fd > 0)
{
    // Code to read all data from the file descriptor goes here
    close(fd);

    int rv = FTPGetCommandResult(ftpSession, resultBuffer, 80, 5 * TICKS_PER*SECOND );

    if ( rv != 226)    // Return code 226 = Closing data connection. Requested file action successful.
        iprintf("Read error result = %d %s\r\n", rv, resultBuffer);
}
else
{
    iprintf("Failed to read file\r\n");
}
```

14.17.2.9 FTPGetFileNames()

```
int FTPGetFileNames (
    int ftp_Session,
    const char * full_dir_name,
    uint16_t timeout)
```

```
#include <ftp.h>
```

Initialize the process to receive just the file names in a directory from a FTP server.

This function opens a TCP connection to a FTP server so that a list of file names may be read. it will return a file descriptor that can then be used to read the file data using file I/O functions such as: [read\(\)](#) and [ReadWithTimeout\(\)](#).

IMPORTANT After reading the file data you must do 2 things:

- The TCP connection must be closed with the [close\(\)](#) function.
- [FTPGetCommandResult\(\)](#) must be called to check the result of the operation.

Parameters

<i>ftp_Session</i>	FTP session number
<i>full_dir_name</i>	Full directory name to read, including the path
<i>timeout</i>	Timeout in system Time Ticks

Returns

TCP file descriptor if greater than 0, otherwise ftpClientReturnCodes

14.17.2.10 FTPGetList()

```
int FTPGetList (
    int ftp_Session,
    const char * full_dir_name,
    uint16_t timeout)
#include <ftp.h>
```

Initialize the process to receive a directory listing from a FTP server.

This function opens a TCP connection to a FTP server so that a directory list may be read. it will return a file descriptor that can then be used to read the file data using file I/O functions such as: [read\(\)](#) and [ReadWithTimeout\(\)](#). IMPORTANT After reading the file data you must do 2 things:

- The TCP connection must be closed with the [close\(\)](#) function.
- [FTPGetCommandResult\(\)](#) must be called to check the result of the operation.

Parameters

<i>ftp_Session</i>	FTP session number
<i>full_dir_name</i>	Full directory name to read, including the path
<i>timeout</i>	Timeout in system Time Ticks

Returns

TCP file descriptor if greater than 0, otherwise ftpClientReturnCodes

14.17.2.11 FTPMakeDir()

```
int FTPMakeDir (
    int ftp_Session,
    const char * dir_to_make,
    uint16_t timeout)
#include <ftp.h>
```

Create a new directory.

Parameters

<i>ftp_Session</i>	FTP session number
<i>dir_to_make</i>	Directory to create
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.17.2.12 FTPPassiveMode()

```
void FTPPassiveMode (
    int ftp_Session)
#include <ftp.h>
Set mode to passive.
```

Parameters

<i>ftp_Session</i>	FTP session number

14.17.2.13 FTPRawCommand()

```
int FTPRawCommand (
    int ftp_Session,
    const char * cmd,
    char * cmd_buf,
    int nbytes,
    uint16_t timeout)
#include <ftp.h>
Send a FTP command to the FTP server.
```

Parameters

<i>ftp_Session</i>	FTP session number.
<i>cmd</i>	The command to send. Do not include termination such as \r\n.
<i>cmd_buf</i>	The buffer to hold the FTP server response, in ASCII.
<i>nbytes</i>	The maximum number of bytes the cmd_buf can hold.
<i>timeout</i>	Timeout in system Time Ticks.

Returns

The FTP server response code if greater than 0, otherwise ftpClientReturnCodes

14.17.2.14 FTPRawStreamCommand()

```
int FTPRawStreamCommand (
    int ftp_Session,
    const char * cmd,
    int * pResult,
    char * cmd_buf,
    int nbytes,
    uint16_t timeout)
#include <ftp.h>
```

Send a command and receive a response over a stream connection.

The FTP server will close the connection after all the data has been read. This function is the basis for such functions as [FTPGetList\(\)](#) and [FTPGetFiles\(\)](#).

IMPORTANT After reading the file data you must call [FTPGetCommandResult\(\)](#) to check the result of the operation.

Parameters

<i>ftp_Session</i>	FTP session number
<i>cmd</i>	Command to send
<i>pResult</i>	The server response code integer value
<i>cmd_buf</i>	The server response code ASCII value (including \r\n)
<i>nbytes</i>	Maximum number of bytes cmd_buf can hold

<i>timeout</i>	Timeout in system Time Ticks

Returns

TCP file descriptor if greater than 0, otherwise ftpClientReturnCodes

14.17.2.15 FTPRenameFile()

```
int FTPRenameFile (
    int ftp_Session,
    const char * old_file_name,
    const char * new_file_name,
    uint16_t timeout)
#include <ftp.h>
```

Rename a file.

Parameters

<i>ftp_Session</i>	FTP session number
<i>old_file_name</i>	Name of file to rename
<i>new_file_name</i>	New name of file
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.17.2.16 FTPSendFile()

```
int FTPSendFile (
    int ftp_Session,
    const char * full_file_name,
    BOOL bBinaryMode,
    uint16_t timeout)
#include <ftp.h>
```

Initialize the process to send a file to s FTP server.

This function opens a TCP connection to a FTP server so that a file may be sent. it will return a file descriptor that can then be used to send the file data using file I/O write functions such as: [write\(\)](#), [writeall\(\)](#), [writestring\(\)](#), etc.

IMPORTANT After sending the file data you must do 2 things:

- The TCP connection must be closed with the [close\(\)](#) function.
- [FTPGetCommandResult\(\)](#) must be called to check the result of the operation.

Parameters

<i>ftp_Session</i>	FTP session number
<i>full_file_name</i>	Name of the file being sent
<i>bBinaryMode</i>	True = send file as binary data, False = send file as ASCII data
<i>timeout</i>	Timeout in system Time Ticks

Returns

TCP file descriptor if greater than 0, otherwise [ftpClientReturnCodes](#)

```
int fd = FTPSendFile(ftp, "testfile.txt", FALSE, 5 * TICKS_PER_SECOND);    // Send file in ASCII mode

if (fd > 0)
{
    writestring(fd, "This is a test file\r\n");
    writestring(fd, "This is line 2 of the test file\r\n");
    writestring(fd, "Last Line\r\n");
    close(fd);

    int rv = FTPGetCommandResult(ftpSession, resultBuffer, 80, 5 * TICKS_PER*SECOND );

    if ( rv != 226)    // Return code 226 = Closing data connection. Requested file action successful.
        iprintf("Write error result = %d %s\r\n", rv, resultBuffer);
}
else
{
    iprintf("Failed to send file\r\n");
}
```

14.17.2.17 FTPSetDir()

```
int FTPSetDir (
    int ftp_Session,
    const char * new_dir,
    uint16_t timeout)
#include <ftp.h>
Set the current working directory.
```

Parameters

<i>ftp_Session</i>	FTP session number
<i>new_dir</i>	Directory path to set
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.17.2.18 FTPUpDir()

```
int FTPUpDir (
    int ftp_Session,
    uint16_t timeout)
#include <ftp.h>
Move up one directory level.
```

Parameters

<i>ftp_Session</i>	FTP session number
<i>timeout</i>	Timeout in system Time Ticks

Returns

[ftpClientReturnCodes](#)

14.18 FTP Server**Topics**

- [FTP Server Callback](#)

Core Functions for running a FTP Server on a NetBurner device.

- [FTP Server with EFFS-FAT](#)
- [FTP Server with EFFS-STD](#)

14.18.1 Detailed Description

There are two APIs to implement an FTP Server:

- The FTP Server Callback API, which enables an application to create an FTP Server and process commands in any manor with the associated callback functions.
- The FTP Server File System (EFFS) API, which utilizes the FTP Callback API to implement a FTP Server using the EFFS-FAT or EFFS-STD file system. This is the most commonly used implementation.

14.18.2 FTP Server Callback

Core Functions for running a FTP Server on a NetBurner device.

Topics

- [FTP Server Core Return Codes](#)
- [FTP Server File Return Codes](#)

Initialization functions

- typedef void [FTPDCallBackReportFunc](#)(int handle, const char *name_to_report)
FTP Session callback typedef Typedef for all directory reporting callbacks This callback type definition is used by the directory reporting functions.
- int [FTPStartSSL](#) (uint16_t port, uint8_t server_priority, bool enableFTPS=false, bool encryptData=false)
Starts the FTP Server task (SSL) Listens for incoming connections. Only one instance of the FTPD is allowed.
- int [FTPStart](#) (uint16_t port, uint8_t server_priority)
Starts the FTP Server task (non-SSL/TLS) Listens for incoming connections. Only one instance of the FTPD is allowed. If FTPD SSL support exists, [FTPStartSSL\(\)](#) may be used instead.
- int [FTPStopReq](#) ()
Stops the FTP Server task Sends a stop request to the currently running FTPD.

FTP Session callback functions that must be implemented by the programmer

- void * [FTPSessionStart](#) (const char *user, const char *passwd, const [IPADDR4](#) hi_ip)
Start an FTP user session (User) This function is called following the creation of a new FTP session. The function needs to determine the validity of the user/password pair. The returned void pointer will be passed to all access functions, which will be asked to determine the validity of the operation based on the permissions associated with the return value.
- void [FTPSessionEnd](#) (void *pSession)
Indicate an FTP user session will be terminated. This callback function gives the user program the opportunity to clean up any storage associated with the void pointer returned from the [FTPSessionStart\(\)](#) call.

FTP Directory callback functions that must be implemented by the programmer

- int [FTPD_DirectoryExists](#) (const char *full_directory, void *pSession)
Called by the FTP Server to test for the existence of a directory Called by the FTP Server as the result of an attempt to change to a new directory. This function can also be used to validate the permissions of the session. This function must be implemented by the programmer.
- int [FTPD_CreateSubDirectory](#) (const char *current_directory, const char *new_dir, void *pSession)
Called by the FTP Server to create a directory Called by the FTP Server as the result of an attempt to create a new directory. This function can also be used to validate the permissions of the session. This function must be implemented by the programmer.
- int [FTPD_DeleteSubDirectory](#) (const char *current_directory, const char *sub_dir, void *pSession)

Called by the FTP Server to delete a directory Called by the FTP Server as the result of an attempt to delete a subdirectory. This function call can be used to validate the permissions of this session. This function must be implemented by the programmer.

- int [FTPD_ListSubDirectories](#) (const char *current_directory, void *pSession, [FTPDCallBackReportFunc](#) *pFunc, int handle)

Called by the FTP Server to list all subdirectories under the current directory Called by the FTP Server as the result of a client's attempt to list the contents of a directory. This function must be implemented by the programmer.

FTP file callback functions that must be implemented by the programmer

- int [FTPD_FileExists](#) (const char *full_directory, const char *file_name, void *pSession)
Report on the whether or not a file exists Check for the existence of a file, usually just before an attempt is made to download the file. This function must be implemented by the programmer.
- int [FTPD_GetFileSize](#) (const char *full_directory, const char *file_name)
Returns the size of a specific file.
- int [FTPD_SendFileToClient](#) (const char *full_directory, const char *file_name, void *pSession, int fd)
Send the contents of a file to a file descriptor Send a file to a FTP client. This function must be implemented by the programmer.
- int [FTPD_AbleToCreateFile](#) (const char *full_directory, const char *file_name, void *pSession)
Report on the ability to create/receive a file Determine if a file can be created. This function must be implemented by the programmer.
- int [FTPD_GetFileFromClient](#) (const char *full_directory, const char *file_name, void *pSession, int fd)
Create/get a file Receive a file from the FTP client. This function must be implemented by the programmer.
- int [FTPD_DeleteFile](#) (const char *current_directory, const char *file_name, void *pSession)
Delete a file Delete a file. This function must be implemented by the programmer.
- int [FTPD_Rename](#) (const char *current_directory, const char *cur_file_name, const char *new_file_name, void *pSession)
Rename a file Rename a file. This function must be implemented by the programmer.
- int [FTPD_ListFile](#) (const char *current_directory, void *pSession, [FTPDCallBackReportFunc](#) *pFunc, int handle)
Lists all files in the current directory List all files in the current directory. This function must be implemented by the programmer.

14.18.2.1 Detailed Description

Core Functions for running a FTP Server on a NetBurner device.

```
#include< ftpd.h>
```

The FTP Server Core Functions described in this section consist of function to start and stop the FTP server, and callback functions to handle FTP processing such as: session handling, directory and file creation, deletion and listings, etc. These core callback functions enable applications to create a FTP server in many different ways, with or without a file system.

Without a file system. Real time processing of files sent or received. For example, application data can be sent in response to a FTP client request as a text file by specifying the file type as .txt and sending the data. There are examples of this method in the "\nburn\examples\FTP" folder.

With a file system. There are 3 choices on your NetBurner platform: external flash cards (EFFS-FAT), on-chip flash memory (EFFS-STD), and ram drives. Examples of these methods are located in the "\nburn\examples\EFFS" folder. When using a file system these core functions do not need to be used directly. Since the choice has been made to use a file system rather than the callback functions, applications should use the functions described in the examples since the work of linking the callbacks to the file system has already been done for you.

Deprecated For NetBurner customers porting from the 2.x tools to 3.x: FTP_FAIL and FTP_OK were deprecated on Jan 16, 2008. These defines were removed and all server functions (denoted as FTPD) were modified to use FTPD_OK and FTPD_FAIL. This was necessary so that the FTP client and server header files could be used at the same time. If you have any errors in your application code, you can safely change all server functions from FTP_OK/FAIL to FTPD_OK/FAIL.

14.18.2.2 Typedef Documentation

14.18.2.2.1 FTPDCallBackReportFuncnt

```
typedef void FTPDCallBackReportFuncnt(int handle, const char *name_to_report)
#include <ftpd.h>
```

FTP Session callback typedef Typedef for all directory reporting callbacks This callback type definition is used by the directory reporting functions.

Parameters

<i>handle</i>	The handle passed into the listing function
<i>name_to_report</i>	The file name to report for use in a directory listing

See also

[FTPD_ListSubDirectories](#), [FTPD_ListFile](#)

14.18.2.3 Function Documentation

14.18.2.3.1 FTPD_AbleToCreateFile()

```
int FTPD_AbleToCreateFile (
    const char * full_directory,
    const char * file_name,
    void * pSession)
#include <ftpd.h>
```

Report on the ability to create/receive a file Determine if a file can be created. This function must be implemented by the programmer.

Parameters

<i>full_directory</i>	The current value of the session directory
<i>file_name</i>	The name of the file to create
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

Return values

<i>FTPD_OK</i>	The requested file can be written/created
<i>FTPD_FAIL</i>	The requested file could not be created

See also

[FTPD_FileExists](#), [FTPD_SendFileToClient](#), [FTPD_GetFileFromClient](#), [FTPD_DeleteFile](#), [FTPD_ListFile](#)

14.18.2.3.2 FTPD_CreateSubDirectory()

```
int FTPD_CreateSubDirectory (
    const char * current_directory,
    const char * new_dir,
    void * pSession)
#include <ftpd.h>
```

Called by the FTP Server to create a directory Called by the FTP Server as the result of an attempt to create a new directory. This function can also be used to validate the permissions of the session. This function must be implemented by the programmer.

Parameters

<i>current_directory</i>	The current value of the session directory
<i>new_dir</i>	The directory to create under the <i>current_directory</i>
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

Return values

<i>FTPD_OK</i>	The requested directory was created
<i>FTPD_FAIL</i>	The requested directory could not be created

See also

[FTPD_DirectoryExists](#), [FTPD_DeleteSubDirectory](#)

14.18.2.3.3 FTPD_DeleteFile()

```
int FTPD_DeleteFile (
    const char * current_directory,
    const char * file_name,
    void * pSession)
```

```
#include <ftpd.h>
```

Delete a file Delete a file. This function must be implemented by the programmer.

Parameters

<i>current_directory</i>	The current value of the session directory
<i>file_name</i>	The name of the file to delete
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

Return values

<i>FTPD_OK</i>	The requested file was deleted
<i>FTPD_FAIL</i>	The requested file could not be deleted

See also

[FTPD_FileExists](#), [FTPD_SendFileToClient](#), [FTPD_AbleToCreateFile](#), [FTPD_GetFileFromClient](#), [FTPD_ListFile](#)

14.18.2.3.4 FTPD_DeleteSubDirectory()

```
int FTPD_DeleteSubDirectory (
    const char * current_directory,
    const char * sub_dir,
    void * pSession)
```

```
#include <ftpd.h>
```

Called by the FTP Server to delete a directory Called by the FTP Server as the result of an attempt to delete a subdirectory. This function call can be used to validate the permissions of this session. This function must be implemented by the programmer.

Parameters

<i>current_directory</i>	The current value of the session current directory

<i>sub_dir</i>	The directory to delete under the <i>current_directory</i>
<i>pSession</i>	The void * object returned from the <code>FTPBSessionStart()</code> function call at the beginning of the session

Return values

<i>FTPD_OK</i>	The requested directory was deleted
<i>FTPD_FAIL</i>	The requested directory could not be deleted

See also

[FTPD_DirectoryExists](#), [FTPD_CreateSubDirectory](#)

14.18.2.3.5 FTPD_DirectoryExists()

```
int FTPD_DirectoryExists (
    const char * full_directory,
    void * pSession)
```

```
#include <ftpd.h>
```

Called by the FTP Server to test for the existence of a directory Called by the FTP Server as the result of an attempt to change to a new directory. This function can also be used to validate the permissions of the session. This function must be implemented by the programmer.

Parameters

<i>full_directory</i>	Name of the new directory to test
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

Return values

<i>FTPD_OK</i>	The requested directory exists
<i>FTPD_FAIL</i>	The requested directory does not exist, or access is not permitted for the user

See also

[FTPD_CreateSubDirectory](#), [FTPD_DeleteSubDirectory](#)

14.18.2.3.6 FTPD_FileExists()

```
int FTPD_FileExists (
    const char * full_directory,
    const char * file_name,
    void * pSession)
```

```
#include <ftpd.h>
```

Report on the whether or not a file exists Check for the existence of a file, usually just before an attempt is made to download the file. This function must be implemented by the programmer.

Parameters

<i>full_directory</i>	The current value of the session directory
<i>file_name</i>	The name of the file to check
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

Return values

<i>FTPD_OK</i>	The requested file exists
<i>FTPD_FAIL</i>	The requested file does not exist

See also

[FTPD_FileExists](#), [FTPD_SendFileToClient](#), [FTPD_AbleToCreateFile](#), [FTPD_GetFileFromClient](#), [FTPD_DeleteFile](#), [FTPD_ListFile](#)

14.18.2.3.7 FTPD_GetFileFromClient()

```
int FTPD_GetFileFromClient (
    const char * full_directory,
    const char * file_name,
    void * pSession,
    int fd)
```

#include <ftpd.h>

Create/get a file Receive a file from the FTP client. This function must be implemented by the programmer.

Parameters

<i>full_directory</i>	The current value of the session directory
<i>file_name</i>	The name of the file to create
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call
<i>fd</i>	The file descriptor that will be used to receive the file

Return values

<i>FTPD_OK</i>	The requested file was written/created
<i>FTPD_FAIL</i>	The requested file was not created

See also

[FTPD_FileExists](#), [FTPD_SendFileToClient](#), [FTPD_AbleToCreateFile](#), [FTPD_DeleteFile](#), [FTPD_ListFile](#)

14.18.2.3.8 FTPD_GetFileSize()

```
int FTPD_GetFileSize (
    const char * full_directory,
    const char * file_name)
```

#include <ftpd.h>

Returns the size of a specific file.

Returns

file size

Return values

<i>FTPD_FILE_SIZE_UNKNOWN</i>	
<i>FTPD_FILE_SIZE_NOSUCH_FILE</i>	

14.18.2.3.9 FTPD_ListFile()

```
int FTPD_ListFile (
    const char * current_directory,
    void * pSession,
    FTPDCallBackReportFunc * pFunc,
    int handle)
```

#include <ftpd.h>

Lists all files in the current directory List all files in the current directory. This function must be implemented by the programmer.

Example: Everything inside the callback function stub must be supplied by the programmer.

The FTP server will automatically call this function and provide values for the function variables. It is the programmer's responsibility to execute `pFunc( )` with the provided handle and a pointer to the string representing the file name. `pFunc( )` must be executed once for each file name. In this example, the variables `number_of_directories` and `FileNames[]` must be declared and initialized elsewhere in the application program.

```
int FTPD_ListFile(const char * current_directory, void * pSession, FTPDCallBackReportFunct * pFunc, int handle)
{
    for (int n = 0; n < numberof_files; n++)
        pFunc(handle, FileNames[n]);
    return FTPD_OK;
}
```

Parameters

<i>current_directory</i>	The current value of the session directory
<i>pSession</i>	The void * object returned from the <code>FTPBSessionStart()</code> function call
<i>pFunc</i>	The pointer to the callback function to be called for each file name. This is a callback function provided and used by the NetBurner internal FTP code.
<i>handle</i>	The handle value to be passed back into the <code>pFunc</code> . This is a handle provided and used by the NetBurner internal FTP code.

Return values

<i>FTPD_OK</i>	The requested files were listed
<i>FTPD_FAIL</i>	The requested file was not listed

See also

[FTPD_FileExists](#), [FTPD_SendFileToClient](#), [FTPD_AbleToCreateFile](#), [FTPD_GetFileFromClient](#), [FTPD_DeleteFile](#)

14.18.2.3.10 FTPD_ListSubDirectories()

```
int FTPD_ListSubDirectories (
    const char * current_directory,
    void * pSession,
    FTPDCallBackReportFunct * pFunc,
    int handle)
```

```
#include <ftpd.h>
```

Called by the FTP Server to list all subdirectories under the current directory Called by the FTP Server as the result of a client's attempt to list the contents of a directory. This function must be implemented by the programmer.

Example:

Everything inside the callback function stub must be supplied by the programmer. The FTP server will automatically call this function and provide values for the function variables. It is the programmer's responsibility to execute `pFunc( )` with the provided handle and a pointer to the string representing the subdirectory name. `pFunc( )` must be executed once for each subdirectory name. In this example, the variables `number_of_directories` and `DirectoryName[]` must be declared and initialized elsewhere in the application program.

```
int FTPD_ListSubDirectories(const char * current_directory, void * pSession, FTPDCallBackReportFunct * pFunc, int handle);
{
    for (int n = 0; n < number_of_dir; n++)
        pFunc(handle, DirectoryName[n]);
    return FTPD_OK;
}
```

Parameters

<i>current_directory</i>	The current value of the session current directory

Parameters

<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call
<i>pFunc</i>	The pointer to the callback function to be called for each subdirectory
<i>handle</i>	The handle value to be passed back into the pFunc

Return values

<i>FTPD_OK</i>	The requested listing was successfully delivered
<i>FTPD_FAIL</i>	The requested directory could not be listed

See also

[FTPD_DirectoryExists](#), [FTPD_DeleteSubDirectory](#), [FTPD_CreateSubDirectory](#)

14.18.2.3.11 FTPD_Rename()

```
int FTPD_Rename (
    const char * current_directory,
    const char * cur_file_name,
    const char * new_file_name,
    void * pSession)
```

```
#include <ftpd.h>
```

Rename a file Rename a file. This function must be implemented by the programmer.

Parameters

<i>current_directory</i>	The current value of the session directory
<i>cur_file_name</i>	The name of the file to rename
<i>new_file_name</i>	
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

Return values

<i>FTPD_OK</i>	The requested file was deleted
<i>FTPD_FAIL</i>	The requested file could not be renamed

See also

[FTPD_FileExists](#), [FTPD_SendFileToClient](#), [FTPD_AbleToCreateFile](#), [FTPD_GetFileFromClient](#), [FTPD_ListFile](#)

14.18.2.3.12 FTPD_SendFileToClient()

```
int FTPD_SendFileToClient (
    const char * full_directory,
    const char * file_name,
    void * pSession,
    int fd)
```

```
#include <ftpd.h>
```

Send the contents of a file to a file descriptor Send a file to a FTP client. This function must be implemented by the programmer.

Parameters

<i>full_directory</i>	The current value of the session directory
<i>file_name</i>	The name of the file to send
<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call
<i>fd</i>	The file descriptor to send to

Return values

<i>FTPD_OK</i>	The requested file was sent.
<i>FTPD_FAIL</i>	The requested file was not sent.

See also

[FTPD_FileExists](#), [FTPD_AbleToCreateFile](#), [FTPD_GetFileFromClient](#), [FTPD_DeleteFile](#), [FTPD_ListFile](#)

14.18.2.3.13 FTPDSessionEnd()

```
void FTPDSessionEnd (
    void * pSession)
#include <ftpd.h>
```

Indicate an FTP user session will be terminated. This callback function gives the user program the opportunity to clean up any storage associated with the void pointer returned from the FTPBSessionStart() call.

Parameters

<i>pSession</i>	The void * object returned from the FTPBSessionStart() function call

See also

[FTPBSessionStart](#)

14.18.2.3.14 FTPDSessionStart()

```
void * FTPDSessionStart (
    const char * user,
    const char * passwd,
    const IPADDR4 hi_ip)
#include <ftpd.h>
```

Start an FTP user session (User) This function is called following the creation of a new FTP session. The function needs to determine the validity of the user/password pair. The returned void pointer will be passed to all access functions, which will be asked to determine the validity of the operation based on the permissions associated with the return value.

Parameters

<i>user</i>	The name of the user attempting to establish an FTP session
<i>passwd</i>	The password of the user attempting to establish an FTP session
<i>hi_ip</i>	The IP address of the server trying to establish this connection

Return values

<i>NULL</i>	The user name/password set is invalid
<i>(obj)</i>	A non-null void pointer to an object that will be associated with this login session

See also

[FTPDSessionEnd](#)

14.18.2.3.15 FTPDStart()

```
int FTPDStart (
    uint16_t port,
    uint8_t server_priority)
#include <ftpd.h>
```

Starts the FTP Server task (non-SSL/TLS) Listens for incoming connections. Only one instance of the FTPD is allowed. If FTPD SSL support exists, [FTPDStartSSL\(\)](#) may be used instead.

Parameters

<i>port</i>	The TCP port to listen to for incoming FTP requests
<i>server_priority</i>	The RTOS task priority for the FTP Server

Return values

<i>FTPD_RUNNING</i>	- The FTPD is already running
<i>FTPD_LISTEN_ERR</i>	- The listen socket was not able to be opened
<i>FTPD_OK</i>	- The FTPD was succesfully started
<i>FTPD_FAIL</i>	- The FTPD task could not be created

See also

[FTPDStartSSL](#), [FTPDStopReq](#)

14.18.2.3.16 FTPDStartSSL()

```
int FTPDStartSSL (
    uint16_t port,
    uint8_t server_priority,
    bool enableFTPS = false,
    bool encryptData = false)
#include <ftpd.h>
```

Starts the FTP Server task (SSL) Listens for incoming connections. Only one instance of the FTPD is allowed.

Parameters

<i>port</i>	The TCP port to listen to for incoming FTP requests
<i>server_priority</i>	The RTOS task priority for the FTP Server
<i>enableFTPS</i>	
<i>encryptData</i>	

Return values

<i>FTPD_RUNNING</i>	- The FTPD is already running
<i>FTPD_LISTEN_ERR</i>	- The listen socket was not able to be opened
<i>FTPD_OK</i>	- The FTPD was succesfully started
<i>FTPD_FAIL</i>	- The FTPD task could not be created

See also

[FTPDStart](#), [FTPDStopReq](#)

14.18.2.3.17 FTPDStopReq()

```
int FTPDStopReq ()  
#include <ftpd.h>
```

Stops the FTP Server task Sends a stop request to the currently running FTPD.

Return values

<i>FTPD_RUNNING</i>	- The FTPD is still running
<i>FTPD_NOT_RUNNING</i>	- The FTPD is no longer running

See also

[FTPDStart](#), [FTPDStartSSL](#)

14.18.2.4 FTP Server Core Return Codes

Macros

- **#define FTPD_FAIL (0)**
Operation failed.
- **#define FTPD_OK (1)**
Operation succeeded.
- **#define FTPD_RUNNING (2)**
FTP Server running.
- **#define FTPD_NOT_RUNNING (3)**
FTP Server not running.
- **#define FTPD_LISTEN_ERR (4)**
FTP listen socket could not be opened, or is not open.

14.18.2.4.1 Detailed Description

14.18.2.5 FTP Server File Return Codes

Macros

- **#define FTPD_FILE_SIZE_NOSUCH_FILE (-1)**
No such file.
- **#define FTPD_FILE_SIZE_UNKNOWN (0)**
File size unknown.

14.18.2.5.1 Detailed Description

14.18.3 FTP Server with EFFS-FAT

```
#include< ftpd_effsfat.h>
```

FTP Server with EFFS-FAT file system implementation. For use with flash cards such as SD and microSD flash cards.

Note

Please refer to the FTP and HTTP examples in "\nburn\examples\EFFS\Fat".

14.18.4 FTP Server with EDFS-STD

```
#include< ftpd_edsstd.h>
```

FTP Server with EDFS-STD file system implementation. Implements a flash file system in the flash chips of your NetBurner device.

Note

Please refer to the HTTP example in "\nburn\examples\EDFS\Std".

14.19 File Descriptor Printf - fdprintf

Printf-style formatted output to file descriptors.

Functions

- int [fdprintf](#) (int fd, const char *format,...)
Print formatted output to a file descriptor.
- int [fdiprintf](#) (int fd, const char *format,...)
Print formatted output to a file descriptor (integer-only, no float)
- int [vfdprintf](#) (int fd, const char *format, va_list args)
Print formatted output to a file descriptor using va_list.
- int [vfdiprintf](#) (int fd, const char *format, va_list args)
Print formatted output to a file descriptor using va_list (integer-only)

14.19.1 Detailed Description

Printf-style formatted output to file descriptors.

```
#include< fdprintf.h>
```

The fdprintf family of functions extends the familiar printf() functionality to work with any file descriptor in the NetBurner system. This enables formatted output to:

- Serial ports (UART)
- TCP/IP network connections
- UDP sockets
- Custom file descriptors
- Any device that implements the file descriptor interface

14.19.2 Overview

Unlike printf() which outputs to stdout (typically the debug serial port), [fdprintf\(\)](#) allows you to direct formatted output to any open file descriptor. This is essential for network protocols, multi-port communications, and custom output devices.

14.19.3 Function Variants

Four variants are provided to suit different needs:

Function	Float Support	Argument Type	Use Case
fdprintf()	Yes	Variable args	General purpose with float
fdiprintf()	No	Variable args	Integer-only (smaller code)
vfdprintf()	Yes	va_list	Wrapper functions with float
vfdiprintf()	No	va_list	Wrapper functions, integer-only

14.19.4 Example Usage

14.19.4.1 Serial Port Output

```
#include <fdprintf.h>
#include <serial.h>

void sendSerialData() {
    int serialFd = SimpleOpenSerial(0, 115200);

    fdprintf(serialFd, "Temperature: %.2f C\r\n", 23.45);
    fdprintf(serialFd, "Status: %s\r\n", "OK");

    close(serialFd);
}
```

14.19.4.2 Network Socket Output

```
#include <fdprintf.h>
#include <tcp.h>

void sendToClient(int clientFd) {
    fdprintf(clientFd, "HTTP/1.1 200 OK\r\n");
    fdprintf(clientFd, "Content-Type: text/html\r\n\r\n");
    fdprintf(clientFd, "<html><body>\r\n");
    fdprintf(clientFd, "<h1>Device Status</h1>\r\n");
    fdprintf(clientFd, "<p>Uptime: %lu seconds</p>\r\n", Secs);
    fdprintf(clientFd, "</body></html>\r\n");
}
```

14.19.4.3 Creating Wrapper Functions

```
#include <fdprintf.h>
#include <stdarg.h>

// Custom logging function that adds timestamps
void logToSerial(const char *format, ...) {
    static int logFd = -1;

    if (logFd < 0) {
        logFd = SimpleOpenSerial(1, 115200);
    }

    // Print timestamp
    fdprintf(logFd, "[%lu] ", Secs);

    // Print user message using va_list
    va_list args;
    va_start(args, format);
    vfdprintf(logFd, format, args);
    va_end(args);
}

// Usage
logToSerial("Sensor reading: %d\n", sensorValue);
```

14.19.4.4 Integer-Only for Code Size

```
#include <fdprintf.h>

// Use fdiprintf when you don't need floating point
// This saves significant code space
void sendIntegerStatus(int fd) {
    fdiprintf(fd, "Counter: %d\r\n", counter);
    fdiprintf(fd, "Error Code: 0x%08X\r\n", errorCode);
    fdiprintf(fd, "Status: %s\r\n", statusString);
}
```

14.19.5 Format Specifiers

[fdprintf\(\)](#) supports standard C printf format specifiers:

- d, i - Signed decimal integer
- u - Unsigned decimal integer
- x, X - Hexadecimal
- o - Octal

- c - Character
- s - String
- p - Pointer
- f, e, g - Floating point (fdprintf/vdprintf only)
- %% - Literal %

Width, precision, and flags are supported:

- %5d - Minimum width
- %05d - Zero-padded width
- %.2f - Precision
- %-10s - Left-aligned
- %+d - Force sign

14.19.6 Performance Considerations

- **Code Size:** `fdiprintf()` is ~10-15KB smaller than `fdprintf()` due to no float support
- **Speed:** Integer formatting is faster than floating point
- **Buffering:** Consider buffering for high-frequency output
- **Network:** `fdprintf()` to network sockets may block if buffer is full

14.19.7 Best Practices

1. **Error Checking:** Always check file descriptor validity before use
2. **Return Value:** Check return value for write errors
3. **Buffer Size:** Be aware of output buffer limits on network sockets
4. **Float Support:** Use `fdiprintf()` when floating point is not needed
5. **Line Endings:** Use `\r\n` for network protocols and serial terminals

14.19.8 Important Notes

Note

The `fdprintf()` family does not append a newline automatically. You must include `\n` or `\r\n` in your format string if desired.

Output to network sockets may block if the socket send buffer is full. Consider using non-blocking I/O or checking buffer space for critical applications.

File descriptors must be properly opened before use and closed when done.

Warning

Floating point formatting (fdprintf/vdprintf) increases code size significantly. Use `fdiprintf` or `vdiprintf` when float support is not required.

Large format strings or many arguments can overflow stack space. Keep format operations reasonably sized.

14.19.9 Example Code

Complete examples are available in the NetBurner SDK:

- `\nburn\examples\Filedescriptor` - File descriptor usage examples
- Examples include custom file descriptor creation and usage

See also

`printf()` Standard printf to stdout

`iprintf()` Integer-only printf to stdout

`snprintf()` Format to string buffer

[writeall\(\)](#) Write raw data to file descriptor

14.19.10 Function Documentation

14.19.10.1 fdprintf()

```
int fdprintf (
    int fd,
    const char * format,
    ...)
```

```
#include <fdprintf.h>
```

Print formatted output to a file descriptor (integer-only, no float)

Similar to [fdprintf\(\)](#) but without floating point support. This significantly reduces code size (~10-15KB smaller) and is faster for integer-only formatting. Use this when you only need to format integers, strings, and other non-float types.

Parameters

<i>fd</i>	File descriptor to write to. Must be a valid, open file descriptor such as: • Serial port (from SimpleOpenSerial()) • TCP socket (from accept() or connect()) • UDP socket (from <code>socket()</code>) • Custom file descriptor
<i>format</i>	Format string using standard printf syntax. Supports all specifiers EXCEPT floating point (f, e, g are not supported): • Integer formats: d, i, u, x, X, o • String format: s • Character format: c • Pointer format: p • Width and precision modifiers
...	Variable arguments corresponding to format specifiers in the format string

Returns

Number of bytes written to the file descriptor, or negative value on error

Return values

>0	Number of bytes successfully written
<0	Error occurred during write operation

Precondition

- fd must be a valid, open file descriptor
- format must not be NULL
- format must not contain floating point specifiers (f, e, g)

Postcondition

- Data is written to the file descriptor's output buffer

Note

This function does NOT support floating point formatting. Attempting to use f, e, or g will produce undefined results.

No newline is automatically appended. Include `\n` or `\r\n` in the format string if line ending is desired.

Warning

Using floating point specifiers (f, e, g) will cause undefined behavior. Use [fdprintf\(\)](#) if float formatting is needed.

Example: Basic Integer Output

```
int fd = SimpleOpenSerial(0, 115200);
if (fd >= 0) {
    fdiprintf(fd, "Counter: %d\r\n", counter);
    fdiprintf(fd, "Status: 0x%08X\r\n", status);
    close(fd);
}
```

Example: Network Status Messages

```
void sendStatus(int clientFd) {
    fdiprintf(clientFd, "Device ID: %d\r\n", deviceId);
    fdiprintf(clientFd, "Uptime: %lu seconds\r\n", Secs);
    fdiprintf(clientFd, "Memory Free: %d bytes\r\n", OSFreeMemory());
}
```

Example: Code Size Optimization

```
// Instead of this (adds 15KB):
fprintf(fd, "Value: %d\n", value);

// Use this (saves 15KB if no other float formatting):
fdiprintf(fd, "Value: %d\n", value);
```

- [vfdiprintf\(\)](#) va_list version for wrapper functions
- [iprintf\(\)](#) Integer-only printf to stdout

14.19.10.2 fdprintf()

```
int fdprintf (
    int fd,
    const char * format,
    ...)
```

```
#include <fdprintf.h>
```

Print formatted output to a file descriptor.

Outputs formatted text to the specified file descriptor using the same format syntax as standard printf(). Supports all standard format specifiers including floating point.

Parameters

<i>fd</i>	File descriptor to write to. Must be a valid, open file descriptor such as: • Serial port (from SimpleOpenSerial()) • TCP socket (from accept() or connect()) • UDP socket (from socket()) • Custom file descriptor
<i>format</i>	Format string using standard printf syntax. Supports: • All standard format specifiers (d, s, f, x, etc.) • Width and precision modifiers (%-10s, %.2f, %05d) • All standard flags (+, -, 0, space, #)
...	Variable arguments corresponding to format specifiers in the format string

Returns

Number of bytes written to the file descriptor, or negative value on error

Return values

>0	Number of bytes successfully written
<0	Error occurred during write operation

Precondition

fd must be a valid, open file descriptor

format must not be NULL

Postcondition

Data is written to the file descriptor's output buffer

On network sockets, data may be queued for transmission

Note

This function includes floating point support which adds ~10-15KB to code size. Use [fdprintf\(\)](#) if floating point is not needed.

No newline is automatically appended. Include `\n` or `\r\n` in the format string if line ending is desired.

Warning

May block if writing to a network socket with a full send buffer. Consider non-blocking I/O for time-critical applications.

Very large format operations may overflow stack space. Keep output operations reasonably sized.

Example: Basic Usage

```
int fd = SimpleOpenSerial(0, 115200);
if (fd >= 0) {
    fdprintf(fd, "Temperature: %.2f C\r\n", 23.45);
    close(fd);
}
```

Example: Network Protocol

```
void sendHTTPResponse(int clientFd, int statusCode) {
    fprintf(clientFd, "HTTP/1.1 %d OK\r\n", statusCode);
    fprintf(clientFd, "Content-Length: %d\r\n", contentLen);
    fprintf(clientFd, "\r\n");
}
```

Example: Error Checking

```
int bytesWritten = fprintf(fd, "Status: %d\n", status);
if (bytesWritten < 0) {
    fprintf("Error writing to file descriptor\n");
}
```

See also

[fprintf\(\)](#) Integer-only version (smaller code size)

[vfprintf\(\)](#) va_list version for wrapper functions

[printf\(\)](#) Standard output version

14.19.10.3 vfprintf()

```
int vfprintf (
    int fd,
    const char * format,
    va_list args)
```

```
#include <fprintf.h>
```

Print formatted output to a file descriptor using va_list (integer-only)

Variant of [fprintf\(\)](#) that accepts a va_list argument instead of variable arguments. This is used for creating wrapper functions that need to forward variable arguments. Does NOT support floating point, resulting in smaller code size.

Parameters

<i>fd</i>	File descriptor to write to. Must be a valid, open file descriptor
<i>format</i>	Format string using standard printf syntax. Supports all specifiers EXCEPT floating point (f, e, g are not supported): - Integer formats: d, i, u, x, X, o - String format: s - Character format: c - Pointer format: p
<i>args</i>	Variable argument list (va_list) containing the arguments specified by the format string. Must be initialized with va_start() and cleaned up with va_end()

Returns

Number of bytes written to the file descriptor, or negative value on error

Return values

>0	Number of bytes successfully written
<0	Error occurred during write operation

Precondition

fd must be a valid, open file descriptor
 format must not be NULL
 format must not contain floating point specifiers (f, e, g)
 args must be properly initialized with va_start()

Postcondition

Data is written to the file descriptor's output buffer
 args parameter is consumed and should not be reused

Note

This function does NOT support floating point formatting. Use [vfdprintf\(\)](#) if float support is needed.
 The caller is responsible for calling va_start() before calling this function and va_end() after the call.
 This function is ~10-15KB smaller than [vfdprintf\(\)](#) due to lack of floating point support.

Warning

Using floating point specifiers (f, e, g) will cause undefined behavior. Use [vfdprintf\(\)](#) if float formatting is needed.

Example: Integer-Only Logging Wrapper

```
#include <fdprintf.h>
#include <stdarg.h>

// Memory-efficient logging (no float support)
void quickLog(int fd, const char *format, ...) {
    va_list args;
    va_start(args, format);
    vfdiprintf(fd, format, args);
    va_end(args);
}

// Usage - only integers and strings
quickLog(logFd, "Counter: %d, Status: %s\n", count, status);
```

Example: Diagnostic Output Wrapper

```
void diagPrint(const char *format, ...) {
    static int diagFd = -1;

    if (diagFd < 0) {
        diagFd = SimpleOpenSerial(2, 115200);
    }

    if (diagFd >= 0) {
        va_list args;
        va_start(args, format);
        vfdiprintf(diagFd, format, args);
        va_end(args);
    }
}

// Usage
diagPrint("Error Code: 0x%08X\n", errorCode);
diagPrint("Free Memory: %d bytes\n", OSFreeMemory());
```

Example: Protocol Wrapper

```
// Modbus protocol wrapper (integer-only)
void modbusResponse(int fd, uint8_t funcCode, ...) {
    fdiprintf(fd, ":%02X", funcCode);

    va_list args;
    va_start(args, funcCode);

    // Additional data fields
    int dataCount = va_arg(args, int);
```

```

    for (int i = 0; i < dataCount; i++) {
        int value = va_arg(args, int);
        fdprintf(fd, "%04X", value);
    }
    va_end(args);

    fdprintf(fd, "\r\n");
}

```

See also

[fdprintf\(\)](#) Direct variable argument version

[va_start\(\)](#) Initialize va_list

[va_end\(\)](#) Clean up va_list

14.19.10.4 vfdprintf()

```

int vfdprintf (
    int fd,
    const char * format,
    va_list args)

```

#include <fdprintf.h>

Print formatted output to a file descriptor using va_list.

Variant of [fdprintf\(\)](#) that accepts a va_list argument instead of variable arguments. This is used for creating wrapper functions that need to forward variable arguments. Includes full floating point support.

Parameters

<i>fd</i>	File descriptor to write to. Must be a valid, open file descriptor
<i>format</i>	Format string using standard printf syntax. Supports all standard format specifiers including floating point
<i>args</i>	Variable argument list (va_list) containing the arguments specified by the format string. Must be initialized with va_start() and cleaned up with va_end()

Returns

Number of bytes written to the file descriptor, or negative value on error

Return values

>0	Number of bytes successfully written
<0	Error occurred during write operation

Precondition

fd must be a valid, open file descriptor

format must not be NULL

args must be properly initialized with va_start()

Postcondition

Data is written to the file descriptor's output buffer

args parameter is consumed and should not be reused

Note

This function is primarily used for creating wrapper functions. Direct application code should typically use [fdprintf\(\)](#) instead.

The caller is responsible for calling `va_start()` before calling this function and `va_end()` after the call.

This function includes floating point support. Use [vfdprintf\(\)](#) for integer-only formatting to save code space.

Example: Creating a Logging Wrapper

```
#include <fdprintf.h>
#include <stdarg.h>

// Custom logging function with automatic timestamp
void logMessage(int fd, const char *format, ...) {
    // Add timestamp prefix
    fdprintf(fd, "[%lu] ", Secs);

    // Forward variable arguments to vfdprintf
    va_list args;
    va_start(args, format);
    vfdprintf(fd, format, args);
    va_end(args);
}

// Usage
int logFd = SimpleOpenSerial(1, 115200);
logMessage(logFd, "Temperature: %.2f C\n", temp);
logMessage(logFd, "Status: %s\n", statusStr);
```

Example: Multi-Destination Output

```
void sendToMultiple(const char *format, ...) {
    va_list args;

    // Send to serial port
    va_start(args, format);
    vfdprintf(serialFd, format, args);
    va_end(args);

    // Send to network client
    va_start(args, format);
    vfdprintf(networkFd, format, args);
    va_end(args);
}
```

Example: Buffered Output Wrapper

```
static char outputBuffer[512];

void bufferedOutput(int fd, const char *format, ...) {
    // Format to buffer first
    va_list args;
    va_start(args, format);
    int len = vsnprintf(outputBuffer, sizeof(outputBuffer), format, args);
    va_end(args);

    // Write buffer to fd
    if (len > 0) {
        writeall(fd, outputBuffer, len);
    }
}
```

14.20 GDB Stub (Remote Debugging)

GDB Stub functions.

Stub Initialization functions

- void [InitGDBStub](#) (int port, int baudrate)

Start the GDB stub and then immediately stop at a break point This function will start the GDB stub, and will stop immediately at a breakpoint. This function is best used during development to stop the system from executing questionable code at startup. It is also useful to control the system execution to debug startup and initialization code.

- void [InitGDBStubNoBreak](#) (int port, int baudrate)

Start the GDB stub and continue without stopping This function will start the GDB stub, and continue with normal program execution. This function is best used to debug a program that is operating correctly and has intermitant bugs or anomallies. The program will run as normal until you connect the debugger. Thus you can operate the program until one needs to debug it.

14.20.1 Detailed Description

GDB Stub functions.

```
#include <gdbstub.h>
```

This module provides code for operating a serial GDB stub. This is used to debug programs running on a NetBurner system. More information can be found in ../nburn/docs/gdb/GDB-Gettingstarted

14.20.2 Function Documentation

14.20.2.1 InitGDBStub()

```
void InitGDBStub (
    int port,
    int baudrate)
#include <gdbstub.h>
```

Start the GDB stub and then immediately stop at a break point This function will start the GDB stub, and will stop immediately at a breakpoint. This function is best used during development to stop the system from executing questionable code at startup. It is also useful to control the system execution to debug startup and initialization code.

Parameters

<i>port</i>	The serial port to use this can be 0 or 1 corresponding to uart 0 or uart 1
<i>baudrate</i>	The baud rate to use on the port.

See also

[InitGDBStubNoBreak](#)

14.20.2.2 InitGDBStubNoBreak()

```
void InitGDBStubNoBreak (
    int port,
    int baudrate)
#include <gdbstub.h>
```

Start the GDB stub and continue without stopping This function will start the GDB stub, and continue with normal program execution. This function is best used to debug a program that is operating correctly and has intermitant bugs or anomallies. The program will run as normal until you connect the debugger. Thus you can operate the program until one needs to debug it.

Parameters

<i>port</i>	The serial port to use this can be 0 or 1 corresponding to uart 0 or uart 1

<i>baudrate</i>	The baud rate to use on the port.

14.22 HAL - Hardware Abstraction Layer

Functions

- void **HardwareSetup** ()
Initializes core system hardware components during the boot sequence.
- void **PostConfigHardwareInit** ()
Initializes hardware components that require configuration data to be loaded.
- void **ForceReboot** (bool fromIRQ=false)
Initiates an immediate hardware-level system reset of the NetBurner device.
- int **HalStorage_Save** (uint8_t area, void *pData, int len, int offset=0)
Save a blob to a specific persistent storage area as defined by the platform. This routine will perform all storage maintenance routines necessary to ensure a valid write.
- int **HalStorage_SavePartial** (uint8_t area, void *pData, int len, int offset)
Save a blob to a specific persistent storage area as defined by the platform. This routine requires that any maintenance required for a valid write be explicitly performed prior to being called.
- int **HalStorage_Prepare** (uint8_t area, int len, int offset=0)
Prepare a storage area for writing new data. For platforms with direct flash mapping this function is an alias for HalStorage_Erase.
- int **HalStorage_Finalize** (uint8_t area)
Finalize a storage area after writing new data. This will perform any final completion or cleanup routines required to persist the previously saved data from HalStorage_SavePartial calls.
- int **HalStorage_Erase** (uint8_t area, int len=-1, int offset=0)
Erase all or part of a storage area. Note: due to physical storage granularities, the total area erased may extend beyond the requested area.
- int **HalStorage_GetAllocated** (uint8_t area)
Obtain the total size allocated to the given persistent storage area.
- int **HalStorage_GetMaxAllocation** (uint8_t area)
Obtain the maximum size that may be allocated to the given persistent storage area. For direct flash mapped platforms, this is aliased to HalStorage_GetAllocated.
- int **HalStorage_RemainingSpace** (uint8_t area)
Obtain the number of remaining bytes available to be written in the given persistent storage area.
- int **HalStorage_WriteOffset** (uint8_t area)
Get the offset of the next byte that can be written in the given persistent storage area.
- int **HalStorage_AddressOffset** (uint8_t area, void *pWhere)
Get the offset within a persistent storage area of an address. A platform may map any address to any offset of its choosing for a given storage area, and may modify its behavior on an area by area basis.
- void **FlashErase** (void *pWhere, int len)
Erases the flash memory.
- void **FlashProgram** (void *pWhere, void *pWhat, int len)
Program flash memory.
- void **FlashProgramApplImage** (void *pWhere, void *pWhat, int len)
Write an application image to flash memory.
- void **DisableCache** ()
Disable the instruction and data cache.
- void **EnableCache** ()
Enable the instruction and data cache.
- uint32_t **spaceleft** ()

- Report how much free unallocated space is left in dynamic memory.*

 - uint16_t [HalGetTickFraction](#) (void)

Returns the fraction of the current system time tick.
- void [StdioCheckIntc](#) (void)

Check STDIO interrupt sources.
- void [SysLogCheckIntc](#) (void)

This is just like the [StdioCheckIntc\(\)](#) function, except that the results are displayed via UDP.
- bool [HalDeviceCertValid](#) ()

Determine if the stored certificate is valid.
- uint8_t * [HalGetDeviceCert](#) ()

Get a pointer to the stored certificate.
- uint16_t [HalGetDeviceCertLen](#) ()

Get the length of the stored certificate.
- uint8_t * [HalGetDeviceKey](#) ()

Get a pointer to the stored certificate.
- uint16_t [HalGetDeviceKeyLen](#) ()

Get the length of the stored key.
- bool [HalSaveNewDeviceCert](#) (const uint8_t *cert, uint16_t certlen, uint8_t format=SSL_FILETYPE_PEM)

Save a device certificate in persistent storage.
- bool [HalSaveNewDeviceKey](#) (const uint8_t *key, uint16_t keylen, uint8_t format=SSL_FILETYPE_PEM)

Save a device key in persistent storage.
- void [HalEraseDeviceCertAndKey](#) ()

Clear the device certificate and key from persistent storage.

Variables

- void(* [watchdog_service_function](#))(void)

Watchdog callback service function.
- uint32_t [HalTickMaxCount](#)

Rollover value for the system hardware tick timer.

14.22.1 Detailed Description

```
#include< hal.h>
```

The HAL provides a common function name interface to the various NetBurner hardware platforms. Other than the [ForceReboot\(\)](#) and [spaceleft\(\)](#) functions, these are advanced functions that should only be used by developers experienced with NetBurner hardware, firmware and memory maps.

14.22.2 Function Documentation

14.22.2.1 FlashErase()

```
void FlashErase (
    void * pWhere,
    int len)
#include <hal.h>
Erases the flash memory.
```

Parameters

<i>pWhere</i>	The starting location in flash memory to begin the erasure
<i>len</i>	Specified the number of bytes to erase

14.22.2.2 FlashProgram()

```
void FlashProgram (
    void * pWhere,
    void * pWhat,
    int len)
#include <hal.h>
Program flash memory.
```

Parameters

<i>pWhere</i>	Pointer to the starting location in flash to begin programming
<i>pWhat</i>	Pointer to the content that will be programmed into flash
<i>len</i>	Number of bytes to program

14.22.2.3 FlashProgramAppImage()

```
void FlashProgramAppImage (
    void * pWhere,
    void * pWhat,
    int len)
#include <hal.h>
```

Write an application image to flash memory.

On some platforms writing the application image may require calling ProgramImage even though it may only call FlashErase and FlashProgram. As a result, ProgramImage should always be used when updating the application image.

Parameters

<i>pWhere</i>	Pointer to the starting location in flash to begin the programming
<i>pWhat</i>	Pointer to the content that will be programmed into flash
<i>len</i>	Number of bytes to write

14.22.2.4 ForceReboot()

```
void ForceReboot (
    bool fromIRQ = false)
#include <hal.h>
```

Initiates an immediate hardware-level system reset of the NetBurner device.

This function triggers a complete system restart by directly commanding the hardware reset mechanisms. The reset is immediate and unconditional - all running processes are terminated, memory contents are cleared, and the system restarts from the boot sequence. This is equivalent to a power cycle but is performed through software control. The function never returns to the calling code as the system undergoes a complete restart.

Parameters

<i>fromIRQ</i>	Optional parameter indicating the reset context true: reset is being triggered from within an interrupt service routine or exception handler, which may require special handling procedures false: reset is being triggered from normal application code (default)

Note

This function never returns - execution does not continue after this call. All unsaved data, network connections, and application state will be lost. File systems and persistent storage should be properly synchronized before calling. The fromIRQ parameter ensures proper reset handling when called from interrupt contexts. After reset, the system will restart from the beginning of the boot sequence. Use this function only when a complete system restart is absolutely necessary.

Warning

This function immediately terminates all system operations without cleanup. Ensure critical data is saved and network connections are properly closed before use.

See also

attribute((noreturn)) indicates this function never returns to the caller

14.22.2.5 HalDeviceCertValid()

```
bool HalDeviceCertValid ()
#include <hal.h>
```

Determine if the stored certificate is valid.

This is the only function recommended to be used to determine the validity of the stored certificate. Is is not recommended to use [HalGetDeviceCert\(\)](#) nor [HalGetDeviceCertLen\(\)](#) to determine validity. For safest use of the cert/key getter functions, use [HalDeviceCertValid\(\)](#) prior.

Return values

<i>true</i>	if the certificate is valid false otherwise

14.22.2.6 HalEraseDeviceCertAndKey()

```
void HalEraseDeviceCertAndKey ()
#include <hal.h>
```

Clear the device certificate and key from persistent storage.

[HalEraseDeviceCertAndKey\(\)](#) is recommended instead of [HalStorage_Erase\(\)](#) to clear the stored certificate and key.

14.22.2.7 HalGetDeviceCert()

```
uint8_t * HalGetDeviceCert ()
#include <hal.h>
```

Get a pointer to the stored certificate.

It is recommended to use [HalDeviceCertValid\(\)](#) prior to calling this function.

Return values

<i>pointer</i>	to the certificate storage location in memory.

14.22.2.8 HalGetDeviceCertLen()

```
uint16_t HalGetDeviceCertLen ()
#include <hal.h>
```

Get the length of the stored certificate.

It is recommended to use [HalDeviceCertValid\(\)](#) prior to calling this function.

Return values

<i>length</i>	of the stored certificate. 0 or 65535 if no certificates is stored.

14.22.2.9 HalGetDeviceKey()

```
uint8_t * HalGetDeviceKey ()
#include <hal.h>
```

Get a pointer to the stored certificate.

It is recommended to use [HalDeviceCertValid\(\)](#) prior to calling this function.

Return values

<i>pointer</i>	to the certificate storage location in memory.

14.22.2.10 HalGetDeviceKeyLen()

```
uint16_t HalGetDeviceKeyLen ()
#include <hal.h>
```

Get the length of the stored key.

It is recommended to use [HalDeviceCertValid\(\)](#) prior to calling this function.

Return values

<i>length</i>	of the stored key. 0 or 65535 if no key is stored.

14.22.2.11 HalGetTickFraction()

```
uint16_t HalGetTickFraction (
    void ) [extern]
#include <hal.h>
```

Returns the fraction of the current system time tick.

return - The current counter value used to generate tick count

14.22.2.12 HalSaveNewDeviceCert()

```
bool HalSaveNewDeviceCert (
    const uint8_t * cert,
    uint16_t certlen,
    uint8_t format = SSL_FILETYPE_PEM)
#include <hal.h>
```

Save a device certificate in persistent storage.

Parameters

<i>cert</i>	Pointer to the buffer containing the certificate
<i>certlen</i>	length of the certificate
<i>format</i>	filetype (SSL_FILETYPE_PEM, or SSL_FILETYPE_ASN1)

Return values

<i>true</i>	if the certificate was successfully stored
<i>false</i>	otherwise

14.22.2.13 HalSaveNewDeviceKey()

```
bool HalSaveNewDeviceKey (
    const uint8_t * key,
    uint16_t keylen,
    uint8_t format = SSL_FILETYPE_PEM)
```

```
#include <hal.h>
```

Save a device key in persistent storage.

Parameters

<i>key</i>	Pointer to the buffer containing the key
<i>keylen</i>	length of the key
<i>format</i>	filetype (SSL_FILETYPE_PEM, or SSL_FILETYPE_ASN1)

Return values

<i>true</i>	if the key was successfully stored
<i>false</i>	otherwise

14.22.2.14 HalStorage_AddressOffset()

```
int HalStorage_AddressOffset (
    uint8_t area,
    void * pWhere)
```

```
#include <hal.h>
```

Get the offset within a persistent storage area of an address. A platform may map any address to any offset of its choosing for a given storage area, and may modify its behavior on an area by area basis.

Parameters

<i>area</i>	The storage area being queried
<i>pWhere</i>	An address value to be translated

Returns

Offset of the requested address within the storage area. Returns negative on error.

14.22.2.15 HalStorage_Erase()

```
int HalStorage_Erase (
    uint8_t area,
    int len = -1,
    int offset = 0)
```

```
#include <hal.h>
```

Erase all or part of a storage area. Note: due to physical storage granularities, the total area erased may extend beyond the requested area.

Parameters

<i>area</i>	The storage area to be erased
<i>len</i>	Number of bytes to be erased (a negative length will erase the entire area)
<i>offset</i>	The location within the area that the erasure should begin

Returns

Number of bytes erased. Returns negative on error.

[HalEraseDeviceCertAndKey\(\)](#)

14.22.2.16 HalStorage_Finalize()

```
int HalStorage_Finalize (  
    uint8_t area)
```

```
#include <hal.h>
```

Finalize a storage area after writing new data. This will perform any final completion or cleanup routines required to persist the previously saved data from HalStorage_SavePartial calls.

Parameters

<i>area</i>	The storage area to finalize

Returns

Returns negative on error.

14.22.2.17 HalStorage_GetAllocated()

```
int HalStorage_GetAllocated (  
    uint8_t area)
```

```
#include <hal.h>
```

Obtain the total size allocated to the given persistent storage area.

Parameters

<i>area</i>	The storage area being queried

Returns

Number of bytes allocated. Returns negative on error.

14.22.2.18 HalStorage_GetMaxAllocation()

```
int HalStorage_GetMaxAllocation (  
    uint8_t area)
```

```
#include <hal.h>
```

Obtain the maximum size that may be allocated to the given persistent storage area. For direct flash mapped platforms, this is aliased to HalStorage_GetAllocated.

Parameters

<i>area</i>	The storage area being queried

Returns

Number of bytes allocated. Returns negative on error.

14.22.2.19 HalStorage_Prepare()

```
int HalStorage_Prepare (
    uint8_t area,
    int len,
    int offset = 0)
```

```
#include <hal.h>
```

Prepare a storage area for writing new data. For platforms with direct flash mapping this function is an alias for HalStorage_Erase.

Parameters

<i>area</i>	The storage area to be readied
<i>len</i>	Number of bytes to be written by later HalStorage_SavePartial calls
<i>offset</i>	The location within the area that the readying should begin

Returns

Number of bytes readied. Returns negative on error.

14.22.2.20 HalStorage_RemainingSpace()

```
int HalStorage_RemainingSpace (
    uint8_t area)
```

```
#include <hal.h>
```

Obtain the number of remaining bytes available to be written in the given persistent storage area.

Parameters

<i>area</i>	The storage area being queried

Returns

Number of bytes available. Returns negative on error.

14.22.2.21 HalStorage_Save()

```
int HalStorage_Save (
    uint8_t area,
    void * pData,
    int len,
    int offset = 0)
```

```
#include <hal.h>
```

Save a blob to a specific persistent storage area as defined by the platform. This routine will perform all storage maintenance routines necessary to ensure a valid write.

Parameters

<i>area</i>	The storage area to be used. A platform is only <i>required</i> to support the areas as defined by HalStorage_t, however it may define additional areas as needed
<i>pData</i>	Pointer to the data to be written
<i>len</i>	Number of bytes to be written to the storage area
<i>offset</i>	Where in the storage area the first byte should be written. Default is 0.

Returns

Number of bytes written. Returns negative on error.

14.22.2.22 HalStorage_SavePartial()

```
int HalStorage_SavePartial (
    uint8_t area,
    void * pData,
    int len,
    int offset)
```

```
#include <hal.h>
```

Save a blob to a specific persistent storage area as defined by the platform. This routine requires that any maintenance required for a valid write be explicitly performed prior to being called.

Parameters

<i>area</i>	The storage area to be used. A platform is only <i>required</i> to support the areas as defined by HalStorage_t, however it may define additional areas as needed.
<i>pData</i>	Pointer to the data to be written
<i>len</i>	Number of bytes to be written to the storage area
<i>offset</i>	Where in the storage area the first byte should be written.

Returns

Number of bytes written. Returns negative on error.

14.22.2.23 HalStorage_WriteOffset()

```
int HalStorage_WriteOffset (
    uint8_t area)
```

```
#include <hal.h>
```

Get the offset of the next byte that can be written in the given persistent storage area.

Parameters

<i>area</i>	The storage area being queried

Returns

Offset of the next byte that can be written. Returns negative on error.

14.22.2.24 HardwareSetup()

```
void HardwareSetup ()
#include <hal.h>
```

Initializes core system hardware components during the boot sequence.

This function performs essential low-level hardware initialization that must occur early in the system startup process. It configures fundamental hardware subsystems including system timers, processor cache settings, and CPU clock frequencies to establish the basic operational environment for the NetBurner device. This initialization is performed using fixed hardware parameters and does not depend on user configuration settings or stored preferences.

Note

This function is typically called automatically during system boot and should not be called directly by user applications. Must be called before any code that depends on accurate timing or cache operations. The initialization sequence is critical and must complete successfully for proper system operation. Clock speed configuration affects all subsequent timing-dependent operations.

See also

[PostConfigHardwareInit\(\)](#) for configuration-dependent hardware initialization

[init\(\)](#) for the main system initialization sequence

14.22.2.25 PostConfigHardwareInit()

```
void PostConfigHardwareInit ()  
#include <hal.h>
```

Initializes hardware components that require configuration data to be loaded.

This function performs hardware initialization for subsystems that depend on stored configuration variables or user settings. It is called after configuration data has been loaded and processed, allowing hardware components like the watchdog timer to be configured according to user preferences or stored settings. This separation ensures that hardware initialization can be customized based on application requirements or stored configuration parameters.

Note

This function is typically called automatically during system initialization after configuration data has been loaded and should not be called directly by user applications. Must be called after configuration variables are available and validated. Watchdog configuration affects system stability and recovery behavior. Some hardware features may remain inactive until this initialization completes.

See also

[HardwareSetup\(\)](#) for core hardware initialization that occurs before configuration loading
[init\(\)](#) for the complete system initialization sequence

14.22.2.26 spaceleft()

```
uint32_t spaceleft ()  
#include <hal.h>
```

Report how much free unallocated space is left in dynamic memory.

Returns

Number of bytes unallocated in dynamic memory

14.22.2.27 StdioCheckIntc()

```
void StdioCheckIntc (  
    void )  
#include <hal.h>
```

Check STDIO interrupt sources.

Checks the interrupt sources used in the system along with their associated interrupt level and priority, and also checks for any conflicts in using the same level and priority between different sources. These results are sent to stdout.

See also

[SysLogCheckIntc\(\)](#)

14.22.2.28 SysLogCheckIntc()

```
void SysLogCheckIntc (  
    void )  
#include <hal.h>
```

This is just like the [StdioCheckIntc\(\)](#) function, except that the results are displayed via UDP.

See also

[StdioCheckIntc\(\)](#)

14.22.3 Variable Documentation

14.22.3.1 HalTickMaxCount

```
uint32_t HalTickMaxCount [extern]
```

```
#include <hal.h>
```

Rollover value for the system hardware tick timer.

Returns

The max/rollover counter value used to generate the tick count

14.22.3.2 watchdog_service_function

```
void(* watchdog_service_function) (void) (
```

```
void ) [extern]
```

```
#include <hal.h>
```

Watchdog callback service function.

If the following function pointer is set to point at a function of the form:

```
void YourFunc( void );
```

Then the system will call this function throughout the AutoUpdate/TCPUpdate process to make sure that the watchdog timer is serviced.

14.23 HTTP and HTML Functions

Classes

- struct [HTTP_Request](#)
HTTP Request Structure.
- class [HtmlPageHandler](#)
Base class for HTTP request handlers that process requests for specific URLs and HTTP methods.
- class [CallBackFunctionPageHandler](#)
Implements the [HtmlPageHandler](#) class as a function pointer callback for GET requests.
- class [CallBackFunctionPostHandler](#)
Implements the [HtmlPostHandler](#) class as a function pointer callback for POST requests.
- class [HtmlPostVariableListCallback](#)
Implements the [HtmlPostVariableListHandler](#) class as a function pointer callback for HTTP POST submissions.

Typedefs

- typedef int [http_gethandlerfunc](#)(int sock, [HTTP_Request](#) &pd)
Implements the [HtmlPageHandler](#) class as a function pointer callback for GET requests.
- typedef int [http_posthandler](#)(int sock, [HTTP_Request](#) &httpReqInfo)
Type definition of the [HtmlPostHandler](#) callback for POST requests.

Enumerations

- enum [HTTP_RequestTypes](#) {
 [tUnknown](#) , [tGet](#) , [tPost](#) , [tDelete](#) ,
 [tPut](#) , [tHead](#) }
HTTP request types for HTTP page handler callback functions.
- enum [HTTP_ACCESS](#) {
 [HTTP_OK_TO_SERVE](#) , [HTTP_NEED_PASSWORD](#) , [HTTP_NOTFOUND](#) , [HTTP_FORBIDEN](#) ,
 [HTTP_RESPONSE_HANDLED](#) }
HTTP page access return values.
- enum [HTTP_REQ_RD_RESULT](#) { [HTTP_RRR_BUF_FULL](#) = 0 , [HTTP_RRR_FINISHED](#) = 1 ,
 [HTTP_RRR_END_FOUND](#) = 2 , [HTTP_RRR SOCK_ERR](#) = -1 }
HTTP Request Read Result.

Functions

- int [SendEmailResponse](#) (int sock, const char *name, const char *attachment)
Send an email with HTML formatting.
- int [SendFullResponse](#) (char const *name, int fd)
Send a file with the proper HTTP header, file specified by file name.
- int [SendFullResponse](#) (HTML_FILE_RECORD *fr, int fd, const char *pUrl)
Send a file with the proper HTTP header, file specified by HTML_FILE_RECORD.
- int [SendHeaderResponse](#) (char const *name, int fd)
Send a HTTP header response for the specified file type.
- int [SendHeaderResponse](#) (HTML_FILE_RECORD *fr, int fd)
Send a HTTP header response for the specified HTML_FILE_RECORD type.
- int32_t [SendFileFragment](#) (char const *name, int32_t fd, PCSTR url=NULL)
Send a file fragment without a header.
- HTML_FILE_RECORD * [GetRecordFromName](#) (char const *name)
Returns a pointer to a HTML_FILE_RECORD for the specified file name.
- CONFIG_RENDER_OBJ [ConfigRenderFunc](#) (int mode, const char *pobj, int len=20, const char *extra=0)
Render a configuration object as HTML for the specified configuration object.
- CONFIG_RENDER_OBJ [ConfigRenderFunc](#) (int mode, config_leaf &cl, int len=20, const char *extra=0)
Render a configuration object as HTML for the specified configuration leaf object.
- void [WriteHtmlVariable](#) (int fd, CONFIG_RENDER_OBJ co)
Send a CONFIG_RENDER_OBJ to the client.
- HTTP_Request * [GetActiveHttpRequest](#) ()
Get the current active running http request. Only valid from within http get or post handling. Also valid during page fill in operations.
- HTTP_ACCESS [CheckHttpAccess](#) (int sock, int access_level, HTTP_Request &Req)
All HTTP requests go through this function.
- void [StartHttp](#) (uint16_t port, bool RunConfigMirror)
Start the HTTP web server. Further documentation in the Initialization section [Initialization - System Initialization Functions](#).
- void [StopHttp](#) ()
Stop the HTTP web server.
- void [SendHTMLHeader](#) (int sock)
Send a HTML response header.
- void [SendHTMLHeaderWCookie](#) (int sock, char *cookie)
Send a HTML response header and cookie.
- void [SendTextHeader](#) (int sock)
Send a HTML plain text header.
- void [SendGifHeader](#) (int sock)
Send a HTML GIF header.
- void [EmptyResponse](#) (int sock)
Send an empty response back.
- void [NoContentResponse](#) (int sock)
Send a no content response back.
- void [RedirectResponse](#) (int sock, PCSTR new_page)
Redirect a HTTP request to a different page.
- void [NotFoundResponse](#) (int sock, PCSTR new_page)
Send a page not found response.
- void [ForbiddenResponse](#) (int sock, PCSTR new_page)
Send a page is forbidden response.
- void [NotAvailableResponse](#) (int sock, PCSTR new_page)
Send a response indicating that the requested resource is not available at this time.

- void [BadRequestResponse](#) (int sock, PCSTR url, PCSTR data)
Send a response indicating that the client request itself is faulty in some manner.
- int [writeallsafestring](#) (int fd, PCSTR str)
Send a string and escape all special characters.
- int [writesafestring](#) (int fd, PCSTR str, size_t strLength)
Send a string with a specified length and escape all special characters.
- int [httpstricmp](#) (PCSTR str1, PCSTR str1sUpper2)
Special string compare. Returns 1 if the strings match until one string ends with a null (0).
- void [StartHttps](#) (uint16_t ssl_port, uint16_t http_port)
Start the HTTPS secure web server.
- void [EnableRemoteConsole](#) ()
Enables the remote webconsole feature.

14.23.1 Detailed Description

```
#include< htmlfiles.h>
```

API to process and delivery files from the web server to clients. In particular, processing of files in a project's html folder.

For the majority of applications these functions will not be necessary; the web server system will automatically handle both static and dynamic content. This API is available if more advances processing is required, such as sending custom response headers or very large amounts of data.

```
#include< http.h>
```

In addition to the functions to start a web server, [StartHttp\(\)](#), this module provides functions used to create a custom web interface. Please refer to the Programmers Guide for additional details on web interface programming and dynamic content.

See also

[StartHttps\(\)](#)

```
#include< httppost.h>
```

```
#include< https.h>
```

14.23.2 Typedef Documentation

14.23.2.1 http_gethandlerfunc

```
typedef int http_gethandlerfunc(int sock, HTTP_Request &pd)
```

```
#include <http.h>
```

Implements the [HtmlPageHandler](#) class as a function pointer callback for GET requests.

Return values

0	Not handled, no changes are made
1	Handled
2	TCP socket will be kept. Socket will get closed by some other method. For example, a large file could be sent from a different task. Any return value other than 2 means the page was processed normally.

14.23.2.2 http_posthandler

```
typedef int http_posthandler(int sock, HTTP\_Request &httpReqInfo)
#include <httppost.h>
```

Type definition of the HtmlPostHandler callback for POST requests.

This should only be used if the specific variable callback implementations will not work in your application. This is mostly an internal use function.

Parameters

<i>sock</i>	The socket the request came in on.
<i>httpReqInfo</i>	Information about the request HTTP_Request .

Return values

0	Not handled, no changes are made
1	Handled
2	TCP socket will be kept. Socket will get closed by some other method. For example, a large file could be sent from a different task. Any return value other than 2 means the page was processed normally.

[HtmlPostVariableListCallback](#)

HtmlPostVariableListHandler

14.23.3 Enumeration Type Documentation

14.23.3.1 HTTP_ACCESS

```
enum HTTP\_ACCESS
```

```
#include <http.h>
```

HTTP page access return values.

Return codes for web page function return codes such as page not found, and if the username/password access group level is granted.

Enumerator

HTTP_OK_TO_SERVE	Ok to serve the page.
HTTP_NEED_PASSWORD	Either the password in the HTTP request is wrong or missing.
HTTP_NOTFOUND	Report the page is not found.
HTTP_FORBIDEN	Report the page forbidden.
HTTP_RESPONSE_HANDLED	This means this function handled the full response, including closing the socket.

14.23.3.2 HTTP_REQ_RD_RESULT

```
enum HTTP\_REQ\_RD\_RESULT
```

```
#include <http.h>
```

HTTP Request Read Result.

Enumerator

HTTP_RRR_BUF_FULL	Buffer full, more data remains to be read.
HTTP_RRR_FINISHED	Read read all content as indicated by headers.
HTTP_RRR_END_FOUND	Read found the trailing \r\n and terminated.
HTTP_RRR_SOCK_ERR	Socket returned error while having no data, probably closed.

14.23.3.3 HTTP_RequestTypes

```
enum HTTP_RequestTypes
```

```
#include <http.h>
```

HTTP request types for HTTP page handler callback functions.

Enumerator

tUnknown	The type of request is not yet known.
tGet	GET request.
tPost	POST request.
tDelete	Delete Request.
tPut	Put request.
tHead	Header request, does not include content.

14.23.4 Function Documentation

14.23.4.1 BadRequestResponse()

```
void BadRequestResponse (
    int sock,
    PCSTR url,
    PCSTR data)
```

```
#include <http.h>
```

Send a response indicating that the client request itself is faulty in some manner.

Parameters

<i>sock</i>	Socket to send response
<i>url</i>	The URL of the page to display
<i>data</i>	An explanation or segment of data to display indicating the fault

See also

[RedirectResponse\(\)](#), [NotFoundResponse\(\)](#), [ForbiddenResponse\(\)](#)

[NotAvailableResponse\(\)](#)

14.23.4.2 CheckHttpAccess()

```
HTTP_ACCESS CheckHttpAccess (
    int sock,
    int access_level,
    HTTP_Request & Req)
```

```
#include <http.h>
```

All HTTP requests go through this function.

By default the library provides a weak reference implementation that approves all transactions. To provide your own just add an implementation of this function to your code.

Parameters

<i>sock</i>	The network socket the request came in on.
<i>access_level</i>	The user defined access level for this request from 0 to 255. A value of 0 means no password is required.
<i>Req</i>	The HTTP request where one can extract the URL , access type, password, etc

Returns

[HTTP_ACCESS](#)

14.23.4.3 ConfigRenderFunc() [1/2]

```
CONFIG_RENDER_OBJ ConfigRenderFunc (
    int mode,
    config_leaf & cl,
    int len = 20,
    const char * extra = 0)
```

```
#include <htmlfiles.h>
```

Render a configuration object as HTML for the specified configuration leaf object.

Parameters

<i>mode</i>	CONFIG_RENDER_OBJ eMode value
<i>cl</i>	Reference to the config_leaf object to render
<i>len</i>	Optional length parameter for text input elements
<i>extra</i>	Pointer to any additional information to be added to the HTML input element. Will be added to the end of the <input> tag.

Returns

A CONFIG_RENDER_OBJ that can be sent to the client using WriteHtmlVariable()

14.23.4.4 ConfigRenderFunc() [2/2]

```
CONFIG_RENDER_OBJ ConfigRenderFunc (
    int mode,
    const char * pobj,
    int len = 20,
    const char * extra = 0)
```

```
#include <htmlfiles.h>
```

Render a configuration object as HTML for the specified configuration object.

Parameters

<i>mode</i>	CONFIG_RENDER_OBJ eMode value
<i>pobj</i>	Pointer to a configuration object. Can be specified as the JSON configuration path. For example, "Config/Sys/NetIf/Ethernet0/StaticAddr".
<i>len</i>	Optional length parameter for text input elements
<i>extra</i>	Pointer to any additional information to be added to the HTML input element. Will be added to the end of the <input> tag.

Returns

A CONFIG_RENDER_OBJ that can be sent to the client using WriteHtmlVariable()

14.23.4.5 EmptyResponse()

```
void EmptyResponse (
    int sock)
#include <http.h>
```

Send an empty response back.

Parameters

<i>sock</i>	Socket to send response

See also

[ForbiddenResponse\(\)](#), [ForbiddenResponse\(\)](#), [SendHTMLHeaderWCookie\(\)](#)
[NotAvailableResponse\(\)](#), [BadRequestResponse\(\)](#), [RedirectResponse\(\)](#)

14.23.4.6 EnableRemoteConsole()

```
void EnableRemoteConsole ()
#include <remoteconsole.h>
```

Enables the remote webconsole feature.

Creates or uses the existing web server and a console.html file as well as a WebSocket listener that sends and receives stdout/stdin such that you can access the "serial" console remotely via a web browser.

See the [Remote Web Console for Serial/stdout](#) for more

Note that there is no security on this by default, so it is best used for development purposes.

14.23.4.7 ForbiddenResponse()

```
void ForbiddenResponse (
    int sock,
    PCSTR new_page)
#include <http.h>
```

Send a page is forbidden response.

Parameters

<i>sock</i>	Socket to send response
<i>new_page</i>	The URL of the page to display

See also

[RedirectResponse\(\)](#), [NotFoundResponse\(\)](#)
[NotAvailableResponse\(\)](#), [BadRequestResponse\(\)](#)

14.23.4.8 GetRecordFromName()

```
HTML_FILE_RECORD * GetRecordFromName (
    char const * name)
#include <htmlfiles.h>
```

Returns a pointer to a HTML_FILE_RECORD for the specified file name.

Parameters

<i>name</i>	Name of file in htmldata.cpp to search for

Return values

<i>A</i>	pointer to a HTML_FILE_RECORD if found
<i>NULL</i>	if file name not found

14.23.4.9 httpstricmp()

```
int httpstricmp (
    PCSTR str1,
    PCSTR strIsUpper2)
```

#include <http.h>

Special string compare. Returns 1 if the strings match until one string ends with a null (0).

strIsUpper2 must be specified in upper case

Used to match URL with stored file prefixes.

Parameters

<i>str1</i>	The string to search
<i>strIsUpper2</i>	The string to search for, must be specified in upper case

Return values

0	if the prefixes do not match
1	if the prefixes match

Example: httpstricmp(str1, "LED.HTML");

str1	Return Value
LED	1
led.HTML	1
led.html	1
LED.HTM?	0

14.23.4.10 NoContentResponse()

```
void NoContentResponse (
    int sock)
```

#include <http.h>

Send a no content response back.

Parameters

<i>sock</i>	Socket to send response

See also

[ForbiddenResponse\(\)](#), [ForbiddenResponse\(\)](#), [SendHTMLHeaderWCookie\(\)](#)
[NotAvailableResponse\(\)](#), [BadRequestResponse\(\)](#), [RedirectResponse\(\)](#)

14.23.4.11 NotAvailableResponse()

```
void NotAvailableResponse (
    int sock,
    PCSTR new_page)
```

#include <http.h>

Send a response indicating that the requested resource is not available at this time.

Parameters

<i>sock</i>	Socket to send response
<i>new_page</i>	The URL of the page to display

See also

[RedirectResponse\(\)](#), [NotFoundResponse\(\)](#), [ForbiddenResponse\(\)](#)
[BadRequestResponse\(\)](#)

14.23.4.12 NotFoundResponse()

```
void NotFoundResponse (
    int sock,
    PCSTR new_page)
#include <http.h>
Send a page not found response.
```

Parameters

<i>sock</i>	Socket to send response
<i>new_page</i>	The URL of the page to display

See also

[ForbiddenResponse\(\)](#), [RedirectResponse\(\)](#)
[NotAvailableResponse\(\)](#), [BadRequestResponse\(\)](#)

14.23.4.13 RedirectResponse()

```
void RedirectResponse (
    int sock,
    PCSTR new_page)
#include <http.h>
Redirect a HTTP request to a different page.
```

Parameters

<i>sock</i>	Socket to send response
<i>new_page</i>	The URL of the new page

See also

[ForbiddenResponse\(\)](#), [ForbiddenResponse\(\)](#), [SendHTMLHeaderWCookie\(\)](#)
[NotAvailableResponse\(\)](#), [BadRequestResponse\(\)](#), [EmptyResponse\(\)](#)

14.23.4.14 SendEmailResponse()

```
int SendEmailResponse (
    int sock,
    const char * name,
    const char * attachment)
#include <htmlfiles.h>
Send an email with HTML formatting.
```

Parameters

<i>sock</i>	Network socket in which to send the data
<i>name</i>	Name of file from project's html folder, this is the email body
<i>attachment</i>	

Return values

1	Success, the file specified the name parameter was found
0	File does not exist

14.23.4.15 SendFileFragment()

```
int32_t SendFileFragment (
    char const * name,
    int32_t fd,
    PCSTR url = NULL)
```

```
#include <htmlfiles.h>
```

Send a file fragment without a header.

Search through the files stored in the system by comphtml in the project's html folder for the specified file name. If found, the file content is sent as a file fragment. A SendHeaderResponse function must be sent prior to sending file fragments.

This function is useful when building HTML responses with large amounts of data. If the file has embedded dynamic HTML function tags and/or variable tags, such a CPPCALL and VARIABLE, they will be processed as the content is delivered.

Parameters

<i>name</i>	Name of the file
<i>fd</i>	File descriptor used to send the file fragment
<i>url</i>	Optional URL string in fragment header

Return values

1	if the file was found
0	otherwise

14.23.4.16 SendFullResponse() [1/2]

```
int SendFullResponse (
    char const * name,
    int fd)
```

```
#include <htmlfiles.h>
```

Send a file with the proper HTTP header, file specified by file name.

This function searches through the files stored in the system by comphtml in the project's html folder for the specified file name. If found, it sends the proper HTTP header and file to the client. If the file has embedded dynamic HTML function tags and/or variable tags, such a CPPCALL and VARIABLE, they will be processed as the content is delivered.

Parameters

<i>name</i>	Name of the file
<i>fd</i>	File descriptor used to send the file

Return values

1	Succes, file was found
0	File does not exist

See also

[SendFullResponse\(HTML_FILE_RECORD *fr, int fd, const char *pUrl\)](#)

14.23.4.17 SendFullResponse() [2/2]

```
int SendFullResponse (
    HTML_FILE_RECORD * fr,
    int fd,
    const char * pUrl)
```

```
#include <htmlfiles.h>
```

Send a file with the proper HTTP header, file specified by HTML_FILE_RECORD.

While the [SendFullResponse\(char const *name, int fd\)](#) function will resolve the file name, this lower level function requires knowledge of the file pointer to the HTML_FILE_RECORD in htmldata.cpp.

Parameters

<i>fr</i>	Pointer to the HTML_FILE_RECORD in htmldata.cpp
<i>fd</i>	File descriptor used to send the file
<i>pUrl</i>	Pointer to a URL string used by response functions such a CPPCALL and VARIABLE callbacks. In default web server processing the URL is automatically set to what the client requested. When processing web requests manually you must specify the URL string. If you are not using dynamic content that relies on the URL, this can be set to NULL.

Return values

<i>1</i>	if the file was found
<i>0</i>	otherwise

See also

[SendFullResponse\(char const *name, int fd\)](#)

14.23.4.18 SendGifHeader()

```
void SendGifHeader (
    int sock)
```

```
#include <http.h>
```

Send a HTML GIF header.

Sends a GIF response header. Can be useful when dynamically creating your own GIF images.

Parameters

<i>sock</i>	Socket to send response

See also

[SendHTMLHeader\(\)](#), [SendTextHeader\(\)](#), [SendHTMLHeaderWCookie\(\)](#)

14.23.4.19 SendHeaderResponse() [1/2]

```
int SendHeaderResponse (
    char const * name,
    int fd)
```

```
#include <htmlfiles.h>
```

Send a HTTP header response for the specified file type.

This function searches through the files stored in the system by comphtml in the project's html folder for the specified file name. If found, it sends the proper HTTP header only to the client. Unlike a full response, only the header is sent.

Parameters

<i>name</i>	Name of the file
<i>fd</i>	File descriptor used to send the file

Return values

1	Succes, file was found
0	File does not exist

See also

[SendHeaderResponse\(HTML_FILE_RECORD *fr, int fd\)](#)

14.23.4.20 SendHeaderResponse() [2/2]

```
int SendHeaderResponse (
    HTML_FILE_RECORD * fr,
    int fd)
```

```
#include <htmlfiles.h>
```

Send a HTTP header response for the specified HTML_FILE_RECORD type.

While the [SendFullResponse\(HTML_FILE_RECORD *fr, int fd, const char *pUrl\)](#); function will resolve the file name, this lower level function requires knowledge of the file pointer to the HTML_FILE_RECORD array in `htmldata.cpp`.

Parameters

<i>fr</i>	Pointer to the HTML_FILE_RECORD in <code>htmldata.cpp</code>
<i>fd</i>	File descriptor used to send the file

Return values

1	Succes, file was found
0	File does not exist

See also

[SendHeaderResponse\(char const *name, int fd\)](#)

14.23.4.21 SendHTMLHeader()

```
void SendHTMLHeader (
    int sock)
```

```
#include <http.h>
```

Send a HTML response header.

Used to build your own HTML response

Parameters

<i>sock</i>	Socket to send response

See also

[SendHTMLHeaderWCookie\(\)](#), [SendTextHeader\(\)](#), [SendGifHeader\(\)](#)

14.23.4.22 SendHTMLHeaderWCookie()

```
void SendHTMLHeaderWCookie (  
    int sock,  
    char * cookie)
```

```
#include <http.h>
```

Send a HTML response header and cookie.

Sends a header as well as a cookie to be stored by the client browser.

Parameters

<i>sock</i>	Socket to send response
<i>cookie</i>	Pointer to the cookie

See also

[SendHTMLHeader\(\)](#), [SendGifHeader\(\)](#), [SendTextHeader\(\)](#)

14.23.4.23 SendTextHeader()

```
void SendTextHeader (  
    int sock)
```

```
#include <http.h>
```

Send a HTML plain text header.

Use as the first part of building your own plain text response.

Parameters

<i>sock</i>	Socket to send response

See also

[SendHTMLHeader\(\)](#), [SendGifHeader\(\)](#), [SendHTMLHeaderWCookie\(\)](#)

14.23.4.24 StartHttp()

```
void StartHttp (  
    uint16_t port,  
    bool RunConfigMirror)
```

```
#include <http.h>
```

Start the HTTP web server. Further documentation in the Initialization section [Initialization - System Initialization Functions](#).

If no parameters are specified it will listen on port 80, and enable the configuration mirror feature so an application can create its own custom configuration web page.

Parameters

<i>port</i>	Listen port, defaults to port 80
<i>RunConfigMirror</i>	Enable configuration mirror, default is true

See also

[StopHttp\(\)](#), [StartHttps\(\)](#)

14.23.4.25 StartHttps()

```
void StartHttps (
    uint16_t ssl_port,
    uint16_t http_port)
```

```
#include <https.h>
```

Start the HTTPS secure web server.

If no parameters are specified, the web server will listen on ports 443 and 80, and enable the configuration mirror feature so an application can create its own custom configuration web page. If no user certificate/key is installed, the default system key will be used.

Default parameter values defined in [init.h](#)

Parameters

<i>ssl_port</i>	Secure listen port, defaults to port 443
<i>http_port</i>	Non-secure listen port, defaults to port 80

See also

[StartHttp\(\)](#), [StopHttp\(\)](#)

14.23.4.26 StopHttp()

```
void StopHttp ()
```

```
#include <http.h>
```

Stop the HTTP web server.

See also

[StartHttp\(\)](#)

14.23.4.27 writeallsafestring()

```
int writeallsafestring (
    int fd,
    PCSTR str)
```

```
#include <http.h>
```

Send a string and escape all special characters.

When sending a HTML text response, certain characters (e.g. '<') are interpreted by the browser as formatting. This function properly escapes the text so it will appear as intended.

Parameters

<i>fd</i>	File descriptor used to send response
<i>str</i>	String to send

Returns

The number of characters sent

14.23.4.28 WriteHtmlVariable()

```
void WriteHtmlVariable (
    int fd,
    CONFIG_RENDER_OBJ co)
```

```
#include <htmlfiles.h>
```

Send a CONFIG_RENDER_OBJ to the client.

The CONFIG_RENDER_OBJ must have been previously created with a [ConfigRenderFunc\(\)](#) function.

Parameters

<i>fd</i>	File descriptor to send data to
<i>co</i>	CONFIG_RENDER_OBJ to send

14.23.4.29 writesafestring()

```
int writesafestring (
    int fd,
    PCSTR str,
    size_t strLength)
```

```
#include <http.h>
```

Send a string with a specified length and escape all special characters.

When sending a HTML text response, certain characters (e.g. '<') are interpreted by the browser as formatting. This function properly escapes the text so it will appear as intended.

Parameters

<i>fd</i>	File descriptor used to send response
<i>str</i>	String to send
<i>strLength</i>	number of characters from str to send

Returns

The number of characters sent

14.24 I2C

Topics

- [Bit Bang I2C \(GPIO\)](#)
- [MOD5441x, NANO54415, SB800EX](#)
- [MODM7AE70, SBE70LC](#)
- [Wire Interface](#)

Implements the same [TwoWire](#) interface as other popular microcontrollers for easy cross-compatibility with third party libraries.

14.24.1 Detailed Description

[I2C](#) API for NetBurner Platforms

The [I2C](#) peripheral interfaces can be controlled four ways:

- The [Wire Interface](#) (recommended), which offers an interface more familiar to users of other platforms.
- The [I2CDevice](#) class (recommended for older hardware)
- The [I2C](#) class, which offers additional low level control for older hardware
- The [WireIntf](#) class, which offers a Two Wire Interface API for older hardware

```
#include< Wire.h >
or
#include< i2c.h > (in the appropriate arch include subfolder)
or
#include< bb\_i2c.h > (if no i2c.h in the appropriate arch)
```

[BBI2C](#) is specifically for platforms without native hardware [I2C](#) support. See other sub-modules for device-specific [I2C](#) details.

Provides access to the all the [I2C](#) peripherals on the processor. The [I2C](#) peripherals available will vary by platform. For example, `Wire.read();` will execute a read operation on [I2C](#) module 0.

14.24.2 Bit Bang I2C (GPIO)

Classes

- class [BBI2C](#)
I2C Peripheral Class.

14.24.2.1 Detailed Description

```
#include< bb_i2c.h>
```

14.24.3 MOD5441x, NANO54415, SB800EX

Functions

- void [MultiChannel_I2CInit](#) (int moduleNum=DEFAULT_I2C_MODULE, uint8_t slave_Addr=0x08, uint8_t freqdiv=0x3C)
Initialize the I2C peripheral module.
- uint8_t [MultiChannel_I2CSendBuf](#) (int moduleNum, uint8_t addr, uint8_t buf, int num, bool stop=true)
Send a buffer of bytes to an I2C device.
- uint8_t [MultiChannel_I2CReadBuf](#) (int moduleNum, uint8_t addr, uint8_t buf, int num, bool stop=true)
Read a number of bytes from an I2C device and store in the specified buffer.
- void [I2CMultiChannelResetPeripheral](#) (int moduleNum)
Reset the specified I2C peripheral module.
- uint8_t [MultiChannel_I2CRestart](#) (int moduleNum, uint8_t addr, bool Read_Not_Write, uint32_t ticks_to_wait=I2C_RX_TX_TIMEOUT)
Restart communication with a I2C device.
- uint8_t [MultiChannel_I2CStart](#) (int moduleNum, uint8_t addr, bool Read_Not_Write, uint32_t ticks_to_wait=I2C_START_TIMEOUT)
Send an I2C start to an I2C device to begin communication.
- uint8_t [MultiChannel_I2CStop](#) (int moduleNum=DEFAULT_I2C_MODULE, uint32_t ticks_to_wait=I2C_RX_TX_TIMEOUT)
Issue an I2C stop terminate communication with an I2C device and release the bus.
- uint8_t [MultiChannel_I2CSend](#) (int moduleNum, uint8_t val, uint32_t ticks_to_wait=I2C_RX_TX_TIMEOUT)
Send a single byte on the I2C bus.
- uint8_t [MultiChannel_I2CRead](#) (int moduleNum, uint8_t val, uint32_t ticks_to_wait=I2C_RX_TX_TIMEOUT)
Read a single byte from the I2C bus.

Multichannel I2C Return Values

Function return values

- #define **I2C_OK** (0)
Last instruction terminated correctly.
- #define **I2C_NEXT_WRITE_OK** (1)
I2C bus is OK for a write.
- #define **I2C_NEXT_READ_OK** (2)
I2C bus is OK for a read.
- #define **I2C_MASTER_OK** (3)
I2C finished transmission but still owns bus (need to stop or restart)
- #define **I2C_TIMEOUT** (4)
A timeout occurred while trying communicate on I2C bus.
- #define **I2C_BUS_NOT_AVAIL** (5)

- *A timeout occurred while trying gain I2C bus control.*
- **#define I2C_NOT_READY (6)**
A read or write was attempted before I2C ready or during a slave transmission.
- **#define I2C_LOST_ARB (7)**
Lost arbitration during start.
- **#define I2C_LOST_ARB_ADD (8)**
Lost arbitration and then winner addressed our slave address.
- **#define I2C_NO_LINK_RX_ACK (9)**
We are in Master TX mode and received no ACK from slave device, possibly during start.

Multichannel I2C Macros

I2C Macros

- **#define I2C_SR_BUSY (((0x20 & I2C_SR) == 0x20))**
Bus is busy (bit 5 of I2SR)
- **#define I2C_CR_SLAVE (((0x20 & I2C_CR) == 0x00))**
Bus set as slave (bit 5 of I2CR)
- **#define I2C_SR_ARB_LOST (((0x10 & I2C_SR) == 0x10))**
Bus arbitration was lost (bit 4 of I2SR)
- **#define I2C_SR_ADRES_AS_SLAVE (((0x40 & I2C_SR) == 0x40))**
Addressed as a slave (bit 6 of I2SR)
- **#define I2C_SR_SLAVE_TX (((0x04 & I2C_SR) == 0x04))**
State of read/write bit of the received address command (bit 2 of I2SR)
- **#define I2C_CR_TX (((0x10 & I2C_CR) == 0x10))**
Configured for transmit (bit 4 of I2CR)
- **#define I2C_SR_RX_ACK (((0x01 & I2C_SR) == 0x00))**
Received a RX ACK after last transmit (bit 0 of I2SR)
- **#define I2C_CR_RX_ACK (((0x08 & I2C_CR) == 0x00))**
Configured to RX Ack.
- **#define I2C_SET_NO_ACK ((I2C_CR |= 0x08))**
Configure I2C module not to send a RX ACK (bit 3 of I2CR)
- **#define I2C_SET_ACK ((I2C_CR &= 0xF7))**
Configure I2C module to send a RX ACK (bit 3 of I2CR)
- **#define I2C_SET_TX ((I2C_CR |= 0x10))**
Configure I2C module to be in TX mode (bit 4 of I2CR)
- **#define I2C_SET_RX ((I2C_CR &= 0xEF))**
Configure I2C module to be in RX mode (bit 4 of I2CR)
- **#define I2C_SET_REPEAT_START ((I2C_CR |= 0x04))**
Configure I2C to send a repeated start signal.
- **#define I2C_CLR_ARB_LOST ((I2C_SR &= 0xEF))**
Clear Arbitration lost error condition.

14.24.3.1 Detailed Description

Supported platforms:

- MOD54415
- MOD54417
- NANO54415

- SB800EX

The platforms have multiple I2C interfaces called "modules". The available I2C modules available on a particular platform are determined by the connector configuration of that platform. Available I2C module numbers are defined below. Since the processor pins are multiplexed with many other functions, the modules chosen are not sequential. The default module number is 0.

I2C MODULE NUMBERS BY PLATFORM:

- MOD5441x: 0, 1, 2, 4, 5.
- NANO54415: 0, 1, 4, 5.

The most common I2C functions used are listed below. They automatically handle I2C start and stop conditions, as well as checking for I2C bus errors and recovery:

- [MultiChannel_I2CInit \(\)](#)
- [MultiChannel_I2CSendBuf \(\)](#)
- [MultiChannel_I2CReadBuf \(\)](#)
- [I2CMultiChannelResetPeripheral\(\)](#)

14.24.3.2 Function Documentation

14.24.3.2.1 I2CMultiChannelResetPeripheral()

```
void I2CMultiChannelResetPeripheral (
    int moduleNum)
#include <multichanneli2c.h>
```

Reset the specified I2C peripheral module.
Clears all interrupts, I2C conditions, and releases the bus.

Parameters

<i>moduleNum</i>	I2C peripheral module number.

14.24.3.2.2 MultiChannel_I2CInit()

```
void MultiChannel_I2CInit (
    int moduleNum = DEFAULT_I2C_MODULE,
    uint8_t slave_Addr = 0x08,
    uint8_t freqdiv = 0x3C)
#include <multichanneli2c.h>
```

Initialize the I2C peripheral module.

The frequency is based on the internal bus clock of the processor. The formula is: $\text{Freq} = (250\text{MHZ (sys clock)}/2) / \text{freqdiv}$ to give max baud rate of the master mode I2C bus clock. Values for freqdiv are found in the i2fdr section of the NXP MCF5441x User Manual.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>slave_Addr</i>	I2C address of the module. If not specified, default value is 0x08.
<i>freqdiv</i>	I2C module frequency divider. If not specified, default value is 0x3C, which is the maximum value of 100KHz.

14.24.3.2.3 MultiChannel_I2CRead()

```
uint8_t MultiChannel_I2CRead (
    int moduleNum,
    uint8_t val,
    uint32_t ticks_to_wait = I2C_RX_TX_TIMEOUT)
```

```
#include <multichanneli2c.h>
```

Read a single byte from the [I2C](#) bus.

Reads a single byte from the [I2C](#) bus and stores it in val. A start or restart must have been previously issued to become the bus master, and a stop must be issued to release the bus when you are finished reading the desired number of bytes.

Does not handle no Ack of last byte, which needs to have a `I2C_SET_NO_ACK` called before the last read.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>val</i>	Location to store the byte read.
<i>ticks_to_wait</i>	Amount of time to wait for a start transmission to complete, specified as system time ticks. The <code>TICKS_PER_SECOND</code> macro can be used with a multiplier or divisor. Includes the time to receive an ack from the I2C device. If not specified, the default time of <code>I2C_RX_TX_TIMEOUT</code> will be used.

Returns

The state of the [I2C](#) bus: [I2C Return Values](#)

14.24.3.2.4 MultiChannel_I2CReadBuf()

```
uint8_t MultiChannel_I2CReadBuf (
    int moduleNum,
    uint8_t addr,
    uint8_t buf,
    int num,
    bool stop = true)
```

```
#include <multichanneli2c.h>
```

Read a number of bytes from an [I2C](#) device and store in the specified buffer.

Sends an [I2C](#) start, reads the specified number of bytes into buf, and finishes with or without an [I2C](#) stop (default is stop). If a stop is not issued, for purposes such as a restart, a stop must be called manually.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>addr</i>	I2C device address.
<i>buf</i>	The buffer to store the data.
<i>num</i>	The number of bytes to read.
<i>stop</i>	Send a stop signal at the end of the transaction. If not specified, the default value is true.

Returns

The state of the [I2C](#) bus: [I2C Return Values](#)

14.24.3.2.5 MultiChannel_I2CRestart()

```
uint8_t MultiChannel_I2CRestart (
    int moduleNum,
    uint8_t addr,
```

```

        bool Read_Not_Write,
        uint32_t ticks_to_wait = I2C_RX_TX_TIMEOUT)
#include <multichanneli2c.h>

```

Restart communication with a [I2C](#) device.

Restarts communication with an [I2C](#) device after completion of a read or write command in which a stop was not issued. Enables communicate on bus again without giving up control as the [I2C](#) bus master.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>addr</i>	I2C device address.
<i>Read_Not_Write</i>	Specifies the next bus operation: true = read, false = write.
<i>ticks_to_wait</i>	Amount of time to wait for a start transmission to complete, specified as system time ticks. The TICKS_PER_SECOND macro can be used with a multiplier or divisor. Includes the time to receive an ack from the I2C device. If not specified, the default time of I2C_RX_TX_TIMEOUT will be used.

Returns

The state of the [I2C](#) bus: [I2C Return Values](#)

14.24.3.2.6 MultiChannel_I2CSend()

```

uint8_t MultiChannel_I2CSend (
    int moduleNum,
    uint8_t val,
    uint32_t ticks_to_wait = I2C_RX_TX_TIMEOUT)
#include <multichanneli2c.h>

```

Send a single byte on the [I2C](#) bus.

Sends a single byte on the [I2C](#) bus. A start or restart must have been previously issued to become the bus master, and a stop must be issued to release the bus when you are finished with writing the desired number of bytes.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>val</i>	Byte to send
<i>ticks_to_wait</i>	Amount of time to wait for a start transmission to complete, specified as system time ticks. The TICKS_PER_SECOND macro can be used with a multiplier or divisor. Includes the time to receive an ack from the I2C device. If not specified, the default time of I2C_RX_TX_TIMEOUT will be used.

Returns

The state of the [I2C](#) bus: [I2C Return Values](#)

14.24.3.2.7 MultiChannel_I2CSendBuf()

```

uint8_t MultiChannel_I2CSendBuf (
    int moduleNum,
    uint8_t addr,
    uint8_t buf,
    int num,
    bool stop = true)
#include <multichanneli2c.h>

```

Send a buffer of bytes to an [I2C](#) device.

Sends an [I2C](#) start, the bytes in buf, and and finishes with our without an [I2C](#) stop (default is stop). If a stop is not issued, for purposes such as a restart, a stop must be called manually.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>addr</i>	I2C device address.
<i>buf</i>	The buffer to send.
<i>num</i>	The number of bytes in the buffer.
<i>stop</i>	Send a stop signal at the end of transmission. If not specified, the default value is true.

Returns

The state of the I2C bus: [I2C Return Values](#)

14.24.3.2.8 MultiChannel_I2CStart()

```
uint8_t MultiChannel_I2CStart (
    int moduleNum,
    uint8_t addr,
    bool Read_Not_Write,
    uint32_t ticks_to_wait = I2C_START_TIMEOUT)
```

```
#include <multichanneli2c.h>
```

Send an I2C start to an I2C device to begin communication.

Restarts communication with an I2C device after completion of a read or write command in which a stop was not issued. Enables communicate on bus again without giving up control as the I2C bus master.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>addr</i>	I2C device address.
<i>Read_Not_Write</i>	Specifies the next bus operation: true = read, false = write.
<i>ticks_to_wait</i>	Amount of time to wait for a start transmission to complete, specified as system time ticks. The TICKS_PER_SECOND macro can be used with a multiplier or divisor. Includes the time to receive an ack from the I2C device. If not specified, the default time of I2C_START_TIMEOUT will be used.

Returns

The state of the I2C bus: [I2C Return Values](#)

14.24.3.2.9 MultiChannel_I2CStop()

```
uint8_t MultiChannel_I2CStop (
    int moduleNum = DEFAULT_I2C_MODULE,
    uint32_t ticks_to_wait = I2C_RX_TX_TIMEOUT)
```

```
#include <multichanneli2c.h>
```

Issue an I2C stop terminate communication with an I2C device and release the bus.

Terminate any communication and release the I2C bus.

Parameters

<i>moduleNum</i>	I2C peripheral module number.
<i>ticks_to_wait</i>	Amount of time to wait for a start transmission to complete, specified as system time ticks. The TICKS_PER_SECOND macro can be used with a multiplier or divisor. Includes the time to receive an ack from the I2C device. If not specified, the default time of I2C_RX_TX_TIMEOUT will be used.

Returns

The state of the [I2C](#) bus: [I2C Return Values](#)

14.24.4 MODM7AE70, SBE70LC**Classes**

- class [WireIntf](#)
Wire Interface Class for [I2C](#).
- class [I2C](#)
[I2C](#) Peripheral Class.
- class [I2CDevice](#)
[I2C](#) Device Class (recommended)

14.24.4.1 Detailed Description

Supported Platforms:

- MODM7AE70
- SBE70LC

The [I2C](#) peripheral interfaces can be controlled three ways:

- The [I2CDevice](#) class (recommended)
- The [I2C](#) Class, which offers additional low level control
- The [WireIntf](#) Class, which offers a Two Wire Interface API

14.24.5 Wire Interface

Implements the same [TwoWire](#) interface as other popular microcontrollers for easy cross-compatibility with third party libraries.

Classes

- class [TwoWire](#)
Wire interface class.

14.24.5.1 Detailed Description

Implements the same [TwoWire](#) interface as other popular microcontrollers for easy cross-compatibility with third party libraries.

```
#include< Wire.h>
```

To use, simply instantiate the [TwoWire](#) class in your main.cpp: [TwoWire](#) Wire; See examples in your NNDK under `examples/I2C/Wire`

14.25 IOSYS - I/O System**Typedefs**

- typedef void [FDCallBack](#)(int fd, [FDChangeType](#) change, void *pData)
Define the function signature for file descriptor notification callbacks.

Functions

- int [close](#) (int fd)
Close the specified file descriptor and free the associated resources.
- int [read](#) (int fd, char *buf, int nbytes)
Read data from a file descriptor (fd).
- int [peek](#) (int fd, char *c)
Peek at the data for the specified file descriptor (fd). Will block forever until at least one byte is available to be read. The byte returned is not removed from the fd buffer, it will be the first byte of data returned on any subsequent read operation.
- int [write](#) (int fd, const char *buf, int nbytes)
Write data to the stream associated with a file descriptor (fd). Can be used to write data to stdio, a TCP socket, or a Serial port.
- int [writestring](#) (int fd, const char *str)
Write a null terminated ascii string to the stream associated with a file descriptor (fd). Can be used to write data to stdio, a TCP socket, or a Serial port.
- int [writeall](#) (int fd, const char *buf, int nbytes=0)
Write the specified number of bytes to a file descriptor. Will block until all bytes are sent, or a file descriptor error occurs (such as a TCP socket error). Can be used to write data to stdio, a TCP socket, or a Serial port.
- int [ReadWithTimeout](#) (int fd, char *buf, int nbytes, unsigned long timeout)
Read data from a file descriptor(fd), or return if at least one byte is not read within the specified timeout. Can be used instead of the [read\(\)](#) function, which will block forever until at least one byte is read. File descriptors include such things as stdio, TCP sockets, TLS sockets, and Serial ports.
- int [ReadWithTickTimeout](#) (int fd, char *buf, int nbytes, TickTimeout &timeout)
Same as [ReadWithTimeout\(\)](#), except the timeout value parameter is of type TickTimeout instead of an unsigned long. The TickTimeout object is more robust in terms of sequential timeout calls and rollover protection.
- int [ReadAllWithTimeout](#) (int fd, char *buf, int nbytes, unsigned long timeout)
Attempt to read the specified number of bytes from a file descriptor, or return with the number of bytes read if the timeout value has expired.
- int [ReadAllWithTickTimeout](#) (int fd, char *buf, int nbytes, TickTimeout &timeout)
Same as [ReadWithTimeout\(\)](#), except the timeout value parameter is of type TickTimeout instead of an unsigned long. The TickTimeout object is more robust in terms of sequential timeout calls and rollover protection.
- int [readall](#) (int fd, char *buf, int nbytes)
Read the specified number of bytes from a file descriptor (fd). This function will block until either the requested number of bytes have been read, or a file descriptor error occurs. It can be used to read from stdio, TCP sockets, or Serial ports.
- int [SockPeekWithTimeout](#) (int fd, char *buf, uint32_t maxtime)
This function peeks at data from a file descriptor (fd), with a specified timeout value (as opposed to the peek function which will block forever until at least one byte is available to be read). This function can be used to peek from stdio, TCP sockets, or Serial ports.
- int [getchar](#) ()
Get a character from stdin. Will block if no character is available, from stdio library. The default stdin is the debug serial port.
- int [dataavail](#) (int fd)
Check the specified file descriptor to determine if data is available to be read.
- int [writeavail](#) (int fd)
Check the specified file descriptor to determine data can be written.
- int [haserror](#) (int fd)
Check if a file descriptor has an error.
- int [charavail](#) ()
Checks to see if data is available for read on stdin. By default, stdin is the boot/debug serial port.
- void [RegisterFDCallback](#) (int fd, [FDCallback](#) *fp, void *pData)
Register a callback function to receive notification when an FD state changes. Register a NULL fp to remove the notification.

- void **FD_ZERO** (fd_set *pfdsets)

Clear (set to 0) a fd_set (file descriptor set) so no file descriptors (fds) are selected.
- void **FD_CLR** (int fd, fd_set *pfdsets)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function clears or removes a specific file descriptor in an fd_set.
- void **FD_SET** (int fd, fd_set *pfdsets)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function sets or adds a specific file descriptor to an fd_set.
- int **FD_ISSET** (int fd, fd_set *pfdsets)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function checks whether or not a particular fd is set in the specified fd_set.
- int **FD_OVERLAP** (const fd_set *f1, const fd_set *f2)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function determines whether there exists a common file descriptor between the two sets.
- void **FD_COPY** (const fd_set *from, fd_set *to)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function copies one file descriptor set to another.
- void **FD_SETFROMSET** (const fd_set *from, fd_set *to)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function adds the file descriptors from one set to another.
- void **FD_CLRFROMSET** (const fd_set *from, fd_set *to)

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function remove the file descriptors in one set from another.
- int **select** (int nfds, fd_set *readfds, fd_set *writefds, fd_set *errorfds, unsigned long timeout)

Wait for events to occur on one or more I/O resources associated with a set of file descriptors (fds), such as data available to be read, a resource is available to write data, or an error has occurred.
- int **ZeroWaitSelect** (int nfds, fd_set *readfds, fd_set *writefds, fd_set *errorfds)

Returns whether events have occurred on one or more I/O resources associated with a set of file descriptors (fds), and returns immediately.
- int **ioctl** (int fd, int cmd)

This function controls the selection of input/output control options for stdio: stdin = 0, stdout = 1 and stderr = 2.
- int **ReplaceStdio** (int stdio_fd, int new_fd)

Maps stdio to any file descriptor (fd).
- int **CurrentStdioFD** (int stdio_fd)

Returns the current file descriptor mapped to the stdio file descriptor.
- void **IrqStdio** ()

Open the system default serial port in interrupt mode using the system default baud rate, and assign this serial port to stdin, stdout and stderr.

FD Change Type

The notifications that a registered FD monitor can receive.

- enum **FDChangeType** { **eReadSet** , **eWriteSet** , **eErrorSet** , **eClosingNow** }
- The notifications that a registered FD monitor can receive.*

I/O Control Options

The legal options for use with **ioctl()** and in conjunction with **ioctlCmdFlags**

- #define **IOCTL_TX_CHANGE_CRLF** (1)

When set, transmitted char \n gets converted to \r\n
- #define **IOCTL_RX_CHANGE_CRLF** (2)

When set, received \r\n get turned into \n
- #define **IOCTL_RX_PROCESS_EDITS** (4)

When set, process backspace and do simple line editing.

- `#define IOCTL_RX_ECHO (8)`
When set, echo chars received to tx.
- `#define IOCTL_TX_NO_BLOCK (32)`
When set, stdout and stderr will drop output instead of blocking.
- `#define IOCTL_ALL_OPTIONS (15)`
When set, turns on all options.

I/O Control Command Flags

The command flags to use in conjunction with `ioctl()` and `ioctlOptions`

- `#define IOCTL_SET (0x4000)`
Set an option.
- `#define IOCTL_CLR (0x2000)`
Clear an option.

14.25.1 Detailed Description

```
#include< fdfuncs.h>
```

Allows you to set and get parameters for FD based connections and status of network interfaces, serial interfaces, and any custom file descriptors created by an application.

```
#include< iosys.h>
```

I/O system functions use file descriptors for communication and status of network interfaces, serial interfaces, and any custom file descriptors created by an application.

14.25.2 Typedef Documentation

14.25.2.1 FDCallBack

```
typedef void FDCallBack(int fd, FDChangeType change, void *pData)
```

```
#include <iosys.h>
```

Define the function signature for file descriptor notification callbacks.

Parameters

<i>fd</i>	The file descriptor number
<i>change</i>	The reason for the call back, <code>FDChangeType</code>
<i>*pData</i>	A void pointer passed into the register function. Can be used to reference objects or other data

See also

[FDChangeType](#), [RegisterFDCallBack](#)

14.25.3 Enumeration Type Documentation

14.25.3.1 FDChangeType

```
enum FDChangeType
```

```
#include <iosys.h>
```

The notifications that a registered FD monitor can receive.

Enumerator

<code>eReadSet</code>	When read data changes from not available to available.

Enumerator

eWriteSet	When an FD changes from not writable to writeable.
eErrorSet	When an FD goes from no error to having an error.
eClosingNow	when the underlying protocol closes the fd

14.25.4 Function Documentation

14.25.4.1 charavail()

```
int charavail ()
#include <iosys.h>
```

Checks to see if data is available for read on stdin. By default, stdin is the boot/debug serial port.

Return values

1	Data available
0	No data available

See also

[dataavail\(\)](#), [getchar\(\)](#), [writeavail\(\)](#), [read\(\)](#)

14.25.4.2 close()

```
int close (
    int fd)
#include <iosys.h>
```

Close the specified file descriptor and free the associated resources.

Parameters

<i>fd</i>	The file descriptor number

Returns

0 on success, or a resource specific error on failure.

See also

[peek\(\)](#)
[PeekWithTimeout\(\)](#)
[read\(\)](#)
[ReadWithTimeout\(\)](#)
[write\(\)](#)

14.25.4.3 CurrentStdioFD()

```
int CurrentStdioFD (
    int stdio_fd)
#include <iosys.h>
```

Returns the current file descriptor mapped to the stdio file descriptor.

Parameters

<i>stdio</i> ↔ <i>_fd</i>	The stdio file descriptor to check. Options are stdin (0), stdout (1), and stderr (2).

Returns

The current file descriptor mapped to `stdio_fd`

14.25.4.4 dataavail()

```
int dataavail (
    int fd)
#include <iosys.h>
```

Check the specified file descriptor to determine if data is available to be read.

Parameters

<i>fd</i>	The file descriptor number

Return values

1	Data available
0	No data available

See also

[charavail\(\)](#), [getchar\(\)](#), [peek\(\)](#), [read\(\)](#), [ReadWithTimeout\(\)](#)

14.25.4.5 FD_CLR()

```
void FD_CLR (
    int fd,
    fd_set * pfdset)
#include <iosys.h>
```

A `fd_set` (file descriptor set) holds a set of file descriptors (fds). This function clears or removes a specific file descriptor in an `fd_set`.

Parameters

<i>fd</i>	The file descriptor number
<i>*pfdset</i>	Pointer to the <code>fd_set</code> to modify

See also

[FD_ZERO\(\)](#), [FD_SET\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.6 FD_CLRFROMSET()

```
void FD_CLRFROMSET (
    const fd_set * from,
    fd_set * to)
#include <iosys.h>
```

A `fd_set` (file descriptor set) holds a set of file descriptors (fds). This function remove the file descriptors in one set from another.

Parameters

<i>*from</i>	Pointer to the fd_set defining which file descriptors to remove.
<i>*to</i>	Pointer to the fd_set containing file descriptors to remove.

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.7 FD_COPY()

```
void FD_COPY (
    const fd_set * from,
    fd_set * to)
#include <iosys.h>
```

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function copies one file descriptor set to another.

Parameters

<i>*from</i>	Pointer to the file descriptor set being copied from.
<i>*to</i>	Pointer to the fd_set to copy to.

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.8 FD_ISSET()

```
int FD_ISSET (
    int fd,
    fd_set * pfdset)
#include <iosys.h>
```

A fd_set (file descriptor set) holds a set of file descriptors (fds). This function checks whether or not a particular fd is set in the specified fd_set.

For example:

```
if ( FD_ISSET( fdListen, &readFds ) )
{
    // do processing for fdListen
}
```

Parameters

<i>fd</i>	The file descriptor number
<i>*pfdset</i>	A pointer to the fd_set to test

Return values

0	File descriptor is not set in the file descriptor set
>0	File descriptor is set in the file descriptor set

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_SET\(\)](#), [FD_OVERLAP\(\)](#), [select\(\)](#)

14.25.4.9 FD_OVERLAP()

```
int FD_OVERLAP (
    const fd_set * f1,
    const fd_set * f2)
```

```
#include <iosys.h>
```

A `fd_set` (file descriptor set) holds a set of file descriptors (fds). This function determines whether there exists a common file descriptor between the two sets.

Parameters

<i>*f1</i>	Pointer to the first file descriptor set.
<i>*f2</i>	Pointer to the second file descriptor set.

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.10 FD_SET()

```
void FD_SET (
    int fd,
    fd_set * pfdset)
```

```
#include <iosys.h>
```

A `fd_set` (file descriptor set) holds a set of file descriptors (fds). This function sets or adds a specific file descriptor to an `fd_set`.

Parameters

<i>fd</i>	The file descriptor number
<i>*pfdset</i>	Pointer to the <code>fd_set</code> to modify

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.11 FD_SETFROMSET()

```
void FD_SETFROMSET (
    const fd_set * from,
    fd_set * to)
```

```
#include <iosys.h>
```

A `fd_set` (file descriptor set) holds a set of file descriptors (fds). This function adds the file descriptors from one set to another.

Parameters

<i>*from</i>	Pointer to the file descriptor set being copied from.
<i>*to</i>	Pointer to the <code>fd_set</code> to add to.

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.12 FD_ZERO()

```
void FD_ZERO (  
    fd_set * pfds)
```

```
#include <iosys.h>
```

Clear (set to 0) a `fd_set` (file descriptor set) so no file descriptors (fds) are selected.

Parameters

<i>*pfds</i>	Pointer to the file descriptor set

See also

[FD_CLR\(\)](#), [FD_SET\(\)](#), [FD_ISSET\(\)](#), [select\(\)](#)

14.25.4.13 getchar()

```
int getchar ()
#include <iosys.h>
```

Get a character from stdin. Will block if no character is available, from stdio library. The default stdin is the debug serial port.

Returns

Character value (int) from stdin.

See also

[charavail\(\)](#), [dataavail\(\)](#), [peek\(\)](#), [read\(\)](#), [ReadWithTimeout\(\)](#)

14.25.4.14 haserror()

```
int haserror (
    int fd)
#include <iosys.h>
```

Check if a file descriptor has an error.

Parameters

<i>fd</i>	File descriptor number

Return values

1	The file descriptor has an error
0	The file descriptor does not have an error

See also

[dataavail\(\)](#), [writeavail\(\)](#), [charavail\(\)](#)

14.25.4.15 ioctl()

```
int ioctl (
    int fd,
    int cmd)
#include <iosys.h>
```

This function controls the selection of input/output control options for stdio: stdin = 0, stdout = 1 and stderr = 2. The legal options are listed in [ioctlOptions](#).

Parameters

<i>fd</i>	The file descriptor number. The three options are stdin (0), stdout (1), and stderr (2).
<i>cmd</i>	The ioctl command options are ioctlCmdFlags and the bit of the associated options as defined by ioctlOptions .

Returns

The old option value.

```
ioctl(0,IOCTL_SET|IOCTL_ALL_OPTIONS); // Sets all options
ioctl(1,IOCTL_CLR|IOCTL_ALL_OPTIONS); // Clears all options
ioctl(1,IOCTL_SET|IOCTL_RX_CHANGE_CRLF|IOCTL_RX_PROCESS_EDITS); // Sets some options
ioctl(2,IOCTL_CLR|IOCTL_RX_CHANGE_CRLF|IOCTL_RX_PROCESS_EDITS); // Clears some options
```

See also

[ReplaceStdio\(\)](#)

14.25.4.16 peek()

```
int peek (
    int fd,
    char * c)
#include <iosys.h>
```

Peek at the data for the specified file descriptor (fd). Will block forever until at least one byte is available to be read. The byte returned is not removed from the fd buffer, it will be the first byte of data returned on any subsequent read operation.

Parameters

<i>fd</i>	File descriptor
<i>*c</i>	Pointer to the read destination character string

Returns

- 1 on success
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[TCP Socket Status](#), [close\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [write\(\)](#)

14.25.4.17 read()

```
int read (
    int fd,
    char * buf,
    int nbytes)
#include <iosys.h>
```

Read data from a file descriptor (fd).

This function will block forever until at least one byte is available to be read from the input buffer of the specified file descriptor. To wait for a period of time if no data is immediately available in the buffer, please see [ReadWithTimeout\(\)](#) File descriptors include: TCP, UDP, Serial and Extra File Descriptors (EFD). EFDs can be used for custom purposes, such as reading/writing to buffers, or any peripheral custom to your application.

The function will return the number of bytes read, or a negative number if there is an error condition. The error value depends on the type of file descriptor, such as TCP or Serial:

- TCP Status Codes: [TCP Socket Status](#)
- Serial Status Codes: [Serial Port Error Codes](#)

Parameters

<i>fd</i>	The file descriptor number.
<i>*buf</i>	Pointer to the read data destination.
<i>nbytes</i>	Maximum number of bytes to read.

Returns

- Number of bytes read
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[TCP Socket Status](#), [close\(\)](#), [peek\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [ReadAllWithTimeout\(\)](#), [readall\(\)](#), [write\(\)](#)

14.25.4.18 readall()

```
int readall (  
    int fd,  
    char * buf,  
    int nbytes)  
#include <iosys.h>
```

Read the specified number of bytes from a file descriptor (fd). This function will block until either the requested number of bytes have been read, or a file descriptor error occurs. It can be used to read from stdio, TCP sockets, or Serial ports.

Parameters

<i>fd</i>	File descriptor
<i>*buf</i>	Pointer to the read destination buffer
<i>nbytes</i>	Number of bytes to read

Returns

- Number of bytes read.
- 0 on timeout.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [ReadAllWithTimeout\(\)](#), [write\(\)](#)

14.25.4.19 ReadAllWithTickTimeout()

```
int ReadAllWithTickTimeout (  
    int fd,  
    char * buf,  
    int nbytes,  
    TickTimeout & timeout)  
#include <iosys.h>
```

Same as [ReadWithTimeout\(\)](#), except the timeout value parameter is of type TickTimeout instead of an unsigned long. The TickTimeout object is more robust in terms of sequential timeout calls and rollover protection. This function can be used to read from stdio, TCP sockets, or Serial ports. This function will block until on of the following conditions occurs:

- The requested number of bytes have been read.
- The timeout expires. The number of bytes read are returned, and buf contains the data.
- An error occurs on the file descriptor, such as a TCP socket error.

Note

The return value must be checked to verify the number of bytes read and that a timeout or error did not occur.

Parameters

<i>fd</i>	The file descriptor number
<i>*buf</i>	A pointer to the read destination
<i>nbytes</i>	Number of bytes to read
<i>timeout</i>	A reference to the timeout value of type TickTimeout.

Returns

- Number of bytes read.
- 0 on timeout.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [ReadAllWithTimeout\(\)](#), [readall\(\)](#), [write\(\)](#)

14.25.4.20 ReadAllWithTimeout()

```
int ReadAllWithTimeout (
    int fd,
    char * buf,
    int nbytes,
    unsigned long timeout)
```

```
#include <iosys.h>
```

Attempt to read the specified number of bytes from a file descriptor, or return with the number of bytes read if the timeout value has expired.

This function can be used to read from stdio, TCP sockets, or Serial ports. This function will block until on of the following conditions occurs:

- The requested number of bytes have been read.
- The timeout expires. The number of bytes read are returned, and buf contains the data.
- An error occurs on the file descriptor, such as a TCP socket error.

Note

The return value must be checked to verify the number of bytes read and that a timeout or error did not occur.

Parameters

<i>fd</i>	The file descriptor number
<i>*buf</i>	A pointer to the read destination
<i>nbytes</i>	Number of bytes to read
<i>timeout</i>	The number of timer ticks to wait for data

Returns

- Number of bytes read.
- 0 on timeout.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [ReadAllWithTickTimeout\(\)](#), [ReadWithTickTimeout\(\)](#), [readall\(\)](#), [write\(\)](#)

14.25.4.21 ReadWithTickTimeout()

```
int ReadWithTickTimeout (
    int fd,
    char * buf,
    int nbytes,
    TickTimeout & timeout)
#include <iosys.h>
```

Same as [ReadWithTimeout\(\)](#), except the timeout value parameter is of type TickTimeout instead of an unsigned long. The TickTimeout object is more robust in terms of sequential timeout calls and rollover protection.

Note

This function operates like the read function in that it reads all available bytes up to the maximum and returns. The addition of a timeout does not cause the function to block until the specified maximum number of bytes are available. As with read, the application must use the return value of the ReadWithTimeout function to determine how many bytes were read, and call the function again if necessary.

When using with a TCP socket, you may want to use the [SockReadWithTimeout\(\)](#) function, which returns additional values related to network connections.

Parameters

<i>fd</i>	The file descriptor number.
<i>*buf</i>	A pointer to the read destination.
<i>nbytes</i>	Maximum number of bytes to read.
<i>timeout</i>	A reference to the timeout value of type TickTimeout.

Returns

- Number of bytes read.
- 0 on timeout.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [ReadAllWithTimeout\(\)](#), [readall\(\)](#), [SockReadWithTimeout\(\)](#), [write\(\)](#)

14.25.4.22 ReadWithTimeout()

```
int ReadWithTimeout (
    int fd,
    char * buf,
    int nbytes,
    unsigned long timeout)
#include <iosys.h>
```

Read data from a file descriptor(fd), or return if at least one byte is not read within the specified timeout. Can be used instead of the [read\(\)](#) function, which will block forever until at least one byte is read. File descriptors include such things as stdio, TCP sockets, TLS sockets, and Serial ports.

Note

This function operates like the read function in that it reads all available bytes up to the maximum and returns. The addition of a timeout does not cause the function to block until the specified maximum number of bytes are available. As with read, the application must use the return value of the ReadWithTimeout function to determine how many bytes were read, and call the function again if necessary.

When using with a TCP socket, you may want to use the [SockReadWithTimeout\(\)](#) function, which returns additional values related to network connections.

Parameters

<i>fd</i>	The file descriptor number.
<i>*buf</i>	A pointer to the read destination.
<i>nbytes</i>	Maximum number of bytes to read.
<i>timeout</i>	The number of timer ticks to wait for data.

Returns

- Number of bytes read.
- 0 on timeout.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTickTimeout\(\)](#), [ReadAllWithTimeout\(\)](#), [readall\(\)](#), [SockReadWithTimeout\(\)](#), [write\(\)](#)

14.25.4.23 RegisterFDCallback()

```
void RegisterFDCallback (
    int fd,
    FDCallback * fp,
    void * pData)
```

```
#include <iosys.h>
```

Register a callback function to receive notification when an FD state changes. Register a NULL fp to remove the notification.

Parameters

<i>fd</i>	The file descriptor number
<i>*fp</i>	The function pointer to call back
<i>*pData</i>	A void * passed to the callback function, can be used for any purpose, such as object references

See also

[FDChangeType](#), [FDCCallback](#)

14.25.4.24 ReplaceStdio()

```
int ReplaceStdio (
    int stdio_fd,
    int new_fd)
```

```
#include <iosys.h>
```

Maps stdio to any file descriptor (fd).

If the file descriptor generates an error (such as a closed TCP connection), then stdio will be remapped to a negative fd (this will cause stdio to generate errors). When this function is used to remap a stdio channel that has errored, then the error will be cleared.

Parameters

<i>stdio↔ _fd</i>	The stdio file descriptor to map to. Options are stdin (0), stdout (1), and stderr (2).
<i>new_fd</i>	The file descriptor to replace stdio with. A value of 0 returns stdio to the default debug monitor based traps.

Return values

0	If stdio had not been previously mapped
>0	The value of the fd for the previous stdio override

See also

[ioctl\(\)](#)

14.25.4.25 select()

```
int select (
    int nfds,
    fd_set * readfds,
    fd_set * writefds,
    fd_set * errorfds,
    unsigned long timeout)
#include <iosys.h>
```

Wait for events to occur on one or more I/O resources associated with a set of file descriptors (fds), such as data available to be read, a resource is available to write data, or an error has occurred.

The most common use for this function is to monitor multiple serial and/or TCP file descriptors at one time to read incoming data. For example, an application could use a single RTOS task and a [select\(\)](#) to process incoming data on multiple TCP sockets at one time, instead of using multiple tasks or looping through each fd sequentially.

The file descriptors of interest are specified with file descriptor sets (fds) for read, write and error conditions. [select\(\)](#) will block until one of the fd conditions are true, or the specified timeout occurs (a value of 0 blocks forever). For example, if the readfds is used for multiple TCP sockets, [select\(\)](#) will return if data is available to read on one or more of them. The application would then use macros such as [FD_ISSET\(\)](#) to handle reading the data.

Note

A timeout value can be used to cause [select\(\)](#) to return periodically for any type of processing an application would like to do in the event no activity is occurring on the fd sets.

Parameters

<i>nfds</i>	The number of file descriptors to examine (This parameter is currently ignored)
<i>*readfds</i>	Pointer to the fd_set to select for read events, or null if no read events are to be monitored. It is modified on exit to reflect the read availability of the selected fds in the set.
<i>*writefds</i>	Pointer to the fd_set to select for write availability events, or null if no events are to be monitored. If non-null, it is modified on exit to reflect the write availability of the selected fds in the set.
<i>*errorfds</i>	Pointer to the fd_set to select for error events, or null if no error events are to be monitored. It is modified on exit to reflect the error state of the selected fds in the set.
<i>timeout</i>	The number of system time ticks to wait before timing out if no events occurred in the selected fd sets. Note: The TICKS_PER_SECOND multiplier should be used to specify the timeout in seconds. For example, TICKS_PER_SECOND * 5 to specify a timeout of 5 seconds.

Return values

0	Timeout occurred
>0	The number of fds in all of the non-null fd_sets

See also

[FD_ZERO\(\)](#), [FD_CLR\(\)](#), [FD_SET\(\)](#), [FD_ISSET\(\)](#)

14.25.4.26 SockPeekWithTimeout()

```
int SockPeekWithTimeout (
    int fd,
    char * buf,
    uint32_t maxtime)
```

```
#include <iosys.h>
```

This function peeks at data from a file descriptor (*fd*), with a specified timeout value (as opposed to the `peek` function which will block forever until at least one byte is available to be read). This function can be used to peek from `stdio`, TCP sockets, or Serial ports.

The byte returned is *not* removed from the *fd*. The byte returned will be the first byte of data returned on the first subsequent `read()`.

Parameters

<i>fd</i>	The file descriptor number
<i>*buf</i>	A pointer to the read destination
<i>maxtime</i>	The number of time ticks to wait for at least 1 byte of data

Returns

- 1 on success.
- 0 on timeout.
- Negative value on error. Error value is determined by the type of *fd*, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[TCP Socket Status](#), [close\(\)](#), [peek\(\)](#), [read\(\)](#), [ReadWithTimeout\(\)](#), [write\(\)](#)

14.25.4.27 write()

```
int write (
    int fd,
    const char * buf,
    int nbytes)
```

```
#include <iosys.h>
```

Write data to the stream associated with a file descriptor (*fd*). Can be used to write data to `stdio`, a TCP socket, or a Serial port.

Note

The function will block until at least 1 byte is written, but will not write all requested bytes if there is not enough space in the write buffer. The return value must always be checked to verify the number of bytes written.

Parameters

<i>fd</i>	File descriptor
<i>*buf</i>	Pointer to the buffer to write
<i>nbytes</i>	Maximum number of bytes to write

Returns

- The number of bytes written to write buffer.
- Negative value on error. Error value is determined by the type of *fd*, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [writestring\(\)](#), [writeall\(\)](#)

14.25.4.28 writeall()

```
int writeall (  
    int fd,  
    const char * buf,  
    int nbytes = 0)
```

```
#include <iosys.h>
```

Write the specified number of bytes to a file descriptor. Will block until all bytes are sent, or a file descriptor error occurs (such as a TCP socket error). Can be used to write data to stdio, a TCP socket, or a Serial port.

Note

The function will block until at least 1 byte is written, but will not write all requested bytes if there is not enough space in the write buffer. The return value must always be checked to verify the number of bytes written.

Parameters

<i>fd</i>	File descriptor
<i>*buf</i>	Pointer to the buffer to write
<i>nbytes</i>	Maximum number of bytes to write

Returns

- The number of bytes written to write buffer.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [write\(\)](#), [writestring\(\)](#)

14.25.4.29 writeavail()

```
int writeavail (  
    int fd)  
#include <iosys.h>
```

Check the specified file descriptor to determine data can be written.

Parameters

<i>fd</i>	File descriptor number

Return values

1	Data can be written
0	Data cannot be written, such as when an output buffer is full

See also

[dataavail\(\)](#), [charavail\(\)](#), [haserror\(\)](#)

14.25.4.30 writestring()

```
int writestring (
    int fd,
    const char * str)
```

```
#include <iosys.h>
```

Write a null terminated ascii string to the stream associated with a file descriptor (fd). Can be used to write data to stdio, a TCP socket, or a Serial port.

Note

The function will block until at least 1 byte is written, but will not write all requested bytes if there is not enough space in the write buffer. The return value must always be checked to verify the number of bytes written.

Parameters

<i>fd</i>	File descriptor
<i>*str</i>	Pointer to the null terminated string to write

Returns

- The number of bytes written to write buffer.
- Negative value on error. Error value is determined by the type of fd, such as TCP [TCP Socket Status](#), or Serial [Serial Port Error Codes](#).

See also

[close\(\)](#), [peek\(\)](#), [read\(\)](#), [PeekWithTimeout\(\)](#), [ReadWithTimeout\(\)](#), [write\(\)](#), [writeall\(\)](#)

14.25.4.31 ZeroWaitSelect()

```
int ZeroWaitSelect (
    int nfd,
    fd_set * readfds,
    fd_set * writefds,
    fd_set * errorfds)
```

```
#include <iosys.h>
```

Returns whether events have occurred on one or more I/O resources associated with a set of file descriptors (fds), and returns immediately.

Parameters

<i>nfd</i>	The number of file descriptors to examine. Note: This parameter is currently ignored.
<i>*readfds</i>	A pointer to the fd_set to select for read events. Note: This parameter can be NULL. It is modified on exit to reflect the read availability of the selected fds in the set.
<i>*writefds</i>	A pointer to the fd_set to select for write availability events. Note: This parameter can be NULL. It is modified on exit to reflect the write availability of the selected fds in the set.
<i>*errorfds</i>	A pointer to the fd_set to select for error events. Note: This parameter can be NULL. It is modified on exit to reflect the error state of the selected fds in the set.

Return values

<i>0</i>	If there is no valid fds
<i>>0</i>	The number of fds in all of the non null fd_sets

14.26 IP

Core IP layer definitions, structures, and functions for IPv4/IPv6 networking.

Topics

- [IPADDR4 Class](#)
- [IPADDR6 Class](#)

Classes

- struct [_IpHeaderIPv4](#)
IP Header Structure (IPv4)
- struct [IPPKT](#)
Internal IPv4 Header Representation.
- struct [UDPPKT](#)
Internal UDP Packet Header Structure.
- struct [PsudeoHeader](#)
UDP/TCP IPv4 Pseudo-header Structure (bits 0 through 95 of the pseudo-header)

Macros

- #define [ICMP_PING_DATA_SIZE](#) (32)
Default data payload size for ICMP echo request and reply packets (32 bytes)

Typedefs

- typedef struct [_IpHeaderIPv4](#) [IpHeaderIPv4](#)
IP Header Structure (IPv4)
- typedef void [FragmentProcessFunction](#)([PoolPtr](#) pp)
User-defined function pointer type for processing fragmented IP packets.
- typedef void [PromiscuousPacketFunc](#)([PoolPtr](#) pp)
User-defined function pointer type for processing promiscuous packets.

Functions

- void [IpProcessEthernetPacket](#) ([PoolPtr](#) poolPtr, uint16_t packetSizeInBytes)
Process an Ethernet packet for IP layer handling.
- uint16_t [GetSum](#) (uint16_t addr, uint16_t count)
Calculate Internet checksum for the specified data.
- uint16_t [GetSum20](#) (uint32_t addr)
Calculate Internet checksum for exactly 20 bytes of data.
- uint16_t [GetSumHdr](#) ([PsudeoHeader](#) &hdr, uint16_t addr, uint16_t count)
Calculate Internet checksum using a pseudo-header.
- BOOL [IsMyIp4](#) ([IPADDR4](#) ip, int ifc=-1)
Check if the specified IPv4 address belongs to this device.
- [IPADDR4](#) [GetSrcIp4](#) ([IPADDR4](#) dst)
Get the appropriate source IPv4 address for reaching a destination.
- [IPADDR4](#) [GetSrcIpwIf4](#) (int ifn, const [IPADDR4](#) dst)
Get the source IPv4 address for a specific interface and destination.
- BOOL [IsMyIp6](#) (const [IPADDR](#) &ip, int ifc=-1)
Check if the specified IPv6 address belongs to this device.
- BOOL [IsMyIp](#) (const [IPADDR](#) &ip, int ifc=-1)
Generic function to check if IP address belongs to this device (uses IPv6 when available)

- [IPADDR GetSrcIp6](#) (const [IPADDR](#) &dst)
Get the appropriate source IPv6 address for reaching a destination.
- [IPADDR GetSrcIp](#) (const [IPADDR](#) &dst)
Generic function to get source IP address for reaching a destination (IPv6 version).
- [IPADDR GetSrcIp6wIf](#) (int ifn, const [IPADDR](#) &dst)
Get the source IPv6 address for a specific interface and destination.
- [IPADDR GetSrcIpwIf](#) (int ifn, const [IPADDR](#) &dst)
Generic function to get source IP address for an interface (IPv6 version).
- void [SendICMPError](#) ([PoolPtr](#) pBadPacket, uint8_t type, uint8_t code)
Send an ICMP error message in response to a bad packet.
- void [FixHeaderAndSend](#) ([PoolPtr](#) p, [PIPPKT](#) plp)
Complete IP header fields and send packet on primary interface.
- void [FixHeaderAndSendViaInterface](#) ([PoolPtr](#) p, [PIPPKT](#) plp, int Interface)
Complete IP header fields and send packet via specified interface.
- void [InitializeStack](#) ()
Initialize the IP protocol stack.
- void [ShowIPBuffer](#) ([PoolPtr](#) rp)
Display the contents of a network buffer for diagnostic purposes.
- int [Ping4](#) ([IPADDR4](#) to, uint16_t id, uint16_t seq, uint16_t maxwaitticks)
Send a "ping" packet and wait the specified timeout for a response.
- int [Ping4ViaInterface](#) ([IPADDR4](#) to, uint16_t id, uint16_t seq, uint16_t wait, int interface)
Send a "ping" packet via a specific network interface and wait for a response.
- int [Ping6](#) (const [IPADDR](#) &to, uint16_t id, uint16_t seq, uint16_t maxwaitticks, int size=32)
Send an IPv6 "ping" packet and wait the specified timeout for a response.
- int [Ping6ViaInterface](#) (const [IPADDR](#) &to, uint16_t id, uint16_t seq, uint16_t wait, int interface, int size=32)
Send an IPv6 "ping" packet via a specific network interface.
- int [Ping](#) (const [IPADDR](#) &to, uint16_t id, uint16_t seq, uint16_t maxwaitticks, int size=32)
Generic ping function that uses IPv6 when IPv6 is enabled.
- int [PingViaInterface](#) (const [IPADDR](#) &to, uint16_t id, uint16_t seq, uint16_t wait, int interface, int size=32)
Generic ping via interface function that uses IPv6 when IPv6 is enabled.
- BOOL [IsLocal4](#) ([IPADDR4](#) ip, int ifc)
Check if an IPv4 address is on the local network segment.
- int [GetProperInterface4](#) ([IPADDR4](#) dst)
Get the appropriate interface number for reaching a destination.
- int [AddInterface](#) ([IPADDR4](#) addr, [IPADDR4](#) mask, [IPADDR4](#) gateway, int root_if=0)
Add a new network interface with the specified configuration.
- int [GetMultiHomeInterface](#) ([IPADDR4](#) ipa, int norgif)
Get the multi-home interface for a specific IP address.
- int [GetLocalIPInterface4](#) ([IPADDR4](#) ipa)
Get the local interface number for a specific IPv4 address.
- int [GetLocalIPInterface6](#) (const [IPADDR](#) &ipa)
Get the local interface number for a specific IPv6 address.
- int [GetLocalIPInterface](#) (const [IPADDR](#) &ipa)
Generic function to get local interface for an IP address (IPv6 version).
- uint16_t [GetEphemeralPort](#) ()
Generate a random ephemeral port number.

Variables

- [FragmentProcessFunction](#) * [pFragFunc](#)
Global function pointer for fragment processing callback.
- [PromiscuousPacketFunc](#) * [pPromiscuousPacketFunc](#)
Global function pointer for promiscuous packet processing callback.
- [TaskPacketFunc](#) * [pTaskPacketFunc](#)
Global function pointer for UDP task packet processing callback.

Global Configuration Variables

These global variables control various IP stack behaviors and can be modified by the application to customize network behavior.

- `uint8_t` **bTTL_Default**
Default Time To Live (hop count) for outgoing IP packets. Typical value is 64 or 128.
- `uint16_t` **wArpLifetime**
[ARP](#) cache entry lifetime in seconds. Entries older than this are refreshed. Typical value is 300-1200 seconds.
- `BOOL` **bQuietStart**
When `TRUE`, suppresses startup messages during network initialization. Set before calling [init\(\)](#).

Get Packet Functions

These inline functions provide convenient access to packet structures at various layers of the network stack. They handle the pointer arithmetic needed to locate specific headers within network buffer pool buffers.

WARNING:

If you use these functions on an uninitialized buffer you will get bogus values for the pointer as the header length field in the IP packet is not yet set up! Always ensure packets are properly initialized before using these accessor functions.

- [PIPPKT GetIpPkt](#) ([PoolPtr](#) p)
Get IP packet pointer from network buffer pool buffer.
- [PIPPKT GetIpPkt](#) ([PEFRAME](#) pFrame)
Get IP packet pointer from pointer to Ethernet frame.
- [PIPPKT GetIpPkt](#) ([PVLEFRAME](#) pFrame)
Get IP packet pointer from pointer to VLAN-tagged Ethernet frame.
- [PUDPPKT GetUdpPkt](#) ([PIPPKT](#) plp)
Get UDP packet pointer from IP packet pointer.

IP Version

Uncomment for debugging IP layer operations

- `#define IP_VERSION_MASK (0xF0)`
Mask for extracting IP version from version/header length byte.
- `#define IP_VERSION_IPv4 (0x40)`
IPv4 version identifier (value 4 in upper nibble)
- `#define IP_VERSION_IPv6 (0x60)`
IPv6 version identifier (value 6 in upper nibble)

Header Length

- `#define IP_HEADER_LENGTH_MASK (0x0F)`
Mask for extracting header length from version/header length byte.
- `#define IP_HEADER_LENGTH_NO_OPTIONS (0x05)`
Header length value when no IP options present (5 32-bit words = 20 bytes)

Flags and Fragment Offset

- **#define IP_FLAGS_MASK** (0xE000)
Mask for extracting IP flags (upper 3 bits of flags/fragment field)
- **#define IP_FRAGMENT_OFFSET_MASK** (0x1FFF)
Mask for extracting fragment offset (lower 13 bits of flags/fragment field)

IP Protocol Numbers

These are IANA-assigned protocol numbers that identify the next-level protocol encapsulated in the IP packet.

- **#define IP_PROTOCOL_ICMP** (0x01)
Internet Control Message Protocol.
- **#define IP_PROTOCOL_IGMP** (0x02)
Internet Group Management Protocol.
- **#define IP_PROTOCOL_INTERNET** (0x04)
IP-in-IP encapsulation (deprecated)
- **#define IP_PROTOCOL_TCP** (0x06)
Transmission Control Protocol.
- **#define IP_PROTOCOL_UDP** (0x11)
User Datagram Protocol (value 17 decimal)

ICMP Message Types and Codes

Internet Control Message Protocol (ICMP) types and codes used for network diagnostics and error reporting. See RFC 792 for details.

- **#define ICMP_TYPE_ECHO_REPLY** (0)
Echo Reply message (response to ping)
- **#define ICMP_CODE_ECHO_REPLY** (0)
Code for Echo Reply (always 0)
- **#define ICMP_TYPE_DEST_UNREACHABLE** (3)
Destination Unreachable error message.
- **#define ICMP_CODE_PORT_UNREACHABLE** (3)
Port Unreachable code within Destination Unreachable.
- **#define ICMP_TYPE_SOURCE_QUENCH** (4)
Source Quench message (deprecated, for flow control)
- **#define ICMP_CODE_SOURCE_QUENCH** (0)
Code for Source Quench (always 0)
- **#define ICMP_TYPE_REDIRECT_MESSAGE** (5)
Redirect message (routing optimization)
- **#define ICMP_TYPE_ECHO_REQUEST** (8)
Echo Request message (ping)
- **#define ICMP_CODE_ECHO_REQUEST** (0)
Code for Echo Request (always 0)

Well-Known Port Numbers

IANA-assigned well-known port numbers for common network services. These ports are reserved for specific protocols and services.

- **#define IANA_ECHO_PORT** (7)
Echo protocol port.
- **#define IANA_DISCARD_PORT** (9)
Discard protocol port (null service)

- `#define IANA_SSH_PORT (22)`
Secure Shell (SSH) protocol port.
- `#define IANA_TELNET_PORT (23)`
Telnet protocol port.
- `#define IANA_NETBIOS_NAME_SERVICE_PORT (137)`
NetBIOS Name Service port.

14.26.1 Detailed Description

Core IP layer definitions, structures, and functions for IPv4/IPv6 networking.

```
#include <ip.h>
```

This module provides comprehensive support for IP networking including:

- Packet structure definitions for IP, UDP, and ICMP
- Address resolution and routing functions
- Ping/ICMP echo request functionality
- Packet checksum calculation
- Multi-homing and multiple interface support
- Promiscuous mode and packet filtering callbacks
- Fragment processing support

14.26.2 Typedef Documentation

14.26.2.1 FragmentProcessFunction

```
typedef void FragmentProcessFunction(PoolPtr pp)
#include <ip.h>
```

User-defined function pointer type for processing fragmented IP packets.

This callback function is called only for IP packets that have the fragmentation flag set in the IP header. Applications can implement this function to handle packet fragmentation and reassembly according to their specific requirements. Typical implementations would:

- Store fragments until all pieces arrive
- Reassemble complete datagrams
- Handle fragment timeout and cleanup
- Free the buffer when done processing

Parameters

<i>pp</i>	Packet pointer from network buffer pool containing the fragmented packet

Note

The callback function is responsible for properly handling and freeing the buffer.

This function is only called for packets with fragmentation flags set.

Fragment reassembly is not provided by default - must be implemented by application.

See also

[pFragFunc](#)

14.26.2.2 IpHeaderIPv4

```
typedef struct _IpHeaderIPv4 IpHeaderIPv4
```

```
#include <ip.h>
```

IP Header Structure (IPv4)

Standard IPv4 packet header as defined in IETF RFC 791 (September 1981) and MIL-STD-1777. This structure represents the 20-byte minimum IP header. IP options, if present, follow this structure and are indicated by a header length value greater than 5.

All multi-byte fields are in network byte order (big-endian) and use the beuint types for automatic endianness handling.

Note

The structure is packed to ensure proper alignment with network packet data.

Standard header is 20 bytes when no options are present (header length = 5).

Maximum header size is 60 bytes (header length = 15) when options are included.

See also

[IPPKT](#) for the internal representation used within NetBurner stack

14.26.2.3 PromisciousPacketFunc

```
typedef void PromisciousPacketFunc(PoolPtr pp)
```

```
#include <ip.h>
```

User-defined function pointer type for processing promiscuous packets.

This callback function is called for packets that fail the "IP address == my address" test. This enables applications to receive and process packets not specifically addressed to this device, useful for:

- Network monitoring and packet capture
- Bridge or router implementations
- Protocol analyzers
- IDS/IPS systems
- Custom routing logic

Parameters

<i>pp</i>	Packet pointer from network buffer pool containing the promiscuous packet

Warning

This function **MUST** free the buffers it receives using [FreeBuffer\(\)](#) or equivalent. Failure to free buffers will result in buffer pool exhaustion and network failure.

Note

This callback is only invoked for packets not addressed to this device's IP address.

Ethernet interface must be set to promiscuous mode to receive these packets.

See also

[pPromisciousPacketFunc](#)

14.26.3 Function Documentation

14.26.3.1 AddInterface()

```
int AddInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
    int root_if) [inline]
#include <ip.h>
```

Add a new network interface with the specified configuration.

Dynamically adds a new network interface to the system with the specified IP address, subnet mask, gateway, and root interface configuration. This is used in multi-homed systems to configure additional network interfaces at runtime.

Typical uses:

- Adding secondary IP addresses to an interface (IP aliasing)
- Configuring Auto-IP link-local addresses
- Setting up virtual interfaces
- Dynamic network reconfiguration

Parameters

<i>addr</i>	IP address for the new interface
<i>mask</i>	Subnet mask for the new interface
<i>gateway</i>	Gateway IP address for the new interface (0.0.0.0 for none)
<i>root_if</i>	Root interface number this interface is associated with (physical interface)

Returns

Interface number of the newly added interface (≥ 0), or negative value on error

Note

Only available when MULTIHOME or AUTOIP is defined.

Used for dynamic interface configuration in multi-homed systems.

The root_if parameter specifies which physical interface this logical interface uses.

```
// Add a secondary IP address to interface 0
IPADDR4 secondary = AsciiToIp4("192.168.1.100");
IPADDR4 mask = AsciiToIp4("255.255.255.0");
IPADDR4 gw = AsciiToIp4("192.168.1.1");
int new_if = AddInterface(secondary, mask, gw, 0);
if (new_if >= 0) {
    iprintf("Added interface %d\r\n", new_if);
}
```

Add a new network interface with the specified configuration.

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>root_if</i>	Optional root physical interface number. If not specified the default is 0, for Ethernt 0.

Returns

Interface number of newly created interface

14.26.3.2 FixHeaderAndSend()

```
void FixHeaderAndSend (
    PoolPtr p,
    PIPPKT pIp)
```

```
#include <ip.h>
```

Complete IP header fields and send packet on primary interface.

Fills in remaining IP header fields (checksum, fragmentation info, etc.) and transmits the packet via the primary network interface. This function handles the final steps of IP packet transmission including:

- Calculating and setting the header checksum
- Setting the Time To Live (TTL) field if not already set
- Handling fragmentation if necessary
- Forwarding to the data link layer

Parameters

<i>p</i>	Network buffer pool pointer containing the packet
<i>p</i> ↔ <i>Ip</i>	Pointer to IP header within the packet

Note

The IP header should be mostly complete before calling this function.

Source and destination addresses must be set before calling.

This function calculates and fills in header checksum and other final fields.

See also

[FixHeaderAndSendViaInterface\(\)](#)

14.26.3.3 FixHeaderAndSendViaInterface()

```
void FixHeaderAndSendViaInterface (
    PoolPtr p,
    PIPPKT pIp,
    int Interface)
```

```
#include <ip.h>
```

Complete IP header fields and send packet via specified interface.

Similar to [FixHeaderAndSend\(\)](#), but allows specification of which network interface to use for transmission. This is useful in multi-homed systems where you need explicit control over the egress interface.

Parameters

<i>p</i>	Network buffer pool pointer containing the packet
<i>pIp</i>	Pointer to IP header within the packet
<i>Interface</i>	Interface number to use for transmission (0-based)

Note

Allows control over which interface transmits the packet.

Useful for routing and multi-homed configurations.

Interface number must be valid or packet will be dropped.

See also

[FixHeaderAndSend\(\)](#)

14.26.3.4 GetEphemeralPort()

```
uint16_t GetEphemeralPort ()
#include <ip.h>
```

Generate a random ephemeral port number.

Returns a random port number suitable for use as a local port in client connections. The port number is selected from the ephemeral (dynamic) port range and avoids well-known ports (0-1023) and registered ports (1024-49151). Ephemeral ports are temporary ports used by the client side of a connection. Each call returns a different random port number to avoid conflicts with other active connections.

Returns

Random ephemeral port number (typically in range 49152-65535 per RFC 6335)

Note

Used internally for automatic local port assignment in client connections.

Avoids conflicts with well-known and registered port numbers.

Each call returns a different random port number.

The random selection reduces the likelihood of port exhaustion and security issues.

```
// Get an ephemeral port for a client connection
uint16_t local_port = GetEphemeralPort();
int fd = connect(server_ip, server_port, local_port, timeout);
```

14.26.3.5 GetIpPkt() [1/3]

```
PIPPKT GetIpPkt (
    PEFRAME pFrame) [inline]
#include <ip.h>
```

Get IP packet pointer from pointer to Ethernet frame.

Returns a pointer to the IP header located immediately after the Ethernet header.

Parameters

<i>pFrame</i>	Pointer to Ethernet frame structure

Returns

Pointer to IP header within the frame

14.26.3.6 GetIpPkt() [2/3]

```
PIPPKT GetIpPkt (
    PoolPtr p) [inline]
#include <ip.h>
```

Get IP packet pointer from network buffer pool buffer.

Calculates the location of the IP header within a network buffer by adding the Ethernet header size (14 bytes) to the buffer's data pointer.

Parameters

<i>p</i>	Network buffer pool pointer

Returns

Pointer to IP header, or NULL if p is NULL

14.26.3.7 GetIpPkt() [3/3]

```
PIPKT GetIpPkt (
    PVLEFRAME pFrame) [inline]
#include <ip.h>
Get IP packet pointer from pointer to VLAN-tagged Ethernet frame.
Returns a pointer to the IP header located after the VLAN Ethernet header.
```

Parameters

<i>pFrame</i>	Pointer to VLAN Ethernet frame structure

Returns

Pointer to IP header within the frame

14.26.3.8 GetLocalIPInterface()

```
int GetLocalIPInterface (
    const IPADDR & ipa) [inline]
#include <ip.h>
Generic function to get local interface for an IP address (IPv6 version).
This inline function provides a generic interface that automatically uses the IPv6 version when IPv6 support is
compiled in.
```

Parameters

<i>ipa</i>	IP address to look up

Returns

Interface number associated with the address

See also

[GetLocalIPInterface6\(\)](#), [GetLocalIPInterface4\(\)](#)

14.26.3.9 GetLocalIPInterface4()

```
int GetLocalIPInterface4 (
    IPADDR4 ipa)
#include <ip.h>
Get the local interface number for a specific IPv4 address.
Determines which local interface is associated with the specified IPv4 address. Searches all interfaces (physical
and virtual) to find the one with the matching address.
```

Parameters

<i>ipa</i>	IPv4 address to look up

Returns

Interface number associated with the address, or -1 if not found

Note

Only available when MULTIHOME or AUTOIP is defined.
Returns -1 if the address is not assigned to any interface.

14.26.3.10 GetLocalIPInterface6()

```
int GetLocalIPInterface6 (  
    const IPADDR & ipa)
```

```
#include <ip.h>
```

Get the local interface number for a specific IPv6 address.

Determines which local interface is associated with the specified IPv6 address. Checks both link-local and global IPv6 addresses on all interfaces.

Parameters

<i>ipa</i>	IPv6 address to look up

Returns

Interface number associated with the address, or -1 if not found

Note

Only available when MULTIHOMER or AUTOIP is defined and IPv6 is enabled.

Important for determining interface for link-local addresses.

14.26.3.11 GetMultiHomeInterface()

```
int GetMultiHomeInterface (  
    IPADDR4 ipa,  
    int norgif)
```

```
#include <ip.h>
```

Get the multi-home interface for a specific IP address.

Finds the appropriate interface number for the specified IP address in a multi-homed system configuration. This searches through all configured interfaces (including virtual interfaces) to find a match.

Parameters

<i>ipa</i>	IP address to look up
<i>norgif</i>	Original interface number (for fallback if address not found)

Returns

Interface number for the specified IP address, or norgif if not found

Note

Only available when MULTIHOMER or AUTOIP is defined.

Returns norgif if the address is not assigned to any interface.

14.26.3.12 GetProperInterface4()

```
int GetProperInterface4 (  
    IPADDR4 dst)
```

```
#include <ip.h>
```

Get the appropriate interface number for reaching a destination.

Performs routing table lookup to determine which interface should be used to reach the specified IPv4 destination address. This considers:

- Direct network connections (local subnets)
- Default gateway routes
- Static routes if configured
- Interface priorities

Parameters

<i>dst</i>	Destination IPv4 address

Returns

Interface number that should be used to reach the destination

Note

Returns the interface number based on routing table configuration.

Used internally for automatic interface selection.

Returns primary interface if no specific route found.

```
IPADDR4 remote = AsciiToIp4("8.8.8.8");
int ifnum = GetProperInterface4(remote);
iprintf("Use interface %d to reach %s\r\n", ifnum, "8.8.8.8");
```

14.26.3.13 GetSrcIp()

```
IPADDR GetSrcIp (
    const IPADDR & dst) [inline]
#include <ip.h>
```

Generic function to get source IP address for reaching a destination (IPv6 version).

This inline function provides a generic interface that automatically uses the IPv6 version when IPv6 support is compiled in.

Parameters

<i>dst</i>	Destination IP address

Returns

Local IP address that should be used as source for packets to dst

See also

[GetSrcIp6\(\)](#), [GetSrcIp4\(\)](#)

14.26.3.14 GetSrcIp4()

```
IPADDR4 GetSrcIp4 (
    IPADDR4 dst)
#include <ip.h>
```

Get the appropriate source IPv4 address for reaching a destination.

Determines which local IPv4 address should be used as the source address when sending packets to the specified destination. This performs routing table lookup and interface selection based on the destination address.

Parameters

<i>dst</i>	Destination IPv4 address

Returns

Local IPv4 address that should be used as source for packets to dst

Note

Returns the IP address of the interface that would be used to reach *dst*.
Considers routing table and interface configuration.
Essential for multi-homed systems to select correct source address.

See also

[GetSrcIp\(\)](#), [GetSrcIpwlf4\(\)](#), [GetSrcIp6\(\)](#)

14.26.3.15 GetSrcIp6()

```
IPADDR GetSrcIp6 (  
    const IPADDR & dst)
```

```
#include <ip.h>
```

Get the appropriate source IPv6 address for reaching a destination.

Determines which local IPv6 address should be used as the source address when sending packets to the specified destination. This performs routing table lookup and interface selection.

Parameters

<i>dst</i>	Destination IPv6 address

Returns

Local IPv6 address that should be used as source for packets to *dst*

Note

Selects appropriate address scope (link-local vs global) based on destination.

See also

[GetSrcIp\(\)](#), [GetSrcIp4\(\)](#), [GetSrcIp6wlf\(\)](#)

14.26.3.16 GetSrcIp6wlf()

```
IPADDR GetSrcIp6wlf (  
    int ifn,  
    const IPADDR & dst)
```

```
#include <ip.h>
```

Get the source IPv6 address for a specific interface and destination.

Returns the IPv6 address that should be used as the source address when sending packets to the specified destination via the specified interface.

Parameters

<i>ifn</i>	Interface number to use
<i>dst</i>	Destination IPv6 address

Returns

Local IPv6 address of the specified interface

Note

Forces use of specified interface, bypassing routing table.

See also

[GetSrcIp6\(\)](#), [GetSrcIpwlf\(\)](#), [GetSrcIpwlf4\(\)](#)

14.26.3.17 GetSrcIpwIf()

```
IPADDR GetSrcIpwIf (  
    int ifn,  
    const IPADDR & dst) [inline]  
#include <ip.h>
```

Generic function to get source IP address for an interface (IPv6 version).

This inline function provides a generic interface that automatically uses the IPv6 version when IPv6 support is compiled in.

Parameters

<i>ifn</i>	Interface number to use
<i>dst</i>	Destination IP address

Returns

Local IP address of the specified interface

See also

[GetSrcIp6wIf\(\)](#), [GetSrcIpwIf4\(\)](#)

14.26.3.18 GetSrcIpwIf4()

```
IPADDR4 GetSrcIpwIf4 (  
    int ifn,  
    const IPADDR4 dst)  
#include <ip.h>
```

Get the source IPv4 address for a specific interface and destination.

Returns the IPv4 address that should be used as the source address when sending packets to the specified destination via the specified interface. This bypasses routing table lookup and uses the specified interface directly.

Parameters

<i>ifn</i>	Interface number to use
<i>dst</i>	Destination IPv4 address

Returns

Local IPv4 address of the specified interface

Note

Forces use of the specified interface regardless of routing table.

Returns the IP address assigned to the specified interface.

The *dst* parameter may be used for interface-specific address selection.

See also

[GetSrcIp4\(\)](#), [GetSrcIpwIf\(\)](#), [GetSrcIp6wIf\(\)](#)

14.26.3.19 GetSum()

```
uint16_t GetSum (  
    uint16_t addr,  
    uint16_t count)
```

```
#include <ip.h>
```

Calculate Internet checksum for the specified data.

Computes the standard Internet checksum (RFC 1071) over the specified data. This is the standard checksum algorithm used in IP, TCP, UDP, and ICMP headers.

The algorithm sums all 16-bit words using one's complement arithmetic, then returns the one's complement of the sum.

Parameters

<i>addr</i>	Pointer to data to checksum (must be 16-bit aligned)
<i>count</i>	Number of bytes to include in checksum (should be even)

Returns

16-bit Internet checksum value

Note

Data should be 16-bit aligned for optimal performance.

If count is odd, the last byte is padded with zero.

This is the general-purpose checksum function for variable-length data.

See also

[GetSum20\(\)](#), [GetSumHdr\(\)](#)

14.26.3.20 GetSum20()

```
uint16_t GetSum20 (  
    uint32_t addr)
```

```
#include <ip.h>
```

Calculate Internet checksum for exactly 20 bytes of data.

Optimized checksum calculation for exactly 20 bytes (5 32-bit words), which is the standard size of an IP header without options. This function is significantly faster than [GetSum\(\)](#) for this common case.

Parameters

<i>addr</i>	Pointer to 20 bytes of data to checksum (must be 32-bit aligned)

Returns

16-bit Internet checksum value

Note

This is an optimized version for the common case of IP header checksums.

Data must be 32-bit aligned for correct operation.

Use [GetSum\(\)](#) if you need to checksum a different amount of data.

See also

[GetSum\(\)](#), [GetSumHdr\(\)](#)

14.26.3.21 GetSumHdr()

```
uint16_t GetSumHdr (
    PsudeoHeader & hdr,
    puint16_t addr,
    uint16_t count)
```

```
#include <ip.h>
```

Calculate Internet checksum using a pseudo-header.

Computes the Internet checksum over a pseudo-header followed by data. This is used for TCP and UDP checksum calculation, which includes a pseudo-header containing source/destination IP addresses and protocol information. The pseudo-header protects against misrouted packets but is not actually transmitted on the wire.

Parameters

<i>hdr</i>	Reference to pseudo-header structure (UDP/TCP pseudo-header)
<i>addr</i>	Pointer to data to checksum following the pseudo-header
<i>count</i>	Number of bytes in the data portion

Returns

16-bit Internet checksum value including pseudo-header and data

Note

The pseudo-header is not transmitted, but is included in checksum calculation.

Used for TCP and UDP checksum computation per RFC specifications.

Provides protection against packets delivered to wrong IP address or protocol.

See also

[GetSum\(\)](#), [GetSum20\(\)](#), [PsudeoHeader](#)

14.26.3.22 GetUdpPkt()

```
PUDPKT GetUdpPkt (
    PIPPKT pIp) [inline]
```

```
#include <ip.h>
```

Get UDP packet pointer from IP packet pointer.

Calculates the location of the UDP header by skipping past the IP header. This function accounts for variable-length IP headers (with or without options) by examining the header length field.

Parameters

$p \leftrightarrow$ <i>Ip</i>	Pointer to IP header

Returns

Pointer to UDP header, or NULL if plp is NULL

Note

If the IP header length is exactly 5 (no options), uses fast path.

Otherwise calculates offset based on header length field.

14.26.3.23 InitializeStack()

```
void InitializeStack ()
```

```
#include <ip.h>
```

Initialize the IP protocol stack.

Initializes the IP layer and underlying network infrastructure. This function should be called once during system startup, before the application calls [init\(\)](#) or configures network interfaces.

This function:

- Initializes the IP layer data structures
- Sets up the routing table
- Prepares the network interface framework
- Allocates necessary system resources

Note

Should be called once and only once before UserMain resets its priority.

The default settings use the configuration record settings.

This provides the network infrastructure for additional network interfaces.

In most applications, this is called automatically by [init\(\)](#).

14.26.3.24 IpProcessEthernetPacket()

```
void IpProcessEthernetPacket (
```

```
    PoolPtr poolPtr,
```

```
    uint16_t packetSizeInBytes)
```

```
#include <ip.h>
```

Process an Ethernet packet for IP layer handling.

This internal function is called by the Ethernet layer to insert received packets into the IP processing pipeline. It handles the transition from Ethernet frame processing to IP packet processing.

Parameters

<i>poolPtr</i>	Pointer to network buffer pool buffer containing the packet
<i>packetSizeInBytes</i>	Total size of the packet in bytes

Note

This is an internal function typically called by the Ethernet driver.

Applications should not normally call this function directly.

14.26.3.25 IsLocal4()

```
BOOL IsLocal4 (
```

```
    IPADDR4 ip,
```

```
    int ifc)
```

```
#include <ip.h>
```

Check if an IPv4 address is on the local network segment.

Determines if the specified IPv4 address is on the same network segment as the specified interface by comparing network portions of the addresses using the interface's subnet mask. This is useful for:

- Routing decisions (local vs gateway)
- [ARP](#) vs routing determination
- Network topology validation

Parameters

<i>ip</i>	IPv4 address to check
<i>ifc</i>	Interface number to check against

Returns

TRUE if the address is on the local network segment, FALSE otherwise

Note

Uses the interface's subnet mask to determine network boundaries.

Returns FALSE if the interface number is invalid.

```
IPADDR4 target = AsciiToIp4("192.168.1.100");
if (IsLocal4(target, 0)) {
    iprintf("Address is on local network - use ARP\r\n");
} else {
    iprintf("Address is remote - use gateway\r\n");
}
```

14.26.3.26 IsMyIp4()

```
BOOL IsMyIp4 (
    IPADDR4 ip,
    int ifc = -1)
```

```
#include <ip.h>
```

Check if the specified IPv4 address belongs to this device.

Determines whether the given IPv4 address is assigned to any interface on this device. Optionally checks only a specific interface.

Parameters

<i>ip</i>	IPv4 address to check
<i>ifc</i>	Interface number to check (default: -1 for all interfaces)

Returns

TRUE if the address belongs to this device, FALSE otherwise

Note

When ifc is -1, all interfaces are checked.

When ifc is specified, only that interface is checked.

Useful for determining if a packet is addressed to this device.

See also

[IsMyIp\(\)](#), [IsMyIp6\(\)](#)

14.26.3.27 IsMyIp6()

```
BOOL IsMyIp6 (
    const IPADDR & ip,
    int ifc = -1)
```

```
#include <ip.h>
```

Check if the specified IPv6 address belongs to this device.

Determines whether the given IPv6 address is assigned to any interface on this device. Optionally checks only a specific interface.

Parameters

<i>ip</i>	IPv6 address to check
<i>ifc</i>	Interface number to check (default: -1 for all interfaces)

Returns

TRUE if the address belongs to this device, FALSE otherwise

Note

When *ifc* is -1, all interfaces are checked.

Checks both link-local and global IPv6 addresses.

See also

[IsMyIp\(\)](#), [IsMyIp4\(\)](#)

14.26.3.28 Ping()

```
int Ping (
    const IPADDR & to,
    uint16_t id,
    uint16_t seq,
    uint16_t maxwaitticks,
    int size = 32) [inline]
```

```
#include <ip.h>
```

Generic ping function that uses IPv6 when IPv6 is enabled.

This inline function provides a generic ping interface that automatically uses the appropriate IPv6 ping function when IPv6 support is compiled in.

Parameters

<i>to</i>	Destination IP address to ping
<i>id</i>	ICMP identifier field
<i>seq</i>	ICMP sequence number field
<i>maxwaitticks</i>	Maximum wait time in system time ticks
<i>size</i>	Size of ping data payload in bytes (default: 32)

Returns

Same as [Ping6\(\)](#)

See also

[Ping6\(\)](#), [Ping4\(\)](#)

14.26.3.29 Ping4()

```
int Ping4 (
    IPADDR4 to,
    uint16_t id,
    uint16_t seq,
    uint16_t maxwaitticks)
```

```
#include <ip.h>
```

Send a "ping" packet and wait the specified timeout for a response.

Sends an ICMP echo request packet to the specified destination address and waits for an echo reply. The ping uses the primary network interface (usually Ethernet). For interface selection, use [Ping4ViaInterface\(\)](#).

The ping packet contains 32 bytes of ASCII data (starting with 'a' (0x61) through 0xFF) and expects an echo reply with the same data. This follows the standard ICMP echo request/reply protocol defined in RFC 792.

Parameters

<i>to</i>	Destination IPv4 address to ping
<i>id</i>	ICMP identifier field (typically process ID or sequence)
<i>seq</i>	ICMP sequence number field (typically increments per ping)
<i>maxwaitticks</i>	Maximum wait time in system time ticks. Use TICKS_PER_SECOND macro for conversion (e.g., TICKS_PER_SECOND * 5 for 5 seconds)

Returns

>=0 Number of ticks elapsed waiting for the response (successful ping) - use this for RTT -1 Timeout occurred
 - no response received within maxwaitticks -2 Error other than timeout occurred (e.g., network unreachable, invalid parameters)

```
// Ping Google DNS with a 3 second timeout
IPADDR4 google_dns = AsciiToIp4("8.8.8.8");
int result = Ping4(google_dns, 0x1234, 1, TICKS_PER_SECOND * 3);
if (result >= 0) {
    iprintf("Ping successful, RTT: %d ticks (%d ms)\r\n",
        result, result * 1000 / TICKS_PER_SECOND);
} else if (result == -1) {
    iprintf("Ping timeout - host unreachable or not responding\r\n");
} else {
    iprintf("Ping error\r\n");
}
```

See also

[Ping4ViaInterface\(\)](#), [Ping\(\)](#), [PingViaInterface\(\)](#)

14.26.3.30 Ping4ViaInterface()

```
int Ping4ViaInterface (
    IPADDR4 to,
    uint16_t id,
    uint16_t seq,
    uint16_t wait,
    int interface)
```

```
#include <ip.h>
```

Send a "ping" packet via a specific network interface and wait for a response.

Similar to [Ping4\(\)](#), but allows selection of a specific network interface for sending the ICMP echo request. This is useful in multi-homed systems where you need to control which interface is used for the ping, such as:

- Testing specific network paths
- Verifying interface connectivity
- Routing diagnostics
- Multi-WAN configurations

Parameters

<i>to</i>	Destination IPv4 address to ping
<i>id</i>	ICMP identifier field (typically process ID)
<i>seq</i>	ICMP sequence number field
<i>wait</i>	Maximum wait time in system time ticks
<i>interface</i>	Network interface number to use for sending the ping (0-based)

Returns

>=0 Number of ticks elapsed waiting for the response (successful ping) -1 Timeout occurred - no response received within wait time -2 Error other than timeout occurred (e.g., invalid interface number)

```
// Ping via interface 1 with a 2 second timeout
IPADDR4 target = AsciiToIp4("192.168.1.1");
int result = Ping4ViaInterface(target, 0x5678, 1, TICKS_PER_SECOND * 2, 1);
```

See also

[Ping4\(\)](#), [Ping\(\)](#), [PingViaInterface\(\)](#)

14.26.3.31 Ping6()

```
int Ping6 (
    const IPADDR & to,
    uint16_t id,
    uint16_t seq,
    uint16_t maxwaitticks,
    int size = 32)
```

```
#include <ip.h>
```

Send an IPv6 "ping" packet and wait the specified timeout for a response.

Sends an ICMPv6 echo request packet to the specified IPv6 destination address and waits for an echo reply. The ping uses the primary network interface. This follows the ICMPv6 echo request/reply protocol defined in RFC 4443.

Parameters

<i>to</i>	Destination IPv6 address to ping
<i>id</i>	ICMP identifier field (typically process ID)
<i>seq</i>	ICMP sequence number field (typically increments per ping)
<i>maxwaitticks</i>	Maximum wait time in system time ticks
<i>size</i>	Size of ping data payload in bytes (default: 32)

Returns

>=0 Number of ticks elapsed waiting for the response (successful ping) -1 Timeout occurred - no response received within maxwaitticks -2 Error other than timeout occurred

Note

IPv6 ping packets may traverse different paths than IPv4 pings to the same host.

Link-local addresses require the appropriate zone ID/interface specification.

See also

[Ping6ViaInterface\(\)](#), [Ping4\(\)](#), [Ping\(\)](#)

14.26.3.32 Ping6ViaInterface()

```
int Ping6ViaInterface (
    const IPADDR & to,
    uint16_t id,
    uint16_t seq,
    uint16_t wait,
    int interface,
    int size = 32)
```

```
#include <ip.h>
```

Send an IPv6 "ping" packet via a specific network interface.

Similar to [Ping6\(\)](#), but allows selection of a specific network interface for sending the ICMPv6 echo request. This is particularly important for IPv6 where link-local addresses are interface-specific.

Parameters

<i>to</i>	Destination IPv6 address to ping
<i>id</i>	ICMP identifier field (typically process ID)
<i>seq</i>	ICMP sequence number field
<i>wait</i>	Maximum wait time in system time ticks
<i>interface</i>	Network interface number to use for sending the ping
<i>size</i>	Size of ping data payload in bytes (default: 32)

Returns

>=0 Number of ticks elapsed waiting for the response (successful ping) -1 Timeout occurred - no response received within wait time -2 Error other than timeout occurred

Note

Required for pinging link-local IPv6 addresses.
Interface selection affects which source address is used.

See also

[Ping6\(\)](#), [Ping4ViaInterface\(\)](#), [PingViaInterface\(\)](#)

14.26.3.33 PingViaInterface()

```
int PingViaInterface (
    const IPADDR & to,
    uint16_t id,
    uint16_t seq,
    uint16_t wait,
    int interface,
    int size = 32) [inline]
```

```
#include <ip.h>
```

Generic ping via interface function that uses IPv6 when IPv6 is enabled.

This inline function provides a generic ping via interface that automatically uses the appropriate IPv6 ping function when IPv6 support is compiled in.

Parameters

<i>to</i>	Destination IP address to ping
<i>id</i>	ICMP identifier field
<i>seq</i>	ICMP sequence number field
<i>wait</i>	Maximum wait time in system time ticks
<i>interface</i>	Network interface number to use
<i>size</i>	Size of ping data payload in bytes (default: 32)

Returns

Same as [Ping6ViaInterface\(\)](#)

See also

[Ping6ViaInterface\(\)](#), [Ping4ViaInterface\(\)](#)

14.26.3.34 SendICMPError()

```
void SendICMPError (
    PoolPtr pBadPacket,
    uint8_t type,
    uint8_t code)
```

```
#include <ip.h>
```

Send an ICMP error message in response to a bad packet.

Generates and sends an appropriate ICMP error message in response to a malformed or problematic IP packet. The original packet data is included in the ICMP error message as required by the ICMP specification (typically the first 8 bytes of the original packet's payload).

Parameters

<i>pBadPacket</i>	Pointer to the buffer containing the problematic packet
<i>type</i>	ICMP error type code (e.g., ICMP_TYPE_DEST_UNREACHABLE)
<i>code</i>	ICMP error code within the type (e.g., ICMP_CODE_PORT_UNREACHABLE)

Note

The function automatically includes the required portion of the original packet.

ICMP error messages are rate-limited to prevent ICMP flooding.

The buffer pBadPacket is typically freed by this function.

See also

ICMP type and code definitions in [ip.h](#)

14.26.3.35 ShowIPBuffer()

```
void ShowIPBuffer (
    PoolPtr rp)
```

```
#include <ip.h>
```

Display the contents of a network buffer for diagnostic purposes.

This function provides a formatted dump of the packet contents in the specified network buffer pool buffer. The output is sent using `iprintf()` and includes both hexadecimal and ASCII representations of the packet data, making it easy to analyze packet structure and contents.

Typical output format:

- Offset in hexadecimal
- 16 bytes per line in hex
- ASCII representation of printable characters
- Non-printable characters shown as '.'

Parameters

<i>rp</i>	Packet pointer from network buffer pool to display

Note

Uses `iprintf()` for output, so output destination depends on the current `iprintf` configuration (typically serial console).

Useful for debugging network packet issues and protocol analysis.

Does not modify or free the buffer.

```
// Display contents of received packet for debugging
ShowIPBuffer(received_packet);
```

14.26.4 Variable Documentation

14.26.4.1 pFragFunc

```
FragmentProcessFunction* pFragFunc [extern]
```

```
#include <ip.h>
```

Global function pointer for fragment processing callback.

Set this pointer to your FragmentProcessFunction implementation to handle fragmented IP packets. Set to NULL (default) to disable fragment processing callbacks, in which case fragmented packets will be silently dropped.

```
void MyFragmentHandler(PoolPtr pp) {
    // Process fragmented packet
    // Store in reassembly buffer
    // Must free the buffer when done or store for later reassembly
    FreeBuffer(pp);
}

// Register the callback during initialization
pFragFunc = MyFragmentHandler;
```

Note

Default value is NULL (fragmented packets dropped).

Only one global handler can be registered.

14.26.4.2 pPromiscuousPacketFunc

```
PromiscuousPacketFunc* pPromiscuousPacketFunc [extern]
```

```
#include <ip.h>
```

Global function pointer for promiscuous packet processing callback.

Set this pointer to your PromiscuousPacketFunc implementation to handle packets not addressed to this device. Set to NULL (default) to disable promiscuous mode, in which case non-local packets will be silently dropped.

```
void MyPromiscuousHandler(PoolPtr pp) {
    // Log packet for monitoring
    ShowIPBuffer(pp);

    // MUST free the buffer when done
    FreeBuffer(pp);
}

// Register the callback
pPromiscuousPacketFunc = MyPromiscuousHandler;
```

Note

Default value is NULL (non-local packets dropped).

Ethernet interface must also be configured for promiscuous mode.

Only one global handler can be registered.

14.26.4.3 pTaskPacketFunc

```
TaskPacketFunc* pTaskPacketFunc [extern]
```

```
#include <ip.h>
```

Global function pointer for UDP task packet processing callback.

Set this pointer to your TaskPacketFunc implementation to handle UDP packets in task context. Set to NULL (default) to disable task-level UDP packet processing.

Note

Default value is NULL (task-level processing disabled).

Only one global handler can be registered.

Regular UDP socket handlers are not affected by this callback.

14.26.5 IPADDR4 Class

Classes

- class [MACADR](#)

Used to store and manipulate MAC addresses.

- class [IPADDR4](#)

Used to store and manipulate IPv4 addresses in dual stack mode.

Typedefs

- typedef class MACADR **MACADR**

Used to store and manipulate MAC addresses.

- typedef [IPADDR6](#) **IPADDR**

IPADDR Object Type (either v4 or v6)

Functions

- bool **operator==** (const [MACADR](#) &i, const [MACADR](#) &j)
Check MAC equality.
- bool **operator!=** (const [MACADR](#) &i, const [MACADR](#) &j)
Check MAC inequality.
- bool **operator>** (const [MACADR](#) &i, const [MACADR](#) &j)
Check MAC greater than.

14.26.5.1 Detailed Description

```
#include< nettypes.h>
```

The IPADDR C++ objects were created to provide a portable and easy implementation to support IPv4 and IPv6 IP addresses. There are 3 types of IPADDR objects:

- [IPADDR4](#): Used exclusively for IPv4 addresses
- IPADDR: Used for either an IPv6 or IPv4 address
- **IPADDR**: The typedef [IPADDR](#) defines a type IPADDR. Its purpose is to provide clarity that an IPADDR object can be used for both IPv4 and IPv6 addresses. Any functions called with a parameter of type IPADDR will automatically execute the correct IPv4 or IPv6 underlying function.

14.26.6 IPADDR6 Class

Classes

- class [IPADDR6](#)

Used to hold and manipulate IPv4 and IPv6 addresses in dual stack mode.

14.26.6.1 Detailed Description

```
#include< ipv6_addr.h>
```

The IPADDR C++ objects were created to provide a portable and easy implementation to support IPv4 and IPv6 IP addresses. There are 3 types of IPADDR objects:

- [IPADDR4](#): Used exclusively for IPv4 addresses
- [IPADDR6](#): Used for either an IPv6 or IPv4 address
- **IPADDR**: The typedef [IPADDR](#) defines a type [IPADDR6](#). Its purpose is to provide clarity that an IPADDR object can be used for both IPv4 and IPv6 addresses. Any functions called with a parameter of type IPADDR will automatically execute the correct IPv4 or IPv6 underlying function.

Topics

- [IPv6 DNS](#)
- [IPv6 Data Structures](#)
- [IPv6 Frame Processing](#)
- [IPv6 Multicast Constants](#)
- [IPv6 Neighbor Discovery](#)
- [IPv6 Routing](#)

Classes

- class [IPv6Interface](#)
Main IPv6 interface management class.

Functions

- void [ShowIP6Counters](#) ()
Display IPv6 counters and statistics.

14.27.1 Detailed Description

```
#include< ipv6_interface.h>
```

Core IPv6 interface operations including address management, routing, and neighbor discovery.

14.27.2 Function Documentation

14.27.2.1 ShowIP6Counters()

```
void ShowIP6Counters ()  
#include <ipv6_interface.h>  
Display IPv6 counters and statistics.  
Dumps IPv6 protocol counters to stdout for debugging and monitoring.
```

14.27.3 IPv6 DNS

Classes

- struct [IPV6_DNS](#)
IPv6 DNS server information element.

14.27.3.1 Detailed Description

```
#include< ipv6_interface.h>
```

IPv6 DNS server configuration and management.

14.27.4 IPv6 Data Structures

Classes

- struct [IPV6_ROOT_EL](#)
Base class for all IPv6 interface elements.
- struct [IPV6_ROOT_EL_CONTAINER](#)
Container for managing collections of IPv6 root elements.

- struct [IPV6_DHCPD](#)
DHCPv6 server information element.
- struct [IPV6_IA_ADDR](#)
DHCPv6 Identity Association address element.

Enumerations

- enum [IPV6_ROOT_EL_TYPE](#) {
[IPV6_ROOT_TYPE_EL](#) = 0 , [IPV6_ROOT_TYPE_EL_CONTAINER](#) = 1 , [IPV6_ROOT_TYPE_ROUTER](#) = 2
, [IPV6_ROOT_TYPE_DHCPD](#) = 3 ,
[IPV6_ROOT_TYPE_PREFIX](#) = 4 , [IPV6_ROOT_TYPE_DNS](#) = 5 , [IPV6_ROOT_TYPE_NEIGHBOR](#) = 6 ,
[IPV6_ROOT_TYPE_DEST](#) = 7 }
IPv6 root element types enumeration.

14.27.4.1 Detailed Description

```
#include< ipv6_interface.h>
```

Core data structures for IPv6 interface management.

14.27.4.2 Enumeration Type Documentation

14.27.4.2.1 IPV6_ROOT_EL_TYPE

```
enum IPV6\_ROOT\_EL\_TYPE
#include <ipv6_interface.h>
```

IPv6 root element types enumeration.
Defines the different types of elements that can be stored in IPv6 interface containers.

Enumerator

IPV6_ROOT_TYPE_EL	Base root element.
IPV6_ROOT_TYPE_EL_CONTAINER	Element container.
IPV6_ROOT_TYPE_ROUTER	Router element.
IPV6_ROOT_TYPE_DHCPD	DHCPv6 server element.
IPV6_ROOT_TYPE_PREFIX	Address prefix element.
IPV6_ROOT_TYPE_DNS	DNS server element.
IPV6_ROOT_TYPE_NEIGHBOR	Neighbor cache element.
IPV6_ROOT_TYPE_DEST	Destination cache element.

14.27.5 IPv6 Frame Processing

Classes

- struct [IPv6FrameProcessingStruct](#)
IPv6 frame processing structure for packet analysis and header walking.

14.27.5.1 Detailed Description

```
#include< ipv6_interface.h>
```

IPv6 packet processing and header walking functionality.

14.27.6 IPv6 Multicast Constants

Macros

- `#define ADDR_ALL_NODES_LINK_LOCAL IPADDR6::AsciiToIp6("FF02::1")`
All nodes on the local link.
- `#define ADDR_ALL_ROUTERS_LINK_LOCAL IPADDR6::AsciiToIp6("FF02::2")`
All routers on the local link.
- `#define ADDR_ALL_NB_LINK_LOCAL IPADDR6::AsciiToIp6("FF02::4e42")`
All NetBurner devices on the local link.
- `#define ADDR_UNICAST_LINK_LOCAL_PREFIX IPADDR6::AsciiToIp6("FE80::")`
Link-local unicast prefix.
- `#define ADDR_MLDV2_REPORTS IPADDR6::AsciiToIp6("FF02::16")`
MLDv2 reports multicast address.
- `#define IPV6_MULTICAST_NODE_LOCAL 0xFF01`
Node-local multicast scope.
- `#define IPV6_MULTICAST_LINK_LOCAL 0xFF02`
Link-local multicast scope.
- `#define IPV6_MULTICAST_REALM_LOCAL 0xFF03`
Realm-local multicast scope.
- `#define IPV6_MULTICAST_ADMIN_LOCAL 0xFF04`
Admin-local multicast scope.
- `#define IPV6_MULTICAST_SITE_LOCAL 0xFF05`
Site-local multicast scope.
- `#define IPV6_MULTICAST_ORG_LOCAL 0xFF08`
Organization-local multicast scope.
- `#define IPV6_MULTICAST_GLOBAL 0xFF0E`
Global multicast scope.

14.27.6.1 Detailed Description

```
#include< ipv6_interface.h>
```

Standard IPv6 multicast addresses and scope constants.

14.27.7 IPv6 Neighbor Discovery

Classes

- struct `IPV6_NEIGHBOR`
IPv6 neighbor cache element.

Enumerations

- enum `eMY_NEIGHBOR_STATE` {
 `eIncomplete` , `eReachable` , `eStale` , `eDelay` ,
 `eProbe` }
IPv6 neighbor states enumeration.

14.27.7.1 Detailed Description

```
#include< ipv6_interface.h>
```

IPv6 Neighbor Discovery protocol support and neighbor cache management.

14.27.7.2 Enumeration Type Documentation

14.27.7.2.1 eMY_NEIGHBOR_STATE

enum [eMY_NEIGHBOR_STATE](#)

```
#include <ipv6_interface.h>
```

IPv6 neighbor states enumeration.

Defines the various states a neighbor entry can be in according to RFC 4861.

Enumerator

eIncomplete	Address resolution in progress.
eReachable	Reachability confirmed within ReachableTime.
eStale	More than ReachableTime since reachability was confirmed.
eDelay	More than ReachableTime, packet sent, waiting for upper layer.
eProbe	Actively probing neighbor reachability.

14.27.8 IPv6 Routing

Classes

- struct [IPV6_ROUTER](#)
IPv6 router information element.
- struct [IPV6_PREFIX](#)
IPv6 prefix and address management element.
- struct [IPV6_DEST](#)
IPv6 destination cache element.

Enumerations

- enum [eMY_ADDR_STATE](#) { [eTenative](#) , [eValid_Preferred](#) , [eValid_Depricated](#) , [eInvalid](#) }
IPv6 address states enumeration.
- enum [ePrefixSource](#) {
 [eLinkLocal](#) , [eRouter](#) , [eDHCP](#) , [eStatic](#) ,
 [eUnknown](#) }
IPv6 prefix source enumeration.
- enum [eRouteOutResult](#) { [eSent](#) , [eDoingND](#) , [eNoRoute](#) }
Route output result enumeration.

14.27.8.1 Detailed Description

```
#include< ipv6_interface.h>
```

IPv6 routing and destination management functionality.

14.27.8.2 Enumeration Type Documentation

14.27.8.2.1 eMY_ADDR_STATE

enum [eMY_ADDR_STATE](#)

```
#include <ipv6_interface.h>
```

IPv6 address states enumeration.

Defines the various states an IPv6 address can be in during its lifecycle.

Enumerator

eTentative	Address is tentative (duplicate address detection in progress)
eValid_Preferred	Address is valid and preferred.
eValid_Deprecated	Address is valid but deprecated.
eInvalid	Address is invalid.

14.27.8.2.2 ePrefixSource

```
enum ePrefixSource
#include <ipv6_interface.h>
```

IPv6 prefix source enumeration.
Identifies how an IPv6 prefix was obtained.

Enumerator

eLinkLocal	Link-local address.
eRouter	From router advertisement.
eDHCP	From DHCPv6.
eStatic	Statically configured.
eUnknown	Unknown source.

14.27.8.2.3 eRouteOutResult

```
enum eRouteOutResult
#include <ipv6_interface.h>
```

Route output result enumeration.
Results from attempting to route a packet to a destination.

Enumerator

eSent	Packet was sent successfully.
eDoingND	Performing neighbor discovery.
eNoRoute	No route available.

14.28 Initialization - System Initialization Functions

Classes

- struct [listen_list_item](#)
Structure to use to create custom lists of listening ports and interfaces.

Functions

- void [init](#) ()
System initialization. Ideally called at the beginning of all applications, since the easiest Recovery procedures pause execution inside of `init`, which is impossible if there is a crash before `init`.
- void [StartHttp](#) (uint16_t port=80)
Start the HTTP web server.
- void [StartHttps](#) (uint16_t ssl_port=443, uint16_t http_port=80)
Start the HTTPS secure web server.
- void [SetHttpsPointers](#) ()

If you are both using the Start Custom below and using https you must call this.

- void [StartHttpCustom](#) ([listen_list_item](#) *pList_Of_Listens)
Start the HTTP web server with a custom list of listen ports.
- bool [WaitForActiveNetwork](#) (uint32_t ticks_to_wait=120 *[TICKS_PER_SECOND](#), int interface=-1)
Wait for an active network connection on at least one interface.
- void [EnableSystemDiagnostics](#) ()
Turn on the diagnostic reports from the config page.
- void [EnableSecureConfigServer](#) (bool bSec_Only)
Enable the minimal http config server to operate over TLS.

14.28.1 Detailed Description

```
#include< init.h>
```

14.28.2 Function Documentation

14.28.2.1 EnableSecureConfigServer()

```
void EnableSecureConfigServer (
    bool bSec_Only)
```

```
#include <init.h>
```

Enable the minimal http config server to operate over TLS.

Due to the nature of the server operating on a non-standard HTTP port, a client (such as a webbrowser) cannot infer whether to utilize TLS unless explicitly told to do so. Therefore, the secure configuration server has two modes it can operate in: a less secure, more compliant manner that allows both plaintext and TLS secured transactions and a HSTS (Http Strict Transport Security) mode that will only respond to plaintext requests with a redirect indicating the TLS requirement.

Parameters

<i>bSec_Only</i>	Whether the SecureConfigServer should disallow non-secure requests

14.28.2.2 EnableSystemDiagnostics()

```
void EnableSystemDiagnostics ()
#include <init.h>
```

Turn on the diagnostic reports from the config page.

This should be used under development. In production it has no performance impact, but could leak possibly sensitive information.

14.28.2.3 init()

```
void init ()
#include <init.h>
```

System initialization. Ideally called at the beginning of all applications, since the easiest Recovery procedures pause execution inside of `init`, which is impossible if there is a crash before `init`.

Initialize the system including the following:

- Enable interrupt driven stdio
- Read the configuration record and set parameters accordingly. If the configuration specifies [DHCP](#), start the [DHCP](#) Client. All interfaces will be checked.
- Initialize the network stack

- Start the configuration server for both web and serial
- Assign the UserMain() task priority to MAIN_PRIO
- Enable the Task Monitor diagnostic tool
- Initialize the GDB stub if in debug mode

14.28.2.4 StartHttp()

```
void StartHttp (
    uint16_t port = 80)
```

```
#include <init.h>
```

Start the HTTP web server.

If no parameters are specified it will listen on port 80, and enable the configuration mirror feature so an application can create its own custom configuration web page.

Parameters

<i>port</i>	Listen port, defaults to port 80

See also

[StartHttps\(\)](#), [StopHttp\(\)](#)

14.28.2.5 StartHttpCustom()

```
void StartHttpCustom (
    listen_list_item * pList_Of_Listens)
```

```
#include <init.h>
```

Start the HTTP web server with a custom list of listen ports.

If no parameters are specified it will listen on port 80, and enable the configuration mirror feature so an application can create its own custom configuration web page.

Parameters

<i>pList_Of_Listens</i>	A static array of listening sockets the last entry must be zero.

See also

[StartHttps\(\)](#), [StopHttp\(\)](#) [SetHttpsPointers\(\)](#);

14.28.2.6 StartHttps()

```
void StartHttps (
    uint16_t ssl_port = 443,
    uint16_t http_port = 80)
```

```
#include <init.h>
```

Start the HTTPS secure web server.

If no parameters are specified the web server will listen on ports 443 and 80, and enable the configuration mirror feature so an application can create its own custom configuration web page. If no user key is installed the default system key will be used.

Parameters

<i>ssl_port</i>	Secure listen port, defaults to port 443
<i>http_port</i>	Non-secure listen port, defaults to port 80

See also

[StartHttp\(\)](#), [StopHttp\(\)](#)

14.28.2.7 WaitForActiveNetwork()

```
bool WaitForActiveNetwork (
    uint32_t ticks_to_wait = 120 *TICKS_PER_SECOND,
    int interface = -1)
#include <init.h>
```

Wait for an active network connection on at least one interface.

If [DHCP](#) is enabled it will wait for a lease. If static IP parameters are configured it will wait for link.

Parameters

<i>ticks_to_wait</i>	Number of system time ticks to wait. Default is 120 seconds.
<i>interface</i>	Interface number to check. Default is -1, which checks all interfaces.

14.29 JSON Lexer

NetBurner's JSON library. See more details and examples below.

Classes

- struct [JsonAllocString](#)
A list of large strings that are created with malloc.
- class [JsonRef](#)
Represents a positional reference (pointer) of a location inside a [ParsedJsonDataSet](#) object.
- class [ParsedJsonDataSet](#)
A class to create, read, and modify a JSON object.
- class [JsonLexerFDAdapter](#)
Get the type name of the JSON primitive type passed in.

Typedefs

- typedef void [CharOutputFn](#)(const char *chars, int len, void *blob)
Helper function typedef for print functions.

Enumerations

- enum [json_primitive_type](#) {
[UNDEFINED](#) , [BEGIN_ARRAY](#) , [BEGIN_OBJECT](#) , [END_ARRAY](#) ,
[END_OBJECT](#) , [NAME](#) , [STRING](#) , [VALUE_SEPERATOR](#) ,
[NUMBER](#) , [FALSE_EL](#) , [TRUE_EL](#) , [NULL_EL](#) ,
[STRING_TOO_BIG](#) , [STRING_CHUNK](#) , [ALLOC_STRING](#) , [NOTFOUND](#) ,
[EOF_EL](#) }

The following types define the basic building blocks that make up a JSON data set. These are the values that will be returned from the functions used to parse the data set. Member functions include operators to return specific data type, as well as type validity checks.

14.29.1 Detailed Description

NetBurner's JSON library. See more details and examples below.

```
#include< json_lexer.h>
```

The library enables rapid, performant parsing, traversal, and querying of JSON data. It also works seamlessly as a [buffer_object](#) for the [Web Client](#)'s [DoGet\(\)](#) function.

[ParsedJsonDataSet](#) is the root object that holds the document, and [JsonRef](#) is the result of each query function, serving as a pointer to a location in the document but also as a chainable query and inspection interface.

See also the [JSON Lexer Example Applications](#).

Example

```
ParsedJsonDataSet pjd;
bool result = DoGet("https://www.example.com/users.json", pjd);
// pjd.PrintObject(true);
// pjd("users").PrintChildren(true);
if (!result ||
    !pjd("users")[0].IsObject() ||
    !pjd("users")[0]("id").IsNumber() ||
    !pjd("users")[0]("name").IsString()
) {
    return false;
}
printf("Got user %d name %s",
       (int)pjd("users")[0]("id"),
       (const char *)pjd("users")[0]("name")
);
```

14.29.2 Typedef Documentation

14.29.2.1 CharOutputFn

```
typedef void CharOutputFn(const char *chars, int len, void *blob)
```

```
#include <json_lexer.h>
```

Helper function typedef for print functions.

Parameters

<i>chars</i>	The characters to print.
<i>len</i>	The length of the characters to print.
<i>blob</i>	A pointer to where they should be printed.

14.29.3 Enumeration Type Documentation

14.29.3.1 json_primitive_type

```
enum json_primitive_type
#include <json_lexer.h>
```

The following types define the basic building blocks that make up a JSON data set. These are the values that will be returned from the functions used to parse the data set. Member functions include operators to return specific data type, as well as type validity checks.

Enumerator

UNDEFINED	Not a defined primitive type. This indicates an error somewhere.
BEGIN_ARRAY	[- Signals the start of an array.
BEGIN_OBJECT	{ - Signals the start of an object.
END_ARRAY	] - Signals the end of an array.
END_OBJECT	} - Signals the end of an object.
NAME	"xxx": - Signals the name of a name/value pair.
STRING	"xxx" - An element with a string value.

Enumerator

VALUE_SEPERATOR	, - Signals the separation between to arrays, objects, or values.
NUMBER	An element with a number value.
FALSE_EL	An element with the value false.
TRUE_EL	An element with the value true.
NULL_EL	An element with the null value.
STRING_TOO_BIG	Error, we got a sting but it was too big to fit in the storage scheme (1500 bytes).
STRING_CHUNK	Not quiet an error, but we got a sting but it was too big to fit in the storage scheme (1500 bytes).
ALLOC_STRING	We allocated a large string.
NOTFOUND	Return value when we don't find what we are looking for.
EOF_EL	Last token in the data set.

14.30 MQTT

NetBurner [MQTT](#) Library.

See the [MQTT](#) namespace for details.

```
#include <mqtt/mqtt.h>
```

Namespaces

- namespace [MQTT](#)
[MQTT](#) Namespace.

Macros

- #define **MQTT_WAIT** ([TICKS_PER_SECOND](#)*10)
- #define **MQTT_TLS_NEGOTIATE_TIMEOUT** ([TICKS_PER_SECOND](#)*50)
- #define **MQTT_OBJ_PRIORITY_COUNT** (16)
- #define **MQTT_OBJ_PRIORITY_MAX** 0
- #define **MQTT_OBJ_PRIORITY_MIN** 15
- #define **MQTT_MAX_PKT_SIZE** (0x2FFFFFFF)
- #define **MQTT_MAX_MAX_SUPPORTED_IN_FLIGHT** (256)
- #define **MQTT_MAX_SUPPORTED_IN_FLIGHT** (16)
- #define **MQTT_MAX_HANDLERS_PER_CONNECTION** (256)
- #define **MQTT_MAX_SUPPORTED_RX_TOPIC_ALIASES** (128)
- #define **MQTT_DEFAULT_SESSION_EXPIRY_INTERVAL** (3600)
- #define **MQTT_DEFAULT_KEEP_ALIVE** (30)
- #define **MQTT_MAX_SUB_IDS** (128)

14.30.1 Detailed Description

NetBurner [MQTT](#) Library.

See the [MQTT](#) namespace for details.

```
#include <mqtt/mqtt.h>
```

To easily begin using [MQTT](#), review the Simple [MQTT](#) example in the Examples folder. In general, all that's needed is:

- `#include <mqtt/mqtt.h>`
- `MQTT::ConfiguredClient mqttClient;`
- and optionally some kind of [MQTT](#) variable like `MQTT::mqtt_int myInt("myIntTopic");`

As soon as an [MQTT](#) client exists in your code, an [MQTT](#) section will be added to your device's Configuration page allowing you to set a broker hostname, Client ID, and other connection or security details.

14.31 Multicast

Functions

- void [RegisterMulticastFifo4](#) ([IPADDR4](#) group, uint16_t dest_port, OS_FIFO *pfifo, int interface=0)
Register to join a Multicast group.
- void [UnregisterMulticastFifo4](#) ([IPADDR4](#) group, uint16_t destination_port, int interface=0)
Unregister from a Multicast group.
- void [RegisterMulticastFifo6](#) ([IPADDR](#) group, uint16_t dest_port, OS_FIFO *pfifo, int interface=0)
Register to join a Multicast group.
- void [UnregisterMulticastFifo6](#) ([IPADDR](#) group, uint16_t destination_port, int interface=0)
Unregister from a Multicast group.

14.31.1 Detailed Description

```
#include< multicast.h>
```

The NetBurner Multicast API

14.31.2 Function Documentation

14.31.2.1 RegisterMulticastFifo4()

```
void RegisterMulticastFifo4 (
    IPADDR4 group,
    uint16_t dest_port,
    OS_FIFO * pfifo,
    int interface = 0)
```

```
#include <multicast.h>
```

Register to join a Multicast group.

Calling RegisterMulticastFifo() in dual stack mode will automatically select the correct IPv4/IPv6 function.

IGMP Multicast is a method for distributing UDP packets within a group of hosts and servers. The NetBurner Multicast functions extend the NetBurner UDP interface. Instead of [RegisterUDPFifo\(\)](#), the RegisterMulticastFifo() function is used to listen for Multicast UDP packets. To transmit Multicast packets, use the UDP Send function with a multicast IP address.

Parameters

<i>group</i>	The IP address of the group to join
<i>dest_port</i>	The port number of the group to join
<i>pfifo</i>	Pointer to the FIFO to store incoming packets

<i>interface</i>	Optional interface number. If not specified or 0, the first system interface will be used.

See also

[UnregisterMulticastFifo4\(\)](#)

14.31.2.2 RegisterMulticastFifo6()

```
void RegisterMulticastFifo6 (
    IPADDR group,
    uint16_t dest_port,
    OS_FIFO * pfifo,
    int interface = 0)
```

```
#include <multicast.h>
```

Register to join a Multicast group.

Calling RegisterMulticastFifo() in dual stack mode will automatically select the correct IPv4/IPv6 function.

IGMP Multicast is a method for distributing UDP packets within a group of hosts and servers. The NetBurner Multicast functions extend the NetBurner UDP interface. Instead of [RegisterUDPFifo\(\)](#), the RegisterMulticastFifo() function is used to listen for Multicast UDP packets. To transmit Multicast packets, use the UDP Send function with a multicast IP address.

Parameters

<i>group</i>	The IP address of the group to join
<i>dest_port</i>	The port number of the group to join
<i>pfifo</i>	Pointer to the FIFO to store incoming packets
<i>interface</i>	Optional interface number. If not specified or 0, the first system interface will be used.

See also

[UnregisterMulticastFifo4\(\)](#)

14.31.2.3 UnregisterMulticastFifo4()

```
void UnregisterMulticastFifo4 (
    IPADDR4 group,
    uint16_t destination_port,
    int interface = 0)
```

```
#include <multicast.h>
```

Unregister from a Multicast group.

Calling UnregisterMulticastFifo() in dual stack mode will automatically select the correct IPv4/IPv6 function.

Parameters

<i>group</i>	The IP address of the group to leave
<i>destination_port</i>	The port number of the group to leave
<i>interface</i>	Specifies the interface number, the default is 0

See also

[RegisterMulticastFifo4\(\)](#)

14.31.2.4 UnregisterMulticastFifo6()

```
void UnregisterMulticastFifo6 (
    IPADDR group,
    uint16_t destination_port,
    int interface = 0)
```

#include <multicast.h>

Unregister from a Multicast group.

Calling UnregisterMulticastFifo() in dual stack mode will automatically select the correct IPv4/IPv6 function.

Parameters

<i>group</i>	The IP address of the group to leave
<i>destination_port</i>	The port number of the group to leave
<i>interface</i>	Optional interface number. If not specified or 0, the first system interface will be used.

See also

[RegisterMulticastFifo4\(\)](#)

14.32 Multihome and VLAN

Functions

- int [AddVlanInterface](#) (IPADDR4 addr, IPADDR4 mask, IPADDR4 gateway, uint16_t vlan_tag, const char *ParentName)
Add a VLAN interface with a Parent Name.
- int [AddVlanInterface](#) (IPADDR4 addr, IPADDR4 mask, IPADDR4 gateway, uint16_t vlan_tag, [InterfaceBlock](#) &parent)
Add a VLAN interface with a Parent [InterfaceBlock](#) reference.
- int [AddVlanInterface](#) (IPADDR4 addr, IPADDR4 mask, IPADDR4 gateway, uint16_t vlan_tag, int root_if=0)
Add a VLAN interface with an interface number.
- int [AddInterface](#) (IPADDR4 addr, IPADDR4 mask, IPADDR4 gateway, const char *ParentName)
Add an interface with a Parent Name.
- int [AddInterface](#) (IPADDR4 addr, IPADDR4 mask, IPADDR4 gateway, [InterfaceBlock](#) &parent)
Add an interface with a Parent [InterfaceBlock](#) reference.
- int [AddInterface](#) (IPADDR4 addr, IPADDR4 mask, IPADDR4 gateway, int root_if)
Add an interface with an interface number.

14.32.1 Detailed Description

```
#include< multihome.h>
```

Create Multihome and VLAN Interfaces

14.32.2 Function Documentation

14.32.2.1 AddInterface() [1/3]

```
int AddInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
    const char * ParentName) [inline]
```

#include <multihome.h>

Add an interface with a Parent Name.

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>ParentName</i>	Name of parent physical interface, such as Ethernet0.

returns Interface number of newly created interface

14.32.2.2 AddInterface() [2/3]

```
int AddInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
    int root_if) [inline]
#include <multihome.h>
Add an interface with an interface number.
Add a new network interface with the specified configuration.
```

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>root_if</i>	Optional root physical interface number. If not specified the default is 0, for Ethernt 0.

Returns

Interface number of newly created interface

14.32.2.3 AddInterface() [3/3]

```
int AddInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
    InterfaceBlock & parent) [inline]
#include <multihome.h>
Add an interface with a Parent InterfaceBlock reference.
```

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>parent</i>	Reference to parent physical interface of type InterfaceBlock .

returns Interface number of newly created interface

14.32.2.4 AddVlanInterface() [1/3]

```
int AddVlanInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
```

```

        uint16_t vlan_tag,
        const char * ParentName)
#include <multihome.h>
Add a VLAN interface with a Parent Name.

```

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>vlan_tag</i>	VLAN tag/id for interface
<i>ParentName</i>	Name of parent physical interface, such as Ethernet0.

returns Interface number of newly created VLAN interface

14.32.2.5 AddVlanInterface() [2/3]

```

int AddVlanInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
    uint16_t vlan_tag,
    int root_if = 0)
#include <multihome.h>
Add a VLAN interface with an interface number.

```

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>vlan_tag</i>	VLAN tag/id for interface
<i>root_if</i>	Optional root physical interface number. If not specified the default is 0 for Ethernet 0.

returns Interface number of newly created VLAN interface

14.32.2.6 AddVlanInterface() [3/3]

```

int AddVlanInterface (
    IPADDR4 addr,
    IPADDR4 mask,
    IPADDR4 gateway,
    uint16_t vlan_tag,
    InterfaceBlock & parent)
#include <multihome.h>
Add a VLAN interface with a Partent InterfaceBlock reference.

```

Parameters

<i>addr</i>	IP address of new interface
<i>mask</i>	IP mask
<i>gateway</i>	IP gateway
<i>vlan_tag</i>	VLAN tag/id for interface
<i>parent</i>	Reference to parent physical interface of type InterfaceBlock

returns Interface number of newly created VLAN interface

14.33 NBRTOS Real Time Operating System

```
#include< nbrtos.h>
```

The NetBurner Real-Time OS

14.34 NBString - NetBurner String Class

Classes

- class [NBString](#)
Lightweight alternative to C++ CString class.
- class [NBInterpolatedString](#)
A wrapper for [NBString::Interpolate\(\)](#) ideal for easy access to ephemeral values.

14.34.1 Detailed Description

```
#include< nbstring.h>
```

The NetBurner lightweight String Class alternative to CString.

14.35 Network Interfaces

Network Interface Functions.

Topics

- [IPADDR4 Functions](#)
Network Interface functions with [IPADDR4](#) return types.
- [Low Level Processing \(NetDoRx\)](#)
Callback functions to add custom Ethernet handlers and pass Ethernet frames at the bottom of the TCP/IP stack.

Classes

- class [InterfaceBlock](#)
Network interface configuration block class for interface control and configuration.

Functions

- void **showIpAddresses** ()
Print system IP addresses to stdout.
- int [Removeinterface](#) (int interface)
Remove a network interface from the system.
- void [EnableMulticast](#) ([MACADR](#) macAddress, int interface=0)
Enable Multicast on an existing interface.
- void [DisableMulticast](#) ([MACADR](#) macAddress, int interface=0)
Disable Multicast on an existing interface.
- [InterfaceBlock](#) * [GetInterfaceBlock](#) (int interface=0)
Get an [InterfaceBlock](#) control and configuration object.
- int32_t [GetFirstInterface](#) (void)
Returns the Interface Number of the first registered network interface.
- int32_t [GetNextInterface](#) (int lastInterface)

- Returns the Interface Number of the next registered network interface.*
- `int32_t GetInterfaceNumber (InterfaceBlock *pifb)`
Returns the Interface Number of the specified network interface [InterfaceBlock](#).
- `int32_t GetInterfaceForMyAddress4 (IPADDR4 ip)`
Returns the Interface Number of the specified network interface IPv4 address.
- `bool GetInterfaceLink (int ifn)`
Returns the network interface link status.
- `MACADDR InterfaceMAC (int interface)`
Returns the MAC address of the specified network interface.
- `bool InterfaceLinkActive (int interface)`
Returns the link status of the specified network interface.
- `int InterfaceLinkSpeed (int interface)`
Returns the 10/100 link speed of the specified network interface.
- `bool InterfaceLinkDuplex (int interface)`
Returns the full or half link duplex of the specified network interface.
- `const char * InterfaceName (int interface)`
Returns the interface name of the specified network interface.

14.35.1 Detailed Description

Network Interface Functions.

Network interface management and low-level frame processing.

```
#include< ipshow.h>
```

```
#include< netinterface.h>
```

Network Interfaces are configured and controlled C++ [InterfaceBlock](#) objects. The [InterfaceBlock](#) contains variables and member functions for things such as:

- The Configuration Server interface
- IP settings for both IPv4 and IPv6 types
- Configuration to static or [DHCP](#), and [DHCP](#) status (both v4 and v6)
- Multihome
- Routing
- AutoIP

Note

While the recommended method for getting and setting network interface parameters is to obtain a pointer to an [InterfaceBlock](#), there are also non-member functions of the object that can be used for situations that are best served by a single function call, such as just getting a single IP address of an interface. When using those functions pay special attention to the return value type. While `IPADDR` should be used because it supports both [IPADDR4](#) and [IPADDR6](#) types automatically, some of these helper functions may specifically return an [IPADDR4](#) type.

```
#include< netrx.h>
```

14.35.2 Function Documentation

14.35.2.1 DisableMulticast()

```
void DisableMulticast (
    MACADDR macAddress,
    int interface = 0)
#include <netinterface.h>
```

Disable Multicast on an existing interface.
Calls registered interface multicast routine.

Parameters

<i>macAddress</i>	Multicast MAC address.
<i>interface</i>	Interface number. If not specified or 0, operates on the first registerd interface.

See also

[EnableMulticast\(MACADDR macAddress, int interface\)](#), [InterfaceBlock::EnableMulticast\(\)](#)

14.35.2.2 EnableMulticast()

```
void EnableMulticast (
    MACADDR macAddress,
    int interface = 0)
#include <netinterface.h>
```

Enable Multicast on an existing interface.
Calls registered interface multicast routine.

Parameters

<i>macAddress</i>	Multicast MAC address.
<i>interface</i>	Interface number. If not specified, default is is 0.

See also

[DisableMulticast\(\)](#), [InterfaceBlock::EnableMulticast\(\)](#)

14.35.2.3 GetFirstInterface()

```
int32_t GetFirstInterface (
    void )
#include <netinterface.h>
```

Returns the Interface Number of the first registered network interface.
If called on a device with wired Ethernet, this will be the first Ethernet interface typical interface number 1.

Returns

Interface number of the first network interface, or 0 if none exist.

14.35.2.4 GetInterfaceBlock()

```
InterfaceBlock * GetInterfaceBlock (
    int interface = 0)
#include <netinterface.h>
```

Get an [InterfaceBlock](#) control and configuration object.

Parameters

<i>interface</i>	Interface number. If not specified or 0, operates on the first registered interface.

Returns

Pointer to an [InterfaceBlock](#) on success, Null if requested interface is invalid.

14.35.2.5 GetInterfaceForMyAddress4()

```
int32_t GetInterfaceForMyAddress4 (
    IPADDR4 ip)
```

```
#include <netinterface.h>
```

Returns the Interface Number of the specified network interface IPv4 address.

Parameters

<i>ip</i>	IPv4 network interface address.

Returns

Interface number of the specified IPv4 address

14.35.2.6 GetInterfaceLink()

```
bool GetInterfaceLink (
    int ifn)
```

```
#include <netinterface.h>
```

Returns the network interface link status.

Parameters

<i>ifn</i>	Network interface number

Returns

True if link, otherwise false

See also

[InterfaceBlock::LinkActive\(\)](#), [InterfaceLinkActive\(\)](#)

14.35.2.7 GetInterfaceNumber()

```
int32_t GetInterfaceNumber (
    InterfaceBlock * pifb)
```

```
#include <netinterface.h>
```

Returns the Interface Number of the specified network interface [InterfaceBlock](#).

Parameters

<i>pifb</i>	Pointer to the InterfaceBlock

Returns

Interface number of the [InterfaceBlock](#).

See also

[InterfaceBlock::GetInterfaceNumber\(\)](#)

14.35.2.8 GetNextInterface()

```
int32_t GetNextInterface (
    int lastInterface)
#include <netinterface.h>
```

Returns the Interface Number of the next registered network interface.

Parameters

<i>lastInterface</i>	Specifies the interface number starting point to begin search.

Returns

Interface number of the next network interface, or 0 if none exist.

14.35.2.9 InterfaceLinkActive()

```
bool InterfaceLinkActive (
    int interface)
#include <netinterface.h>
```

Returns the link status of the specified network interface.

Parameters

<i>interface</i>	Interface number

Returns

True if link is active, otherwise false

See also

[InterfaceBlock::LinkActive\(\)](#), [GetInterfaceLink\(\)](#)

14.35.2.10 InterfaceLinkDuplex()

```
bool InterfaceLinkDuplex (
    int interface)
#include <netinterface.h>
```

Returns the full or half link duplex of the specified network interface.

Parameters

<i>interface</i>	Interface number

Returns

True if full duplex, false if half duplex

See also

[InterfaceBlock::LinkDuplex\(\)](#)

14.35.2.11 InterfaceLinkSpeed()

```
int InterfaceLinkSpeed (
    int interface)
#include <netinterface.h>
```

Returns the 10/100 link speed of the specified network interface.

Parameters

<i>interface</i>	Interface number

Returns

10 or 100 representing the Mbps speed

See also

[InterfaceBlock::LinkSpeed\(\)](#)

14.35.2.12 InterfaceMAC()

```
MACADDR InterfaceMAC (  
    int interface)  
#include <netinterface.h>  
Returns the MAC address of the specified network interface.
```

Parameters

<i>interface</i>	Interface number

Returns

MAC address of type [MACADDR](#)

14.35.2.13 InterfaceName()

```
const char * InterfaceName (  
    int interface)  
#include <netinterface.h>  
Returns the interface name of the specified network interface.
```

Parameters

<i>interface</i>	Interface number

Returns

Pointer to a character string containing the name of the network interface

See also

[InterfaceBlock::GetInterfaceName\(\)](#)

14.35.2.14 Removeinterface()

```
int Removeinterface (  
    int interface)  
#include <netinterface.h>  
Remove a network interface from the system.
```

Parameters

<i>interface</i>	Interface number

Returns

1 if successful, 0 if invalid interface number

See also

[InterfaceBlock::RegisterInterface\(\)](#)

14.35.3 IPADDR4 Functions

Network Interface functions with [IPADDR4](#) return types.

Functions

- [IPADDR4 InterfaceIP](#) (int interface)
Returns the IPv4 IP address of the specified network interface.
- [IPADDR4 InterfaceAutoIP](#) (int interface)
Returns the IPv4 IP AutoIP address of the specified network interface.
- [IPADDR4 InterfaceDNS](#) (int interface)
Returns the IPv4 DNS address of the specified network interface.
- [IPADDR4 InterfaceDNS2](#) (int interface)
Returns the second IPv4 DNS address of the specified network interface.
- [IPADDR4 InterfaceMASK](#) (int interface)
Returns the IPv4 network mask of the specified network interface.
- [IPADDR4 InterfaceGate](#) (int interface)
Returns the IPv4 gateway address of the specified network interface.
- bool [HaveActiveNetwork](#) (int interface=-1)
Returns the network routability of the specified network interface.

14.35.3.1 Detailed Description

Network Interface functions with [IPADDR4](#) return types.

```
#include< netinterface.h>
```

Note

While the recommended method for getting and setting network interface parameters is to obtain a pointer to an [InterfaceBlock](#), there are also non-member functions of the object that can be used for situations that are best served by a single function call, such as just getting a single IP address of an interface. When using those functions pay special attention to the return value type. While IPADDR should be used because it supports both [IPADDR4](#) and [IPADDR6](#) types automatically, some of these helper functions may specifically return an [IPADDR4](#) type.

14.35.3.2 Function Documentation**14.35.3.2.1 HaveActiveNetwork()**

```
bool HaveActiveNetwork (
    int interface = -1)
#include <netinterface.h>
```

Returns the network routability of the specified network interface.

Parameters

<i>interface</i>	Interface number, -1 for Any Interface

Returns

True if interface is routable, otherwise false

See also

[InterfaceBlock::LinkActive\(\)](#), [GetInterfaceLink\(\)](#)

14.35.3.2.2 InterfaceAutoIP()

```
IPADDR4 InterfaceAutoIP (  
    int interface)  
#include <netinterface.h>
```

Returns the IPv4 IP AutoIP address of the specified network interface.

Parameters

<i>interface</i>	Interface number

Returns

IPv4 IP address of type [IPADDR4](#)

14.35.3.2.3 InterfaceDNS()

```
IPADDR4 InterfaceDNS (  
    int interface)  
#include <netinterface.h>
```

Returns the IPv4 DNS address of the specified network interface.

Parameters

<i>interface</i>	Interface number

Returns

IPv4 IP address of type [IPADDR4](#)

14.35.3.2.4 InterfaceDNS2()

```
IPADDR4 InterfaceDNS2 (  
    int interface)  
#include <netinterface.h>
```

Returns the second IPv4 DNS address of the specified network interface.

Parameters

<i>interface</i>	Interface number

Returns

IPv4 IP address of type [IPADDR4](#)

14.35.3.2.5 InterfaceGate()

```
IPADDR4 InterfaceGate (  
    int interface)  
#include <netinterface.h>
```

Returns the IPv4 gateway address of the specified network interface.

Parameters

<i>interface</i>	Interface number

Returns

IPv4 IP address of type [IPADDR4](#)

14.35.3.2.6 InterfaceIP()

```
IPADDR4 InterfaceIP (
    int interface)
#include <netinterface.h>
```

Returns the IPv4 IP address of the specified network interface.

Parameters

<i>interface</i>	Interface number

Returns

IPv4 IP address of type [IPADDR4](#)

14.35.3.2.7 InterfaceMASK()

```
IPADDR4 InterfaceMASK (
    int interface)
#include <netinterface.h>
```

Returns the IPv4 network mask of the specified network interface.

Parameters

<i>interface</i>	Interface number

Returns

IPv4 network mask of type [IPADDR4](#)

14.35.4 Low Level Processing (NetDoRx)

Callback functions to add custom Ethernet handlers and pass Ethernet frames at the bottom of the TCP/IP stack.

Typedefs

- typedef int(* [netDoRXFunc](#)) ([PoolPtr](#) pp, uint16_t ocount, int if_num)
Function pointer type for custom network receive handlers.

Functions

- [netDoRXFunc SetCustomNetDoRX](#) ([netDoRXFunc](#) customFunc)
Register a custom Ethernet frame handler.
- [netDoRXFunc ClearCustomNetDoRX](#) ()
Remove the currently registered custom Ethernet handler.
- int [NetDoRX](#) ([PoolPtr](#) pp, uint16_t ocount, int if_num)
Main entry point for Ethernet frames into the TCP/IP stack.

Variables

- [netDoRXFunc CustomNetDoRX](#)

Global pointer to the currently registered custom receive handler.

14.35.4.1 Detailed Description

Callback functions to add custom Ethernet handlers and pass Ethernet frames at the bottom of the TCP/IP stack.

```
#include <netrx.h>
```

This module provides the infrastructure for inserting custom Ethernet frame handlers into the network receive path. Custom handlers run before the standard TCP/IP processing and can filter, modify, or consume frames.

Common use cases include:

- Custom protocol implementation
- Frame filtering or monitoring
- Network statistics collection
- Protocol bridging or tunneling

Note

Custom handlers require that the system is (re)compiled with the `ALLOW_CUSTOM_NET_DO_RX` macro defined.

Warning

These functions are for advanced developers only! Code written can affect all receive network processing and must handle frames efficiently to avoid packet loss or network degradation.

14.35.4.2 Typedef Documentation

14.35.4.2.1 netDoRXFunc

```
typedef int (* netDoRXFunc) (PoolPtr pp, uint16_t ocount, int if_num)
#include <netrx.h>
```

Function pointer type for custom network receive handlers.

This typedef defines the signature for custom Ethernet frame processing functions. Functions of this type are called for each received Ethernet frame before standard TCP/IP processing occurs.

The handler function should:

- Examine the frame data in the buffer
- Decide whether to process or pass the frame
- Return 1 if the frame was consumed (will be released)
- Return 0 if the frame should continue to standard processing

Parameters

<i>pp</i>	Pointer to PoolBuffer containing the received Ethernet frame. The buffer contains the complete frame including Ethernet header.
<i>ocount</i>	Total number of octets (bytes) in the received frame, including all headers and payload.
<i>if_num</i>	Network interface index that received the frame. Zero-based index identifying which physical interface the frame arrived on.

Returns

Status indicating whether the frame was handled:

- 1: Frame was processed and consumed by the handler. The buffer will be released and no further processing will occur.
- 0: Frame was not processed. Continue with standard TCP/IP stack processing.

Note

The handler must not modify the buffer or its contents unless it returns 1 to indicate it has consumed the frame.

Warning

Performance critical! This function is called for EVERY received frame. Inefficient implementations can cause packet loss and network degradation.

```
// Example: Custom handler that monitors ARP frames
int MyArpMonitor(PoolPtr pp, uint16_t ocount, int if_num) {
    // Get pointer to Ethernet header
    uint8_t *frame = (uint8_t *)pp->pData;

    // Check if this is an ARP frame (EtherType 0x0806)
    if (ocount >= 14 && frame[12] == 0x08 && frame[13] == 0x06) {
        // Log ARP frame (but don't consume it)
        iprintf("ARP frame received on interface %d\r\n", if_num);
    }

    // Don't consume - let stack process normally
    return 0;
}
```

14.35.4.3 Function Documentation**14.35.4.3.1 ClearCustomNetDoRX()**

```
netDoRXFunc ClearCustomNetDoRX () [inline]
#include <netrx.h>
```

Remove the currently registered custom Ethernet handler.

Clears the custom Ethernet frame handler by setting it to NULL. After calling this function, all received frames will go directly to standard TCP/IP processing without any custom pre-processing.

This is a convenience function equivalent to calling SetCustomNetDoRX(NULL).

Returns

Pointer to the previously registered custom handler, or NULL if no handler was registered. The returned pointer can be saved to restore the handler later if needed.

Note

This function is thread-safe and can be called at any time.

```
// Example: Temporarily disabling a handler
netDoRXFunc savedHandler = ClearCustomNetDoRX();

// ... do something without custom handler ...

// Restore the handler
if (savedHandler != NULL) {
    SetCustomNetDoRX(savedHandler);
}
```

14.35.4.3.2 NetDoRX()

```
int NetDoRX (
    PoolPtr pp,
    uint16_t ocount,
    int if_num)
#include <netrx.h>
```

Main entry point for Ethernet frames into the TCP/IP stack.

This function is the primary entry point for all received Ethernet frames into the NetBurner TCP/IP stack. It is called by the network driver when a frame has been received and is ready for processing.

The function performs the following operations:

1. If a custom handler is registered, calls it first
2. If custom handler returns 1, releases the buffer and returns
3. Otherwise, processes the frame through standard TCP/IP layers:
 - Ethernet layer processing
 - IP layer processing (if IP frame)
 - Transport layer processing (TCP/UDP/ICMP)
 - Application layer delivery

Parameters

<i>pp</i>	Pointer to PoolBuffer containing the complete Ethernet frame. The buffer includes the Ethernet header and all subsequent data. The buffer is released by this function unless an error occurs.
<i>ocount</i>	Number of octets (bytes) in the Ethernet frame, including the Ethernet header. This is the total frame size as received from the network interface.
<i>if_num</i>	Zero-based index of the network interface that received the frame. This identifies which physical network interface (Ethernet port) the frame arrived on. Used for multi-interface routing decisions.

Returns

The number of system timer ticks to wait before this function should be called again for additional processing. A return value of 0 indicates immediate readiness for more frames. This is primarily used internally by the network driver.

Note

This function is typically called only by network driver code and should not be called directly by application code.

The PoolPtr buffer is managed internally and will be released after processing unless an error occurs.

Warning

Do not call this function from application code unless implementing a custom network driver or performing specialized network operations.

14.35.4.3.3 SetCustomNetDoRX()

```
netDoRXFunc SetCustomNetDoRX (
    netDoRXFunc customFunc) [inline]
#include <netrx.h>
```

Register a custom Ethernet frame handler.

Installs a custom handler function that will be called for every received Ethernet frame before standard TCP/IP processing. Only one custom handler can be active at a time; calling this function replaces any previously registered handler.

The custom handler is invoked in the network receive interrupt context and should:

- Execute quickly to avoid blocking other network processing
- Be thread-safe if accessing shared resources
- Return 1 only if completely handling/consuming the frame
- Return 0 to pass the frame to standard processing

Parameters

<i>customFunc</i>	Pointer to the custom netDoRXFunc handler to register. Pass NULL to clear the custom handler.

Returns

Pointer to the previously registered custom handler, or NULL if no handler was previously registered. This allows chaining handlers or restoring the previous handler later.

Note

This function is thread-safe and can be called at any time.

Warning

The handler runs in interrupt context with network interrupts enabled. It must be efficient and non-blocking.

```
// Example: Installing and later restoring a handler
int MyHandler(PoolPtr pp, uint16_t ocount, int if_num) {
    // Process frame...
    return 0;
}

void InstallHandler() {
    // Save previous handler
    netDoRXFunc oldHandler = SetCustomNetDoRX(MyHandler);

    // ... later, restore previous handler ...
    SetCustomNetDoRX(oldHandler);
}
```

14.35.4.4 Variable Documentation**14.35.4.4.1 CustomNetDoRX**

```
netDoRXFunc CustomNetDoRX [extern]
#include <netrx.h>
```

Global pointer to the currently registered custom receive handler.

This external variable holds the function pointer to the active custom network receive handler. If NULL, no custom handler is registered and all frames go directly to standard TCP/IP processing.

Note

Do not modify this variable directly. Use [SetCustomNetDoRX\(\)](#) and [ClearCustomNetDoRX\(\)](#) for proper handler registration.

14.36 PEM Conversion Utilities

Privacy-Enhanced Mail (PEM) format conversion and endianness utilities.

Topics

- [PEM Data Type Identifiers](#)
Return values indicating the type of PEM data that was converted.
- [PEM Format Footers](#)
Standard PEM footer markers for different data types.
- [PEM Format Headers](#)
Standard PEM header markers for different data types.

Macros

- `#define` [CONVERT_BUFFER_LENGTH_MAX](#) `((4 * 1024) - 1)`
Maximum data buffer length in bytes for PEM conversion.

Functions

- int [ConvertPEMFormattedData](#) (puint8_t dataPtr, const char *pemEncodedData, uint32_t dataSize, puint32_t convertedDataLength, char **nextPtr=NULL)
Convert data from Privacy-Enhanced Mail (PEM) format to binary DER format.
- uint16_t [convertLittleEndianWord](#) (uint16_t hData)
Convert 16-bit data between host byte order and little-endian format.
- uint32_t [convertLittleEndianDword](#) (uint32_t hData)
Convert 32-bit data between host byte order and little-endian format.

14.36.1 Detailed Description

Privacy-Enhanced Mail (PEM) format conversion and endianness utilities.

```
#include< convert.h>
```

This module provides functions for converting between PEM-encoded cryptographic data and binary formats, as well as byte-order conversion utilities. PEM format is commonly used for storing and transmitting cryptographic keys and certificates in a text-based, Base64-encoded format.

14.36.1.1 Supported PEM Types

- X.509 Certificates
- RSA Private Keys
- DSA Private Keys
- ECDSA (Elliptic Curve) Private Keys

14.36.1.2 Typical Use Cases

- Loading SSL/TLS certificates and private keys
- Converting keys from PEM files for use with cryptographic libraries
- Preparing certificates for secure network communications
- Byte-order conversion for cross-platform data exchange

Note

- All PEM data must be NULL-terminated strings.
- Buffer sizes should be at least CONVERT_BUFFER_LENGTH_MAX bytes.

14.36.2 Macro Definition Documentation

14.36.2.1 CONVERT_BUFFER_LENGTH_MAX

```
#define CONVERT_BUFFER_LENGTH_MAX ((4 * 1024) - 1)
#include <convert.h>
```

Maximum data buffer length in bytes for PEM conversion.

This defines the maximum size of the output buffer needed for PEM conversion operations. The buffer must be at least this size to safely convert PEM data.

Value: 4095 bytes (4KB - 1)

Note

This is a practical limit based on typical certificate and key sizes. Most X.509 certificates and private keys are well under 4KB.

14.36.3 Function Documentation

14.36.3.1 convertLittleEndianDword()

```
uint32_t convertLittleEndianDword (
    uint32_t hData)
```

```
#include <convert.h>
```

Convert 32-bit data between host byte order and little-endian format.

Converts a 32-bit value to or from little-endian byte order. This function is bidirectional - it performs the same operation regardless of conversion direction. On little-endian systems (x86, ARM in little-endian mode), this is a no-op. On big-endian systems (ColdFire, PowerPC), it swaps the byte order.

14.36.3.2 Byte Order Formats

- **Little-Endian:** Least significant byte first (e.g., 0x12345678 -> [0x78, 0x56, 0x34, 0x12])
- **Big-Endian:** Most significant byte first (e.g., 0x12345678 -> [0x12, 0x34, 0x56, 0x78])

Parameters

<i>hData</i>	32-bit value to convert. Can be in either host or little-endian format.

Returns

32-bit value in the opposite byte order from input:

- If input is host order: returns little-endian
- If input is little-endian: returns host order

Note

This function is its own inverse: calling it twice returns the original value.

On little-endian platforms, this function may be optimized to a no-op.

Commonly used for reading/writing file formats that specify little-endian encoding.

See also

[convertLittleEndianWord\(\)](#) for 16-bit conversion

Expand for Example Usage

Examples

Example 1: File header with little-endian fields

```
struct FileHeader {
    uint32_t signature;    // Little-endian
    uint32_t fileSize;    // Little-endian
    uint32_t dataOffset;  // Little-endian
};

void WriteFileHeader(FILE *fp, uint32_t size, uint32_t offset) {
    FileHeader header;

    // Convert to little-endian for file storage
    header.signature = convertLittleEndianDword(0x12345678);
    header.fileSize = convertLittleEndianDword(size);
    header.dataOffset = convertLittleEndianDword(offset);

    fwrite(&header, sizeof(header), 1, fp);
    fprintf("Wrote header: size=%lu, offset=%lu\r\n", size, offset);
}

bool ReadFileHeader(FILE *fp, FileHeader *header) {
    if (fread(header, sizeof(FileHeader), 1, fp) != 1) {
        return false;
    }

    // Convert from little-endian to host
    header->signature = convertLittleEndianDword(header->signature);
    header->fileSize = convertLittleEndianDword(header->fileSize);
    header->dataOffset = convertLittleEndianDword(header->dataOffset);

    return true;
}
```

Example 2: Cross-platform data exchange

```
// Write timestamp in little-endian format
void SaveTimestamp(FILE *fp) {
    uint32_t timestamp = (uint32_t)time(NULL);
    uint32_t leTimestamp = convertLittleEndianDword(timestamp);
    fwrite(&leTimestamp, sizeof(leTimestamp), 1, fp);
}

// Read timestamp from little-endian format
time_t LoadTimestamp(FILE *fp) {
    uint32_t leTimestamp;
    fread(&leTimestamp, sizeof(leTimestamp), 1, fp);
    uint32_t timestamp = convertLittleEndianDword(leTimestamp);
    return (time_t)timestamp;
}
```

Example 3: Binary data structure conversion

```
struct SensorData {
    uint32_t timestamp;
    uint32_t sensorId;
    uint16_t temperature;
    uint16_t humidity;
};

// Convert structure to little-endian for storage/transmission
void ConvertToLittleEndian(SensorData *data) {
    data->timestamp = convertLittleEndianDword(data->timestamp);
    data->sensorId = convertLittleEndianDword(data->sensorId);
    data->temperature = convertLittleEndianWord(data->temperature);
    data->humidity = convertLittleEndianWord(data->humidity);
}

// Convert structure from little-endian to host order
void ConvertFromLittleEndian(SensorData *data) {
    data->timestamp = convertLittleEndianDword(data->timestamp);
    data->sensorId = convertLittleEndianDword(data->sensorId);
    data->temperature = convertLittleEndianWord(data->temperature);
    data->humidity = convertLittleEndianWord(data->humidity);
}
```

14.36.3.3 convertLittleEndianWord()

```
uint16_t convertLittleEndianWord (
    uint16_t hData)
```

```
#include <convert.h>
```

Convert 16-bit data between host byte order and little-endian format.

Converts a 16-bit value to or from little-endian byte order. This function is bidirectional - it performs the same operation regardless of conversion direction. On little-endian systems (x86, ARM in little-endian mode), this is a no-op. On big-endian systems (ColdFire, PowerPC), it swaps the byte order.

14.36.3.4 Byte Order Formats

- **Little-Endian:** Least significant byte first (e.g., 0x1234 -> [0x34, 0x12])
- **Big-Endian:** Most significant byte first (e.g., 0x1234 -> [0x12, 0x34])

Parameters

<i>hData</i>	16-bit value to convert. Can be in either host or little-endian format.

Returns

16-bit value in the opposite byte order from input:

- If input is host order: returns little-endian
- If input is little-endian: returns host order

Note

This function is its own inverse: calling it twice returns the original value.

On little-endian platforms, this function may be optimized to a no-op.

Commonly used for reading/writing file formats that specify little-endian encoding.

See also

[convertLittleEndianDword\(\)](#) for 32-bit conversion

Expand for Example Usage**Examples****Example 1: Converting data for file I/O**

```
// Writing data in little-endian format to file
uint16_t hostValue = 0x1234;
uint16_t fileValue = convertLittleEndianWord(hostValue);
fwrite(&fileValue, sizeof(fileValue), 1, fp);

// Reading data from little-endian file
uint16_t readValue;
fread(&readValue, sizeof(readValue), 1, fp);
uint16_t hostValue2 = convertLittleEndianWord(readValue);

iprintf("Original: 0x%04X, Converted: 0x%04X, Read back: 0x%04X\r\n",
        hostValue, fileValue, hostValue2);
```

Example 2: Network protocol with mixed endianness

```
struct LittleEndianPacket {
    uint16_t length; // Little-endian
    uint16_t checksum; // Little-endian
    uint8_t data[256];
};

void SendPacket(const uint8_t *data, uint16_t len) {
    LittleEndianPacket packet;

    // Convert to little-endian for transmission
    packet.length = convertLittleEndianWord(len);

    memcpy(packet.data, data, len);

    uint16_t chk = CalculateChecksum(data, len);
    packet.checksum = convertLittleEndianWord(chk);

    send(&packet, sizeof(packet));
}
```

14.36.3.5 ConvertPEMFormattedData()

```
int ConvertPEMFormattedData (
    uint8_t *dataPtr,
    const char * pemEncodedData,
    uint32_t dataSize,
    uint32_t convertedDataLength,
    char ** nextPtr = NULL)
```

#include <convert.h>

Convert data from Privacy-Enhanced Mail (PEM) format to binary DER format.

This function converts PEM-encoded cryptographic data (certificates or private keys) from Base64-encoded text format to binary DER (Distinguished Encoding Rules) format. It automatically detects the type of PEM data based on the header/footer markers.

The function performs:

1. PEM header/footer validation
2. Base64 decoding of the content between header and footer
3. Binary DER format output
4. Type identification

14.36.3.6 PEM Format Structure

```
-----BEGIN [TYPE]-----
[Base64 Encoded Data]
-----END [TYPE]-----
```

Parameters

out	<i>dataPtr</i>	Pointer to buffer for converted binary data. Must be at least <code>CONVERT_BUFFER_LENGTH_MAX</code> bytes. The buffer will contain the DER-encoded binary representation of the key or certificate.
in	<i>pemEncodedData</i>	Pointer to NULL-terminated string containing PEM-encoded data. May contain multiple PEM objects; function will process the first valid one found.
in	<i>dataSize</i>	Size of the output buffer pointed to by <i>dataPtr</i> , in bytes. Should be at least <code>CONVERT_BUFFER_LENGTH_MAX</code> .
out	<i>convertedDataLength</i>	Pointer to <code>uint32_t</code> where the actual length of converted data will be stored. This value will be less than or equal to <i>dataSize</i> .
out	<i>nextPtr</i>	Optional pointer to char pointer. If provided and not NULL, will be set to point to the character immediately following the converted PEM data. Useful for processing multiple PEM objects in a single string. Pass NULL if not needed.

Returns

PEM data type identifier:

Return values

<code>CONVERT_NONE</code>	Malformed data, calling parameters invalid, or conversion failed
<code>CONVERT_CERTIFICATE</code>	Successfully converted X.509 certificate
<code>CONVERT_RSA_PRIVATE_KEY</code>	Successfully converted RSA private key
<code>CONVERT_DSA_PRIVATE_KEY</code>	Successfully converted DSA private key
<code>CONVERT_ECDSA_PRIVATE_KEY</code>	Successfully converted ECDSA private key

Notes:

- The *pemEncodedData* string must be NULL-terminated.
- The output buffer (*dataPtr*) must be large enough to hold the decoded data.
- The function only processes one PEM object per call; use *nextPtr* to process multiple objects.
- The converted data is in binary DER format, suitable for use with SSL/TLS libraries and cryptographic functions.

Warnings:

- Private keys should be handled securely. Consider:
 - Zeroing buffers after use
 - Limiting key exposure in memory
 - Using secure storage when possible
- Ensure adequate buffer size to prevent overflow. If *dataSize* is too small, the function will return `CONVERT_↵_NONE`.

Expand for Example Usage

Examples

Example 1: Converting a single certificate

```

const char *pemCert =
    "-----BEGIN CERTIFICATE-----\n"
    "MIIDXTCCAkWgAwIBAgIJAKJ9VJN8ER5jMA0GCSqGSIb3DQEBCwUAMEUxCzAJBgNV\n"
    "BAYTAkFVMRMwEQYDVQIDApTb211LVN0YXRlMSEwHwYDVQQKDBhJbnRlcm5ldCBX\n"
    "aWRnaXRzIFB0eSBMdGQwHhcNMTgwMzEyMTkyODUyWhcNMTkwMzEyMTkyODUyWjBF\n"
    "MQswCQYDVQQGEwJBVTETMBEGA1UECAwKU29tZS1TdGF0ZTEhMB8GA1UECgwYSW50\n"
    "ZXJuZXQgV2l0cyBQdHkgTHRkMIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIB\n"
    "CgKCAQEAw5TLyD3m...\n"
    "-----END CERTIFICATE-----\n";

uint8_t binaryData[CONVERT_BUFFER_LENGTH_MAX];
uint32_t dataLength;

int result = ConvertPEMFormattedData(binaryData, pemCert,
                                     sizeof(binaryData), &dataLength);

if (result == CONVERT_CERTIFICATE) {
    printf("Certificate converted successfully\r\n");
    printf("Binary data length: %lu bytes\r\n", dataLength);
    // Use binaryData with SSL/TLS functions
} else {
    printf("Failed to convert certificate\r\n");
}

```

Example 2: Converting an RSA private key

```

const char *pemKey =
    "-----BEGIN RSA PRIVATE KEY-----\n"
    "MIIEpAIBAAKCAQEAw5TLyD3m8F7xWQKLp6F5xoTUlqVJYALZ+qYQVQM8FnDtqZKr\n"
    "... \n"
    "-----END RSA PRIVATE KEY-----\n";

uint8_t keyData[CONVERT_BUFFER_LENGTH_MAX];
uint32_t keyLength;

int result = ConvertPEMFormattedData(keyData, pemKey,
                                     sizeof(keyData), &keyLength);

if (result == CONVERT_RSA_PRIVATE_KEY) {
    printf("RSA key converted: %lu bytes\r\n", keyLength);

    // Use the key with crypto library
    // ...

    // Security: Zero the key buffer when done
    memset(keyData, 0, sizeof(keyData));
} else {
    printf("Failed to convert RSA key\r\n");
}

```

Example 3: Processing multiple PEM objects

```

const char *multiPEM =
    "-----BEGIN CERTIFICATE-----\n"
    "... \n"
    "-----END CERTIFICATE-----\n"
    "-----BEGIN RSA PRIVATE KEY-----\n"
    "... \n"
    "-----END RSA PRIVATE KEY-----\n";

uint8_t buffer[CONVERT_BUFFER_LENGTH_MAX];
uint32_t length;
char *nextPEM = (char*)multiPEM;
int objectCount = 0;

while (nextPEM && *nextPEM) {
    int type = ConvertPEMFormattedData(buffer, nextPEM,
                                       sizeof(buffer), &length, &nextPEM);

    if (type == CONVERT_NONE) {
        break; // No more valid PEM data
    }

    objectCount++;

    switch (type) {
        case CONVERT_CERTIFICATE:
            printf("Object %d: Certificate (%lu bytes)\r\n",
                  objectCount, length);
            break;
        case CONVERT_RSA_PRIVATE_KEY:
            printf("Object %d: RSA Key (%lu bytes)\r\n",
                  objectCount, length);
            break;
        case CONVERT_ECDSA_PRIVATE_KEY:

```

```

        printf("Object %d: ECDSA Key (%lu bytes)\r\n",
               objectCount, length);
        break;
    }
}

printf("Processed %d PEM objects\r\n", objectCount);

```

Example 4: Loading certificate and key for SSL/TLS

```

bool LoadSSLCredentials(const char *certPEM, const char *keyPEM) {
    uint8_t certData[CONVERT_BUFFER_LENGTH_MAX];
    uint8_t keyData[CONVERT_BUFFER_LENGTH_MAX];
    uint32_t certLen, keyLen;

    // Convert certificate
    int certType = ConvertPEMFormattedData(certData, certPEM,
                                           sizeof(certData), &certLen);

    if (certType != CONVERT_CERTIFICATE) {
        printf("Error: Invalid certificate format\r\n");
        return false;
    }

    // Convert private key
    int keyType = ConvertPEMFormattedData(keyData, keyPEM,
                                           sizeof(keyData), &keyLen);

    if (keyType != CONVERT_RSA_PRIVATE_KEY &&
        keyType != CONVERT_ECDSA_PRIVATE_KEY) {
        printf("Error: Invalid private key format\r\n");
        return false;
    }

    // Load into SSL context
    if (!SSL_LoadCertificate(certData, certLen)) {
        printf("Failed to load certificate\r\n");
        memset(keyData, 0, sizeof(keyData)); // Clear sensitive data
        return false;
    }

    if (!SSL_LoadPrivateKey(keyData, keyLen)) {
        printf("Failed to load private key\r\n");
        memset(keyData, 0, sizeof(keyData));
        return false;
    }

    // Security: Clear sensitive key data
    memset(keyData, 0, sizeof(keyData));

    printf("SSL credentials loaded successfully\r\n");
    return true;
}

```

Example 5: Error handling and validation

```

int SafeConvertPEM(const char *pem, uint8_t *output,
                  uint32_t outputSize, uint32_t *outLen) {
    // Validate inputs
    if (!pem || !output || !outLen) {
        printf("Error: NULL pointer\r\n");
        return CONVERT_NONE;
    }

    if (outputSize < CONVERT_BUFFER_LENGTH_MAX) {
        printf("Error: Buffer too small (need %d bytes)\r\n",
               CONVERT_BUFFER_LENGTH_MAX);
        return CONVERT_NONE;
    }

    // Attempt conversion
    int result = ConvertPEMFormattedData(output, pem, outputSize, outLen);

    if (result == CONVERT_NONE) {
        printf("Error: PEM conversion failed\r\n");
        printf(" Check PEM format and headers/footers\r\n");
        return CONVERT_NONE;
    }

    // Validate output length
    if (*outLen == 0 || *outLen > outputSize) {
        printf("Error: Invalid output length: %lu\r\n", *outLen);
        return CONVERT_NONE;
    }

    return result;
}

```

Example 6: Reading PEM data from file

```

#include <stdio.h>

bool ConvertPEMFile(const char *filename) {
    FILE *fp = fopen(filename, "r");
    if (!fp) {
        printf("Error: Cannot open %s\r\n", filename);
        return false;
    }

    // Read entire file into buffer
    char pemBuffer[8192];
    size_t bytesRead = fread(pemBuffer, 1, sizeof(pemBuffer) - 1, fp);
    fclose(fp);

    if (bytesRead == 0) {
        printf("Error: Empty file\r\n");
        return false;
    }

    pemBuffer[bytesRead] = '\0'; // Ensure NULL termination

    // Convert PEM data
    uint8_t binaryData[CONVERT_BUFFER_LENGTH_MAX];
    uint32_t dataLen;

    int type = ConvertPEMFormattedData(binaryData, pemBuffer,
                                       sizeof(binaryData), &dataLen);

    switch (type) {
        case CONVERT_CERTIFICATE:
            printf("Converted certificate from %s\r\n", filename);
            break;
        case CONVERT_RSA_PRIVATE_KEY:
            printf("Converted RSA key from %s\r\n", filename);
            break;
        case CONVERT_ECDSA_PRIVATE_KEY:
            printf("Converted ECDSA key from %s\r\n", filename);
            break;
        default:
            printf("Error: Invalid PEM data in %s\r\n", filename);
            return false;
    }

    return true;
}

```

14.36.4 PEM Data Type Identifiers

Return values indicating the type of PEM data that was converted.

Macros

- #define **CONVERT_NONE** (0)
No valid PEM data found or conversion failed.
- #define **CONVERT_RSA_PRIVATE_KEY** (1)
RSA Private Key in PKCS#1 format.
- #define **CONVERT_DSA_PRIVATE_KEY** (2)
DSA Private Key.
- #define **CONVERT_CERTIFICATE** (3)
X.509 Certificate.
- #define **CONVERT_ECDSA_PRIVATE_KEY** (4)
ECDSA (Elliptic Curve) Private Key.

14.36.4.1 Detailed Description

Return values indicating the type of PEM data that was converted.

14.36.4.2 Macro Definition Documentation

14.36.4.2.1 CONVERT_CERTIFICATE

```
#define CONVERT_CERTIFICATE (3)
#include <convert.h>
```

X.509 Certificate.

Indicates successful conversion of an X.509 certificate. The converted binary data contains the certificate in DER format.

Note

X.509 certificates contain public keys and identity information, signed by a Certificate Authority (CA).

14.36.4.2.2 CONVERT_DSA_PRIVATE_KEY

```
#define CONVERT_DSA_PRIVATE_KEY (2)
#include <convert.h>
```

DSA Private Key.

Indicates successful conversion of a DSA (Digital Signature Algorithm) private key. The converted binary data contains the key in DER format.

Note

DSA keys are used for digital signatures only, not encryption.

14.36.4.2.3 CONVERT_ECDSA_PRIVATE_KEY

```
#define CONVERT_ECDSA_PRIVATE_KEY (4)
#include <convert.h>
```

ECDSA (Elliptic Curve) Private Key.

Indicates successful conversion of an ECDSA private key. The converted binary data contains the key in DER format.

Note

ECDSA provides equivalent security to RSA with smaller key sizes, making it efficient for embedded systems.

14.36.4.2.4 CONVERT_NONE

```
#define CONVERT_NONE (0)
#include <convert.h>
```

No valid PEM data found or conversion failed.

Returned when:

- Input data is malformed or missing PEM headers/footers
- Base64 decoding fails
- Buffer size is insufficient
- Invalid parameters passed to conversion function

14.36.4.2.5 CONVERT_RSA_PRIVATE_KEY

```
#define CONVERT_RSA_PRIVATE_KEY (1)
#include <convert.h>
```

RSA Private Key in PKCS#1 format.

Indicates successful conversion of an RSA private key. The converted binary data contains the key in DER format.

Note

RSA keys are used for asymmetric encryption and digital signatures.

14.36.5 PEM Format Footers

Standard PEM footer markers for different data types.

Macros

- **#define CONVERT_CERTIFICATE_FOOTER** "-----END CERTIFICATE-----"
PEM footer for X.509 certificates.
- **#define CONVERT_RSA_PRIVATE_KEY_FOOTER** "-----END RSA PRIVATE KEY-----"
PEM footer for RSA private keys.
- **#define CONVERT_DSA_PRIVATE_KEY_FOOTER** "-----END DSA PRIVATE KEY-----"
PEM footer for DSA private keys.
- **#define CONVERT_ECDSA_PRIVATE_KEY_FOOTER** "-----END EC PRIVATE KEY-----"
PEM footer for ECDSA private keys.

14.36.5.1 Detailed Description

Standard PEM footer markers for different data types.

14.36.6 PEM Format Headers

Standard PEM header markers for different data types.

Macros

- **#define CONVERT_CERTIFICATE_HEADER** "-----BEGIN CERTIFICATE-----"
PEM header for X.509 certificates.
- **#define CONVERT_RSA_PRIVATE_KEY_HEADER** "-----BEGIN RSA PRIVATE KEY-----"
PEM header for RSA private keys.
- **#define CONVERT_DSA_PRIVATE_KEY_HEADER** "-----BEGIN DSA PRIVATE KEY-----"
PEM header for DSA private keys.
- **#define CONVERT_ECDSA_PRIVATE_KEY_HEADER** "-----BEGIN EC PRIVATE KEY-----"
PEM header for ECDSA private keys.

14.36.6.1 Detailed Description

Standard PEM header markers for different data types.

14.37 POP3 - Post Office Protocol

Topics

- [POP3 Return Codes](#)

Functions

- int [POPGetResultCode](#) (int fd, uint32_t timeout)
Returns the result code of the previous POP3 operation.
- int [POP3_InitializeSession](#) (IPADDR server_address, uint16_t port, PCSTR UserName, PCSTR Password, uint32_t timeout)
Create a connection to the POP3 server and log in.
- int [POP3_CloseSession](#) (int session)
Close a POP3 session.
- int [POP3_StatCmd](#) (int session, uint32_t *num_messages, uint32_t *total_bytes, uint32_t timeout)
Returns the status of the mailstore on the POP3 server.
- int [POP3_ListCmd](#) (int session, uint32_t message_number, uint32_t *total_bytes, uint32_t timeout)

Get the size of a message on the server.

- int [POP3_DeleteCmd](#) (int session, uint32_t message_number, uint32_t timeout)

Delete a pending message on the server.

- int [POP3_RetrieveMessage](#) (int session, uint32_t message_number, char *buffer, char **subject_ptr, char **body_ptr, int max_bufferlen, uint32_t timeout)

Retrieve a message from the server.

- PCSTR [GetPOPErrorString](#) (int err)

Returns the error text for an error code.

- int [SSL_POP3_InitializeSession](#) ([IPADDR](#) server_address, uint16_t port, PCSTR UserName, PCSTR Password, uint32_t time_out)

Initialize Post Office Protocol Version 3 (POP3) on a SSL socket.

14.37.1 Detailed Description

```
#include< pop3.h>
```

14.37.2 Function Documentation

14.37.2.1 GetPOPErrorString()

```
PCSTR GetPOPErrorString (
    int err)
```

```
#include <pop3.h>
```

Returns the error text for an error code.

Parameters

<i>err</i>	Error number to decode

Returns

Pointer to a string containing the error code text

14.37.2.2 POP3_CloseSession()

```
int POP3_CloseSession (
    int session)
```

```
#include <pop3.h>
```

Close a POP3 session.

Parameters

<i>session</i>	The session number returned by POP3_InitializeSession()

Returns

[POP3 Return Codes](#)

14.37.2.3 POP3_DeleteCmd()

```
int POP3_DeleteCmd (  
    int session,  
    uint32_t message_number,  
    uint32_t timeout)
```

```
#include <pop3.h>
```

Delete a pending message on the server.

Note: the server will not actually delete the message until the session is closed.

Parameters

<i>session</i>	The session number returned by POP3_InitializeSession() .
<i>message_number</i>	The message number to delete. The message number can be obtained by POP3_StatCmd() .
<i>timeout</i>	Timeout in system Time Ticks.

Returns

Return code [POP3 Return Codes](#)

14.37.2.4 POP3_InitializeSession()

```
int POP3_InitializeSession (
    IPADDR server_address,
    uint16_t port,
    PCSTR UserName,
    PCSTR Password,
    uint32_t timeout)
#include <pop3.h>
Create a connection to the POP3 server and log in.
```

Parameters

<i>server_address</i>	Server IP address
<i>port</i>	Server port number
<i>UserName</i>	Account username
<i>Password</i>	Account password
<i>timeout</i>	Timeout in system Time Ticks

Returns

The POP3 session number if greater than 0, otherwise error code [POP3 Return Codes](#)

See also

[SSL_POP3_InitializeSession](#)

14.37.2.5 POP3_ListCmd()

```
int POP3_ListCmd (
    int session,
    uint32_t message_number,
    uint32_t * total_bytes,
    uint32_t timeout)
#include <pop3.h>
Get the size of a message on the server.
```

Parameters

<i>session</i>	The session number returned by POP3_InitializeSession() .
<i>message_number</i>	The message number to query. The message number can be obtained by POP3_StatCmd() .
<i>total_bytes</i>	Pointer to the variable in which to store the total number of bytes of the pending message.
<i>timeout</i>	Timeout in system Time Ticks.

Returns

Return code [POP3 Return Codes](#)

14.37.2.6 POP3_RetrieveMessage()

```
int POP3_RetrieveMessage (
    int session,
    uint32_t message_number,
    char * buffer,
    char ** subject_ptr,
    char ** body_ptr,
    int max_bufferlen,
    uint32_t timeout)
#include <pop3.h>
```

Retrieve a message from the server.

The message is retrieved as a block of bytes including the header, subject, etc. The headers will appear first. Note that the message is left on the server and will not be deleted until the [POP3_DeleteCmd\(\)](#) function is called for the message number.

Parameters

<i>session</i>	The session number returned by POP3_InitializeSession() .
<i>message_number</i>	The message number to retrieve. The message number can be obtained by POP3_StatCmd() .
<i>buffer</i>	Pointer to the buffer to store the entire message, including headers
<i>subject_ptr</i>	If not NULL, a pointer to the start of the subject in the message buffer
<i>body_ptr</i>	If not NULL, a pointer to the start of the body in the message buffer
<i>max_bufferlen</i>	Maximum length of the buffer
<i>timeout</i>	Timeout in system Time Ticks.

Returns

Return code [POP3 Return Codes](#)

14.37.2.7 POP3_StatCmd()

```
int POP3_StatCmd (
    int session,
    uint32_t * num_messages,
    uint32_t * total_bytes,
    uint32_t timeout)
#include <pop3.h>
```

Returns the status of the mailstore on the POP3 server.

Parameters

<i>session</i>	The session number returned by POP3_InitializeSession()
<i>num_messages</i>	Pointer to the variable in which to store the number of pending messages
<i>total_bytes</i>	Pointer to the variable in which to store the total number of bytes of the pending messages
<i>timeout</i>	Timeout in system Time Ticks

Returns

Return code [POP3 Return Codes](#)

14.37.2.8 POPGetResultCode()

```
int POPGetResultCode (
    int fd,
    uint32_t timeout)
```

```
#include <pop3.h>
```

Returns the result code of the previous POP3 operation.

Parameters

<i>fd</i>	TCP socket file descriptor for the active session
<i>timeout</i>	Timeout in system Time Ticks

Returns

[POP3 Return Codes](#)

14.37.2.9 SSL_POP3_InitializeSession()

```
int SSL_POP3_InitializeSession (
    IPADDR server_address,
    uint16_t port,
    PCSTR UserName,
    PCSTR PassWord,
    uint32_t time_out)
```

```
#include <ssl_pop3.h>
```

Initialize Post Office Protocol Version 3 (POP3) on a SSL socket.

Note: Routine makes the connection to the POP server and logs in with the provided UserName and PassWord.

Session is release with POP3_CloseSession in [pop3.h](#).

Post Office Protocol, Version 3 (POP3) is defined in RFC1939.

Parameters

<i>server_address</i>	IP address of the server.
<i>port</i>	Port to connect to the server.
<i>UserName</i>	Account user name string.
<i>PassWord</i>	Account password string.
<i>time_out</i>	Number of ticks to wait.

Return values

<i>>=0</i>	The session handle
<i><0</i>	Error code from POP3 Return Codes

See also

[POP3_InitializeSession](#)

14.37.3 POP3 Return Codes**Macros**

- #define **POP_OK** (0)
No errors occurred.
- #define **POP_TIMEOUT** (-1)
Time out.

- **#define POP_PASSWORDERROR** (-2)
Password error.
- **#define POP_CONNECTFAIL** (-3)
Connection failed.
- **#define POP_COMMANDFAIL** (-4)
Command failed.
- **#define POP_BADSESSION** (-5)
Session error.
- **#define POP_NETWORKERROR** (-6)
Network error.
- **#define POP_BUFFER_FULL** (-7)
Receive buffer full.

14.37.3.1 Detailed Description

```
#include< pop3.h>
```

14.38 PPP - Point to Point Protocol

Topics

- [PPP Connection State](#)
- [PPP Return Codes](#)

14.38.1 Detailed Description

```
#include< ppp.h>
```

Like Ethernet, Point to Point Protocol (PPP) is a data link layer which transfers data between nodes on a network. The main difference is that PPP is used between two end points, whereas Ethernet is a multidrop configuration. PPP can be used over many types of physical networks, including: fiber, phone line, serial cable and cellular telephone. Once you have created a PPP connection to or from your NetBurner device you can use it with all the standard network applications such as the web server, tcp, udp, ftp, email, etc. Internet Service Providers (ISP) can implement PPP with many different options that vary from ISP to ISP. The PPP example program included in the development kit examples directory specifies the most common ISP options and can be used as a code example to specify any specific options you may need in your application.

14.38.2 PPP Connection State

Enumerations

- enum [enum_PPPState](#) {
[eClosed](#) , [eInitializingModem](#) , [eDialing](#) , [eWait4Ring](#) ,
[eAnswering](#) , [eWaitForTrain](#) , [eLCPNegotiate](#) , [ePAPAuthenticate](#) ,
[eCHAPAuthenticate](#) , [eNCPNegotiate](#) , [eOpen](#) , [eClosing](#) }
PPP States.

```

14.38.2.2 Enumeration Type Documentation

14.38.2.2.1 enum_PPPState

```
enum enum_PPPState
#include <ppp.h>
PPP States.
```

Enumerator

eClosed	Connection closed.
eInitializingModem	Initializing modem.
eDialing	Dialing.
eWait4Ring	Waiting for ring indicator.
eAnswering	Answering incoming connection.
eWaitForTrain	Waiting for train.
eLCPNegotiate	LCP negotiation.
ePAPAuthenticate	PAP authentication.
eCHAPAuthenticate	CHAP authentication.
eNCPNegotiate	NCP negotiation.
eOpen	Connection open.
eClosing	Connection closing.

14.38.3 PPP Return Codes

Macros

- #define **ERR_PPP_SUCCESS** (0)
Success.
- #define **ERR_PPP_ALREADY_OPEN** (-1)
A session is already open.
- #define **ERR_PPP_NO_DIALTONE** (-2)
No dial tone.
- #define **ERR_PPP_NO_ANSWER** (-3)
The remote client did not answer.
- #define **ERR_PPP_BUSY** (-4)
The remote client is sending a busy signal.
- #define **ERR_PPP_FAIL** (-5)
The attempted action has failed.
- #define **ERR_PPP_PASSFAIL** (-6)
Pass/Fail.
- #define **ERR_PPP_LOSTCARRIER** (-7)
Lost connection carrier signal.
- #define **ERR_PPP_NO_MODEM** (-8)
No modem detected.
- #define **ERR_PPP_LCP_FAILED** (-9)
LCP negotiation has failed.
- #define **ERR_PPP_CHAPFAIL** (-10)
CHAP negotiation has failed.

14.38.3.1 Detailed Description

```
#include< ppp.h>
```

14.39 Pit

Classes

- struct [_pit_config](#)
PIT configuration structure.

Typedefs

- typedef enum [_pit_chnl](#) [pit_chnl_t](#)
List of PIT channels.
- typedef enum [_pit_interrupt_enable](#) [pit_interrupt_enable_t](#)
List of PIT interrupts.
- typedef enum [_pit_status_flags](#) [pit_status_flags_t](#)
List of PIT status flags.
- typedef struct [_pit_config](#) [pit_config_t](#)
PIT configuration structure.

Enumerations

- enum [_pit_chnl](#) { [kPIT_Chnl_0](#) = 0U , [kPIT_Chnl_1](#) , [kPIT_Chnl_2](#) , [kPIT_Chnl_3](#) }
List of PIT channels.
- enum [_pit_interrupt_enable](#) { [kPIT_TimerInterruptEnable](#) = PIT_TCTRL_TIE_MASK }
List of PIT interrupts.
- enum [_pit_status_flags](#) { [kPIT_TimerFlag](#) = PIT_TFLG_TIF_MASK }
List of PIT status flags.

Initialization and deinitialization

- void [PIT_Init](#) (PIT_Type *base, const [pit_config_t](#) *config)
Ungates the PIT clock, enables the PIT module, and configures the peripheral for basic operations.
- void [PIT_Deinit](#) (PIT_Type *base)
Gates the PIT clock and disables the PIT module.

Driver version

- #define [FSL_PIT_DRIVER_VERSION](#) (MAKE_VERSION(2, 0, 5))
PIT Driver Version 2.0.5.

14.39.1 Detailed Description

14.39.2 Typedef Documentation

14.39.2.1 pit_chnl_t

```
typedef enum _pit_chnl pit_chnl_t
#include <fsl_pit.h>
List of PIT channels.
```

Note

Actual number of available channels is SoC dependent

14.39.2.2 pit_config_t

```
typedef struct _pit_config pit_config_t
#include <fsl_pit.h>
```

PIT configuration structure.

This structure holds the configuration settings for the PIT peripheral. To initialize this structure to reasonable defaults, call the PIT_GetDefaultConfig() function and pass a pointer to your config structure instance.

The configuration structure can be made constant so it resides in flash.

14.39.3 Enumeration Type Documentation**14.39.3.1 _pit_chnl**

```
enum _pit_chnl
#include <fsl_pit.h>
```

List of PIT channels.

Note

Actual number of available channels is SoC dependent

Enumerator

kPIT_Chnl↔ _0	PIT channel number 0
kPIT_Chnl↔ _1	PIT channel number 1
kPIT_Chnl↔ _2	PIT channel number 2
kPIT_Chnl↔ _3	PIT channel number 3

14.39.3.2 _pit_interrupt_enable

```
enum _pit_interrupt_enable
#include <fsl_pit.h>
```

List of PIT interrupts.

Enumerator

kPIT_TimerInterruptEnable	Timer interrupt enable

14.39.3.3 _pit_status_flags

```
enum _pit_status_flags
#include <fsl_pit.h>
```

List of PIT status flags.

Enumerator

kPIT_TimerFlag	Timer flag

14.39.4 Function Documentation

14.39.4.1 PIT_Deinit()

```
void PIT_Deinit (
    PIT_Type * base)
#include <fsl_pit.h>
```

Gates the PIT clock and disables the PIT module.

Parameters

<i>base</i>	PIT peripheral base address

brief Gates the PIT clock and disables the PIT module.

param base PIT peripheral base address

14.39.4.2 PIT_Init()

```
void PIT_Init (
    PIT_Type * base,
    const pit_config_t * config)
#include <fsl_pit.h>
```

Ungates the PIT clock, enables the PIT module, and configures the peripheral for basic operations.

Note

This API should be called at the beginning of the application using the PIT driver.

Parameters

<i>base</i>	PIT peripheral base address
<i>config</i>	Pointer to the user's PIT config structure

brief Ungates the PIT clock, enables the PIT module, and configures the peripheral for basic operations.

note This API should be called at the beginning of the application using the PIT driver.

param base PIT peripheral base address param config Pointer to the user's PIT config structure

Vector offset definitions for predefined ColdFire exception and interrupt vectors.

Functions

- `uint16_t GetSR_IntLevel ()`
Get the current interrupt mask level from the Status Register (SR).
- `void SetSR_IntLevel (uint16_t sv)`
Set the interrupt mask level in the Status Register (SR).

14.40.2.2.1 Detailed Description

14.40.2.2.2 Function Documentation

14.40.2.2.2.1 GetSR_IntLevel()

```
uint16_t GetSR_IntLevel ()
#include <cfinter.h>
```

Get the current interrupt mask level from the Status Register (SR).

Retrieves the interrupt priority mask from bits 8-10 of the ColdFire Status Register. The interrupt mask determines which interrupt priority levels are currently blocked. Only interrupts with priority higher than the current mask level can be serviced.

The returned value represents the interrupt mask level:

- 0x0000 (0): All interrupts enabled (no masking)
- 0x0100 (1): Block priority 1 and lower
- 0x0200 (2): Block priority 2 and lower
- 0x0300 (3): Block priority 3 and lower
- 0x0400 (4): Block priority 4 and lower
- 0x0500 (5): Block priority 5 and lower
- 0x0600 (6): Block priority 6 and lower
- 0x0700 (7): All interrupts masked (except level 7 NMI)

Returns

Current interrupt mask level from SR register (bits 8-10), formatted as 0x0X00 where X is the priority level (0-7).

See also

[SetSR_IntLevel\(\)](#)

Expand for Example Usage

Examples

Example 1: Reading and displaying current interrupt mask level

```

void DisplayInterruptStatus() {
    uint16_t currentLevel = GetSR_IntLevel();

    printf("Current interrupt mask level: 0x%04X\r\n", currentLevel);

    // Extract just the level bits
    uint8_t level = (currentLevel » 8) & 0x07;
    printf("Masking interrupts at priority %u and below\r\n", level);

    if (level == 0) {
        printf("All interrupts enabled\r\n");
    } else if (level == 7) {
        printf("All maskable interrupts disabled\r\n");
    } else {
        printf("Interrupts %u and lower are masked\r\n", level);
    }
}

```

14.40.2.2.2.2 SetSR_IntLevel()

```

void SetSR_IntLevel (
    uint16_t sv)
#include <cfinter.h>

```

Set the interrupt mask level in the Status Register (SR).

Sets the interrupt priority mask in bits 8-10 of the ColdFire Status Register. The interrupt mask controls which interrupt priority levels are blocked. Only interrupts with priority strictly higher than the mask level can be serviced. Valid interrupt mask values:

- 0x0000 (0): Enable all interrupts (no masking)
- 0x0100 (1): Block priority 1, allow 2-7
- 0x0200 (2): Block priority 1-2, allow 3-7
- 0x0300 (3): Block priority 1-3, allow 4-7
- 0x0400 (4): Block priority 1-4, allow 5-7
- 0x0500 (5): Block priority 1-5, allow 6-7
- 0x0600 (6): Block priority 1-6, allow 7 only
- 0x0700 (7): Block all maskable interrupts (only level 7 NMI allowed)

Parameters

sv	The interrupt mask level to set, formatted as 0x0X00 where X is the priority level (0-7). Only bits 8-10 are used; other bits in the SR are preserved.

Note

Setting the mask to 0x0700 disables all maskable interrupts. Use with caution as this can affect RTOS operation and real-time responsiveness.

Level 7 interrupts (NMI) cannot be masked and will always be serviced.

Warning

Improper use of this function can cause:

- Missed real-time deadlines
- RTOS scheduler dysfunction
- System deadlock if interrupts remain disabled
- Communication timeouts

Always save the previous interrupt level with [GetSR_IntLevel\(\)](#) before modifying it, and restore the saved level when done.

See also

[GetSR_IntLevel\(\)](#)

Expand for Example Usage

Examples

Example 1: Selective interrupt masking for priority management

```
void MediumPriorityWork() {
    uint16_t savedLevel = GetSR_IntLevel();

    // Block interrupts priority 2 and lower, allow 3+
    SetSR_IntLevel(0x0200);

    // This work can be interrupted by priority 3+ interrupts
    // but not by lower priority interrupts
    ProcessMediumPriorityData();

    SetSR_IntLevel(savedLevel);
}

void HighPriorityWork() {
    uint16_t savedLevel = GetSR_IntLevel();

    // Block interrupts priority 5 and lower, allow 6-7
    SetSR_IntLevel(0x0500);

    // Only highest priority interrupts can preempt this
    ProcessHighPriorityData();

    SetSR_IntLevel(savedLevel);
}
```

User-Defined Interrupt Vector Base (Vector 64)

14.40.2.2.3.1 Detailed Description

Vector offset definitions for predefined ColdFire exception and interrupt vectors.

These definitions specify the vector table offsets for various ColdFire processor exceptions, traps, and interrupt sources. The vector table is an array of function pointers where each entry corresponds to a specific exception or interrupt handler.

Vector Table Organization

The ColdFire vector table is organized into several regions:

- **Vectors 0-15:** System exceptions and errors
- **Vectors 24-31:** Autovectored interrupts and spurious interrupt
- **Vectors 32-47:** TRAP instructions (software interrupts)
- **Vectors 64+:** User-defined peripheral interrupts

Usage

Vector offsets are used to install interrupt handlers in the vector table:

```
extern void myHandler();  
vectors[CF_AUTOVECTOR_IRQ5] = myHandler;
```

Note

The actual vector table base address is stored in the Vector Base Register (VBR).

Vectors 0-1 are reserved for the initial stack pointer and program counter.

See also

INTERRUPT

14.40.2.2.3.2 Macro Definition Documentation

CF_ACCESSERROR_VECTOR

```
#define CF_ACCESSERROR_VECTOR 2  
#include <cfinter.h>
```

Access Error Exception Vector (Vector 2)

Triggered when an illegal memory access occurs, such as:

- Attempting to write to read-only memory
- Accessing unmapped memory regions
- Bus timeout or bus error
- Memory protection violations

Note

This is a critical exception that typically indicates a hardware fault or programming error such as dereferencing a NULL or invalid pointer.

Warning

If this exception occurs, the system state may be unstable. The handler should log diagnostic information and consider system reset.

Expand for Example Usage

Examples

Example: Installing an access error handler

```

void AccessErrorHandler() {
    // Log error information
    printf("FATAL: Access Error Exception\r\n");
    printf("PC: 0x%08lX\r\n", GetExceptionPC());

    // Optionally reset the system
    ForceReboot();
}

void UserMain(void *pd) {
    init();

    // Install access error handler
    extern void AccessErrorHandler();
    vectors[CF_ACCESSERROR_VECTOR] = AccessErrorHandler;

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

CF_ADDRESSERROR_VECTOR

```

#define CF_ADDRESSERROR_VECTOR 3
#include <cfinter.h>

```

Address Error Exception Vector (Vector 3)

Triggered when the processor attempts to access a misaligned address or perform an invalid address operation:

- Word access (16-bit) on odd address
- Long word access (32-bit) on non-aligned address
- Invalid instruction fetch address

Note

ColdFire processors require proper data alignment. Word accesses must be word-aligned, and long word accesses must be long-word aligned.

Warning

Address errors often indicate pointer arithmetic errors or structure packing issues. Check your data structure alignment.

CF_AUTOVECTOR_IRQ1

```

#define CF_AUTOVECTOR_IRQ1 25
#include <cfinter.h>

```

Autovector IRQ Level 1 (Vector 25)

Autovector interrupt request level 1 (lowest priority maskable interrupt).

Note

Autovector interrupt requests provide automatic vector generation without requiring the interrupting device to supply a vector number.

See also

[CF_AUTOVECTOR_IRQ2](#) through [CF_AUTOVECTOR_IRQ7](#) for higher priority levels

CF_AUTOVECTOR_IRQ2

```

#define CF_AUTOVECTOR_IRQ2 26
#include <cfinter.h>

```

Autovector IRQ Level 2 (Vector 26)

Autovector interrupt request level 2.

CF_AUTOVECTOR_IRQ3

```
#define CF_AUTOVECTOR_IRQ3 27
#include <cfinter.h>
Autovector IRQ Level 3 (Vector 27)
Autovectored interrupt request level 3.
```

CF_AUTOVECTOR_IRQ4

```
#define CF_AUTOVECTOR_IRQ4 28
#include <cfinter.h>
Autovector IRQ Level 4 (Vector 28)
Autovectored interrupt request level 4.
```

CF_AUTOVECTOR_IRQ5

```
#define CF_AUTOVECTOR_IRQ5 29
#include <cfinter.h>
Autovector IRQ Level 5 (Vector 29)
Autovectored interrupt request level 5.
```

CF_AUTOVECTOR_IRQ6

```
#define CF_AUTOVECTOR_IRQ6 30
#include <cfinter.h>
Autovector IRQ Level 6 (Vector 30)
Autovectored interrupt request level 6.
```

CF_AUTOVECTOR_IRQ7

```
#define CF_AUTOVECTOR_IRQ7 31
#include <cfinter.h>
Autovector IRQ Level 7 (Vector 31)
Autovectored interrupt request level 7 (highest priority, non-maskable).
```

Note

Level 7 interrupts cannot be masked by the interrupt priority mask in the status register and will always be serviced.

Warning

Use level 7 only for critical, non-maskable events such as power failure or critical hardware faults.

CF_DEBUG_INTERRUPT

```
#define CF_DEBUG_INTERRUPT 12
#include <cfinter.h>
Debug Interrupt Exception Vector (Vector 12)
Triggered by the on-chip debug module for hardware breakpoints and debugging. Used by BDM (Background Debug Mode) and JTAG debuggers.
```

Note

This vector is typically managed by the debugging tools and should not be modified by application code.

CF_FORMAT_ERR_VECTOR

```
#define CF_FORMAT_ERR_VECTOR 14
```

```
#include <cfinter.h>
```

Format Error Exception Vector (Vector 14)

Triggered when the processor encounters an invalid stack frame format during an exception return (RTE instruction).

Note

This typically indicates stack corruption or an attempt to return from an exception with an improperly formatted exception frame.

Warning

Often indicates serious stack corruption issues.

CF_ILLEGAL_INSTRUCTION_VECTOR

```
#define CF_ILLEGAL_INSTRUCTION_VECTOR 4
```

```
#include <cfinter.h>
```

Illegal Instruction Exception Vector (Vector 4)

Triggered when the processor attempts to execute:

- An undefined or invalid opcode
- A corrupted instruction
- Code from a data region

Note

This can occur due to:

- Executing data as code (bad function pointer)
- Stack corruption causing return to invalid address
- Flash memory corruption

Warning

Often indicates serious firmware corruption or programming errors.

CF_PRIVLEDGE_VIOLATION_VECTOR

```
#define CF_PRIVLEDGE_VIOLATION_VECTOR 8
```

```
#include <cfinter.h>
```

Privilege Violation Exception Vector (Vector 8)

Triggered when user mode code attempts to execute a privileged instruction or access a privileged resource that requires supervisor mode.

Privileged operations include:

- Modifying the status register (SR)
- Accessing certain control registers
- Executing STOP, RESET, or RTE instructions

Note

Most NetBurner applications run in supervisor mode, so this exception is uncommon unless explicitly using user/supervisor mode separation.

CF_SPURIOUS_INT_VECTOR

```
#define CF_SPURIOUS_INT_VECTOR 24
```

```
#include <cfinter.h>
```

Spurious Interrupt Exception Vector (Vector 24)

Triggered when an interrupt is acknowledged but no interrupt source is found. This can occur due to:

- Interrupt line noise or glitches
- Interrupt cleared between assertion and acknowledgment
- Hardware malfunction

Note

A spurious interrupt handler should simply return without taking action.

Frequent spurious interrupts may indicate hardware problems.

Expand for Example Usage**Examples**

Example: Spurious interrupt handler with counter

```
volatile uint32_t spuriousIntCount = 0;

INTERRUPT(spuriousIntHandler, 0x2000)
{
    spuriousIntCount++;
    // Just return - no action needed
}

void UserMain(void *pd) {
    init();

    extern void spuriousIntHandler();
    vectors[CF_SPURIOUS_INT_VECTOR] = spuriousIntHandler;

    while(1) {
        if (spuriousIntCount > 100) {
            printf("WARNING: Excessive spurious interrupts: %lu\r\n",
                  spuriousIntCount);
        }
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

CF_TRACE_VECTOR

```
#define CF_TRACE_VECTOR 9
```

```
#include <cfinter.h>
```

Trace Exception Vector (Vector 9)

Triggered after each instruction when trace mode is enabled in the status register. Used for single-stepping through code during debugging.

Note

This is primarily used by debuggers and development tools.

The T0 and T1 bits in the SR control trace mode operation.

CF_TRAP0_VECTOR

```
#define CF_TRAP0_VECTOR 32
```

```
#include <cfinter.h>
```

TRAP #0 Instruction Vector (Vector 32)

Software interrupt triggered by the TRAP #0 instruction. TRAP instructions provide a mechanism for software-generated exceptions and system calls.

Note

TRAP instructions are often used to implement system call interfaces or breakpoints in debugging.

Expand for Example Usage**Examples****Example: Using TRAP for system calls**

```
// System call handler
INTERRUPT(trap0Handler, 0x2700)
{
    // Read D0 register to determine system call number
    // Implement system call dispatch logic
    HandleSystemCall();
}

void UserMain(void *pd) {
    init();

    extern void trap0Handler();
    vectors[CF_TRAP0_VECTOR] = trap0Handler;

    // Application can now use: asm("trap #0");

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

CF_TRAP10_VECTOR

```
#define CF_TRAP10_VECTOR 42
```

```
#include <cfinter.h>
```

TRAP #10 Instruction Vector (Vector 42)

Software interrupt triggered by the TRAP #10 instruction.

CF_TRAP11_VECTOR

```
#define CF_TRAP11_VECTOR 43
```

```
#include <cfinter.h>
```

TRAP #11 Instruction Vector (Vector 43)

Software interrupt triggered by the TRAP #11 instruction.

CF_TRAP12_VECTOR

```
#define CF_TRAP12_VECTOR 44
```

```
#include <cfinter.h>
```

TRAP #12 Instruction Vector (Vector 44)

Software interrupt triggered by the TRAP #12 instruction.

CF_TRAP13_VECTOR

```
#define CF_TRAP13_VECTOR 45
```

```
#include <cfinter.h>
```

TRAP #13 Instruction Vector (Vector 45)

Software interrupt triggered by the TRAP #13 instruction.

CF_TRAP14_VECTOR

```
#define CF_TRAP14_VECTOR 46
```

```
#include <cfinter.h>
```

TRAP #14 Instruction Vector (Vector 46)

Software interrupt triggered by the TRAP #14 instruction.

CF_TRAP15_VECTOR

```
#define CF_TRAP15_VECTOR 47
```

```
#include <cfinter.h>
```

TRAP #15 Instruction Vector (Vector 47)

Software interrupt triggered by the TRAP #15 instruction.

CF_TRAP1_VECTOR

```
#define CF_TRAP1_VECTOR 33
```

```
#include <cfinter.h>
```

TRAP #1 Instruction Vector (Vector 33)

Software interrupt triggered by the TRAP #1 instruction.

CF_TRAP2_VECTOR

```
#define CF_TRAP2_VECTOR 34
```

```
#include <cfinter.h>
```

TRAP #2 Instruction Vector (Vector 34)

Software interrupt triggered by the TRAP #2 instruction.

CF_TRAP3_VECTOR

```
#define CF_TRAP3_VECTOR 35
```

```
#include <cfinter.h>
```

TRAP #3 Instruction Vector (Vector 35)

Software interrupt triggered by the TRAP #3 instruction.

CF_TRAP4_VECTOR

```
#define CF_TRAP4_VECTOR 36
```

```
#include <cfinter.h>
```

TRAP #4 Instruction Vector (Vector 36)

Software interrupt triggered by the TRAP #4 instruction.

CF_TRAP5_VECTOR

```
#define CF_TRAP5_VECTOR 37
```

```
#include <cfinter.h>
```

TRAP #5 Instruction Vector (Vector 37)

Software interrupt triggered by the TRAP #5 instruction.

CF_TRAP6_VECTOR

```
#define CF_TRAP6_VECTOR 38
```

```
#include <cfinter.h>
```

TRAP #6 Instruction Vector (Vector 38)

Software interrupt triggered by the TRAP #6 instruction.

CF_TRAP7_VECTOR

```
#define CF_TRAP7_VECTOR 39
```

```
#include <cfinter.h>
```

TRAP #7 Instruction Vector (Vector 39)

Software interrupt triggered by the TRAP #7 instruction.

CF_TRAP8_VECTOR

```
#define CF_TRAP8_VECTOR 40
```

```
#include <cfinter.h>
```

TRAP #8 Instruction Vector (Vector 40)

Software interrupt triggered by the TRAP #8 instruction.

CF_TRAP9_VECTOR

```
#define CF_TRAP9_VECTOR 41
#include <cfinter.h>
TRAP #9 Instruction Vector (Vector 41)
Software interrupt triggered by the TRAP #9 instruction.
```

CF_UNIMPLMENTED_A_VECTOR

```
#define CF_UNIMPLMENTED_A_VECTOR 10
#include <cfinter.h>
Unimplemented Line-A Opcode Exception Vector (Vector 10)
Triggered when the processor encounters an instruction with bits 15-12 = 1010 (0xA). These opcodes are reserved and unimplemented on ColdFire processors.
```

Note

Can be used to implement software emulation of missing instructions or for custom instruction extensions.

CF_UNIMPLMENTED_F_VECTOR

```
#define CF_UNIMPLMENTED_F_VECTOR 11
#include <cfinter.h>
Unimplemented Line-F Opcode Exception Vector (Vector 11)
Triggered when the processor encounters an instruction with bits 15-12 = 1111 (0xF). These opcodes are reserved and unimplemented on ColdFire processors.
```

Note

Can be used to implement co-processor emulation or custom extensions.

CF_UNINITIALIZED_VECTOR

```
#define CF_UNINITIALIZED_VECTOR 15
#include <cfinter.h>
Uninitialized Interrupt Exception Vector (Vector 15)
Triggered when an interrupt occurs but the interrupt controller has not been properly initialized or the interrupt vector has not been programmed.
```

Note

This can occur during system startup if interrupts are enabled before the vector table is fully initialized.

Warning

All interrupt vectors should be initialized before enabling interrupts to avoid this exception.

CF_USER_BASE_VECTOR

```
#define CF_USER_BASE_VECTOR 64
#include <cfinter.h>
User-Defined Interrupt Vector Base (Vector 64)
Starting vector number for user-defined peripheral interrupts. Vectors 64 and above are available for assignment to custom interrupt sources such as:
```

- Timers
- UART/Serial ports
- GPIO interrupts

- DMA controllers
- ADC converters
- Custom peripherals

The actual vector number for a peripheral interrupt is typically: `CF_USER_BASE_VECTOR + peripheral_`
`irq_number`

Note

The specific IRQ numbers and mappings are platform-dependent. Consult your NetBurner platform documentation for peripheral interrupt assignments.

Vectors 48-63 are reserved by Freescale/NXP and should not be used.

Expand for Example Usage

Examples

Example 1: Installing a timer interrupt handler

```
#define TIMER0_IRQ 0 // Platform-specific IRQ number

INTERRUPT(timer0Handler, 0x2300)
{
    // Timer interrupt service routine
    static uint32_t timerTicks = 0;
    timerTicks++;

    // Clear timer interrupt flag
    TIMER0_STATUS_REG |= TIMER_INT_FLAG;
}

void UserMain(void *pd) {
    init();

    // Install handler at user vector base + IRQ number
    extern void timer0Handler();
    vectors[CF_USER_BASE_VECTOR + TIMER0_IRQ] = timer0Handler;

    // Enable timer interrupt
    TIMER0_CONTROL_REG |= TIMER_ENABLE | TIMER_INT_ENABLE;

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

Example 2: Multiple peripheral interrupts

```
// Platform-specific IRQ assignments
#define UART0_IRQ 0
#define UART1_IRQ 1
#define TIMER0_IRQ 2
#define GPIO_IRQ 3

INTERRUPT(uart0Handler, 0x2300)
{
    HandleUART0Interrupt();
}

INTERRUPT(uart1Handler, 0x2300)
{
    HandleUART1Interrupt();
}

INTERRUPT(timer0Handler, 0x2400)
{
    HandleTimer0Interrupt();
}

INTERRUPT(gpioHandler, 0x2200)
{
    HandleGPIOInterrupt();
}

void InitializeInterrupts() {
    extern void uart0Handler();
    extern void uart1Handler();
    extern void timer0Handler();
    extern void gpioHandler();

    // Install all handlers
    vectors[CF_USER_BASE_VECTOR + UART0_IRQ] = uart0Handler;
```

```

    vectors[CF_USER_BASE_VECTOR + UART1_IRQ] = uart1Handler;
    vectors[CF_USER_BASE_VECTOR + TIMER0_IRQ] = timer0Handler;
    vectors[CF_USER_BASE_VECTOR + GPIO_IRQ] = gpioHandler;

    printf("All interrupt handlers installed\r\n");
}

```

Example 3: Vector table dump utility

```

void DumpVectorTable() {
    printf("\r\n=== ColdFire Vector Table ===\r\n");

    printf("\r\nException Vectors:\r\n");
    printf("  Access Error:      %d (0x%08lX)\r\n",
           CF_ACCESSERROR_VECTOR, (uint32_t)vectors[CF_ACCESSERROR_VECTOR]);
    printf("  Address Error:      %d (0x%08lX)\r\n",
           CF_ADDRESSERROR_VECTOR, (uint32_t)vectors[CF_ADDRESSERROR_VECTOR]);
    printf("  Illegal Instruction: %d (0x%08lX)\r\n",
           CF_ILLEGAL_INSTRUCTION_VECTOR, (uint32_t)vectors[CF_ILLEGAL_INSTRUCTION_VECTOR]);

    printf("\r\nAutovector IRQs:\r\n");
    for (int i = 1; i <= 7; i++) {
        printf("  IRQ%d: Vector %d (0x%08lX)\r\n",
               i, CF_AUTOVECTOR_IRQ1 + (i-1),
               (uint32_t)vectors[CF_AUTOVECTOR_IRQ1 + (i-1)]);
    }

    printf("\r\nTRAP Vectors:\r\n");
    for (int i = 0; i <= 15; i++) {
        printf("  TRAP #d: Vector %d (0x%08lX)\r\n",
               i, CF_TRAP0_VECTOR + i,
               (uint32_t)vectors[CF_TRAP0_VECTOR + i]);
    }

    printf("\r\nUser Vectors (first 10):\r\n");
    for (int i = 0; i < 10; i++) {
        printf("  Vector %d: 0x%08lX\r\n",
               CF_USER_BASE_VECTOR + i,
               (uint32_t)vectors[CF_USER_BASE_VECTOR + i]);
    }
}

```

Example 4: Safe vector installation with validation

```

bool InstallUserInterruptHandler(uint8_t irqNum, void (*handler)(),
                                const char *name)
{
    if (handler == NULL) {
        printf("Error: NULL handler for %s\r\n", name);
        return false;
    }

    uint32_t vectorNum = CF_USER_BASE_VECTOR + irqNum;

    if (vectorNum >= 256) {
        printf("Error: Vector %lu out of range for %s\r\n", vectorNum, name);
        return false;
    }

    // Check if vector already assigned
    if (vectors[vectorNum] != NULL && vectors[vectorNum] != handler) {
        printf("Warning: Vector %lu already assigned for %s\r\n",
               vectorNum, name);
    }

    vectors[vectorNum] = handler;
    printf("Installed %s at vector %lu (IRQ %u)\r\n",
           name, vectorNum, irqNum);

    return true;
}

void UserMain(void *pd) {
    init();

    extern void timer0Handler();
    extern void uart0Handler();

    InstallUserInterruptHandler(0, timer0Handler, "Timer0");
    InstallUserInterruptHandler(1, uart0Handler, "UART0");

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

14.40.3 MODM7AE70, SBE70LC

Topics

- [EBI - External Bus Interface](#)

14.40.3.1 Detailed Description

APIs applicable to MODM7AE70, SBE70LC

14.40.3.2 EBI - External Bus Interface

Classes

- struct [EBI_CS_cfg_t](#)
Configuration structure for an External Bus Interface (EBI) chip select.

Enumerations

- enum [EBI_CS_BusWidth_t](#) { [EBI_BUS_WIDTH_8](#) = 0 , [EBI_BUS_WIDTH_16](#) = 1 }
Data bus width configuration for External Bus Interface.
- enum [EBI_CS_ByteAccess_t](#) { [EBI_BYTE_ACCESS_SELECT](#) = 0 , [EBI_BYTE_ACCESS_WRITE](#) = 1 }
Byte access mode for 16-bit bus configurations.
- enum [EBI_CS_NWait_t](#) { [EBI_NWAIT_DISABLED](#) = 0 , [EBI_NWAIT_FROZEN](#) = 2 , [EBI_NWAIT_READY](#) = 3 }
NWAIT signal configuration for bus cycle extension.
- enum [EBI_CS_WrMode_t](#) { [EBI_WRITE_MODE_NCS](#) = 0 , [EBI_WRITE_MODE_NWE](#) = 1 }
Write control signal selection.
- enum [EBI_CS_RdMode_t](#) { [EBI_READ_MODE_NCS](#) = 0 , [EBI_READ_MODE_NRD](#) = 1 }
Read control signal selection.

Functions

- void [ConfigureEBI_CSPin](#) (int csNum)
Configure the I/O pin for a given Chip Select for the external data bus.
- void [ConfigureEBI_NWRPin](#) ()
Configure the I/O pin for the active low write/read (NWR) bus signal.
- void [ConfigureEBI_NRDPin](#) ()
Configure the I/O pin for the active low read (NRD) bus signal.
- void [ConfigureEBI_CS](#) (uint32_t csNum, const [EBI_CS_cfg_t](#) &&cfg)
Configure the given Chip Select for the external data bus (rvalue reference version).
- void [ConfigureEBI_CS](#) (uint32_t csNum, const [EBI_CS_cfg_t](#) &cfg)
Configure the given Chip Select for the external data bus (lvalue reference version).

14.40.3.2.1 Detailed Description

Supported Platforms: MODM7AE70

The Microchip SAME70 EBI peripheral is a parallel communication port that can only operate in "host" mode to communicate with "slave" devices. The EBI peripheral consists of a set of up to 16 data signals, up to 24 address signals and up to 10 different control signals. Some of the benefits of using the EBI bus are that it has high performance in both throughput and latency. It is directly memory mapped to the processor so it is very easy to use in software once configured. The downsides are mostly that it has many signals which will greatly complicate hardware designs and increase the size of external peripheral chips.

The EBI peripheral is highly configurable to fit the specifications of many types of external devices.

A consequence to this high configurability is that there are many timing parameters which makes configuration complicated. The NetBurner examples specify a conservative set of timing parameters with the goal of being compatible with a wide range of peripherals such as FPGAs, CPLDs, buffers, latches displays, flash memory and SRAM. Once successful communication is obtained with the slave target device, these default settings should be refined to increase the performance to match the device you are interfacing with.

Advanced EBI functionality is currently not supported by this examples or this driver. Advanced functionality includes interfacing with SDRAM or NAND memories. Page mode, burst operations and scrambling functionality are all not currently configurable via this driver.

In most applications you will only need to verify the last 5 parameters meet your peripheral requirements: bus width (8 or 16), byte Access 16-bit mode only), timing parameters, read mode (chip select or read signal) and write mode (chip select or write signal).

There are 3 sources of information that are very useful for understanding the EBI:

1. The EBI section of the Microchip SAME70 manual located in "`\nburn\docs`". It is very important to do this as the first step to understand the signal terminology in the examples and header files. Additionally the Static Memory Controller chapter in this processor manual is essential as it explains all the settings and timing parameters exposed by this driver.
2. The NetBurner EBI examples described in the manual and located in "`\nburn\examples\PlatformSpecific\↵MODM7AE70`"
3. The SAME70 [ebi.h](#) header file located in "`\nburn\arch\cortex-m7\cpu\SAME70\include`"

The EBI supports Chip Selects as well as Read and Write signals to interface with peripherals. The basic procedure for configuring the bus is:

- As noted in the examples, the MODM7AE70 has onboard bus buffers to reduce noise and help signal integrity. The following 4 signals must always be configured for EBI functionality as they are control the enable/disable and direction control of the bus buffer ICs:

```
P1[5].function(PINP1_5_NCS2);    // chip select 2, active low
P1[6].function(PINP1_6_NCS0);    // chip select 0, active low
P1[7].function(PINP1_7_NCS3);    // chip select 3, active low
P1[8].function(PINP1_8_NRD);     // Bus read, active low
```

- Declare a Configuration Structure of type [EBI_CS_cfg_t](#). An easy way is to copy one from the examples. Then modify any parameters necessary to meet your specific peripheral requirements, such as bus width, byte access in 16-bit mode, timing parameters, etc.
- Configure the desired chip select using the [ConfigureEBI_CS\(\)](#) function. Note that when enabling the EBI, the MODM7AE70 module requires all three chip selects (NCS0, NCS02, NCS03) to be assigned as chip selects. Additionally the NRD signal must also be configured for NRD bus operation. All of these signals are used for controlling the enable/direction logic of the external bus buffer hardware - they cannot use their alternate functions. Each chip select has a predefined fixed 16MB address range ([MODM7AE70 Memory Map](#)). The

NetBurner API supplied predefined base address variables to make access easier as demonstrated in the EBI examples:

```
extern volatile uint8_t ebi_0_base[]; // Chip select 0
extern volatile uint8_t ebi_1_base[]; // Chip select 1
extern volatile uint8_t ebi_2_base[]; // Chip select 2
extern volatile uint8_t ebi_3_base[]; // Chip select 3
```

In this way you can do a bus write with code such as (please refer to EBI examples for latest code):

```
const uint8_t  EBITestData8 = 0x5A;           // Data byte for testing
const uint32_t EBITestAddressOffset = 0xA5A5; // Address offset from chip select base address

ebi_0_base[EBITestAddressOffset] = EBITestData8; // Write data to EBI, chip select 0
ebi_0_base[0xA5A5] = 0x5A;                     // Same write with hard coded values

uint32_t EBIdata = ebi_0_base[EBITestAddressOffset]; // Read data from EBI, chip select 0
```

Warning

When enabling the EBI for the MODM7AE70 module, NCS0, NCS2, NCS3 and NRD must all be configured for their bus functionality as chip selects or nRead signals, even if not used by your application - they cannot be assigned their alternate functions. Additionally the "void EnableExtBusBuff(bool enable);" function from bsp.h must be used to enable the external bus buffer hardware.

14.40.3.2.2 Enumeration Type Documentation

14.40.3.2.2.1 EBI_CS_BusWidth_t

```
enum EBI_CS_BusWidth_t
#include <ebi.h>
```

Data bus width configuration for External Bus Interface.

Specifies the data bus width for communication with external devices on the EBI. The bus width must match the physical connection and capabilities of the external device connected to the chip select.

Note

The bus width setting affects how data is transferred and accessed on the external bus. Ensure the external device supports the selected width.

See also

[EBI_CS_ByteAccess_t](#)

Enumerator

EBI_BUS_WIDTH_8	8-bit data bus width (D0-D7)
EBI_BUS_WIDTH_16	16-bit data bus width (D0-D15)

14.40.3.2.2.2 EBI_CS_ByteAccess_t

```
enum EBI_CS_ByteAccess_t
#include <ebi.h>
```

Byte access mode for 16-bit bus configurations.

Controls how 8-bit accesses are handled when the bus is configured for 16-bit mode. This setting determines which control signal (chip select or write enable) is used to select the high or low byte during 8-bit transfers on a 16-bit bus.

Note

This setting is only relevant when using EBI_BUS_WIDTH_16. It has no effect in 8-bit bus mode.

Warning

Incorrect byte access configuration can result in data corruption when performing byte-level operations on a 16-bit bus.

[EBI_CS_BusWidth_t](#)

Expand for Example Usage

Examples

Example 1: Configuring byte access using chip select

```
void ConfigureEBI_16BitWithByteAccess() {
    EBI_CS_BusWidth_t busWidth = EBI_BUS_WIDTH_16;
    EBI_CS_ByteAccess_t byteAccess = EBI_BYTE_ACCESS_SELECT;

    // Configure for 16-bit bus with CS-controlled byte access
    // This allows upper/lower byte selection via chip select

    iprintf("16-bit bus configured with CS byte select\r\n");
}
```

Example 2: Configuring byte access using write signal

```
void ConfigureEBI_16BitWithWriteByteAccess() {
    EBI_CS_BusWidth_t busWidth = EBI_BUS_WIDTH_16;
    EBI_CS_ByteAccess_t byteAccess = EBI_BYTE_ACCESS_WRITE;

    // Configure for 16-bit bus with write-controlled byte access
    // This uses the write signal to select upper/lower byte

    iprintf("16-bit bus configured with write signal byte select\r\n");
}
```

Enumerator

EBI_BYTE_ACCESS_SELECT	Use chip select signal to access individual bytes on 16-bit bus.
EBI_BYTE_ACCESS_WRITE	Use write enable signal to access individual bytes on 16-bit bus.

14.40.3.2.2.3 EBI_CS_NWait_t

```
enum EBI_CS_NWait_t
#include <ebi.h>
```

NWAIT signal configuration for bus cycle extension.

Controls how the external NWAIT signal is used to extend read/write cycles when interfacing with slow external devices. The NWAIT signal allows external devices to insert wait states, extending the access time as needed.

This is commonly used with:

- Slow flash memory devices
- Variable-speed peripherals
- Devices that need dynamic timing adjustment

Note

When disabled, the NWAIT signal is ignored and all timing is determined by the configured setup, pulse, and hold times.

In Frozen mode, the NWAIT signal can extend the access time indefinitely while the signal is asserted.

In Ready mode, the NWAIT signal is sampled and can control cycle extension based on device readiness.

Warning

Using NWAIT modes with devices that don't properly drive the NWAIT signal can result in bus hangs or indefinite waits.

Expand for Example Usage

Examples

Example 1: Disabled NWAIT for fast SRAM

```
void ConfigureFastSRAM() {
    EBI_CS_NWait_t nwaitMode = EBI_NWAIT_DISABLED;

    // Fast SRAM doesn't need wait states
    // All timing controlled by setup/pulse/hold registers

    iprintf("EBI configured for fast SRAM (NWAIT disabled)\r\n");
}
```

Example 2: Frozen mode for slow flash memory

```
void ConfigureSlowFlash() {
    EBI_CS_NWait_t nwaitMode = EBI_NWAIT_FROZEN;

    // Flash can extend cycles as needed via NWAIT
    // Useful for write operations that need variable time

    iprintf("EBI configured for flash with frozen NWAIT mode\r\n");
}
```

Example 3: Ready mode for variable-speed peripheral

```
void ConfigureVariableSpeedDevice() {
    EBI_CS_NWait_t nwaitMode = EBI_NWAIT_READY;

    // Device can signal when it's ready via NWAIT
    // Allows dynamic timing based on device state

    iprintf("EBI configured with ready mode NWAIT\r\n");
}
```

Example 4: Comparing NWAIT modes for different device types

```
void ConfigureMultipleDevices() {
    // CS0: Fast SRAM - no wait states needed
    EBI_CS_NWait_t cs0_nwait = EBI_NWAIT_DISABLED;

    // CS1: Flash memory - can hold bus during programming
    EBI_CS_NWait_t cs1_nwait = EBI_NWAIT_FROZEN;

    // CS2: Variable speed FPGA - signals readiness
    EBI_CS_NWait_t cs2_nwait = EBI_NWAIT_READY;

    iprintf("Configured 3 devices with different NWAIT modes\r\n");
}
```

Enumerator

EBI_NWAIT_DISABLED	NWAIT signal ignored, all timing from configuration registers.
EBI_NWAIT_FROZEN	NWAIT can freeze/extend the access cycle indefinitely.
EBI_NWAIT_READY	NWAIT sampled to determine device ready state.

14.40.3.2.2.4 EBI_CS_RdMode_t

```
enum EBI_CS_RdMode_t
```

```
#include <ebi.h>
```

Read control signal selection.

Determines which signal controls read operations from external devices on the EBI. This setting affects how read cycles are generated and controlled.

- **NCS mode:** Read cycle controlled by chip select assertion
- **NRD mode:** Read cycle controlled by dedicated read enable signal

Note

NRD (Read Enable) mode provides more precise read timing control and is commonly used with memory devices that have separate read enable inputs.

NCS mode may be suitable for simpler devices or when minimizing control signal requirements.

[EBI_CS_WrMode_t](#)

[ConfigureEBI_NRDPin\(\)](#)

Expand for Example Usage

Examples

Example 1: Using NRD for standard SRAM

```
void ConfigureSRAM_WithReadEnable() {
    EBI_CS_RdMode_t readMode = EBI_READ_MODE_NRD;

    // Standard SRAM with dedicated OE/RD pin
    // Provides precise read pulse timing
    ConfigureEBI_NRDPin(); // Configure the read enable pin

    iprintf("SRAM configured with NRD read control\r\n");
}
```

Example 2: Using NCS for simple peripheral

```
void ConfigureSimpleReadDevice() {
    EBI_CS_RdMode_t readMode = EBI_READ_MODE_NCS;

    // Simple device controlled only by chip select
    // Data output when CS is asserted

    iprintf("Device configured with NCS read control\r\n");
}
```

Example 3: Complete read/write configuration

```
void ConfigureExternalMemory() {
    EBI_CS_WrMode_t writeMode = EBI_WRITE_MODE_NWE;
    EBI_CS_RdMode_t readMode = EBI_READ_MODE_NRD;

    // Configure pins for read and write operations
    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();

    iprintf("Memory configured with NRD/NWE control signals\r\n");
}
```

Example 4: Mixed control modes for different chip selects

```
void ConfigureMixedDevices() {
    // CS0: Memory with dedicated control signals
    EBI_CS_RdMode_t cs0_read = EBI_READ_MODE_NRD;
    EBI_CS_WrMode_t cs0_write = EBI_WRITE_MODE_NWE;

    // CS1: Simple I/O using only chip select
    EBI_CS_RdMode_t cs1_read = EBI_READ_MODE_NCS;
    EBI_CS_WrMode_t cs1_write = EBI_WRITE_MODE_NCS;

    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();

    iprintf("CS0: Full control signals (NRD/NWE)\r\n");
    iprintf("CS1: Chip select only (NCS)\r\n");
}
```

Enumerator

EBI_READ_MODE_NCS	Read controlled by chip select (NCS) assertion.
EBI_READ_MODE_NRD	Read controlled by read enable (NRD) signal.

14.40.3.2.2.5 EBI_CS_WrMode_t

```
enum EBI_CS_WrMode_t
```

```
#include <ebi.h>
```

Write control signal selection.

Determines which signal controls write operations to external devices on the EBI. This setting affects how write cycles are generated and controlled.

- **NCS mode:** Write cycle controlled by chip select assertion

- **NWE mode:** Write cycle controlled by dedicated write enable signal

Note

NWE (Write Enable) mode provides more precise write timing control and is commonly used with memory devices that have separate write enable inputs.

NCS mode may be suitable for simpler devices or when minimizing control signal requirements.

```
void ConfigureEBI_CS (
    uint32_t csNum,
    const EBI_CS_cfg_t && cfg)

#include <ebi.h>
```

Configure the given Chip Select for the external data bus (rvalue reference version).

Configures an External Bus Interface (EBI) chip select with the specified timing and control parameters. This overload accepts an rvalue reference, allowing efficient configuration with temporary configuration objects.

This function sets up all timing parameters (setup, pulse, hold times), control signal modes, bus width, and wait state configuration for the specified chip select line.

Parameters

<i>csNum</i>	The EBI Chip Select number to configure (typically 0-3, platform-dependent).
<i>cfg</i>	Rvalue reference to the configuration structure. The configuration is moved into the function, making this efficient for temporary configuration objects.

Note

This function should be called after pin configuration functions:

- [ConfigureEBI_CSPin\(\)](#)
- [ConfigureEBI_NWRPin\(\)](#) (if using write operations)
- [ConfigureEBI_NRDPin\(\)](#) (if using read operations)

All timing parameters in the configuration are specified in EBI clock cycles. Calculate the required values based on your EBI clock frequency and device datasheet.

Warning

Incorrect timing configuration can cause data corruption or device malfunction. Always verify timing parameters against the external device datasheet.

Ensure the chip select number is valid for your platform. Invalid values may result in undefined behavior.

Examples

Example 1: Configure CS0 with temporary configuration object

```
void InitializeExternalSRAM() {
    // Configure the chip select pin first
    ConfigureEBI_CSPin(0);
    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();

    // Configure CS0 using temporary configuration (rvalue)
    // This overload is efficient when creating config inline
    ConfigureEBI_CS(0, EBI_CS_cfg_t{
        .ncs_rd_setup = 2,
        .nrd_setup = 2,
        .ncs_rd_pulse = 10,
        .nrd_pulse = 10,
        .nrd_cycles = 15,
        .ncs_wr_setup = 2,
        .nwe_setup = 2,
        .ncs_wr_pulse = 10,
        .nwe_pulse = 10,
        .nwe_cycles = 15,
        .tdf_cycles = 2,
        .busWidth = EBI_BUS_WIDTH_16,
        .byteAccess = EBI_BYTE_ACCESS_WRITE,
        .nWait = EBI_NWAIT_DISABLED,
        .wrMode = EBI_WRITE_MODE_NWE,
        .rdMode = EBI_READ_MODE_NRD
    });

    iprintf("CS0 configured for SRAM\r\n");
}
```

Example 2: Using a factory function that returns configuration

```
EBI_CS_cfg_t CreateFastSRAMConfig() {
    return EBI_CS_cfg_t{
        .ncs_rd_setup = 2, .nrd_setup = 2,
        .ncs_rd_pulse = 10, .nrd_pulse = 10,
        .nrd_cycles = 15,
        .ncs_wr_setup = 2, .nwe_setup = 2,
        .ncs_wr_pulse = 10, .nwe_pulse = 10,
        .nwe_cycles = 15,
        .tdf_cycles = 2,
        .busWidth = EBI_BUS_WIDTH_16,
        .byteAccess = EBI_BYTE_ACCESS_WRITE,
        .nWait = EBI_NWAIT_DISABLED,
        .wrMode = EBI_WRITE_MODE_NWE,
        .rdMode = EBI_READ_MODE_NRD
    };
}

void UserMain(void *pd) {
    init();

    ConfigureEBI_CSPin(0);
    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();

    // Rvalue overload called with returned temporary
    ConfigureEBI_CS(0, CreateFastSRAMConfig());

    iprintf("CS0 configured using factory function\r\n");

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

Example 3: Chain configuration with std::move

```
void ConfigureMultipleChipSelects() {
    ConfigureEBI_CSPin(0);
    ConfigureEBI_CSPin(1);
    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();

    EBI_CS_cfg_t baseConfig = {
        .ncs_rd_setup = 2, .nrd_setup = 2,
        .ncs_rd_pulse = 10, .nrd_pulse = 10,
        .nrd_cycles = 15,
        .ncs_wr_setup = 2, .nwe_setup = 2,
        .ncs_wr_pulse = 10, .nwe_pulse = 10,
        .nwe_cycles = 15,
        .tdf_cycles = 2,
        .busWidth = EBI_BUS_WIDTH_16,
        .byteAccess = EBI_BYTE_ACCESS_WRITE,
        .nWait = EBI_NWAIT_DISABLED,
        .wrMode = EBI_WRITE_MODE_NWE,
        .rdMode = EBI_READ_MODE_NRD
    };

    // Configure CS0 with the base config
    ConfigureEBI_CS(0, baseConfig); // Uses lvalue overload

    // Modify for CS1 (slower device)
    baseConfig.nrd_cycles = 20;
    baseConfig.nwe_cycles = 20;

    // Move to CS1 configuration
    ConfigureEBI_CS(1, std::move(baseConfig)); // Uses rvalue overload

    iprintf("CS0 and CS1 configured\r\n");
}
```

14.40.3.2.3.2 ConfigureEBI_CS() [2/2]

```
void ConfigureEBI_CS (
    uint32_t csNum,
    const EBI_CS_cfg_t & cfg)
```

```
#include <ebi.h>
```

Configure the given Chip Select for the external data bus (lvalue reference version).

Configures an External Bus Interface (EBI) chip select with the specified timing and control parameters. This overload accepts an lvalue reference, allowing configuration with existing configuration objects that may be reused.

This function sets up all timing parameters (setup, pulse, hold times), control signal modes, bus width, and wait state configuration for the specified chip select line.

Parameters

<i>csNum</i>	The EBI Chip Select number to configure (typically 0-3, platform-dependent).
<i>cfg</i>	Const reference to the configuration structure. The configuration is copied, allowing the original to be reused for other chip selects.

Note

This function should be called after pin configuration functions:

- [ConfigureEBI_CSPin\(\)](#)
- [ConfigureEBI_NWRPin\(\)](#) (if using write operations)
- [ConfigureEBI_NRDPin\(\)](#) (if using read operations)

All timing parameters in the configuration are specified in EBI clock cycles. Calculate the required values based on your EBI clock frequency and device datasheet.

Warning

Incorrect timing configuration can cause data corruption or device malfunction. Always verify timing parameters against the external device datasheet.

Ensure the chip select number is valid for your platform. Invalid values may result in undefined behavior.

Examples

Example 1: Basic CS configuration with persistent config object

```
void InitializeExternalMemory() {
    // Configure the necessary pins
    ConfigureEBI_CSPin(0);
    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();

    // Create configuration object
    EBI_CS_cfg_t sramConfig = {
        .ncs_rd_setup = 2,
        .nrd_setup = 2,
        .ncs_rd_pulse = 10,
        .nrd_pulse = 10,
        .nrd_cycles = 15,
        .ncs_wr_setup = 2,
        .nwe_setup = 2,
        .ncs_wr_pulse = 10,
        .nwe_pulse = 10,
        .nwe_cycles = 15,
        .tdf_cycles = 2,
        .busWidth = EBI_BUS_WIDTH_16,
        .byteAccess = EBI_BYTE_ACCESS_WRITE,
        .nWait = EBI_NWAIT_DISABLED,
        .wrMode = EBI_WRITE_MODE_NWE,
        .rdMode = EBI_READ_MODE_NRD
    };

    // Configure CS0 using lvalue reference
    ConfigureEBI_CS(0, sramConfig);

    iprintf("CS0 configured for SRAM\r\n");
}
```

Example 2: Reusing configuration for multiple chip selects

```

void ConfigureMultipleSimilarDevices() {
    // Configure pins for all chip selects
    ConfigureEBI_CSPin(0);
    ConfigureEBI_CSPin(1);
    ConfigureEBI_CSPin(2);
    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();

    // Base configuration for similar devices
    EBI_CS_cfg_t baseConfig = {
        .ncs_rd_setup = 2, .nrd_setup = 2,
        .ncs_rd_pulse = 10, .nrd_pulse = 10,
        .nrd_cycles = 15,
        .ncs_wr_setup = 2, .nwe_setup = 2,
        .ncs_wr_pulse = 10, .nwe_pulse = 10,
        .nwe_cycles = 15,
        .tdf_cycles = 2,
        .busWidth = EBI_BUS_WIDTH_16,
        .byteAccess = EBI_BYTE_ACCESS_WRITE,
        .nWait = EBI_NWAIT_DISABLED,
        .wrMode = EBI_WRITE_MODE_NWE,
        .rdMode = EBI_READ_MODE_NRD
    };

    // Configure multiple chip selects with same timing
    ConfigureEBI_CS(0, baseConfig); // Config object still valid
    ConfigureEBI_CS(1, baseConfig); // Reused for CS1
    ConfigureEBI_CS(2, baseConfig); // Reused for CS2

    iprintf("CS0, CS1, CS2 configured with identical timing\r\n");
}

```

Example 3: Configuration with device-specific variations

```

void ConfigureMixedDevices() {
    ConfigureEBI_CSPin(0);
    ConfigureEBI_CSPin(1);
    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();

    // Fast SRAM on CS0
    EBI_CS_cfg_t fastConfig = {
        .ncs_rd_setup = 2, .nrd_setup = 2,
        .ncs_rd_pulse = 10, .nrd_pulse = 10,
        .nrd_cycles = 15,
        .ncs_wr_setup = 2, .nwe_setup = 2,
        .ncs_wr_pulse = 10, .nwe_pulse = 10,
        .nwe_cycles = 15,
        .tdf_cycles = 2,
        .busWidth = EBI_BUS_WIDTH_16,
        .byteAccess = EBI_BYTE_ACCESS_WRITE,
        .nWait = EBI_NWAIT_DISABLED,
        .wrMode = EBI_WRITE_MODE_NWE,
        .rdMode = EBI_READ_MODE_NRD
    };

    // Slow flash on CS1
    EBI_CS_cfg_t slowConfig = {
        .ncs_rd_setup = 3, .nrd_setup = 3,
        .ncs_rd_pulse = 15, .nrd_pulse = 15,
        .nrd_cycles = 22,
        .ncs_wr_setup = 3, .nwe_setup = 3,
        .ncs_wr_pulse = 20, .nwe_pulse = 20,
        .nwe_cycles = 28,
        .tdf_cycles = 3,
        .busWidth = EBI_BUS_WIDTH_8,
        .byteAccess = EBI_BYTE_ACCESS_SELECT,
        .nWait = EBI_NWAIT_FROZEN,
        .wrMode = EBI_WRITE_MODE_NWE,
        .rdMode = EBI_READ_MODE_NRD
    };

    ConfigureEBI_CS(0, fastConfig);
    ConfigureEBI_CS(1, slowConfig);

    iprintf("CS0: Fast SRAM, CS1: Slow Flash\r\n");
}

```

Example 4: Complete initialization with error checking

```

bool InitializeEBI_Device(uint32_t csNum, const EBI_CS_cfg_t &config) {
    // Validate chip select number
    if (csNum > 3) {
        iprintf("Error: Invalid chip select %lu\r\n", csNum);
        return false;
    }

    // Validate TDF cycles
    if (config.tdf_cycles > 15) {
        iprintf("Error: TDF cycles must be 0-15\r\n");
        return false;
    }

    // Configure the hardware
    ConfigureEBI_CS_Pin(csNum);

    if (config.wrMode == EBI_WRITE_MODE_NWE) {
        ConfigureEBI_NWRP_Pin();
    }

    if (config.rdMode == EBI_READ_MODE_NRD) {
        ConfigureEBI_NRP_Pin();
    }

    // Apply configuration
    ConfigureEBI_CS(csNum, config);

    iprintf("CS%lu configured successfully\r\n", csNum);
    return true;
}

void UserMain(void *pd) {
    init();

    EBI_CS_cfg_t myConfig = {
        .ncs_rd_setup = 2, .nrd_setup = 2,
        .ncs_rd_pulse = 10, .nrd_pulse = 10,
        .nrd_cycles = 15,
        .ncs_wr_setup = 2, .nwe_setup = 2,
        .ncs_wr_pulse = 10, .nwe_pulse = 10,
        .nwe_cycles = 15,
        .tdf_cycles = 2,
        .busWidth = EBI_BUS_WIDTH_16,
        .byteAccess = EBI_BYTE_ACCESS_WRITE,
        .nWait = EBI_NWAIT_DISABLED,
        .wrMode = EBI_WRITE_MODE_NWE,
        .rdMode = EBI_READ_MODE_NRD
    };

    if (InitializeEBI_Device(0, myConfig)) {
        iprintf("Device ready for operations\r\n");
    }

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

Example 5: Configuration storage and retrieval

```

// Global storage for configurations
EBI_CS_cfg_t g_csConfigs[4];

void StoreConfiguration(uint32_t csNum, const EBI_CS_cfg_t &config) {
    if (csNum < 4) {
        g_csConfigs[csNum] = config;
        iprintf("Configuration stored for CS%lu\r\n", csNum);
    }
}

void ApplyStoredConfiguration(uint32_t csNum) {
    if (csNum < 4) {
        ConfigureEBI_CS(csNum, g_csConfigs[csNum]);
        iprintf("Applied stored configuration to CS%lu\r\n", csNum);
    }
}

void UserMain(void *pd) {
    init();

    // Create and store configurations
    EBI_CS_cfg_t sramConfig = {
        .ncs_rd_setup = 2, .nrd_setup = 2,
        .ncs_rd_pulse = 10, .nrd_pulse = 10,
        .nrd_cycles = 15,

```

```

        .ncs_wr_setup = 2, .nwe_setup = 2,
        .ncs_wr_pulse = 10, .nwe_pulse = 10,
        .nwe_cycles = 15,
        .tdf_cycles = 2,
        .busWidth = EBI_BUS_WIDTH_16,
        .byteAccess = EBI_BYTE_ACCESS_WRITE,
        .nWait = EBI_NWAIT_DISABLED,
        .wrMode = EBI_WRITE_MODE_NWE,
        .rdMode = EBI_READ_MODE_NRD
    };

    StoreConfiguration(0, sramConfig);

    // Later, apply the stored configuration
    ConfigureEBI_CSPin(0);
    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();
    ApplyStoredConfiguration(0);

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

Example 6: Dynamic configuration based on clock frequency

```

EBI_CS_cfg_t CreateTimingConfig(uint32_t ebiClockMHz,
                                uint32_t setupNs,
                                uint32_t pulseNs,
                                uint32_t holdNs)
{
    float nsPerCycle = 1000.0f / ebiClockMHz;

    uint8_t setupCycles = (uint8_t)((setupNs + nsPerCycle - 1) / nsPerCycle);
    uint8_t pulseCycles = (uint8_t)((pulseNs + nsPerCycle - 1) / nsPerCycle);
    uint8_t holdCycles = (uint8_t)((holdNs + nsPerCycle - 1) / nsPerCycle);
    uint16_t totalCycles = setupCycles + pulseCycles + holdCycles;

    return EBI_CS_cfg_t{
        .ncs_rd_setup = setupCycles, .nrd_setup = setupCycles,
        .ncs_rd_pulse = pulseCycles, .nrd_pulse = pulseCycles,
        .nrd_cycles = totalCycles,
        .ncs_wr_setup = setupCycles, .nwe_setup = setupCycles,
        .ncs_wr_pulse = pulseCycles, .nwe_pulse = pulseCycles,
        .nwe_cycles = totalCycles,
        .tdf_cycles = 2,
        .busWidth = EBI_BUS_WIDTH_16,
        .byteAccess = EBI_BYTE_ACCESS_WRITE,
        .nWait = EBI_NWAIT_DISABLED,
        .wrMode = EBI_WRITE_MODE_NWE,
        .rdMode = EBI_READ_MODE_NRD
    };
}

void InitializeDeviceWithTiming() {
    ConfigureEBI_CSPin(0);
    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();

    // Create config for 150MHz clock, 20ns setup, 70ns pulse, 10ns hold
    EBI_CS_cfg_t timing = CreateTimingConfig(150, 20, 70, 10);

    // Apply configuration
    ConfigureEBI_CS(0, timing);

    iprintf("Device configured with calculated timing\r\n");
}

```

14.40.3.2.3.3 ConfigureEBI_CSPin()

```

void ConfigureEBI_CSPin (
    int csNum)
#include <ebi.h>

```

Configure the I/O pin for a given Chip Select for the external data bus.

This function configures the GPIO pin associated with a specific chip select line on the External Bus Interface (EBI). The chip select pin is configured for proper timing and electrical characteristics to control external memory or peripheral devices connected to the data bus.

Parameters

<i>csNum</i>	The chip select number to configure (typically 0-3 depending on platform). Valid range depends on the specific NetBurner platform being used.

Note

This function should be called before attempting to access any external devices connected to the specified chip select line.

Warning

Ensure the chip select number is valid for your platform. Invalid values may result in undefined behavior.

Examples

Example 1: Configuring a single chip select for external SRAM

```
void UserMain(void *pd) {
    init();

    // Configure chip select 0 for external SRAM
    ConfigureEBI_CSPin(0);
    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();

    iprintf("EBI CS0 configured for external memory\r\n");

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

Example 2: Configuring multiple chip selects for different peripherals

```
void InitializeExternalBus() {
    // Configure CS0 for external SRAM
    ConfigureEBI_CSPin(0);

    // Configure CS1 for external FPGA
    ConfigureEBI_CSPin(1);

    // Configure CS2 for external display controller
    ConfigureEBI_CSPin(2);

    // Configure control signals shared by all devices
    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();

    iprintf("External bus configured for 3 devices\r\n");
}

void UserMain(void *pd) {
    init();
    InitializeExternalBus();

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

14.40.3.2.3.4 ConfigureEBI_NRDPin()

```
void ConfigureEBI_NRDPin ()
#include <ebi.h>
```

Configure the I/O pin for the active low read (NRD) bus signal.

This function configures the GPIO pin for the NRD (Not Read) signal on the External Bus Interface (EBI). The NRD signal is an active-low control signal that indicates when the bus is performing a read operation from an external device.

Note

This function must be called once during initialization before performing any read operations from external devices on the EBI bus.

The NRD pin is typically shared across all chip selects on the external bus.

    }
}
```

Example 3: Complete external bus setup with error checking

```
bool InitializeExternalBus(int csNum) {
    if (csNum < 0 || csNum > 3) {
        iprintf("Error: Invalid chip select %d\r\n", csNum);
        return false;
    }

    // Configure all necessary signals
    ConfigureEBI_CSPin(csNum);
    ConfigureEBI_NWRPin();
    ConfigureEBI_NRDPin();

    iprintf("EBI CS%d fully configured\r\n", csNum);
    return true;
}

void UserMain(void *pd) {
    init();

    if (InitializeExternalBus(0)) {
        iprintf("External device ready for operations\r\n");
    }
}
```

```

    }

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

14.40.3.2.3.5 ConfigureEBI_NWRPin()

```

void ConfigureEBI_NWRPin ()
#include <ebi.h>

```

Configure the I/O pin for the active low write/read (NWR) bus signal.

This function configures the GPIO pin for the NWR (Not Write) signal on the External Bus Interface (EBI). The NWR signal is an active-low control signal that indicates when the bus is performing a write operation to an external device.

Note

This function must be called once during initialization before performing any write operations to external devices on the EBI bus.

The NWR pin is typically shared across all chip selects on the external bus.

    ConfigureEBI_CSPin(0);

    // Configure write control signal
    ConfigureEBI_NWRPin();

    // Configure read control signal
    ConfigureEBI_NRDPin();

    iprintf("EBI configured for read/write operations\r\n");
}

void UserMain(void *pd) {
    init();
    InitializeEBI();

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

Example 2: Write-only external bus configuration

```

void InitializeWriteOnlyDevice() {
    // Configure CS for write-only display
    ConfigureEBI_CSPin(1);

    // Only need write signal for this device
    ConfigureEBI_NWRPin();

    iprintf("Write-only EBI device configured on CS1\r\n");
}

void UserMain(void *pd) {
    init();
    InitializeWriteOnlyDevice();

    // Device ready for write operations
    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

14.40.3.2.4 Variable Documentation

14.40.3.2.4.1 busWidth

`EBI_CS_BusWidth_t EBI_CS_cfg_t::busWidth`

Data bus width configuration.

Specifies whether the external device uses 8-bit or 16-bit data transfers. Must match the physical connection and device capabilities.

See also

[EBI_CS_BusWidth_t](#)

14.40.3.2.4.2 byteAccess

`EBI_CS_ByteAccess_t EBI_CS_cfg_t::byteAccess`

Byte access mode for 16-bit bus configurations.

Controls how 8-bit accesses are handled on a 16-bit bus. Only relevant when busWidth is set to `EBI_BUS_WIDTH_16`.

See also

[EBI_CS_ByteAccess_t](#)

Note

This setting is ignored for 8-bit bus configurations.

14.40.3.2.4.3 ncs_rd_pulse

`uint8_t EBI_CS_cfg_t::ncs_rd_pulse`

NCS (Chip Select) pulse width during read operations, in clock cycles. Defines how long the chip select remains asserted during a read.

Formula: NCS pulse length = $(256 \times \text{ncs\_rd\_pulse}[6] + \text{ncs\_rd\_pulse}[5:0])$ clock cycles

Range: 0-63 standard (0-16319 with extended bit)

Note

The pulse width determines the active time of the signal.

14.40.3.2.4.4 ncs_rd_setup

`uint8_t EBI_CS_cfg_t::ncs_rd_setup`

NCS (Chip Select) setup time for read operations, in clock cycles. Defines the time from CS assertion to read signal assertion.

Formula: NCS setup length = $(128 \times \text{ncs\_rd\_setup}[5] + \text{ncs\_rd\_setup}[4:0])$ clock cycles

Range: 0-63 standard (0-8063 with extended bit)

Note

This sets when the chip select activates before the read signal.

14.40.3.2.4.5 ncs_wr_pulse

`uint8_t EBI_CS_cfg_t::ncs_wr_pulse`

NCS (Chip Select) pulse width during write operations, in clock cycles. Defines how long the chip select remains asserted during a write.

Formula: NCS pulse length = $(256 \times \text{ncs\_wr\_pulse}[6] + \text{ncs\_wr\_pulse}[5:0])$ clock cycles

Range: 0-63 standard (0-16319 with extended bit)

14.40.3.2.4.6 ncs_wr_setup

`uint8_t EBI_CS_cfg_t::ncs_wr_setup`

NCS (Chip Select) setup time for write operations, in clock cycles. Defines the time from CS assertion to write signal assertion.

Formula: NCS setup length = $(128 \times \text{ncs\_wr\_setup}[5] + \text{ncs\_wr\_setup}[4:0])$ clock cycles

Range: 0-63 standard (0-8063 with extended bit)

14.40.3.2.4.7 nrd_cycles

`uint16_t EBI_CS_cfg_t::nrd_cycles`

Total read cycle length in clock cycles.

The total read cycle length is the complete duration of a read operation, equal to the sum of setup, pulse, and hold times for NRD and NCS signals.

Formula: Read cycle length = $(\text{nrd\_cycles}[8:7] \times 256 + \text{nrd\_cycles}[6:0])$ clock cycles

Range: 0-127 standard (0-32639 with extended bits)

Calculation: $\text{nrd\_cycles} = \text{ncs\_rd\_setup} + \text{ncs\_rd\_pulse} + \text{hold\_time}$

Note

The hold time is implicit: $\text{Hold} = \text{nrd\_cycles} - (\text{setup} + \text{pulse})$

14.40.3.2.4.8 nrd_pulse

`uint8_t EBI_CS_cfg_t::nrd_pulse`

NRD (Read Enable) pulse width, in clock cycles. Defines how long the read enable signal remains asserted.

Formula: NRD pulse length = $(256 \times \text{nrd\_pulse}[6] + \text{nrd\_pulse}[5:0])$ clock cycles

Range: 0-63 standard (0-16319 with extended bit)

Note

This is typically the minimum access time required by the device.

14.40.3.2.4.9 nrd_setup

`uint8_t EBI_CS_cfg_t::nrd_setup`

NRD (Read Enable) setup time, in clock cycles. Defines the delay from CS assertion to read enable assertion.

Formula: NRD setup length = $(128 \times \text{nrd\_setup}[5] + \text{nrd\_setup}[4:0])$ clock cycles

Range: 0-63 standard (0-8063 with extended bit)

14.40.3.2.4.10 nWait

`EBI_CS_NWait_t EBI_CS_cfg_t::nWait`

NWAIT signal mode for bus cycle extension.

Configures how the external NWAIT signal is used to extend read/write cycles for slow devices. Commonly used with flash memory or variable-speed peripherals.

See also

[EBI_CS_NWait_t](#)

Note

When disabled, all timing is strictly controlled by the configured values.

14.40.3.2.4.11 nwe_cycles

`uint16_t EBI_CS_cfg_t::nwe_cycles`

Total write cycle length in clock cycles.

The total write cycle length is the complete duration of a write operation, equal to the sum of setup, pulse, and hold times for NWE and NCS signals.

Formula: Write cycle length = (nwe_cycles[8:7] × 256 + nwe_cycles[6:0]) clock cycles

Range: 0-127 standard (0-32639 with extended bits)

Calculation: nwe_cycles = ncs_wr_setup + ncs_wr_pulse + hold_time

Note

The hold time is implicit: Hold = nwe_cycles - (setup + pulse)

14.40.3.2.4.12 nwe_pulse

uint8_t EBI_CS_cfg_t::nwe_pulse

NWE (Write Enable) pulse width, in clock cycles. Defines how long the write enable signal remains asserted.

Formula: NWE pulse length = (256 × nwe_pulse[6] + nwe_pulse[5:0]) clock cycles

Range: 0-63 standard (0-16319 with extended bit)

Note

This is typically the minimum write pulse time required by the device.

14.40.3.2.4.13 nwe_setup

uint8_t EBI_CS_cfg_t::nwe_setup

NWE (Write Enable) setup time, in clock cycles. Defines the delay from CS assertion to write enable assertion.

Formula: NWE setup length = (128 × nwe_setup[5] + nwe_setup[4:0]) clock cycles

Range: 0-63 standard (0-8063 with extended bit)

14.40.3.2.4.14 rdMode

EBI_CS_RdMode_t EBI_CS_cfg_t::rdMode

Read control signal selection.

Determines which signal (NCS or NRD) controls read operations from the external device.

See also

[EBI_CS_RdMode_t](#)

[ConfigureEBI_NRDPin\(\)](#)

14.40.3.2.4.15 tdf_cycles

uint8_t EBI_CS_cfg_t::tdf_cycles

Data Float time - number of clock cycles for the external device to release the data after the rising edge of the read controlling signal.

This represents the time the external device needs to tri-state its outputs after a read operation completes. The SMC always provides one full cycle of bus turnaround after this TDF period.

Valid range: 0-15 clock cycles

Note

This prevents bus contention when switching between read and write operations.

A value of 0-2 is typical for fast devices; 3-5 for slower devices.

14.40.3.2.4.16 wrMode

EBI_CS_WrMode_t EBI_CS_cfg_t::wrMode

Write control signal selection.

Determines which signal (NCS or NWE) controls write operations to the external device.

14.40.4.2 QTMR (Quad Timer)

The QTMR is a peripheral module that contains a set of general-purpose, 16-bit timers. These timers are very flexible and can be used for a wide range of timing, counting, and control tasks, including:

Classes

- [struct _qtmr_config](#)
Quad Timer config structure.

Typedefs

- typedef enum [_qtmr_primary_count_source](#) [qtmr_primary_count_source_t](#)
Quad Timer primary clock source selection.
- typedef enum [_qtmr_input_source](#) [qtmr_input_source_t](#)
Quad Timer input sources selection.
- typedef enum [_qtmr_counting_mode](#) [qtmr_counting_mode_t](#)
Quad Timer counting mode selection.
- typedef enum [_qtmr_pwm_out_state](#) [qtmr_pwm_out_state_t](#)
Quad Timer PWM output state.
- typedef enum [_qtmr_output_mode](#) [qtmr_output_mode_t](#)
Quad Timer output mode selection.
- typedef enum [_qtmr_input_capture_edge](#) [qtmr_input_capture_edge_t](#)
Quad Timer input capture edge mode, rising edge, or falling edge.
- typedef enum [_qtmr_preload_control](#) [qtmr_preload_control_t](#)
Quad Timer input capture edge mode, rising edge, or falling edge.
- typedef enum [_qtmr_debug_action](#) [qtmr_debug_action_t](#)
List of Quad Timer run options when in Debug mode.
- typedef enum [_qtmr_interrupt_enable](#) [qtmr_interrupt_enable_t](#)
List of Quad Timer interrupts.
- typedef enum [_qtmr_status_flags](#) [qtmr_status_flags_t](#)
List of Quad Timer flags.
- typedef enum [_qtmr_channel_selection](#) [qtmr_channel_selection_t](#)
List of channel selection.
- typedef enum [_qtmr_dma_enable](#) [qtmr_dma_enable_t](#)
List of Quad Timer DMA enable.
- typedef struct [_qtmr_config](#) [qtmr_config_t](#)
Quad Timer config structure.

Enumerations

- enum `_qtmr_primary_count_source` {
`kQTMR_ClockCounter0InputPin` = 0 , `kQTMR_ClockCounter1InputPin` , `kQTMR_ClockCounter2InputPin` ,
`kQTMR_ClockCounter3InputPin` ,
`kQTMR_ClockCounter0Output` , `kQTMR_ClockCounter1Output` , `kQTMR_ClockCounter2Output` ,
`kQTMR_ClockCounter3Output` ,
`kQTMR_ClockDivide_1` , `kQTMR_ClockDivide_2` , `kQTMR_ClockDivide_4` , `kQTMR_ClockDivide_8` ,
`kQTMR_ClockDivide_16` , `kQTMR_ClockDivide_32` , `kQTMR_ClockDivide_64` , `kQTMR_ClockDivide_128` }
Quad Timer primary clock source selection.
- enum `_qtmr_input_source` { `kQTMR_Counter0InputPin` = 0 , `kQTMR_Counter1InputPin` , `kQTMR_Counter2InputPin` ,
`kQTMR_Counter3InputPin` }
Quad Timer input sources selection.
- enum `_qtmr_counting_mode` {
`kQTMR_NoOperation` = 0 , `kQTMR_PriSrcRiseEdge` , `kQTMR_PriSrcRiseAndFallEdge` , `kQTMR_PriSrcRiseEdgeSecInpHigh` ,
`kQTMR_QuadCountMode` , `kQTMR_PriSrcRiseEdgeSecDir` , `kQTMR_SecSrcTrigPriCnt` , `kQTMR_CascadeCount` }
Quad Timer counting mode selection.
- enum `_qtmr_pwm_out_state` { `kQTMR_PwmLow` = 0 , `kQTMR_PwmHigh` }
Quad Timer PWM output state.
- enum `_qtmr_output_mode` {
`kQTMR_AssertWhenCountActive` = 0 , `kQTMR_ClearOnCompare` , `kQTMR_SetOnCompare` , `kQTMR_ToggleOnCompare` ,
`kQTMR_ToggleOnAltCompareReg` , `kQTMR_SetOnCompareClearOnSecSrcInp` , `kQTMR_SetOnCompareClearOnCountRoll` ,
`kQTMR_EnableGateClock` }
Quad Timer output mode selection.
- enum `_qtmr_input_capture_edge` { `kQTMR_NoCapture` = 0 , `kQTMR_RisingEdge` , `kQTMR_FallingEdge` ,
`kQTMR_RisingAndFallingEdge` }
Quad Timer input capture edge mode, rising edge, or falling edge.
- enum `_qtmr_preload_control` { `kQTMR_NoPreload` = 0 , `kQTMR_LoadOnComp1` , `kQTMR_LoadOnComp2` }
Quad Timer input capture edge mode, rising edge, or falling edge.
- enum `_qtmr_debug_action` { `kQTMR_RunNormalInDebug` = 0U , `kQTMR_HaltCounter` , `kQTMR_ForceOutToZero` ,
`kQTMR_HaltCountForceOutZero` }
List of Quad Timer run options when in Debug mode.
- enum `_qtmr_interrupt_enable` {
`kQTMR_CompareInterruptEnable` = (1U << 0) , `kQTMR_Compare1InterruptEnable` = (1U << 1) ,
`kQTMR_Compare2InterruptEnable` = (1U << 2) , `kQTMR_OverflowInterruptEnable` = (1U << 3) ,
`kQTMR_EdgeInterruptEnable` = (1U << 4) }
List of Quad Timer interrupts.
- enum `_qtmr_status_flags` {
`kQTMR_CompareFlag` = (1U << 0) , `kQTMR_Compare1Flag` = (1U << 1) , `kQTMR_Compare2Flag` = (1U << 2) ,
`kQTMR_OverflowFlag` = (1U << 3) ,
`kQTMR_EdgeFlag` = (1U << 4) }
List of Quad Timer flags.
- enum `_qtmr_channel_selection` { `kQTMR_Channel_0` = 0U , `kQTMR_Channel_1` , `kQTMR_Channel_2` ,
`kQTMR_Channel_3` }
List of channel selection.
- enum `_qtmr_dma_enable` { `kQTMR_InputEdgeFlagDmaEnable` = (1U << 0) , `kQTMR_ComparatorPreload1DmaEnable` =
(1U << 1) , `kQTMR_ComparatorPreload2DmaEnable` = (1U << 2) }
List of Quad Timer DMA enable.

Functions

- status_t [QTMR_SetupPwm](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel, uint32_t pwmFreqHz, uint8_t dutyCyclePercent, bool outputPolarity, uint32_t srcClock_Hz)
Sets up Quad timer module for PWM signal output.
- void [QTMR_SetupInputCapture](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel, [qtmr_input_source_t](#) capturePin, bool inputPolarity, bool reloadOnCapture, [qtmr_input_capture_edge_t](#) captureMode)
Allows the user to count the source clock cycles until a capture event arrives.

Initialization and deinitialization

- void [QTMR_Init](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel, const [qtmr_config_t](#) *config)
Ungates the Quad Timer clock and configures the peripheral for basic operation.
- void [QTMR_Deinit](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel)
Stops the counter and gates the Quad Timer clock.
- void [QTMR_GetDefaultConfig](#) ([qtmr_config_t](#) *config)
Fill in the Quad Timer config struct with the default settings.

Interrupt Interface

- void [QTMR_EnableInterrupts](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel, uint32_t mask)
Enables the selected Quad Timer interrupts.
- void [QTMR_DisableInterrupts](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel, uint32_t mask)
Disables the selected Quad Timer interrupts.
- uint32_t [QTMR_GetEnabledInterrupts](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel)
Gets the enabled Quad Timer interrupts.

Status Interface

- uint32_t [QTMR_GetStatus](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel)
Gets the Quad Timer status flags.
- void [QTMR_ClearStatusFlags](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel, uint32_t mask)
Clears the Quad Timer status flags.

Read and Write the timer period

- void [QTMR_SetTimerPeriod](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel, uint16_t ticks)
Sets the timer period in ticks.
- void [QTMR_SetCompareValue](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel, uint16_t ticks)
Set compare value.

Enable and Disable the Quad Timer DMA

- void [QTMR_EnableDma](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel, uint32_t mask)
Enable the Quad Timer DMA.
- void [QTMR_DisableDma](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel, uint32_t mask)
Disable the Quad Timer DMA.
- void [QTMR_SetPwmOutputToggle](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel, bool idleStatus)
Set PWM output in idle status (high or low).
- uint8_t [QTMR_GetPwmChannelStatus](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel)
Get the PWM channel dutycycle value.
- void [QTMR_SetPwmClockMode](#) (TMR_Type *base, [qtmr_channel_selection_t](#) channel, [qtmr_primary_count_source_t](#) prescaler)
This function set the value of the prescaler on QTimer channels.

Driver version

- #define `FSL_QTMR_DRIVER_VERSION` (MAKE_VERSION(2, 2, 2))

14.40.4.2.1 Detailed Description

The QTMR is a peripheral module that contains a set of general-purpose, 16-bit timers. These timers are very flexible and can be used for a wide range of timing, counting, and control tasks, including:

- Input capture
- Output compare
- PWM (Pulse-Width Modulation) signal generation
- Quadrature decoding

14.40.4.2.2 Macro Definition Documentation**14.40.4.2.2.1 FSL_QTMR_DRIVER_VERSION**

```
#define FSL_QTMR_DRIVER_VERSION (MAKE_VERSION(2, 2, 2))
#include <fsl_qtmr.h>
Version
```

14.40.4.2.3 Typedef Documentation**14.40.4.2.3.1 qtmr_config_t**

```
typedef struct _qtmr_config qtmr_config_t
#include <fsl_qtmr.h>
```

Quad Timer config structure.

This structure holds the configuration settings for the Quad Timer peripheral. To initialize this structure to reasonable defaults, call the [QTMR_GetDefaultConfig\(\)](#) function and pass a pointer to your config structure instance.

The config struct can be made const so it resides in flash

14.40.4.2.4 Enumeration Type Documentation**14.40.4.2.4.1 _qtmr_channel_selection**

```
enum _qtmr_channel_selection
#include <fsl_qtmr.h>
```

List of channel selection.

Enumerator

kQTMR_Channel↵ _0	TMR Channel 0
kQTMR_Channel↵ _1	TMR Channel 1
kQTMR_Channel↵ _2	TMR Channel 2
kQTMR_Channel↵ _3	TMR Channel 3

14.40.4.2.4.2 _qtmr_counting_mode

```
enum _qtmr_counting_mode
#include <fsl_qtmr.h>
```

Quad Timer counting mode selection.

Enumerator

kQTMR_NoOperation	No operation
kQTMR_PriSrcRiseEdge	Count rising edges of primary source
kQTMR_PriSrcRiseAndFallEdge	Count rising and falling edges of primary source
kQTMR_PriSrcRiseEdgeSecInpHigh	Count rise edges of pri SRC while sec inp high active
kQTMR_QuadCountMode	Quadrature count mode, uses pri and sec sources
kQTMR_PriSrcRiseEdgeSecDir	Count rising edges of pri SRC; sec SRC specifies dir
kQTMR_SecSrcTrigPriCnt	Edge of sec SRC trigger primary count until compare
kQTMR_CascadeCount	Cascaded count mode (up/down)

14.40.4.2.4.3 _qtmr_debug_action

```
enum _qtmr_debug_action
```

```
#include <fsl_qtmr.h>
```

List of Quad Timer run options when in Debug mode.

Enumerator

kQTMR_RunNormalInDebug	Continue with normal operation
kQTMR_HaltCounter	Halt counter
kQTMR_ForceOutToZero	Force output to logic 0
kQTMR_HaltCountForceOutZero	Halt counter and force output to logic 0

14.40.4.2.4.4 _qtmr_dma_enable

```
enum _qtmr_dma_enable
```

```
#include <fsl_qtmr.h>
```

List of Quad Timer DMA enable.

Enumerator

kQTMR_InputEdgeFlagDmaEnable	Input Edge Flag DMA Enable.
kQTMR_ComparatorPreload1DmaEnable	Comparator Preload Register 1 DMA Enable.
kQTMR_ComparatorPreload2DmaEnable	Comparator Preload Register 2 DMA Enable.

14.40.4.2.4.5 _qtmr_input_capture_edge

```
enum _qtmr_input_capture_edge
```

```
#include <fsl_qtmr.h>
```

Quad Timer input capture edge mode, rising edge, or falling edge.

Enumerator

kQTMR_NoCapture	Capture is disabled
kQTMR_RisingEdge	Capture on rising edge (IPS=0) or falling edge (IPS=1)
kQTMR_FallingEdge	Capture on falling edge (IPS=0) or rising edge (IPS=1)
kQTMR_RisingAndFallingEdge	Capture on both edges

14.40.4.2.4.6 _qtmr_input_source

```
enum _qtmr_input_source
#include <fsl_qtmr.h>
Quad Timer input sources selection.
```

Enumerator

kQTMR_Counter0InputPin	Use counter 0 input pin
kQTMR_Counter1InputPin	Use counter 1 input pin
kQTMR_Counter2InputPin	Use counter 2 input pin
kQTMR_Counter3InputPin	Use counter 3 input pin

14.40.4.2.4.7 _qtmr_interrupt_enable

```
enum _qtmr_interrupt_enable
#include <fsl_qtmr.h>
List of Quad Timer interrupts.
```

Enumerator

kQTMR_CompareInterruptEnable	Compare interrupt.
kQTMR_Compare1InterruptEnable	Compare 1 interrupt.
kQTMR_Compare2InterruptEnable	Compare 2 interrupt.
kQTMR_OverflowInterruptEnable	Timer overflow interrupt.
kQTMR_EdgeInterruptEnable	Input edge interrupt.

14.40.4.2.4.8 _qtmr_output_mode

```
enum _qtmr_output_mode
#include <fsl_qtmr.h>
Quad Timer output mode selection.
```

Enumerator

kQTMR_AssertWhenCountActive	Assert OFLAG while counter is active
kQTMR_ClearOnCompare	Clear OFLAG on successful compare
kQTMR_SetOnCompare	Set OFLAG on successful compare
kQTMR_ToggleOnCompare	Toggle OFLAG on successful compare
kQTMR_ToggleOnAltCompareReg	Toggle OFLAG using alternating compare registers
kQTMR_SetOnCompareClearOnSecSrcInp	Set OFLAG on compare, clear on sec SRC input edge
kQTMR_SetOnCompareClearOnCountRoll	Set OFLAG on compare, clear on counter rollover
kQTMR_EnableGateClock	Enable gated clock output while count is active

14.40.4.2.4.9 _qtmr_preload_control

```
enum _qtmr_preload_control
#include <fsl_qtmr.h>
Quad Timer input capture edge mode, rising edge, or falling edge.
```

Enumerator

kQTMR_NoPreload	Never preload

Enumerator

kQTMR_LoadOnComp1	Load upon successful compare with value in COMP1
kQTMR_LoadOnComp2	Load upon successful compare with value in COMP2

14.40.4.2.4.10 _qtmr_primary_count_source

```
enum _qtmr_primary_count_source
```

```
#include <fsl_qtmr.h>
```

Quad Timer primary clock source selection.

Enumerator

kQTMR_ClockCounter0InputPin	Use counter 0 input pin
kQTMR_ClockCounter1InputPin	Use counter 1 input pin
kQTMR_ClockCounter2InputPin	Use counter 2 input pin
kQTMR_ClockCounter3InputPin	Use counter 3 input pin
kQTMR_ClockCounter0Output	Use counter 0 output
kQTMR_ClockCounter1Output	Use counter 1 output
kQTMR_ClockCounter2Output	Use counter 2 output
kQTMR_ClockCounter3Output	Use counter 3 output
kQTMR_ClockDivide_1	IP bus clock divide by 1 prescaler
kQTMR_ClockDivide_2	IP bus clock divide by 2 prescaler
kQTMR_ClockDivide_4	IP bus clock divide by 4 prescaler
kQTMR_ClockDivide_8	IP bus clock divide by 8 prescaler
kQTMR_ClockDivide_16	IP bus clock divide by 16 prescaler
kQTMR_ClockDivide_32	IP bus clock divide by 32 prescaler
kQTMR_ClockDivide_64	IP bus clock divide by 64 prescaler
kQTMR_ClockDivide_128	IP bus clock divide by 128 prescaler

14.40.4.2.4.11 _qtmr_pwm_out_state

```
enum _qtmr_pwm_out_state
```

```
#include <fsl_qtmr.h>
```

Quad Timer PWM output state.

Enumerator

kQTMR_PwmLow	The output state of PWM channel is low
kQTMR_PwmHigh	The output state of PWM channel is low

14.40.4.2.4.12 _qtmr_status_flags

```
enum _qtmr_status_flags
```

```
#include <fsl_qtmr.h>
```

List of Quad Timer flags.

Enumerator

kQTMR_CompareFlag	Compare flag

Enumerator

kQTMR_Compare1Flag	Compare 1 flag
kQTMR_Compare2Flag	Compare 2 flag
kQTMR_OverflowFlag	Timer overflow flag
kQTMR_EdgeFlag	Input edge flag

14.40.4.2.5 Function Documentation

14.40.4.2.5.1 QTMR_ClearStatusFlags()

```
void QTMR_ClearStatusFlags (
    TMR_Type * base,
    qtmr_channel_selection_t channel,
    uint32_t mask)
#include <fsl_qtmr.h>
Clears the Quad Timer status flags.
```

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number
<i>mask</i>	The status flags to clear. This is a logical OR of members of the enumeration qtmr_status_flags_t

brief Clears the Quad Timer status flags.

param base Quad Timer peripheral base address param channel Quad Timer channel number param mask The status flags to clear. This is a logical OR of members of the enumeration [qtmr_status_flags_t](#)

14.40.4.2.5.2 QTMR_Deinit()

```
void QTMR_Deinit (
    TMR_Type * base,
    qtmr_channel_selection_t channel)
#include <fsl_qtmr.h>
Stops the counter and gates the Quad Timer clock.
```

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number

brief Stops the counter and gates the Quad Timer clock

param base Quad Timer peripheral base address param channel Quad Timer channel number

14.40.4.2.5.3 QTMR_DisableDma()

```
void QTMR_DisableDma (
    TMR_Type * base,
    qtmr_channel_selection_t channel,
    uint32_t mask)
#include <fsl_qtmr.h>
Disable the Quad Timer DMA.
```

Parameters

<i>base</i>	Quad Timer peripheral base address

<i>channel</i>	Quad Timer channel number
<i>mask</i>	The DMA to enable. This is a logical OR of members of the enumeration qtmr_dma_enable_t

brief Disable the Quad Timer DMA.

param base Quad Timer peripheral base address param channel Quad Timer channel number param mask The DMA to enable. This is a logical OR of members of the enumeration [qtmr_dma_enable_t](#)

14.40.4.2.5.4 QTMR_DisableInterrupts()

```
void QTMR_DisableInterrupts (
    TMR_Type * base,
    qtmr_channel_selection_t channel,
    uint32_t mask)
```

```
#include <fsl_qtmr.h>
```

Disables the selected Quad Timer interrupts.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number
<i>mask</i>	The interrupts to enable. This is a logical OR of members of the enumeration qtmr_interrupt_enable_t

brief Disables the selected Quad Timer interrupts

param base Quad Timer peripheral base address param channel Quad Timer channel number param mask The interrupts to enable. This is a logical OR of members of the enumeration [qtmr_interrupt_enable_t](#)

14.40.4.2.5.5 QTMR_EnableDma()

```
void QTMR_EnableDma (
    TMR_Type * base,
    qtmr_channel_selection_t channel,
    uint32_t mask)
```

```
#include <fsl_qtmr.h>
```

Enable the Quad Timer DMA.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number
<i>mask</i>	The DMA to enable. This is a logical OR of members of the enumeration qtmr_dma_enable_t

brief Enable the Quad Timer DMA.

param base Quad Timer peripheral base address param channel Quad Timer channel number param mask The DMA to enable. This is a logical OR of members of the enumeration [qtmr_dma_enable_t](#)

14.40.4.2.5.6 QTMR_EnableInterrupts()

```
void QTMR_EnableInterrupts (
    TMR_Type * base,
    qtmr_channel_selection_t channel,
    uint32_t mask)
```

```
#include <fsl_qtmr.h>
```

Enables the selected Quad Timer interrupts.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number
<i>mask</i>	The interrupts to enable. This is a logical OR of members of the enumeration qtmr_interrupt_enable_t

brief Enables the selected Quad Timer interrupts

param base Quad Timer peripheral base address param channel Quad Timer channel number param mask The interrupts to enable. This is a logical OR of members of the enumeration [qtmr_interrupt_enable_t](#)

14.40.4.2.5.7 QTMR_GetDefaultConfig()

```
void QTMR_GetDefaultConfig (
    qtmr_config_t * config)
#include <fsl_qtmr.h>
```

Fill in the Quad Timer config struct with the default settings.

The default values are:

```
config->debugMode = kQTMR_RunNormalInDebug;
config->enableExternalForce = false;
config->enableMasterMode = false;
config->faultFilterCount = 0;
config->faultFilterPeriod = 0;
config->primarySource = kQTMR_ClockDivide_2;
config->secondarySource = kQTMR_Counter0InputPin;
```

Parameters

<i>config</i>	Pointer to user's Quad Timer config structure.

brief Fill in the Quad Timer config struct with the default settings

The default values are: code config->debugMode = kQTMR_RunNormalInDebug; config->enableExternalForce = false; config->enableMasterMode = false; config->faultFilterCount = 0; config->faultFilterPeriod = 0; config->primarySource = kQTMR_ClockDivide_2; config->secondarySource = kQTMR_Counter0InputPin; end-code param config Pointer to user's Quad Timer config structure.

14.40.4.2.5.8 QTMR_GetEnabledInterrupts()

```
uint32_t QTMR_GetEnabledInterrupts (
    TMR_Type * base,
    qtmr_channel_selection_t channel)
#include <fsl_qtmr.h>
```

Gets the enabled Quad Timer interrupts.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number

Returns

The enabled interrupts. This is the logical OR of members of the enumeration [qtmr_interrupt_enable_t](#)

brief Gets the enabled Quad Timer interrupts

param base Quad Timer peripheral base address param channel Quad Timer channel number

return The enabled interrupts. This is the logical OR of members of the enumeration [qtmr_interrupt_enable_t](#)

14.40.4.2.5.9 QTMR_GetPwmChannelStatus()

```
uint8_t QTMR_GetPwmChannelStatus (
    TMR_Type * base,
    qtmr_channel_selection_t channel)
```

```
#include <fsl_qtmr.h>
```

Get the PWM channel dutycycle value.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number

Returns

Current channel dutycycle value.

brief Get the PWM channel dutycycle value.

param base Quad Timer peripheral base address param channel Quad Timer channel number

return Current channel dutycycle value.

14.40.4.2.5.10 QTMR_GetStatus()

```
uint32_t QTMR_GetStatus (
    TMR_Type * base,
    qtmr_channel_selection_t channel)
```

```
#include <fsl_qtmr.h>
```

Gets the Quad Timer status flags.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number

Returns

The status flags. This is the logical OR of members of the enumeration [qtmr_status_flags_t](#)

brief Gets the Quad Timer status flags

param base Quad Timer peripheral base address param channel Quad Timer channel number

return The status flags. This is the logical OR of members of the enumeration [qtmr_status_flags_t](#)

14.40.4.2.5.11 QTMR_Init()

```
void QTMR_Init (
    TMR_Type * base,
    qtmr_channel_selection_t channel,
    const qtmr_config_t * config)
```

```
#include <fsl_qtmr.h>
```

Ungates the Quad Timer clock and configures the peripheral for basic operation.

Note

This API should be called at the beginning of the application using the Quad Timer driver.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number
<i>config</i>	Pointer to user's Quad Timer config structure

brief Ungates the Quad Timer clock and configures the peripheral for basic operation.

note This API should be called at the beginning of the application using the Quad Timer driver.

param base Quad Timer peripheral base address param channel Quad Timer channel number param config Pointer to user's Quad Timer config structure

14.40.4.2.5.12 QTMR_SetCompareValue()

```
void QTMR_SetCompareValue (
    TMR_Type * base,
    qtmr_channel_selection_t channel,
    uint16_t ticks)
```

```
#include <fsl_qtmr.h>
```

Set compare value.

This function sets the value used for comparison with the counter value.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number
<i>ticks</i>	Timer period in units of ticks.

brief Set compare value.

This function sets the value used for comparison with the counter value.

param base Quad Timer peripheral base address param channel Quad Timer channel number param ticks Timer period in units of ticks.

14.40.4.2.5.13 QTMR_SetPwmClockMode()

```
void QTMR_SetPwmClockMode (
    TMR_Type * base,
    qtmr_channel_selection_t channel,
    qtmr_primary_count_source_t prescaler)
```

```
#include <fsl_qtmr.h>
```

This function set the value of the prescaler on QTimer channels.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number
<i>prescaler</i>	Set prescaler value

brief This function set the value of the prescaler on QTimer channels.

param base Quad Timer peripheral base address param channel Quad Timer channel number param prescaler Set prescaler value

14.40.4.2.5.14 QTMR_SetPwmOutputToIdle()

```
void QTMR_SetPwmOutputToIdle (
    TMR_Type * base,
    qtmr_channel_selection_t channel,
    bool idleStatus)
```

```
#include <fsl_qtmr.h>
```

Set PWM output in idle status (high or low).

Note

When the PWM is set again, the counting needs to be restarted.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number
<i>idleStatus</i>	True: PWM output is high in idle status; false: PWM output is low in idle status.

brief Set PWM output in idle status (high or low).

Note: When the PWM is set again, the counting needs to be restarted.

param base Quad Timer peripheral base address param channel Quad Timer channel number param idleStatus True: PWM output is high in idle status; false: PWM output is low in idle status.

14.40.4.2.5.15 QTMR_SetTimerPeriod()

```
void QTMR_SetTimerPeriod (
    TMR_Type * base,
    qtmr_channel_selection_t channel,
    uint16_t ticks)
```

```
#include <fsl_qtmr.h>
```

Sets the timer period in ticks.

Timers counts from initial value till it equals the count value set here. The counter will then reinitialize to the value specified in the Load register.

Note

1. This function will write the time period in ticks to COMP1 or COMP2 register depending on the count direction
2. User can call the utility macros provided in [fsl_common.h](#) to convert to ticks
3. This function supports cases, providing only primary source clock without secondary source clock.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number
<i>ticks</i>	Timer period in units of ticks

brief Sets the timer period in ticks.

Timers counts from initial value till it equals the count value set here. The counter will then reinitialize to the value specified in the Load register.

note

1. This function will write the time period in ticks to COMP1 or COMP2 register depending on the count direction
2. User can call the utility macros provided in [fsl_common.h](#) to convert to ticks
3. This function supports cases, providing only primary source clock without secondary source clock.
4. The load register is reset before the counter is reinitialized to the value specified in the load register.

param base Quad Timer peripheral base address param channel Quad Timer channel number param ticks Timer period in units of ticks

14.40.4.2.5.16 QTMR_SetupInputCapture()

```
void QTMR_SetupInputCapture (
    TMR_Type * base,
    qtmr_channel_selection_t channel,
    qtmr_input_source_t capturePin,
    bool inputPolarity,
    bool reloadOnCapture,
    qtmr_input_capture_edge_t captureMode)
```

```
#include <fsl_qtmr.h>
```

Allows the user to count the source clock cycles until a capture event arrives.

The count is stored in the capture register.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number
<i>capturePin</i>	Pin through which we receive the input signal to trigger the capture
<i>inputPolarity</i>	true: invert polarity of the input signal, false: no inversion
<i>reloadOnCapture</i>	true: reload the counter when an input capture occurs, false: no reload
<i>captureMode</i>	Specifies which edge of the input signal triggers a capture

brief Allows the user to count the source clock cycles until a capture event arrives.

The count is stored in the capture register.

param base Quad Timer peripheral base address param channel Quad Timer channel number param capturePin Pin through which we receive the input signal to trigger the capture param inputPolarity true: invert polarity of the input signal, false: no inversion param reloadOnCapture true: reload the counter when an input capture occurs, false: no reload param captureMode Specifies which edge of the input signal triggers a capture

14.40.4.2.5.17 QTMR_SetupPwm()

```
status_t QTMR_SetupPwm (
    TMR_Type * base,
    qtmr_channel_selection_t channel,
    uint32_t pwmFreqHz,
    uint8_t dutyCyclePercent,
    bool outputPolarity,
    uint32_t srcClock_Hz)
```

```
#include <fsl_qtmr.h>
```

Sets up Quad timer module for PWM signal output.

The function initializes the timer module according to the parameters passed in by the user. The function also sets up the value compare registers to match the PWM signal requirements.

Parameters

<i>base</i>	Quad Timer peripheral base address
<i>channel</i>	Quad Timer channel number
<i>pwmFreqHz</i>	PWM signal frequency in Hz
<i>dutyCyclePercent</i>	PWM pulse width, value should be between 0 to 100 0=inactive signal(0% duty cycle)... 100=active signal (100% duty cycle)
<i>outputPolarity</i>	true: invert polarity of the output signal, false: no inversion
<i>srcClock_Hz</i>	Main counter clock in Hz.

Returns

Returns an error if there was error setting up the signal.

brief Sets up Quad timer module for PWM signal output.

The function initializes the timer module according to the parameters passed in by the user. The function also sets up the value compare registers to match the PWM signal requirements.

param base Quad Timer peripheral base address param channel Quad Timer channel number param pwmFreqHz PWM signal frequency in Hz param dutyCyclePercent PWM pulse width, value should be between 0 to 100 0=inactive signal(0% duty cycle)... 100=active signal (100% duty cycle) param outputPolarity true: invert polarity of the output signal, false: no inversion param srcClock_Hz Main counter clock in Hz.

return Returns an error if there was error setting up the signal.

14.40.4.3 SEMC

Smart External Memory Controller functions (SOMRT1061)

Classes

- struct [SEMC_cfg_t](#)

Configuration structure for SEMC (Smart External Memory Controller) interface.

Enumerations

- enum class [SEMC_BusWidth_t](#) : uint8_t { [SEMC_BusWidth_t::Width_8](#) = 0 , [SEMC_BusWidth_t::Width_16](#) = 1 }
- Data bus width configuration for SEMC interface.*
- enum class [SEMC_AddrMux_t](#) : uint8_t { [SEMC_AddrMux_t::Mux](#) = 0 , [SEMC_AddrMux_t::AdvMux](#) = 1 , [SEMC_AddrMux_t::Bus](#) = 2 }
- Address multiplexing mode configuration.*
- enum class [SEMC_ColAddrWidth_t](#) : uint8_t { [SEMC_ColAddrWidth_t::Width_12](#) = 0 , [SEMC_ColAddrWidth_t::Width_11](#) = 1 , [SEMC_ColAddrWidth_t::Width_10](#) = 2 , [SEMC_ColAddrWidth_t::Width_9](#) = 3 , [SEMC_ColAddrWidth_t::Width_8](#) = 4 , [SEMC_ColAddrWidth_t::Width_7](#) = 5 , [SEMC_ColAddrWidth_t::Width_6](#) = 6 , [SEMC_ColAddrWidth_t::Width_5](#) = 7 , [SEMC_ColAddrWidth_t::Width_4](#) = 8 , [SEMC_ColAddrWidth_t::Width_3](#) = 9 , [SEMC_ColAddrWidth_t::Width_2](#) = 10 , [SEMC_ColAddrWidth_t::Width_0](#) = 12 }
- Column address width configuration for memory devices.*
- enum class [SEMC_ClkMode_t](#) : uint8_t { [SEMC_ClkMode_t::Async](#) = 0 , [SEMC_ClkMode_t::Sync](#) = 1 }
- Clock mode configuration for SEMC interface.*
- enum class [SEMC_Burst_t](#) : uint8_t { [SEMC_Burst_t::Burst_1](#) = 0 , [SEMC_Burst_t::Burst_2](#) = 1 , [SEMC_Burst_t::Burst_4](#) = 2 , [SEMC_Burst_t::Burst_8](#) = 3 , [SEMC_Burst_t::Burst_16](#) = 4 , [SEMC_Burst_t::Burst_32](#) = 5 , [SEMC_Burst_t::Burst_64](#) = 6 }
- Burst transfer length configuration.*

Functions

- void [ConfigureSEMC](#) (uint32_t baseAddr, uint32_t siz, [SEMC_cfg_t](#) &&cfg)
Configure a Chip Select for the external data bus with rvalue reference configuration.
- void [ConfigureSEMC](#) (uint32_t baseAddr, uint32_t siz, [SEMC_cfg_t](#) &cfg)
Configure a Chip Select for the external data bus with lvalue reference configuration.

14.40.4.3.1 Detailed Description

Smart External Memory Controller functions (SOMRT1061)

```
#include< semc.h>
```

14.40.4.3.2 SEMC Overview

The Smart External Memory Controller (SEMC) provides a flexible interface for connecting external parallel memory devices to the i.MX RT1061 processor. The SEMC supports various memory types including SRAM, PSRAM, NOR Flash, and other parallel bus devices.

14.40.4.3.2.1 Key Features

- Multiple chip select support (CS0-CS3)
- Configurable data bus widths (8-bit, 16-bit)
- Asynchronous and synchronous clock modes
- Burst transfer support (1, 2, 4, 8, 16, 32, 64 beats)
- Multiplexed and non-multiplexed addressing modes

- Independent timing configuration per chip select
- Memory-mapped access via standard pointers
- Address range: 0x80000000 - 0x9FFFFFFF

14.40.4.3.2.2 Memory Address Map

Memory Region Layout:

14.40.4.3.2.3 Basic Usage Workflow

14.40.4.3.2.4 Operating Modes

Asynchronous Mode (`SEMC_ClkMode_t::Async`)

Timing Diagram (`Async` Read):

Synchronous Mode (`SEMC_ClkMode_t::Sync`)

Timing Diagram (`Sync` Burst Read):

14.40.4.3.2.5 Addressing Modes

Multiplexed Mode ([SEMC_AddrMux_t::Mux](#))

Address and Data share the same bus pins:

```
AD_BUS[15:0]  <ADDRESS> <===== DATA =====>
CS            \-----/
ADV           \-----/
```

- Reduces pin count
- Address latched by ADV signal
- Common **for** SRAM and PSRAM devices

Non-Multiplexed Mode ([SEMC_AddrMux_t::Bus](#))

Separate Address and Data buses:

```
ADDR[n:0]     <===== ADDRESS =====>
DATA[15:0]    <===== DATA =====>
CS            \-----/
```

- Faster access times
- More pins required
- Better **for** high-performance applications

14.40.4.3.2.6 Timing Calculation

All timing values are specified in SEMC clock cycles. The actual time depends on the SEMC clock frequency configured in your system.

Example: SEMC Clock = 100 MHz (10 ns per cycle)

If device datasheet specifies:

- Address Setup Time: 15 ns minimum
- Read Enable Low: 30 ns minimum
- Read Enable High: 50 ns minimum

Calculate cycles needed:

```
addr_setup = ceil(15 ns / 10 ns) - 1 = 2 - 1 = 1
rd_en_lo   = ceil(30 ns / 10 ns) - 1 = 3 - 1 = 2
rd_en_hi   = ceil(50 ns / 10 ns) - 1 = 5 - 1 = 4
```

Note: Many timing parameters are (n+1) cycles, so subtract 1 from the calculated value.

14.40.4.3.2.7 Configuration Structure

The [SEMC_cfg_t](#) structure uses unions to provide both hardware register access and structured field access:

Memory Layout:

```
+-----+ CR0 (Control Register 0)
| busWidth      :1| Bus width selection
| clkMode       :1| Clock mode (Async/Sync)
| RESERVED      :2|
| burstLen      :3| Burst length
| RESERVED      :1|
| muxMode       :2| Address multiplexing mode
| advPol        :1| ADV signal polarity
| advHoldLvl    :1| ADV hold level
| colAddrWidth  :4| Column address width
+-----+

+-----+ CR1 (Control Register 1)
| cs_setup      :4| Chip select setup time (n+1)
| cs_hold_min   :4| Chip select hold time (n+1)
| addr_setup    :4| Address setup time (n+1)
| addr_hold     :4| Address hold time
| wr_en_lo      :4| Write enable low time (n+1)
| wr_en_hi      :4| Write enable high time (n+1)
| rd_en_lo      :4| Read enable low time (n+1)
| rd_en_hi      :4| Read enable high time (n+1)
+-----+

+-----+ CR2 (Control Register 2)
| wr_dat_setup  :4| Write data setup (n+1)
| wr_dat_hold   :4| Write data hold (n)
| addr_wr_hold  :4| Address write hold (n+1)
```

```

| turnaround      :4| Turnaround time (n)
| latency         :4| Read latency (n)
| rd_cycle        :4| Read cycle time (n+1)
| cs_min_intv     :4| CS minimum interval (n+1)
| rd_hold         :4| Read hold time (n)
+-----+

+-----+
| clkPin (PinIO) | Clock pin assignment
+-----+

+-----+
| csPin (PinIO)  | Chip select pin assignment
+-----+

```

14.40.4.3.2.8 Multiple Chip Select Configuration

Memory Map Example with Multiple CS:

```

+-----+ 0x9FFFFFFF
| Unused Space |
+-----+ 0x80180000
| CS2: 16-bit   | ConfigureSEMC(0x80100000, 0x80000, cfg2)
| Flash (512 KB)|
+-----+ 0x80100000
| CS1: 8-bit    | ConfigureSEMC(0x80080000, 0x80000, cfg1)
| SRAM (512 KB) |
+-----+ 0x80080000
| CS0: 16-bit   | ConfigureSEMC(0x80000000, 0x80000, cfg0)
| PSRAM (512 KB)|
+-----+ 0x80000000 <-- SEMC_Base[]

```

Requirements:

- Base addresses must be aligned to size boundary
- Memory regions must not overlap
- Each CS can have independent timing configuration
- Different CS pins must be used **for each** region

14.40.4.3.2.9 Common Configuration Examples

Typical Async SRAM Configuration:

Device Type: IS61WV51216BLL (512K x 16-bit SRAM)
Access Time: 10ns
SEMC Clock: 100 MHz

```

SEMC_cfg_t cfg {
    .busWidth = SEMC_BusWidth_t::Width_16,
    .clkMode = SEMC_ClkMode_t::Async,
    .burstLen = SEMC_Burst_t::Burst_1,
    .muxMode = SEMC_AddrMux_t::Mux,
    .colAddrWidth = SEMC_ColAddrWidth_t::Width_0,
    .cs_setup = 1,           // 2 cycles = 20ns
    .cs_hold_min = 1,       // 2 cycles = 20ns
    .addr_setup = 1,        // 2 cycles = 20ns
    .addr_hold = 1,         // 2 cycles = 20ns
    .wr_en_lo = 2,          // 3 cycles = 30ns
    .wr_en_hi = 2,          // 3 cycles = 30ns
    .rd_en_lo = 2,          // 3 cycles = 30ns
    .rd_en_hi = 4,          // 5 cycles = 50ns
};

```

Typical Sync Burst PSRAM Configuration:

Device Type: IS66/67WVE4M16EBLL (Synchronous PSRAM)
Clock: 100 MHz
Latency: 3 cycles

```

SEMC_cfg_t cfg {
    .busWidth = SEMC_BusWidth_t::Width_16,
    .clkMode = SEMC_ClkMode_t::Sync,
    .burstLen = SEMC_Burst_t::Burst_8,
    .muxMode = SEMC_AddrMux_t::Mux,
    .colAddrWidth = SEMC_ColAddrWidth_t::Width_8,
    .cs_setup = 2,           // CS setup before clock
    .cs_hold_min = 2,       // CS hold after clock
    .addr_setup = 1,        // Address setup
    .addr_hold = 1,         // Address hold
    .wr_dat_setup = 1,      // Write data setup
    .wr_dat_hold = 0,       // Write data hold
    .latency = 3,           // Read latency cycles
};

```

```

        .rd_cycle = 5,          // Total read cycle time
        .cs_min_intv = 1,      // Minimum CS interval
        .rd_hold = 1,         // Read data hold
};

```

14.40.4.3.2.10 Memory Access Patterns

Direct Memory Access:

```

// Configure SEMC for external SRAM
ConfigureSEMC(0x80000000, 0x100000, cfg);

// Access as standard memory
uint8_t *bytePtr = (uint8_t *)0x80000000;
uint16_t *wordPtr = (uint16_t *)0x80000000;
uint32_t *dwordPtr = (uint32_t *)0x80000000;

// Byte access
bytePtr[0] = 0x42;
uint8_t value = bytePtr[0];

// Word access (16-bit)
wordPtr[0] = 0x1234;
uint16_t word = wordPtr[0];

// Double-word access (32-bit)
dwordPtr[0] = 0xDEADBEEF;
uint32_t dword = dwordPtr[0];

```

Bulk Data Transfer:

```

uint8_t *extMem = (uint8_t *)0x80000000;
uint8_t buffer[1024];

// Write block of data
memcpy(extMem, buffer, sizeof(buffer));

// Read block of data
memcpy(buffer, extMem, sizeof(buffer));

// Pattern fill
memset(extMem, 0xFF, 1024);

```

Structure Access:

```

struct DataRecord {
    uint32_t id;
    uint16_t value;
    uint8_t status;
    uint8_t flags;
};

// Place structure array in external memory
DataRecord *records = (DataRecord *)0x80000000;

// Access structure members
records[0].id = 1234;
records[0].value = 0x5678;
records[0].status = 0x01;

// Iterate through records
for (int i = 0; i < 100; i++) {
    records[i].id = i;
    records[i].value = i * 2;
}

```

14.40.4.3.2.11 Troubleshooting Guide

Common Issues and Solutions:

```

Issue: Data corruption or incorrect reads
+-----+
| Check: |

14.40.4.3.2.12 Best Practices

- Always add timing margin (10-20%) beyond minimum datasheet specifications
- Initialize SEMC during system startup, before any memory access
- Verify timing calculations against datasheet at your SEMC clock frequency
- Use const for read-only data stored in external Flash memory
- Consider cache implications for frequently accessed data
- Test memory thoroughly after configuration changes
- Document the specific memory device part number and timing calculations
- Use volatile keyword when hardware registers might change externally
- Align data structures to natural boundaries for best performance
- Implement error detection/correction if data integrity is critical

14.40.4.3.2.13 Performance Considerations

Access Performance Comparison (approximate):

Memory Type	Typical Access	Throughput
Internal SRAM	1 cycle	Maximum
External SRAM (Async)	5-10 cycles	Medium
External SRAM (Sync)	3-6 cycles	High
External Flash (Async)	10-20 cycles	Low

Burst Mode Benefits:

- First access: Full latency
- Subsequent accesses: 1 cycle each
- Best for sequential data access
- Up to 8x performance for burst-8 mode

14.40.4.3.2.14 Memory Region Symbols

The linker provides symbols for SEMC memory regions:

```

extern uint8_t SEMC_Base[];      // Start of SEMC address space
extern uint8_t _s_data_bus[];    // Start of data bus region
extern uint8_t _e_data_bus[];    // End of data bus region

```

Usage example:

```

void CheckSEMCRegion(void *ptr) {
    uintptr_t addr = (uintptr_t)ptr;
    uintptr_t base = (uintptr_t)SEMC_Base;

    if (addr >= base && addr < (base + 0x20000000)) {
        iprintf("Address is in SEMC region\n");
    }
}

```

Note

For detailed timing parameter descriptions, see [SEMC_cfg_t](#) structure documentation.

Consult your external memory device datasheet for specific timing requirements.

SEMC configuration should be done early in UserMain() before accessing external memory.

See also

[ConfigureSEMC\(\)](#)
[SEMC_cfg_t](#)

14.40.4.3.3 Enumeration Type Documentation

14.40.4.3.3.1 SEMC_AddrMux_t

```
enum class SEMC_AddrMux_t : uint8_t [strong]
#include <semc.h>
```

Address multiplexing mode configuration.

Determines how address signals are presented on the bus interface. The mode affects pin usage, timing characteristics, and compatibility with different memory devices.

Note

Multiplexed modes reduce pin count by sharing address and data pins.

Non-multiplexed mode provides fastest access but requires separate address pins.

Consult your memory device datasheet for supported addressing modes.

Warning

Bus mode (non-multiplexed) performs reads as AD-Mux due to hardware limitation.

See also

[SEMC_cfg_t::muxMode](#)

Enumerator

Mux	Multiplexed address/data mode. Address and data share the same pins. Requires ADV signal to latch address.
AdvMux	Advanced multiplexed mode. Enhanced multiplexing with additional control signals for complex timing.
Bus	Non-multiplexed bus mode (write only). Separate address and data buses. Reads are performed as AD-Mux. Best for write-heavy applications.

14.40.4.3.3.2 SEMC_Burst_t

```
enum class SEMC_Burst_t : uint8_t [strong]
#include <semc.h>
```

Burst transfer length configuration.

Specifies the number of data beats (words) transferred in a single burst operation. Burst transfers improve throughput for sequential memory accesses by eliminating address overhead after the first access.

Note

Burst mode is most effective in synchronous clock mode ([SEMC_ClkMode_t::Sync](#)).

The external memory device must support the selected burst length.

Larger burst sizes provide better performance for sequential access patterns.

Single-beat (Burst_1) effectively disables burst mode.

Burst Performance Example ([Sync](#) Mode, 100 MHz SEMC Clock):

```
Single Access (Burst_1):
+-----+-----+-----+-----+
| Addr | Data | Addr | Data | = 4 cycles for 2 words
+-----+-----+-----+-----+
```

```

Throughput: 50 million words/sec

Burst-4 Access:
+-----+-----+-----+-----+-----+
| Addr  | Data0  | Data1  | Data2  | Data3  | = 5 cycles for 4 words
+-----+-----+-----+-----+-----+
Throughput: 80 million words/sec (1.6x faster)

Burst-8 Access:
+-----+-----+-----+-----+
| Addr  | Data0  | ...   | Data7  |      = 9 cycles for 8 words
+-----+-----+-----+-----+
Throughput: 88.9 million words/sec (1.78x faster)

Performance Improvement:
- Burst_2: ~1.3x faster than single
- Burst_4: ~1.6x faster than single
- Burst_8: ~1.8x faster than single
- Burst_16: ~1.9x faster than single
- Burst_32: ~1.94x faster than single

```

Warning

Verify your memory device supports the selected burst length before use.
Some devices may have alignment requirements for burst addresses.

See also

[SEMC_cfg_t::burstLen](#)
[SEMC_ClkMode_t::Sync](#)

Enumerator

Burst_1	Single-beat transfer. No burst mode. Each access requires full address cycle. Use for random access or non-burst devices.
Burst_2	2-beat burst transfer. Address once, transfer 2 consecutive data words. Minimal burst mode.
Burst_4	4-beat burst transfer. Address once, transfer 4 consecutive data words. Common burst length for many devices.
Burst_8	8-beat burst transfer. Address once, transfer 8 consecutive data words. Optimal for cache line fills (32 bytes with 16-bit bus).
Burst_16	16-beat burst transfer. Address once, transfer 16 consecutive data words. High-performance sequential access.
Burst_32	32-beat burst transfer. Address once, transfer 32 consecutive data words. Maximum sequential performance.
Burst_64	64-beat burst transfer. Address once, transfer 64 consecutive data words. Extreme burst length for specialized applications.

14.40.4.3.3.3 SEMC_BusWidth_t

```

enum class SEMC_BusWidth_t : uint8_t [strong]
#include <semc.h>

```

Data bus width configuration for SEMC interface.

Specifies the width of the data bus connecting the processor to the external memory device. The bus width must match the physical memory device's data interface width.

Note

16-bit bus width provides higher throughput but requires more pins.
8-bit bus width uses fewer pins but requires more bus cycles for wide data transfers.
Verify your hardware PCB design supports the selected bus width.

See also

[SEMC_cfg_t::busWidth](#)

Enumerator

Width_8	8-bit data bus (D[7:0]). Suitable for 8-bit memory devices or low pin-count designs.
Width_16	16-bit data bus (D[15:0]). Suitable for 16-bit memory devices. Provides 2x throughput compared to 8-bit.

14.40.4.3.3.4 SEMC_ClkMode_t

```
enum class SEMC_ClkMode_t : uint8_t [strong]
```

```
#include <semc.h>
```

Clock mode configuration for SEMC interface.

Determines whether the memory interface operates in asynchronous or synchronous mode. This affects timing requirements, performance characteristics, and which timing parameters in [SEMC_cfg_t](#) are used.

Note

Asynchronous mode is simpler and works with most SRAM and NOR Flash devices.

Synchronous mode provides better performance with SDRAM and synchronous PSRAM.

Different timing parameters apply depending on the selected mode.

Mode Comparison:

Characteristic	Async Mode	Sync Mode
Timing	Fixed delays	Clock-synchronized
Performance	Moderate	Higher
Burst Support	Limited	Full support
Device Types	SRAM, NOR Flash	SDRAM, Sync PSRAM
Complexity	Simple	More complex

Timing Parameters Used:

Async Mode:

- cs_setup, cs_hold_min
- addr_setup, addr_hold
- wr_en_lo, wr_en_hi
- rd_en_lo, rd_en_hi
- addr_wr_hold
- turnaround

Sync Mode:

- cs_setup, cs_hold_min
- addr_setup, addr_hold
- wr_dat_setup, wr_dat_hold
- latency
- rd_cycle
- rd_hold

See also

[SEMC_cfg_t::clkMode](#)

[SEMC_cfg_t](#) (for timing parameter details)

Enumerator

Async	Asynchronous mode. Timing based on fixed delays. No clock synchronization required. Best for SRAM and asynchronous NOR Flash devices.
Sync	Synchronous mode. All signals synchronized to SEMC clock. Supports burst transfers. Best for SDRAM and synchronous PSRAM devices.

14.40.4.3.3.5 SEMC_ColAddrWidth_t

```
enum class SEMC_ColAddrWidth_t : uint8_t [strong]
```

```
#include <semc.h>
```

Column address width configuration for memory devices.

Specifies the number of column address bits used by the external memory device. This setting determines how many address pins are configured and affects the memory organization and access patterns.

Note

Width_0 disables address pin configuration - use for simple SRAM/Flash without column addressing.

For SDRAM and burst-capable devices, match this to the device's column address width.

Incorrect width settings can cause address aliasing or inaccessible memory regions.

Example Device Specifications:

Memory Device	Column Addresses	Use Setting
Simple SRAM/Flash	N/A	Width_0
SDRAM (8-bit columns)	A[7:0]	Width_8
SDRAM (10-bit columns)	A[9:0]	Width_10
SDRAM (12-bit columns)	A[11:0]	Width_12

See also

[SEMC_cfg_t::colAddrWidth](#)

Enumerator

Width_12	12-bit column address (A[11:0]). Maximum column address width, suitable for large SDRAM devices.
Width_11	11-bit column address (A[10:0]). Common for medium-density SDRAM.
Width_10	10-bit column address (A[9:0]). Common for standard SDRAM configurations.
Width_9	9-bit column address (A[8:0]). Used in some SDRAM and synchronous memory devices.
Width_8	8-bit column address (A[7:0]). Common for smaller SDRAM and burst-capable PSRAM.
Width_7	7-bit column address (A[6:0]). Used in specialized or smaller memory configurations.
Width_6	6-bit column address (A[5:0]). Minimal column addressing for compact devices.
Width_5	5-bit column address (A[4:0]). Very limited column addressing.
Width_4	4-bit column address (A[3:0]). Minimal configuration for small burst regions.
Width_3	3-bit column address (A[2:0]). Extremely limited addressing, rarely used.
Width_2	2-bit column address (A[1:0]). Minimal burst addressing capability.
Width_0	No column addressing. Do not configure address pins for column mode. Use for simple SRAM/NOR Flash without column addressing requirements.

14.40.4.3.4 Function Documentation**14.40.4.3.4.1 ConfigureSEMC() [1/2]**

```
void ConfigureSEMC (
    uint32_t baseAddr,
    uint32_t siz,
    SEMC_cfg_t && cfg)
```

```
#include <semc.h>
```

Configure a Chip Select for the external data bus with rvalue reference configuration.

This function configures the Smart External Memory Controller (SEMC) for a specific chip select with the provided memory region and timing parameters. This overload accepts an rvalue reference, making it suitable for temporary configuration objects.

The SEMC controller manages external memory devices connected to the RT1061's parallel bus interface. Configuration includes timing parameters, bus width, addressing modes, and signal characteristics required by the external memory device.

Parameters

<i>baseAddr</i>	The base address to assign to the configured chip select. This address must be within the valid SEMC memory region and properly aligned based on the size parameter. Typical range: 0x80000000 - 0x9FFFFFFF for SEMC CS0-CS3.

Parameters

<i>size</i>	The size (in bytes) of the memory region assigned to this chip select. Must be a power of 2 and properly aligned with the base address. Common values include 64KB (0x10000), 128KB (0x20000), 256KB (0x40000), etc.
<i>cfg</i>	Rvalue reference to the SEMC_cfg_t structure containing the configuration parameters. This allows passing temporary configuration objects efficiently.

Note

The base address and size must not overlap with other configured chip selects.

Ensure all timing parameters in the *cfg* structure match your external device's datasheet requirements.

The *clkPin* and *csPin* in the configuration must be properly initialized before calling this function.

Warning

Incorrect timing parameters can cause data corruption or system instability.

This function should be called during system initialization before accessing the external memory region.

Examples

Basic SRAM Configuration (Async Mode, 8-bit)

```
#include <semc.h>

void UserMain(void *pd) {
    init();

    // Configure SEMC for an 8-bit async SRAM at 0x80000000
    ConfigureSEMC(
        0x80000000,    // Base address
        0x40000,      // 256KB size
        SEMC_cfg_t{
            .busWidth = SEMC_BusWidth_t::Width_8,
            .clkMode = SEMC_ClkMode_t::Async,
            .burstLen = SEMC_Burst_t::Burst_1,
            .muxMode = SEMC_AddrMux_t::Mux,
            .colAddrWidth = SEMC_ColAddrWidth_t::Width_0,
            .cs_setup = 1,
            .cs_hold_min = 1,
            .addr_setup = 1,
            .addr_hold = 1,
            .wr_en_lo = 2,
            .wr_en_hi = 2,
            .rd_en_lo = 2,
            .rd_en_hi = 4,
            .clkPin = Pins[10], // Example clock pin
            .csPin = Pins[11]  // Example CS pin
        }
    );

    // Access external memory
    uint8_t *extMem = (uint8_t *)0x80000000;
    extMem[0] = 0x42;
    iprintf("Value written: 0x%02X\n", extMem[0]);
}
```

16-bit Synchronous Burst Memory

```
#include <semc.h>

void ConfigureSyncMemory() {
    // Configure SEMC for 16-bit synchronous burst memory
    ConfigureSEMC(
        0x80000000,    // Base address
        0x100000,      // 1MB size
        SEMC_cfg_t{
            .busWidth = SEMC_BusWidth_t::Width_16,
            .clkMode = SEMC_ClkMode_t::Sync,
            .burstLen = SEMC_Burst_t::Burst_8,
            .muxMode = SEMC_AddrMux_t::Mux,
            .colAddrWidth = SEMC_ColAddrWidth_t::Width_8,
            .cs_setup = 2,
            .cs_hold_min = 2,
            .addr_setup = 1,
        }
    );
}
```

```

        .addr_hold = 1,
        .wr_dat_setup = 1,
        .wr_dat_hold = 0,
        .latency = 3,
        .rd_cycle = 5,
        .cs_min_intv = 1,
        .rd_hold = 1,
        .clkPin = Pins[10],
        .csPin = Pins[11]
    }
};

```

Multiple Chip Selects with Non-Multiplexed Addressing

```

#include <semc.h>

void ConfigureMultipleMemories() {
    // First memory region - 8-bit SRAM
    ConfigureSEMC(
        0x80000000,
        0x80000, // 512KB
        SEMC_cfg_t{
            .busWidth = SEMC_BusWidth_t::Width_8,
            .clkMode = SEMC_ClkMode_t::Async,
            .muxMode = SEMC_AddrMux_t::Bus,
            .colAddrWidth = SEMC_ColAddrWidth_t::Width_0,
            .cs_setup = 1,
            .cs_hold_min = 1,
            .addr_setup = 2,
            .addr_hold = 2,
            .wr_en_lo = 3,
            .wr_en_hi = 3,
            .rd_en_lo = 3,
            .rd_en_hi = 5,
            .turnaround = 2,
            .clkPin = Pins[10],
            .csPin = Pins[11]
        }
    );

    // Second memory region - 16-bit Flash
    ConfigureSEMC(
        0x80080000, // Non-overlapping base address
        0x100000, // 1MB
        SEMC_cfg_t{
            .busWidth = SEMC_BusWidth_t::Width_16,
            .clkMode = SEMC_ClkMode_t::Async,
            .muxMode = SEMC_AddrMux_t::Mux,
            .colAddrWidth = SEMC_ColAddrWidth_t::Width_0,
            .cs_setup = 2,
            .cs_hold_min = 2,
            .addr_setup = 3,
            .addr_hold = 3,
            .wr_en_lo = 5,
            .wr_en_hi = 5,
            .rd_en_lo = 6,
            .rd_en_hi = 8,
            .clkPin = Pins[10],
            .csPin = Pins[12] // Different CS pin
        }
    );
}

```

14.40.4.3.4.2 ConfigureSEMC() [2/2]

```

void ConfigureSEMC (
    uint32_t baseAddr,
    uint32_t siz,
    SEMC_cfg_t & cfg)

```

```
#include <semc.h>
```

Configure a Chip Select for the external data bus with lvalue reference configuration.

This function configures the Smart External Memory Controller (SEMC) for a specific chip select with the provided memory region and timing parameters. This overload accepts an lvalue reference, making it suitable for reusing existing configuration objects.

The SEMC controller manages external memory devices connected to the RT1061's parallel bus interface. Configuration includes timing parameters, bus width, addressing modes, and signal characteristics required by the external memory device.

Parameters

<i>baseAddr</i>	The base address to assign to the configured chip select. This address must be within the valid SEMC memory region and properly aligned based on the size parameter. Typical range: 0x80000000 - 0x9FFFFFFF for SEMC CS0-CS3.
<i>sz</i>	The size (in bytes) of the memory region assigned to this chip select. Must be a power of 2 and properly aligned with the base address. Common values include 64KB (0x10000), 128KB (0x20000), 256KB (0x40000), etc.
<i>cfg</i>	Lvalue reference to the SEMC_cfg_t structure containing the configuration parameters. This allows reusing configuration objects across multiple calls.

Note

The base address and size must not overlap with other configured chip selects.

Ensure all timing parameters in the *cfg* structure match your external device's datasheet requirements.

The *clkPin* and *csPin* in the configuration must be properly initialized before calling this function.

Warning

Incorrect timing parameters can cause data corruption or system instability.

This function should be called during system initialization before accessing the external memory region.

TEMPMON alarm mode.

Enumerations

- enum [_tempmon_alarm_mode](#) { [kTEMPMON_HighAlarmMode](#) = 0U , [kTEMPMON_PanicAlarmMode](#) = 1U ,
[kTEMPMON_LowAlarmMode](#) = 2U }
TEMPMON alarm mode.

Functions

- void [TEMPMON_Init](#) (TEMPMON_Type *base, const [tempmon_config_t](#) *config)
Initializes the TEMPMON module.
- void [TEMPMON_Deinit](#) (TEMPMON_Type *base)
Deinitializes the TEMPMON module.
- void [TEMPMON_GetDefaultConfig](#) ([tempmon_config_t](#) *config)
Gets the default configuration structure.
- float [TEMPMON_GetCurrentTemperature](#) (TEMPMON_Type *base)
Get current temperature with the fused temperature calibration data.
- void [TEMPMON_SetTempAlarm](#) (TEMPMON_Type *base, int8_t tempVal, [tempmon_alarm_mode](#) alarm↔
Mode)
Set the temperature count (raw sensor output) that will generate an alarm interrupt.

Driver version

- #define [FSL_TEMPMON_DRIVER_VERSION](#) (MAKE_VERSION(2, 1, 1))
TEMPMON driver version.

14.40.4.4.1 Detailed Description

i.MX RT1061 Processor Temperature Monitor

14.40.4.4.2 Enumeration Type Documentation

14.40.4.4.2.1 _tempmon_alarm_mode

```
enum \_tempmon\_alarm\_mode
#include <fsl\_tempmon.h>
TEMPMON alarm mode.
```

Enumerator

kTEMPMON_HighAlarmMode	The high alarm temperature interrupt mode.
kTEMPMON_PanicAlarmMode	The panic alarm temperature interrupt mode.
kTEMPMON_LowAlarmMode	The low alarm temperature interrupt mode.

14.40.4.4.3 Function Documentation**14.40.4.4.3.1 TEMPMON_Deinit()**

```
void TEMPMON_Deinit (
    TEMPMON_Type * base)
#include <fsl_tempmon.h>
Deinitializes the TEMPMON module.
```

Parameters

<i>base</i>	TEMPMON base pointer

14.40.4.4.3.2 TEMPMON_GetCurrentTemperature()

```
float TEMPMON_GetCurrentTemperature (
    TEMPMON_Type * base)
#include <fsl_tempmon.h>
Get current temperature with the fused temperature calibration data.
```

Parameters

<i>base</i>	TEMPMON base pointer

Returns

current temperature with degrees Celsius.

14.40.4.4.3.3 TEMPMON_GetDefaultConfig()

```
void TEMPMON_GetDefaultConfig (
    tempmon_config_t * config)
#include <fsl_tempmon.h>
Gets the default configuration structure.
```

This function initializes the TEMPMON configuration structure to a default value. The default values are: tempmonConfig->frequency = 0x02U; tempmonConfig->highAlarmTemp = 44U; tempmonConfig->panicAlarmTemp = 90U; tempmonConfig->lowAlarmTemp = 39U;

Parameters

<i>config</i>	Pointer to a configuration structure.

14.40.4.4.3.4 TEMPMON_Init()

```
void TEMPMON_Init (
    TEMPMON_Type * base,
    const tempmon_config_t * config)
#include <fsl_tempmon.h>
Initializes the TEMPMON module.
```

Parameters

<i>base</i>	TEMPMON base pointer
<i>config</i>	Pointer to configuration structure.

14.40.4.4.3.5 TEMPMON_SetTempAlarm()

```
void TEMPMON_SetTempAlarm (
    TEMPMON_Type * base,
    int8_t tempVal,
    tempmon_alarm_mode alarmMode)
```

```
#include <fsl_tempmon.h>
```

Set the temperature count (raw sensor output) that will generate an alarm interrupt.

Parameters

<i>base</i>	TEMPMON base pointer
<i>tempVal</i>	The alarm temperature with degrees Celsius
<i>alarmMode</i>	The alarm mode.

14.41 SMTP - Send Email

Topics

- [MIME Content Types](#)
- [SMTP Error Codes](#)
- [SSL SMTP Functions](#)

Functions

- int [SendMail](#) (IPADDR smtp_server, PCSTR userid, PCSTR from_addr, PCSTR to_addr, PCSTR subject, PCSTR textbox)

Send an email message. The function will open a TCP connection to the specified SMTP server, create a message based on the parameters, and send the message.
- int [SendMailAuth](#) (IPADDR smtp_server, PCSTR userid, PCSTR pass, PCSTR from_addr, PCSTR to_addr, PCSTR subject, PCSTR textbox)

Send an email message with plain text authentication. The function will open a TCP connection to the specified SMTP server, create a message based on the parameters, and send the message.
- int [SendMailEx](#) (IPADDR smtp_server, PCSTR userid, PCSTR from_addr_rev_path, PCSTR from_addr, PCSTR to_addr, PCSTR subject, PCSTR textbox)

Send an email message function, extended version.
- int [IsMailError](#) ()

Returns the error status of the last send mail transaction.
- void [PrintNError](#) (int fd=0)

If an error occurred, prints the error information received from the SMTP server.
- void [PrintServerLog](#) (int fd=0)

Prints the server log of the last send mail transaction.
- int [SendMailAuthStartMIME](#) (IPADDR smtp_server, PCSTR userid, PCSTR pass, PCSTR from_addr, PCSTR to_addr, PCSTR subject, int &fd)

Start a Multi-purpose Internet Mail Extension (MIME) session.
- int [SendMailAuthAddMIME](#) (int fd, int ContentType, const char *pContent, const char *FileName)

Add a MIME part or attachment to an open MIME Session.
- int [SendMailAuthEndMIME](#) (int fd, PCSTR userid)

Send a MIME email message and close the SMTP session.

- enum [CONTENT_TYPE_ENUM](#) {
[CONTENT_TYPE_PLAIN_TEXT](#) , [CONTENT_TYPE_PLAIN_TEXT_ATTACH](#) , [CONTENT_TYPE_BINARY_ATTACH](#)
, [CONTENT_TYPE_HTML_DECOMP](#) ,
[CONTENT_TYPE_END](#) }

SMTP MIME Conetnet Types.

14.41.1 Detailed Description

```
#include< mailto.h>
```

Send emails using the SMTP specification. The Send Mail functions provide a variety of sending options for simple sending an email, or sending with authentication. The IsMailError function is used to check for errors after an email is sent.

14.41.2 Enumeration Type Documentation

14.41.2.1 CONTENT_TYPE_ENUM

```
enum CONTENT\_TYPE\_ENUM
#include <mailto.h>
SMTP MIME Conetnet Types.
```

Enumerator

CONTENT_TYPE_PLAIN_TEXT	Plain text.
CONTENT_TYPE_PLAIN_TEXT_ATTACH	Plain text attachment.
CONTENT_TYPE_BINARY_ATTACH	Binary attachment.
CONTENT_TYPE_HTML_DECOMP	HTML.
CONTENT_TYPE_END	Additional content types can be added above this line.

14.41.3 Function Documentation

14.41.3.1 IsMailError()

```
int IsMailError ()
#include <mailto.h>
```

Returns the error status of the last send mail transaction.

Returns

0 if no error occurred, [SMTP Error Codes](#).

See also

[PrintNError\(\)](#), [PrintServerLog\(\)](#)

14.41.3.2 PrintNError()

```
void PrintNError (
    int fd = 0)
#include <mailto.h>
```

If an error occurred, prints the error information received from the SMTP server.

If an error occurs when sending an email, the system will record the error information received from the SMTP server. The information is only valid for the last transaction.

Parameters

<i>fd</i>	If no parameter is specified information will be sent to stdout. Otherwise it will be sent to the specified file descriptor.

See also

[IsMailError\(\)](#), [PrintServerLog\(\)](#)

14.41.3.3 PrintServerLog()

```
void PrintServerLog (
    int fd = 0)
#include <mailto.h>
```

Prints the server log of the last send mail transaction.

The results of each send mail transaction are logged to a buffer. This function will send the results of the last transaction to stdout, or the specified file descriptor. The information is only valid for the last transaction.

Parameters

<i>fd</i>	If no parameter is specified information will be sent to stdout. Otherwise it will be sent to the specified file descriptor.

See also

[IsMailError\(\)](#), [PrintNError\(\)](#)

14.41.3.4 SendMail()

```
int SendMail (
    IPADDR smtp_server,
    PCSTR userid,
    PCSTR from_addr,
    PCSTR to_addr,
    PCSTR subject,
    PCSTR textbody)
```

```
#include <mailto.h>
```

Send an email message. The function will open a TCP connection to the specified SMTP server, create a message based on the parameters, and send the message.

Parameters

<i>smtp_server</i>	IP address of the destination SMTP server.
<i>userid</i>	ASCII string representing the RFC 931 identification.
<i>from_addr</i>	"From" email address
<i>to_addr</i>	Destination email address
<i>subject</i>	Email subject
<i>textbody</i>	Body of email message

Returns

0 on failure, 1 on success.

See also

[SendMailAuth\(\)](#)

14.41.3.5 SendMailAuth()

```
int SendMailAuth (
    IPADDR smtp_server,
    PCSTR userid,
    PCSTR pass,
    PCSTR from_addr,
    PCSTR to_addr,
    PCSTR subject,
    PCSTR textbody)
```

```
#include <mailto.h>
```

Send an email message with plain text authentication. The function will open a TCP connection to the specified SMTP server, create a message based on the parameters, and send the message.

Send an email message with SMTP plain text authentication per RFC 931. The function will open a TCP connection to the specified SMTP server, authenticate the connection with the specified username and password, create a message based on the parameters, and send the message.

Parameters

<i>smtp_server</i>	IP address of the destination SMTP server.
<i>userid</i>	ASCII string representing the RFC 931 identification.
<i>pass</i>	ASCII string to provide for AUTH identification.
<i>from_addr</i>	"From" email address
<i>to_addr</i>	Destination email address
<i>subject</i>	Email subject
<i>textbody</i>	Body of email message

Returns

0 on failure, 1 on success.

See also

[SendMail\(\)](#)

14.41.3.6 SendMailAuthAddMIME()

```
int SendMailAuthAddMIME (
    int fd,
    int ContentType,
    const char * pContent,
    const char * FileName)
```

```
#include <mailto.h>
```

Add a MIME part or attachment to an open MIME Session.

Must only be called for an open session started with [SendMailAuthStartMIME\(\)](#). It can be called as many times as needed to add each MIME part or attachment to the message.

Parameters

<i>fd</i>	The file descriptor of the open MIME session.
<i>ContentType</i>	The MIME content type, such as: CONTENT_TYPE_PLAIN_TEXT, CONTENT_TYPE_PLAIN_TEXT_ATTACH, CONTENT_TYPE_BINARY_ATTACH.
<i>*pContent</i>	Pointer to the content to add.
<i>*FileName</i>	File name for the attachment.

Returns

0 on failure, 1 on success.

See also

[SendMailAuthStartMIME\(\)](#), [SendMailAuthEndMIME\(\)](#)

14.41.3.7 SendMailAuthEndMIME()

```
int SendMailAuthEndMIME (
    int fd,
    PCSTR userid)
```

```
#include <mailto.h>
```

Send a MIME email message and close the SMTP session.

Must only be called for an open session started with [SendMailAuthStartMIME\(\)](#).

Parameters

<i>fd</i>	The file descriptor of the open MIME session.
<i>*userid</i>	The user ID that was used by SendMailAuthStartMIME() to open the session.

Returns

0 on failure, 1 on success.

See also

[SendMailAuthStartMIME\(\)](#), [SendMailAuthAddMIME\(\)](#)

14.41.3.8 SendMailAuthStartMIME()

```
int SendMailAuthStartMIME (
    IPADDR smtp_server,
    PCSTR userid,
    PCSTR pass,
    PCSTR from_addr,
    PCSTR to_addr,
    PCSTR subject,
    int & fd)
```

```
#include <mailto.h>
```

Start a Multi-purpose Internet Mail Extension (MIME) session.

Start a MIME session with plain text password authentication. This function will open a TCP connection to the SMTP server, authenticate, then return while leaving the TCP connection open. The Session file descriptor is returned in the "int &fd" reference variable. This function must be called before any other SendMail MIME function.

Sending an E-Mail message with Multipurpose Internet Mail Extensions (MIME) is a multi step process:

- Call [SendMailAuthStartMIME\(\)](#) to begin a Session with the SMTP server, connection will remain open.
- Call [SendMailAuthAddMIME\(\)](#) for each MIME attachment you want to add.
- Call [SendMailAuthEndMIME\(\)](#) to send the email message and close the Session.

The following MIME types are supported by default. The binary attachment should cover most types such as jpg, gif, etc. The types are defined in \nburn\nbrtos\include\mailto.h, and the functions are implemented in \nburn\system\mailto.cpp.

MIME Content Types defined by [MIME Content Types](#).

Parameters

<i>smtp_server</i>	IP address of the destination SMTP server.
<i>userid</i>	ASCII string representing the RFC 931 identification.
<i>pass</i>	Password.
<i>from_addr</i>	Reverse path per RFC 821, reverse source route.
<i>to_addr</i>	Destination email address.
<i>subject</i>	Email subject.
<i>fd</i>	A reference (or pointer) to an integer value of the calling function. The value of fd is modified by this function and will contain the file descriptor for the open SMTP Session. This value must always be checked to be greater than 0 for a valid Session. The fd is passed to other MIME functions to identify the open Session.

Returns

0 on failure, 1 on success.

See also

[SendMailAuthAddMIME\(\)](#), [SendMailAuthEndMIME\(\)](#)

14.41.3.9 SendMailEx()

```
int SendMailEx (
    IPADDR smtp_server,
    PCSTR userid,
    PCSTR from_addr_rev_path,
    PCSTR from_addr_memo_hdr,
    PCSTR to_addr,
    PCSTR subject,
    PCSTR textbody)
```

#include <mailto.h>

Send an email message function, extended version.

Send an email message with extended parameters. The function will open a TCP connection to the specified SMTP server, create a message based on the parameters, and send the message. This function is identical to [SendMail\(\)](#), with the addition of the from_addr_rev_path and from_addr_memo_hdr parameters.

Parameters

<i>smtp_server</i>	IP address of the destination SMTP server.
<i>userid</i>	ASCII string representing the RFC 931 identification.
<i>from_addr_rev_path</i>	Reverse path per RFC 821, reverse source route.
<i>from_addr_memo_hdr</i>	From address memo header per RFC 821. Contains items such as date, subject, to:, CC: and from:.
<i>to_addr</i>	Destination email address
<i>subject</i>	Email subject
<i>textbody</i>	Body of email message

Returns

0 on failure, 1 on success.

See also

[SendMail\(\)](#)

14.41.4 MIME Content Types

```
#include< mailto.h>
```

14.41.5 SMTP Error Codes

Macros

- **#define STATUS_OK (0)**
OK, no errors.
- **#define CONNECT_TO_SMTP_SERVER_FAILED (-1)**
Could not connect to SMTP server.
- **#define INITIAL_SERVER_REPLY_FAILED (-2)**
Initial server reply failed.
- **#define HELO_SERVER_REPLY_FAILED (-3)**
Server HELO reply failed.
- **#define MAIL_FROM_SERVER_REPLY_FAILED (-4)**
Mail From server reply failed.
- **#define RCPT_TO_SERVER_REPLY_FAILED (-5)**
Receipt To server reply failed.
- **#define DATA_SERVER_REPLY_FAILED (-6)**
Data server reply failed.
- **#define DATA_END_SERVER_REPLY_FAILED (-7)**
Date end server reply failed.
- **#define AUTH_LOGIN_SERVER_REPLY_FAILED (-8)**
AUTH login server reply failed.
- **#define USER_ID_SERVER_REPLY_FAILED (-9)**
User ID server reply failed.
- **#define PASSWORD_SERVER_REPLY_FAILED (-10)**
Password server reply failed.
- **#define CONNECT931_SMTP_SERVER_FAILED (-11)**
SMTP connection failed.

14.41.5.1 Detailed Description

```
#include< mailto.h>
```

14.41.6 SSL SMTP Functions

Functions

- int [SSL_SendMail](#) ([IPADDR](#) smtp_server, PCSTR userid, PCSTR pass, PCSTR from_addr, PCSTR to_↵
addr, PCSTR subject, PCSTR textbody, BOOL STARTTLS=false, int remotePort=-1, const char *server↵
Name=nullptr, bool verifyPeer=false, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_↵
_t certBuffFormat=SSL_FILETYPE_PEM)
Send an email message using SSL encryption.
- int [SSL_SendMailHTML](#) ([IPADDR](#) smtp_server, PCSTR userid, PCSTR pass, PCSTR from_addr, PCSTR
to_addr, PCSTR subject, const char *filename, BOOL STARTTLS=false, int remotePort=-1, const char
*serverName=nullptr, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuff↵
Format=SSL_FILETYPE_PEM)

Send an HTML email message from a file using SSL encryption.

- int [SSL_SendMailStartMIME](#) (IPADDR smtp_server, PCSTR userid, PCSTR pass, PCSTR from_addr, PCSTR to_addr, PCSTR subject, BOOL STARTTLS=false, int remotePort=-1, const char *serverName=nullptr, bool verifyPeer=false, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM)

Start a Multi-purpose Internet Mail Extension (MIME) session using SSL encryption.

14.41.6.1 Detailed Description

The following functions is very similar to the unencrypted [SendMail\(\)](#) function. The initial connection of the SMTP server can happen in one of two ways:

1) An SSL connection is negotiated immediately. 2) A TCP connection is opened first, and a SSL connection is negotiated when the SMTP server sends a STARTTLS command to the NetBurner device.

Setting STARTTLS = TRUE enables the second mode of operation.

14.41.6.2 Function Documentation

14.41.6.2.1 SSL_SendMail()

```
int SSL_SendMail (
    IPADDR smtp_server,
    PCSTR userid,
    PCSTR pass,
    PCSTR from_addr,
    PCSTR to_addr,
    PCSTR subject,
    PCSTR textbody,
    BOOL STARTTLS = false,
    int remotePort = -1,
    const char * serverName = nullptr,
    bool verifyPeer = false,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)
```

```
#include <ssl_mailto.h>
```

Send an email message using SSL encryption.

Parameters

<i>smtp_server</i>	IP address of the SMTP server.
<i>userid</i>	Ascii String to provide for RFC931 IDentification.
<i>pass</i>	Ascii String to provide for AUTH IDentification.
<i>from_addr</i>	From email address.
<i>to_addr</i>	To email address.
<i>subject</i>	The email subject.
<i>textbody</i>	The email body.
<i>STARTTLS</i>	Enable/disable STARTTLS functionality. Default is disabled.
<i>remotePort</i>	Port number to connect to on the SMTP server.
<i>serverName</i>	Server common name to use for certificate name verification and when sending SNI extensions.
<i>verifyPeer</i>	Set true to verify the server's certificate against a Certificate Authority list. Default if false.
<i>certBuff</i>	Buffer containing the certificate data.Default is null.
<i>certBuffSize</i>	Size of the buffer containing the certificate data.
<i>certBuffFormat</i>	The format of the certificate buffer. Default is SSL_FILETYPE_PEM.

Return values

0	Send failed
1	Send was successful

See also

[SSL_SendMailHTML\(\)](#)

[SSL_SendMailStartMIME\(\)](#)

[SendMail\(\)](#)

14.41.6.2.2 SSL_SendMailHTML()

```
int SSL_SendMailHTML (
    IPADDR smtp_server,
    PCSTR userid,
    PCSTR pass,
    PCSTR from_addr,
    PCSTR to_addr,
    PCSTR subject,
    const char * filename,
    BOOL STARTTLS = false,
    int remotePort = -1,
    const char * serverName = nullptr,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)
#include <ssl_mailto.h>
```

Send an HTML email message from a file using SSL encryption.

Parameters

<i>smtp_server</i>	IP address of the SMTP server.
<i>userid</i>	Ascii string to provide for RFC931 IDentification.
<i>pass</i>	Ascii string to provide for AUTH IDentification.
<i>from_addr</i>	From email address.
<i>to_addr</i>	To email address.
<i>subject</i>	The email subject.
<i>filename</i>	HTTP server filename to send.
<i>STARTTLS</i>	Enable/disable STARTTLS functionality. Default is disabled.
<i>remotePort</i>	Port number to connect to on the SMTP server.
<i>serverName</i>	Server name to use for certificate name verification and when sending SNI extensions.
<i>certBuff</i>	Buffer containing the certificate data. Default is null.
<i>certBuffSize</i>	Size of the buffer containing the certificate data.
<i>certBuffFormat</i>	The format of the certificate buffer. Default is SSL_FILETYPE_PEM.

Return values

0	Send failed
1	Send was successful

[SSL_SendMail\(\)](#)

[SSL_SendMailStartMIME\(\)](#)

[SendMail\(\)](#)

14.41.6.2.3 SSL_SendMailStartMIME()

```
int SSL_SendMailStartMIME (
    IPADDR smtp_server,
    PCSTR userid,
    PCSTR pass,
    PCSTR from_addr,
    PCSTR to_addr,
    PCSTR subject,
    BOOL STARTTLS = false,
    int remotePort = -1,
    const char * serverName = nullptr,
    bool verifyPeer = false,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)

#include <ssl_mailto.h>
```

Start a Multi-purpose Internet Mail Extension (MIME) session using SSL encryption.

Sending an E-Mail message with Multipurpose Internet Mail Extensions (MIME) is a multi step process:

- Call [SSL_SendMailStartMIME\(\)](#) to begin a Session with the SMTP server, connection will remain open.
- Call [SendMailAuthAddMIME\(\)](#) for each MIME attachment you want to add.
- Call [SendMailAuthEndMIME\(\)](#) to send the email message and close the Session.

The following MIME types are supported by default. The binary attachment should cover most types such as jpg, gif, etc. The types are defined by [MIME Content Types](#).

Parameters

<i>smtp_server</i>	IP address of the SMTP server.
<i>userid</i>	Ascii string to provide for RFC931 IDentification.
<i>pass</i>	Ascii string to provide for AUTH IDentification.
<i>from_addr</i>	From email address.
<i>to_addr</i>	To email address.
<i>subject</i>	The email subject.
<i>STARTTLS</i>	Enable/disable STARTTLS functionality. Default is disabled.
<i>remotePort</i>	Port number to connect to on the SMTP server.
<i>serverName</i>	Server name to use for certificate name verification and when sending SNI extensions.
<i>verifyPeer</i>	Set true to verify the server's certificate against a Certificate Authority list. Default if false.
<i>certBuff</i>	Buffer containing the certificate data. Default is null.
<i>certBuffSize</i>	Size of the buffer containing the certificate data.
<i>certBuffFormat</i>	The format of the certificate buffer.

Return values

0	Send failed
1	Send was successful

14.42 SOCKS

Topics

- [SOCKS Error Codes](#)

Macros

- `#define SOCKS_MAX_UNAME_SIZE 255`
Max character length for usernames. Defined in RFC 1929.
- `#define SOCKS_MAX_PASSWD_SIZE 255`
Max character length for passwords. Defined in RFC 1929.

Enumerations

- enum [SocksAuthType](#) : unsigned char { [eSocksAuthTypeGssApi](#) = 0x01 , [eSocksAuthTypeUnPw](#) = 0x02 , [eSocksAuthTypeNoAuth](#) = 0x04 }
- SOCKS Authorization Types.*
- enum [SocksClientCmd](#) : unsigned char { [eSocksClientCmdConnect](#) = 1 , [eSocksClientCmdBind](#) = 2 , [eSocksClientCmdUdpAssoc](#) = 3 }
- SOCKS Client Commands.*
- enum [SocksAdrType](#) : unsigned char { [eSocksAdrTypeNone](#) = 0x00 , [eSocksAdrTypeIpv4](#) = 0x01 , [eSocksAdrTypeDomain](#) = 0x03 , [eSocksAdrTypeIpv6](#) = 0x04 }
- SOCKS Address Types.*

Functions

- bool [AuthWithGssApi](#) ()
A weak function that should be overridden by the developer in order to support GSSAPI authorization.
- void [SetSocksProxySettings](#) (SocksProxy *socksProxy)
Set the system level SOCKS proxy settings object to the one that is passed in. If this object is set and is marked as enabled, calls to [CoreConnect\(\)](#) (made from [connect\(\)](#), [DoGet\(\)](#), etc), will all initially connect to the proxy server using the SOCKS5 protocol.
- SocksProxy * [GetSocksProxySettings](#) ()
Get a pointer to the currnetly set Socks proxy settings object.

14.42.1 Detailed Description

```
#include< Socks.h>
```

The NetBurner SOCKS Library

14.42.2 Enumeration Type Documentation

14.42.2.1 SocksAdrType

```
enum SocksAdrType : unsigned char
#include <Socks.h>
SOCKS Address Types.
```

Enumerator

eSocksAdrTypeNone	None.
eSocksAdrTypeIpv4	IPv4.
eSocksAdrTypeDomain	Domain.
eSocksAdrTypeIpv6	IPv6.

14.42.2.2 SocksAuthType

```
enum SocksAuthType : unsigned char
#include <Socks.h>
SOCKS Authorization Types.
```

Enumerator

eSocksAuthTypeGssApi	GSS API.
eSocksAuthTypeUnPw	User name and password.
eSocksAuthTypeNoAuth	Not as defined in RFC so that it could be properly tested against when being set by user.

14.42.2.3 SocksClientCmd

```
enum SocksClientCmd : unsigned char
#include <Socks.h>
SOCKS Client Commands.
```

Enumerator

eSocksClientCmdConnect	Connect.
eSocksClientCmdBind	Not currently supported, see RFC 1928.
eSocksClientCmdUdpAssoc	Not currently supported, see RFC 1928.

14.42.3 Function Documentation**14.42.3.1 AuthWithGssApi()**

```
bool AuthWithGssApi ()
#include <Socks.h>
```

A weak function that should be overridden by the developer in order to support GSSAPI authorization.

Return values

<i>true</i>	The GSSAPI authorization succeeded.
<i>false</i>	The GSSAPI authorization failed.

14.42.3.2 GetSocksProxySettings()

```
SocksProxy * GetSocksProxySettings ()
#include <Socks.h>
```

Get a pointer to the currently set Socks proxy settings object.

Returns

SocksProxy*

14.42.3.3 SetSocksProxySettings()

```
void SetSocksProxySettings (
    SocksProxy * socksProxy)
#include <Socks.h>
```

Set the system level SOCKS proxy settings object to the one that is passed in. If this object is set and is marked as enabled, calls to CoreConnect() (made from [connect\(\)](#), [DoGet\(\)](#), etc), will all initially connect to the proxy server using the SOCKS5 protocol.

Parameters

<code>socksProxy</code>	The proxy object that the system should reference.

14.42.4 SOCKS Error Codes

Macros

- **#define SOCKS_SUCCESS** (0)
The connection was successful.
- **#define SOCKS_ERR_TIMEOUT** (-500)
The connection timed out.
- **#define SOCKS_BAD_ADR_TYPE** (-501)
Address type specified does not match the address provided.
- **#define SOCKS_CONN_ABORTED** (-502)
The other side aborted the connection.
- **#define SOCKS_BAD_AUTH_TYPE** (-503)
The server doesn't support the requested authorization types.
- **#define SOCKS_BAD_UN_PW** (-504)
The server did not approve the username and password provided.
- **#define SOCKS_UN_TOO_LONG** (-505)
The specified username is too long.
- **#define SOCKS_PW_TOO_LONG** (-506)
The specified password is too long.
- **#define SOCKS_BAD_REPLY** (-507)
The server reply was not successful.
- **#define SOCKS_BAD_DOMAIN** (-508)
Unable to resolve domain name passed.
- **#define SOCKS_CMD_NOT_SUPPORTED** (-509)
The requested command aren't supported.
- **#define SOCKS_BAD_PARAM** (-510)
The passed in parameters are not valid.

14.42.4.1 Detailed Description

14.43.1 Detailed Description

Serial Peripheral Interface (SPI) is an interface bus commonly used to send data between microcontrollers and small peripherals over a short distance, such as port expanders, FPGAs, CPLDs, shift registers, sensors, and flash SD cards. Unlike an asynchronous UART that does not use a separate clock, the SPI operates in a synchronous mode using a single clock for both sender and receiver that determines the data rate as well as when each bit of data is valid. This API uses the "native" SPI mode with the following signals:

- Clock (CLK). Synchronous clock signal.
- Master out, Slave in (MOSI). Data signal from master to slave device.
- Master in, Slave out (MISO). Data signal from slave to master.
- Chip select (CS). Chip selects can be part of the SPI peripheral, or can be general purpose I/O.

An advantage of SPI is that the receiving hardware can be a simple shift register. This is a much simpler and less expensive than a UART implementation.

14.43.2 MCF5441x (DSPI)

DSPI for MCF5441x (MOD5441x, NANO, SB800EX)

Classes

- struct [dspiDMAStruct](#)
DSPI DMA structure.
- struct [dspiDriverStruct](#)
Major variables/configurations used for a DSPI transfer.
- class [DSPIModule](#)
DSPIModule is a SPI communications driver. It is an object based driver, which allows for low overhead multiplexing between peripherals with different bus configurations.

Macros

- #define [DEFAULT_DSPI_MODULE](#) 1
- #define [DSPI_MODULE_COUNT](#) 4

Enumerations

- enum `csReturnType` { `DEASSERT_NEVER` = 0 , `DEASSERT_AFTER_LAST` = 1 , `DEASSERT_EVERY_TRANSFER` = 2 }

14.43.2.1 Detailed Description

DSPI for MCF5441x (MOD5441x, NANO, SB800EX)

Supported platforms:

- MOD54415
- MOD54417
- NANO54415
- SB800EX

The DMA serial peripheral interface (DSPI) interfaces (up to 3 depending on your platform) provide a synchronous serial bus for communication between the processor and an external peripheral device. DSPI interface modules are numbered from 0 to 3. DSPI 0 is reserved for system use. The DSPI supports up to 32 queued SPI transfers (16 receive and 16 transmit) in the DSPI resident FIFOs eliminating CPU intervention between transfers.

The DSPI specification allows for sharing the SPI bus with multiple devices. However, when designing your system, you must consider what devices are connected and the desired throughput. For example, if you are using the Embedded Flash File System (EPPS) with external Flash cards, or the WiFi module, they will require exclusive use of the DSPI interface.

The DSPI uses the following hardware signals:

- SCLK Serial clock output from master.
- MOSI Master data output (transmit), slave data input (receive).
- MISO Master data input (receive), slave data output (transmit).
- QSPI_CS_n Optional QSPI chip selects. Note that you can also use GPIO signals and control them manually for the chip select functionality. In some cases, there are advantages to doing it this way.

DSPI Configuration and Initialization

Use of the DSPI requires:

1. Identify which pins on your NetBurner device provide primary or secondary QSPI functionality. Use the NetBurner Pins class functions to configure these pins for QSPI operation.
2. Single task applications: you can choose to call the [DSPIDone\(\)](#) function to determine when the DSPI transfer is complete, or use a semaphore and pend for completion.
3. Multi-task applications: If your application has more than one task that will access the same DSPI, you must create a semaphore to control access to the DSPI resource, just as you would with any shared resource.
4. Initialize the DSPI with the [DSPIInit\(\)](#) function.
5. When you have data to send, or want to read data from the DSPI slave device, call the [QSPIStart\(\)](#) function to initiate the data transfer.
6. The semaphore will post when the data transfer is complete.

#define TCD_XOFF_2uint8_t 0x0002
#include <dspi.h>
```

14.43.2.3 Enumeration Type Documentation**14.43.2.3.1 csReturnType**

```
enum csReturnType
#include <dspi.h>
```

Chip select return types.

Chip select deassertion modes. Used to determine when the driver should deassert chip selects during SPI transfer.

Enumerator

DEASSERT_NEVER	The chip select used for the transaction should remain asserted, even after the transaction is complete.
DEASSERT_AFTER_LAST	The chip select should remain asserted for the full duration of the transaction, and only be deasserted after the final transfer.
DEASSERT_EVERY_TRANSFER	The chip select should be deasserted between every transfer within the transaction.

14.43.2.3.2 spiChipSelect

```
enum spiChipSelect
#include <dspi.h>
```

Chip select number.

If supported by the SPI peripheral, these values can be used to configure the chip select to be used during a SPI transfer.

Enumerator

CHIP_SELECT_0	Configure bit mask for SPI chip select 0.
CHIP_SELECT_1	Configure bit mask for SPI chip select 1.
CHIP_SELECT_2	Configure bit mask for SPI chip select 2.
CHIP_SELECT_3	Configure bit mask for SPI chip select 3.
CHIP_SELECT_DISABLED	Configure bit mask to disable chip select.

14.43.2.3.3 spiChipSelectPolarity

```
enum spiChipSelectPolarity
```

```
#include <dspi.h>
```

Chip select polarity.

These values can be used to configure the chip select's asserted/deasserted logic level. These values will configure all chip selects to the same configuration. If you intend on using an SPI peripheral with multiple chip selects with different polarities, these values cannot not be used.

Enumerator

CS_ASSERT_LOW	Bit mask configures all active chip selects as active low, inactive high.
CS_ASSERT_HIGH	Bit mask configures all active chip selects as inactive low, active high.

14.43.2.4 Function Documentation

14.43.2.4.1 DSPIDone()

```
BOOL DSPIDone (
    uint8_t SPIModule = DEFAULT_DSPI_MODULE)
```

```
#include <dspi.h>
```

Check current DSPI Data Transfer.

Parameters: None

Return: Progress of transfer - TRUE is finished, FALSE is active

Notes: None

14.43.2.4.2 DSPIInit()

```
uint8_t DSPIInit (
    uint8_t SPIModule = DEFAULT_DSPI_MODULE,
    uint32_t Baudrate = 2000000,
    uint8_t QueueBitSize = 8,
    uint8_t CS = 0x00,
    uint8_t CSPol = 0x0F,
    uint8_t ClkPolarity = 0,
    uint8_t ClkPhase = 1,
    BOOL DoutHiz = TRUE,
    uint8_t QCD = 0,
    uint8_t DTL = 0)
```

```
#include <dspi.h>
```

Initialize a DSPI module.

Notes:

- The maximum baud rate is CPU_CLOCK / 3
- Will initialize to the highest available baud rate that does not exceed the maximum
- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for greater than 8 bits per transfer then the data must be uint16_t aligned
- If configured for greater than 16 bits per transfer then the data must be uint32_t aligned
- Chip select is based on chipSelectPolarity
- 0 data captured leading edge of DSPI_CLK, changed following edge.
- 1 data changed leading edge of DSPI_CLK, captured following edge.
- 0 default is as close to 1/2 DSPI_CLK without going under, keeping with the interface to SPI
- 0 default is 17/(system clock / 2), in keeping with interface to QSPI

Parameters

<i>SPIModule</i>	SPI module number, 0 - 1
<i>Baudrate</i>	Maximum baud rate requested
<i>QueueBitSize</i>	Number of bits per transfer: 8, 16 or 32
<i>CS</i>	SPI chip selects to use for transfer
<i>CSPol</i>	0 = inactive logic level low, 1 = high
<i>ClkPolarity</i>	0 = inactive logic level low, 1 = high
<i>ClkPhase</i>	0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge.
<i>DoutHiz</i>	Data output high impedance between transfers
<i>QCD</i>	Delay from chip select to valid clock (default is 0). QCD is a value in the QDLYR register and will change the delay between the assertion of the chip select and the start of the DSPI clock. Default setting of one half DSPI clk will be used if parameter is specified as 0x0 or not included.
<i>DTL</i>	DTL is a value in the QDLYR register and will change the delay following a transfer of a single uint16_t in the DSPI queue. Default reset value of 17/(fsys/2) will be used if parameter is specified 0 or not included.

Returns

Current stat of DSPI bus [MOD5441xDspiStates](#)

14.43.2.4.3 DSPIStart()

```
uint8_t DSPIStart (
    uint8_t SPIModule,
    puint8_t transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    OS_SEM * finishedSem = NULL,
    uint8_t enableDMA = TRUE,
    int csReturnToInactive = DEASSERT_AFTER_LAST)
```

#include <dspi.h>

Start DSPI Data Transfer.

Parameters:

transmitBufferPtr	- Buffer with data to send, NULL for receiving
receiveBufferPtr	- Buffer to receive data, NULL for sending
byteCount	- Count of bytes to send or receive
SPIModule	- Selects the dspi module to use
finishedSem	- Optional semaphore to set when completed

Return:

Current DSPI state - DSPI_OK success or DSPI_BUSY busy

Notes:

None

14.43.2.4.4 QSPIdone()

```
BOOL QSPIdone (
    void ) [inline]
```

#include <dspi.h>

Can be called after [QSPIStart\(\)](#). Returns TRUE when transfer is complete. This is an alternative to using a semaphore.

Return values

<i>TRUE</i>	When transfer is complete
<i>FALSE</i>	On error

See also

[QSPInit\(\)](#)[QSPStart\(\)](#)

14.43.2.4.5 QSPInit()

```
uint8_t QSPInit (
    uint32_t baudRateInBps = 2000000,
    uint8_t transferSizeInBits = 8,
    uint8_t peripheralChipSelects = 0x0F,
    uint8_t chipSelectPolarity = 1,
    uint8_t clockPolarity = 0,
    uint8_t clockPhase = 1,
    BOOL doutHiz = TRUE,
    uint8_t csToClockDelay = 0,
    uint8_t delayAfterTransfer = 0) [inline]
#include <dsapi.h>
```

Initialize Queued Serial Peripheral Interface (QSPI)

Notes: (3) Transfers > 8 must be word aligned (4) Select based on chipSelectPolarity (5) 0 data captured leading edge of QSPI_CLK, changed following edge. (6) 1 data changed leading edge of QSPI_CLK, captured following edge. (7) 0 default is 1/2 QSPI_CLK or see MFCXXXX reference manual (8) 0 default is 8192/(system clock / 2) see MFCXXXX reference manual

Parameters

<i>baudRateInBps</i>	Maximum requested baud rate in bits per second. The maximum possible baud rate is determined by the system clock. The function will select the highest possible baud rate if the specified value cannot be achieved.
<i>transferSizeInBits</i>	Size of data values to be transferred. Values can be 8, 16 or 32 bits. Note that 16 and 32 bit size values must be word (16-bit) aligned (16-bit).
<i>peripheralChipSelects</i>	Peripheral chip select drive level. Used to select an external device for serial data transfer. More than one chip select may be active at once, and more than one device can be connected to each chip select. Bits 3-0 map directly to QSPI_CS[3:0], respectively. For each bit: • 0 = Chip select is 0 during a transfer. • 1 = Chip select is 1 during a transfer.
<i>chipSelectPolarity</i>	Peripheral chip select inactive level (no transfer in progress). Applies to all chip selects. • 0 = 0 when inactive • 1 = 1 when inactive
<i>clockPolarity</i>	Clock polarity: • 0 = The inactive state value of QSPI_CLK is logic level 0. • 1 = The inactive state value of QSPI_CLK is logic level 1.

Parameters

<i>clockPhase</i>	Clock phase: • 0 = Data captured on the leading edge of QSPI_CLK and changed on the following edge of QSPI_CLK. • 1 = Data changed on the leading edge of QSPI_CLK and captured on the following edge of QSPI_CLK.
<i>doutHiz</i>	Data output high impedance enable. Selects QSPI_DOUT mode of operation. • 0 = Default value after reset. QSPI_DOUT is actively driven between transfers. • 1 = QSPI_DOUT is high impedance between transfers.
<i>csToClockDelay</i>	QCD, QSPICLK delay. When the DSCK bit in the command RAM is set this field determines the length of the delay from assertion of the chip selects to valid QSPI_CLK transition.
<i>delayAfterTransfer</i>	Delay after transfer. When the DT bit in the command RAM is set this field determines the length of delay after the serial transfer.

Returns

groupQspiState

See also

[QSPiInit\(\)](#)

[QSPiStart\(\)](#)

14.43.2.4.6 QSPiStart()

```
uint8_t QSPiStart (
    uint8_t transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    OS_SEM * finishedSem = NULL) [inline]
#include <dsapi.h>
Start QSPI Data Transfer.
```

Parameters

<i>transmitBufferPtr</i>	Pointer to the buffer to use in the transfer. Specify NULL for receive only.
<i>receiveBufferPtr</i>	Pointer to buffer to store received data. NULL for transmit only.
<i>byteCount</i>	Number of bytes to send or receive. If the data size is greater than 8-bit, you must provide the total number of bytes.
<i>finishedSem</i>	Pointer to preinitialized semaphore to post to when transfer is complete. A value of NULL disables the semaphore function.

Returns

groupQspiState

This struct contains the major variables/configurations used for a QSPI transfer.

Functions

- `uint8_t QSPIInit (uint32_t baudRateInBps=2000000, uint8_t transferSizeInBits=8, uint8_t peripheralChipSelects=0x0F, uint8_t chipSelectPolarity=1, uint8_t clockPolarity=0, uint8_t clockPhase=1, BOOL doutHiz=TRUE, uint8_t csToClockDelay=0, uint8_t delayAfterTransfer=0)`

Initialize Queued Serial Peripheral Interface (QSPI)

- `uint8_t QSPIStart (puint8_t transmitBufferPtr, volatile uint8_t *receiveBufferPtr, uint32_t byteCount, OS_SEM *finishedSem=NULL)`

Start QSPI Data Transfer.

- `BOOL QSPIdone (void)`

Can be called after [QSPIStart\(\)](#). Returns TRUE when transfer is complete. This is an alternative to using a semaphore.

14.43.3.1 Detailed Description

QSPI for MCF5441x (MOD5441x, NANO, SB800EX)

```
#include< qspi.h>
```

Supported platforms:

- MOD54415
- MOD54417
- NANO54415
- SB800EX

Note

The SPI interface modules (up to 4 depending on the platform) on the MCF5441x processor are termed DMA SPI (DSPI). Earlier ColdFire processors had a single SPI with a queue, and were termed QSPI. This header file is here as a guide for customers using earlier ColdFire processors to make porting code easier. However, we highly recommend using the DSPI driver instead. The calls are nearly identical.

Introduction

The Queued Serial Peripheral Interface (QSPI) is a full duplex synchronous serial data link that operates in master/slave mode. The QSPI is similar to SPI, but also provided a hardware queue for transmit data, receive data, and commands. Up to 16 transfers can be queued at one time, eliminating CPU intervention between transfers. The NetBurner QSPI driver and API provide interrupt driven QSPI communication.

The QSPI specification allows for sharing the QSPI bus with multiple devices. However, when designing your system you must consider what devices are connected and the desired throughput. For example, if you are using the Embedded Flash File System (EFlash) with external SD flash cards, or the WiFi module, they will require exclusive use of the QSPI.

The QSPI uses the following hardware signals:

- SCLK Serial clock output from master
- MOSI Master data output (transmit), slave data input (receive)
- MISO Master data input (receive), slave data output (transmit)
- QSPI_CS Optional QSPI chip selects

Programming tip: If you are new to QSPI and require a chip select for your device, we recommend using a GPIO signal during initial development to simplify your application code. Once proper operation has been achieved, modify the code to use the QSPI chip selects.

QSPI Configuration and Initialization

Use of the QSPI requires:

1. Identify which pins on your NetBurner device provide primary or secondary QSPI functionality. Use the NetBurner Pins class functions to configure these pins for QSPI operation.
2. Single task applications: you can choose to call the [QSPIdone\(\)](#) function to determine when the QSPI transfer is complete, or use a semaphore and pend for completion.
3. Multi-task applications: If your application has more than one task that will access the QSPI, you must create a semaphore to control access to the QSPI resource.
4. Initialize the QSPI with the [QSPInit\(\)](#) function.
5. When you have data to send, or want to read data from the QSPI slave device, call the [QSPIStart\(\)](#) function to initiate the data transfer.
6. The semaphore will post when the data transfer is complete.

14.43.3.2 Function Documentation

14.43.3.2.1 QSPIdone()

```

BOOL QSPIdone (
    void ) [inline]
#include <qspi.h>

```

Can be called after [QSPIStart\(\)](#). Returns TRUE when transfer is complete. This is an alternative to using a semaphore.

Return values

<i>TRUE</i>	When transfer is complete
<i>FALSE</i>	On error

See also

[QSPInit\(\)](#)

[QSPIStart\(\)](#)

Can be called after [QSPIStart\(\)](#). Returns TRUE when transfer is complete. This is an alternative to using a semaphore.

Returns

true if DSPI is finished, false if active

14.43.3.2.2 QSPInit()

```
uint8_t QSPInit (
    uint32_t baudRateInBps = 2000000,
    uint8_t transferSizeInBits = 8,
    uint8_t peripheralChipSelects = 0x0F,
    uint8_t chipSelectPolarity = 1,
    uint8_t clockPolarity = 0,
    uint8_t clockPhase = 1,
    BOOL doutHiz = TRUE,
    uint8_t csToClockDelay = 0,
    uint8_t delayAfterTransfer = 0) [inline]
```

```
#include <qspi.h>
```

Initialize Queued Serial Peripheral Interface (QSPI)

Notes: (3) Transfers > 8 must be word aligned (4) Select based on chipSelectPolarity (5) 0 data captured leading edge of QSPI_CLK, changed following edge. (6) 1 data changed leading edge of QSPI_CLK, captured following edge. (7) 0 default is 1/2 QSPI_CLK or see MFCXXXX reference manual (8) 0 default is 8192/(system clock / 2) see MFCXXXX reference manual

Parameters

<i>baudRateInBps</i>	Maximum requested baud rate in bits per second. The maximum possible baud rate is determined by the system clock. The function will select the highest possible baud rate if the specified value cannot be achieved.
<i>transferSizeInBits</i>	Size of data values to be transferred. Values can be 8, 16 or 32 bits. Note that 16 and 32 bit size values must be word (16-bit) aligned (16-bit).
<i>peripheralChipSelects</i>	Peripheral chip select drive level. Used to select an external device for serial data transfer. More than one chip select may be active at once, and more than one device can be connected to each chip select. Bits 3-0 map directly to QSPI_CS[3:0], respectively. For each bit: • 0 = Chip select is 0 during a transfer. • 1 = Chip select is 1 during a transfer.
<i>chipSelectPolarity</i>	Peripheral chip select inactive level (no transfer in progress). Applies to all chip selects. • 0 = 0 when inactive • 1 = 1 when inactive
<i>clockPolarity</i>	Clock polarity: • 0 = The inactive state value of QSPI_CLK is logic level 0. • 1 = The inactive state value of QSPI_CLK is logic level 1.
<i>clockPhase</i>	Clock phase: • 0 = Data captured on the leading edge of QSPI_CLK and changed on the following edge of QSPI_CLK. • 1 = Data changed on the leading edge of QSPI_CLK and captured on the following edge of QSPI_CLK.
<i>doutHiz</i>	Data output high impedance enable. Selects QSPI_DOUT mode of operation. • 0 = Default value after reset. QSPI_DOUT is actively driven between transfers. • 1 = QSPI_DOUT is high impedance between transfers.

Parameters

<i>csToClockDelay</i>	QCD, QSPICLK delay. When the DSCK bit in the command RAM is set this field determines the length of the delay from assertion of the chip selects to valid QSPI_CLK transition.
<i>delayAfterTransfer</i>	Delay after transfer. When the DT bit in the command RAM is set this field determines the length of delay after the serial transfer.

Returns

groupQspiState

See also

[QSPiInit\(\)](#)

[QSPiStart\(\)](#)

14.43.3.2.3 QSPiStart()

```
uint8_t QSPiStart (
    puint8_t transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    OS_SEM * finishedSem = NULL) [inline]
#include <qspi.h>
Start QSPI Data Transfer.
```

Parameters

<i>transmitBufferPtr</i>	Pointer to the buffer to use in the transfer. Specify NULL for receive only.
<i>receiveBufferPtr</i>	Pointer to buffer to store received data. NULL for transmit only.
<i>byteCount</i>	Number of bytes to send or receive. If the data size is greater than 8-bit, you must provide the total number of bytes.
<i>finishedSem</i>	Pointer to preinitialized semaphore to post to when transfer is complete. A value of NULL disables the semaphore function.

Returns

groupQspiState

Initialize a DSPI module.
- uint8_t [DSPIInit](#) (uint8_t [SPIModule](#)=[DEFAULT_DSPI_MODULE](#), uint32_t Baudrate=2000000, uint8_t QueueBitSize=8, [PinIO](#) gpioChipSelect=PinDef_INVALID, uint8_t CSPol=0x0F, uint8_t ClkPolarity=0, uint8_t ClkPhase=1, BOOL Douthiz=TRUE, uint8_t QCD=0, uint8_t DTL=0)
Initialize a DSPI module.

- `uint8_t DSPIStart (uint8_t SPIModule, uint8_t transmitBufferPtr, volatile uint8_t *receiveBufferPtr, uint32_t byteCount, OS_SEM *finishedSem=NULL, uint8_t enableDMA=TRUE, int csReturnToInactive=DEASSERT_AFTER_LAST)`
Start a DSPI transfer.
- `BOOL DSPIDone (uint8_t SPIModule=DEFAULT_DSPI_MODULE)`
Check SPI status.

Variables

- `LPSPi_Type * lpspiBases []`
Pointers to LPSPi_Type for each instance.

DMA CHANNEL NUMBERS

- `#define DMA_CH_DSPI_1_RX 0x06`
DMA Channel allocated to LPSPi1 Rx (DMA Channel 6)
- `#define DMA_CH_DSPI_1_TX 0x07`
DMA Channel allocated to LPSPi1 Tx (DMA Channel 7)
- `#define DMA_CH_DSPI_2_RX 0x04`
DMA Channel allocated to LPSPi2 Rx (DMA Channel 4)
- `#define DMA_CH_DSPI_2_TX 0x05`
DMA Channel allocated to LPSPi2 Tx (DMA Channel 5)
- `#define DMA_CH_DSPI_4_RX 0x08`
DMA Channel allocated to LPSPi4 Rx (DMA Channel 8)
- `#define DMA_CH_DSPI_4_TX 0x09`
DMA Channel allocated to LPSPi4 Tx (DMA Channel 9)

14.43.4.1 Detailed Description

DSPI for ARM MIMX10xx (SOMRT1061)

Note that for the MIMXRT10xx there are 3 types of SPI peripherals:

- SPI using the SPI peripheral: Provides the most configuration options. Used in single data channel mode: SCLK, MISO, MOSI, Chip Selects.
- SPI using the QSPI peripheral: Single data channel as with SPI, but fewer configuration options.
- SPI using the USART peripheral: Single data channel as with SPI, but fewer configuration options.

14.43.4.2 Enumeration Type Documentation

14.43.4.2.1 csReturnType

```
enum csReturnType
```

```
#include <dspi.h>
```

Chip select deassertion modes. Used to determine when the driver should deassert chip selects during SPI transfer.

Enumerator

DEASSERT_NEVER	The chip select used for the transaction should remain asserted, even after the transaction is complete.
DEASSERT_AFTER_LAST	The chip select should remain asserted for the full duration of the transaction, and only be deasserted after the final transfer.
DEASSERT_EVERY_TRANSFER	The chip select should be deasserted between every transfer within the transaction. Deassert chip select After every transfer.

14.43.4.2.2 spiChipSelect

```
enum spiChipSelect
#include <dspi.h>
```

Chip select number.

If supported by the SPI peripheral, these values can be used to configure the chip select to be used during a SPI transfer.

Enumerator

CHIP_SELECT_0	Configure the SPI peripheral to use chip select 0.
CHIP_SELECT_1	Configure the SPI peripheral to use chip select 1.
CHIP_SELECT_2	Configure the SPI peripheral to use chip select 2.
CHIP_SELECT_3	Configure the SPI peripheral to use chip select 3.
CHIP_SELECT_DISABLED	Configure the SPI peripheral to disable chip select.

14.43.4.2.3 spiChipSelectPolarity

```
enum spiChipSelectPolarity
#include <dspi.h>
```

Chip select polarity.

This enum exists for API compatibility between platforms. The MIMXRT10xx's SPI peripheral does not support modifying chip select polarity. The SPI peripheral only supports asserting chip select to logic level LOW during a transaction. If you need to assert the chip select to logic level HIGH during a transaction, your alternative is to use a GPIO for chip select.

Enumerator

CS_ASSERT_LOW	Assert all chip selects to logic level LOW during a SPI transaction.
CS_ASSERT_HIGH	Assert all chip selects to logic level HIGH during a SPI transaction.

14.43.4.3 Function Documentation

14.43.4.3.1 DSPIDone()

```
BOOL DSPIDone (
    uint8_t SPIModule = DEFAULT_DSPI_MODULE)
#include <dspi.h>
```

Check SPI status.

Returns

true if DSPI is finished, false if active

14.43.4.3.2 DSPIInit() [1/2]

```
uint8_t DSPIInit (
    uint8_t SPIModule = DEFAULT_DSPI_MODULE,
    uint32_t Baudrate = 2000000,
    uint8_t QueueBitSize = 8,
    PinIO gpioChipSelect = PinDef_INVALID,
    uint8_t CSPol = 0x0F,
    uint8_t ClkPolarity = 0,
    uint8_t ClkPhase = 1,
    BOOL DoutHiz = TRUE,
    uint8_t QCD = 0,
    uint8_t DTL = 0)
```

```
#include <dspi.h>
```

Initialize a DSPI module.

Notes:

- The maximum baud rate is CPU_CLOCK / 3
- Will initialize to the highest available baud rate that does not exceed the maximum
- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for greater than 8 bits per transfer then the data must be uint16_t aligned
- If configured for greater than 16 bits per transfer then the data must be uint32_t aligned
- Chip select is based on chipSelectPolarity
- 0 data captured leading edge of DSPI_CLK, changed following edge.
- 1 data changed leading edge of DSPI_CLK, captured following edge.
- 0 default is as close to 1/2 DSPI_CLK without going under, keeping with the interface to SPI
- 0 default is 17/(system clock / 2), in keeping with interface to QSPI

Parameters

<i>SPIModule</i>	SPI module number, 0 - 1
<i>Baudrate</i>	Maximum baud rate requested
<i>QueueBitSize</i>	Number of bits per transfer: 8, 16 or 32
<i>gpioChipSelect</i>	PinIO to be configured as GPIO and used as chip select. Only supports spiDriverStruct::csReturnToInactive values of DEASSERT_AFTER_LAST and DEASSERT_NEVER
<i>CSPol</i>	0 = inactive logic level low, 1 = high
<i>ClkPolarity</i>	0 = inactive logic level low, 1 = high
<i>ClkPhase</i>	0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge.
<i>DoutHiz</i>	Data output high impedance between transfers
<i>QCD</i>	Delay from chip select to valid clock (default is 0)
<i>DTL</i>	Chip select mode dsppiChipSelectMode

Returns

Current stat of DSPI bus [dsppiState](#)

14.43.4.3.3 DSPIInit() [2/2]

```
uint8_t DSPIInit (
    uint8_t SPIModule = DEFAULT_DSPI_MODULE,
    uint32_t Baudrate = 2000000,
    uint8_t QueueBitSize = 8,
    uint8_t CS = 0x00,
    uint8_t CSPol = 0x0F,
    uint8_t ClkPolarity = 0,
    uint8_t ClkPhase = 1,
    BOOL DoutHiz = TRUE,
    uint8_t QCD = 0,
    uint8_t DTL = 0)
```

```
#include <dspi.h>
```

Initialize a DSPI module.

Notes:

- The maximum baud rate is $\text{CPU\_CLOCK} / 3$
- Will initialize to the highest available baud rate that does not exceed the maximum
- If configured for 8 bits per transfer then the data must be `uint8_t` aligned
- If configured for greater than 8 bits per transfer then the data must be `uint16_t` aligned
- If configured for greater than 16 bits per transfer then the data must be `uint32_t` aligned
- Chip select is based on `chipSelectPolarity`
- 0 data captured leading edge of `DSPI_CLK`, changed following edge.
- 1 data changed leading edge of `DSPI_CLK`, captured following edge.
- 0 default is as close to $1/2 \text{ DSPI\_CLK}$ without going under, keeping with the interface to SPI
- 0 default is $17/(\text{system clock} / 2)$, in keeping with interface to QSPI

Parameters

<i>SPIModule</i>	SPI module number, 0 - 1
<i>Baudrate</i>	Maximum baud rate requested
<i>QueueBitSize</i>	Number of bits per transfer: 8, 16 or 32
<i>CS</i>	SPI chip selects to use for transfer
<i>CSPol</i>	0 = inactive logic level low, 1 = high
<i>ClkPolarity</i>	0 = inactive logic level low, 1 = high
<i>ClkPhase</i>	0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge.
<i>DoutHiz</i>	Data output high impedance between transfers
<i>QCD</i>	Delay from chip select to valid clock (default is 0)
<i>DTL</i>	Chip select mode dspicChipSelectMode

Returns

Current stat of DSPI bus [dspistate](#)

14.43.4.3.4 DSPIStart()

```
uint8_t DSPIStart (
    uint8_t SPIModule,
    puint8_t transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    OS_SEM * finishedSem = NULL,
    uint8_t enableDMA = TRUE,
    int csReturnToInactive = DEASSERT_AFTER_LAST)
```

#include <dsapi.h>

Start a DSPI transfer.

- If configured for 8 bits per transfer then the data must be `uint8_t` aligned
- If configured for > than 8 bits per transfer then the data must be `uint16_t` aligned
- If configured for > than 16 bits per transfer then the data must be `uint32_t` aligned
- If either RX or TX pointer is assigned 'null' then that communication direction will not occur.
- If `DSPI_Finished` points to a semaphore, then the DSPI will POST to it when the transfer is complete.
- The semaphore is optional, but it can increase efficiency.

Parameters

<i>SPIModule</i>	DSPI module to use, 0 - 1
<i>transmitBufferPtr</i>	Pointer to the buffer containing the data to transmit
<i>receiveBufferPtr</i>	Pointer to the buffer to store the received data
<i>byteCount</i>	Number of bytes to transmit
<i>finishedSem</i>	Optional semaphore to post to when finished
<i>enableDMA</i>	Enable DMA transfers
<i>csReturnToInactive</i>	Chip select state

Returns

The current state of the SPI bus [dspiParam](#)

14.43.4.4 DspiModuleNumber

DSPI Peripheral Module .

Macros

- #define **DEFAULT_DSPI_MODULE** 2
Default DSPI module.
- #define **DSPI_MODULE_COUNT** 4
Number of modules: LPSPi modules 1, 2, 4 are available to the user. LPSPi 3 is dedicated to SPiFlash.

14.43.4.4.1 Detailed Description

DSPI Peripheral Module .

14.43.4.5 DspiState

DSPI Bus State .

Macros

- #define **DSPI_OK** (0)
DSPI OK.
- #define **DSPI_BUSY** (1)
DSPI Busy.
- #define **DSPI_ERROR** (2)
DSPI Error.
- #define **DSPI_HW_CFG_ERR** (3)
DSPI Hardware Config Error: Rx with DEASSERT_NEVER is only supported if a GPIO Chip Select is configured.

DSPI Bus State .

14.43.5 SAME70 (DSPI)

DSPI for ARM SAME70 (MODM7AE70, SBE70LC)

Classes

- struct [spiDriverStruct](#)
Variables/configurations for a DSPI transfer.
- class [SPIModule](#)
SPI Peripheral Module Class.

Enumerations

- enum **csReturnType** { **DEASSERT_NEVER** = 0 , **DEASSERT_AFTER_LAST** = 1 , **DEASSERT EVERY_TRANSFER** = 2 }
Chip select deassertion modes. Used to determine when the driver should deassert chip selects during SPI transfer.
- enum **spiChipSelectPolarity** { **CS_ASSERT_LOW** = 0 , **CS_ASSERT_HIGH** = 1 }
Chip select polarity.

Functions

- uint8_t **DSPIInit** (uint8_t **SPIModule**=**DEFAULT_DSPI_MODULE**, uint32_t Baudrate=2000000, uint8_t QueueBitSize=8, uint8_t CS=0x00, uint8_t CSPol=0x0F, uint8_t ClkPolarity=0, uint8_t ClkPhase=1, BOOL DoutHiz=TRUE, uint8_t QCD=0, uint8_t DTL=0)
Initialize a DSPI module.
- uint8_t **DSPIStart** (uint8_t **SPIModule**, uint8_t transmitBufferPtr, volatile uint8_t *receiveBufferPtr, uint32_t byteCount, OS_SEM *finishedSem=NULL, uint8_t enableDMA=TRUE, int csReturnToInactive=**DEASSERT_AFTER_LAST**)
Start a DSPI transfer.
- BOOL **DSPIDone** (uint8_t **SPIModule**=**DEFAULT_DSPI_MODULE**)
Check SPI status.

Variables

- const uint8_t **CHIP_SELECT_0** = 0
Chip select number.
- const uint8_t **CHIP_SELECT_1** = 1
Configure the SPI peripheral to use chip select 1.
- const uint8_t **CHIP_SELECT_2** = 2
Configure the SPI peripheral to use chip select 2.
- const uint8_t **CHIP_SELECT_3** = 3
Configure the SPI peripheral to use chip select 3.
- const uint8_t **CHIP_SELECT_DISABLED** = 0xFF
Or flag to set multi bit chipselect.

QSPI to DSPI Translation macros

(Compatibility function for previous drivers, note that the 'Q' stands for Queued SPI)

- uint8_t **QSPIInit** (uint32_t baudRateInBps=2000000, uint8_t transferSizeInBits=8, uint8_t peripheralChipSelects=0x0F, uint8_t chipSelectPolarity=1, uint8_t clockPolarity=0, uint8_t clockPhase=1, BOOL doutHiz=TRUE, uint8_t csToClockDelay=0, uint8_t delayAfterTransfer=0)
Initialize Queued Serial Peripheral Interface (QSPI)
- uint8_t **QSPIStart** (uint8_t transmitBufferPtr, volatile uint8_t *receiveBufferPtr, uint32_t byteCount, OS_SEM *finishedSem=NULL)
Start QSPI Data Transfer.
- BOOL **QSPIDone** ()
Check SPI status. (Compatibility function for previous drivers, note that the 'Q' stands for Queued SPI)

DSPI Bus State

- #define **DSPI_OK** (0)
DSPI OK.
- #define **DSPI_BUSY** (1)
DSPI Busy.
- #define **DSPI_ERROR** (2)
DSPI Error.

DSPI Peripheral Module

- #define **DEFAULT_DSPI_MODULE** 0
Default DSPI module.
- #define **DSPI_MODULE_COUNT** 1
Number of modules: 0, 1.

14.43.5.1 Detailed Description

DSPI for ARM SAME70 (MODM7AE70, SBE70LC)

Supported Platforms:

- MODM7AE70
- SBE70LC

Note that for the SAME70 there are 3 types of SPI peripherals:

- SPI using the SPI peripheral: Provides the most configuration options. Used in single data channel mode: SCLK, MISO, MOSI, Chip Selects.
- SPI using the QSPI peripheral: Single data channel as with SPI, but fewer configuration options.
- SPI using the USART peripheral: Single data channel as with SPI, but fewer configuration options.

14.43.5.2 Enumeration Type Documentation

14.43.5.2.1 csReturnType

```
enum csReturnType
```

```
#include <dspi.h>
```

Chip select deassertion modes. Used to determine when the driver should deassert chip selects during SPI transfer.

Enumerator

DEASSERT_NEVER	The chip select used for the transaction should remain asserted, even after the transaction is complete.
DEASSERT_AFTER_LAST	The chip select should remain asserted for the full duration of the transaction, and only be deasserted after the final transfer.
DEASSERT_EVERY_TRANSFER	The chip select should be deasserted between every transfer within the transaction. Deassert chip select After every transfer.

14.43.5.2.2 spiChipSelectPolarity

```
enum spiChipSelectPolarity
```

```
#include <dspi.h>
```

Chip select polarity.

This enum exists for API compatibility between platforms. The SAME70's SPI peripheral does not support modifying chip select polarity. The SPI peripheral only supports asserting chip select to logic level LOW during a transaction. If you need to assert the chip select to logic level HIGH during a transaction, your alternative is to use a GPIO for chip select.

Enumerator

CS_ASSERT_LOW	Assert all chip selects to logic level LOW during a SPI transaction.
CS_ASSERT_HIGH	Assert all chip selects to logic level HIGH during a SPI transaction.

14.43.5.3 Function Documentation

14.43.5.3.1 DSPIdone()

```

BOOL DSPIdone (
    uint8_t SPIModule = DEFAULT_DSPI_MODULE)
#include <dspi.h>
Check SPI status.

```

Returns

true if DSPI is finished, false if active

14.43.5.3.2 DSPIInit()

```

uint8_t DSPIInit (
    uint8_t SPIModule = DEFAULT_DSPI_MODULE,
    uint32_t Baudrate = 2000000,
    uint8_t QueueBitSize = 8,
    uint8_t CS = 0x00,
    uint8_t CSPol = 0x0F,
    uint8_t ClkPolarity = 0,
    uint8_t ClkPhase = 1,
    BOOL DoutHiz = TRUE,
    uint8_t QCD = 0,
    uint8_t DTL = 0)
#include <dspi.h>
Initialize a DSPI module.

```

Initialize a DSPI module.

Notes:

- The maximum baud rate is CPU_CLOCK / 3
- Will initialize to the highest available baud rate that does not exceed the maximum
- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for greater than 8 bits per transfer then the data must be uint16_t aligned
- If configured for greater than 16 bits per transfer then the data must be uint32_t aligned
- Chip select is based on chipSelectPolarity
- 0 data captured leading edge of DSPI_CLK, changed following edge.
- 1 data changed leading edge of DSPI_CLK, captured following edge.
- 0 default is as close to 1/2 DSPI_CLK without going under, keeping with the interface to SPI
- 0 default is 17/(system clock / 2), in keeping with interface to QSPI

Parameters

<i>SPIModule</i>	SPI module number, 0 - 1
<i>Baudrate</i>	Maximum baud rate requested
<i>QueueBitSize</i>	Number of bits per transfer: 8, 16 or 32
<i>CS</i>	SPI chip selects to use for transfer
<i>CSPol</i>	0 = inactive logic level low, 1 = high
<i>ClkPolarity</i>	0 = inactive logic level low, 1 = high
<i>ClkPhase</i>	0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge.
<i>DoutHiz</i>	Data output high impedance between transfers

<i>QCD</i>	Delay from chip select to valid clock (default is 0)
<i>DTL</i>	Chip select mode dsPICChipSelectMode

Returns

Current stat of DSPI bus [dsPICState](#)

14.43.5.3.3 DSPIStart()

```
uint8_t DSPIStart (
    uint8_t SPIModule,
    uint8_t * transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    OS_SEM * finishedSem = NULL,
    uint8_t enableDMA = TRUE,
    int csReturnToInactive = DEASSERT_AFTER_LAST)
```

```
#include <dsPIC.h>
```

Start a DSPI transfer.

- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for > than 8 bits per transfer then the data must be uint16_t aligned
- If configured for > than 16 bits per transfer then the data must be uint32_t aligned
- If either RX or TX pointer is assigned 'null' then that communication direction will not occur.
- If DSPI_Finished points to a semaphore, then the DSPI will POST to it when the transfer is complete.
- The semaphore is optional, but it can increase efficiency.

Parameters

SPIModule	DSPI module to use, 0 - 1
<i>transmitBufferPtr</i>	Pointer to the buffer containing the data to transmit
<i>receiveBufferPtr</i>	Pointer to the buffer to store the received data
<i>byteCount</i>	Number of bytes to transmit
<i>finishedSem</i>	Optional semaphore to post to when finished
<i>enableDMA</i>	Enable DMA transfers
<i>csReturnToInactive</i>	Chip select state

Returns

The current state of the SPI bus [dsPICState](#)

14.43.5.3.4 QSPIDone()

```
BOOL QSPIDone (
    void ) [inline]
#include <dsPIC.h>
```

Check SPI status. (Compatibility function for previous drivers, note that the 'Q' stands for Queued SPI)

Can be called after [QSPIDone\(\)](#). Returns TRUE when transfer is complete. This is an alternative to using a semaphore.

Returns

true if DSPI is finished, false if active

14.43.5.3.5 QSPIInit()

```
uint8_t QSPIInit (
    uint32_t baudRateInBps = 2000000,
    uint8_t transferSizeInBits = 8,
    uint8_t peripheralChipSelects = 0x0F,
    uint8_t chipSelectPolarity = 1,
    uint8_t clockPolarity = 0,
    uint8_t clockPhase = 1,
    BOOL doutHiz = TRUE,
    uint8_t csToClockDelay = 0,
    uint8_t delayAfterTransfer = 0) [inline]
#include <dspi.h>
```

Initialize Queued Serial Peripheral Interface (QSPI)

Notes: (3) Transfers > 8 must be word aligned (4) Select based on chipSelectPolarity (5) 0 data captured leading edge of QSPI_CLK, changed following edge. (6) 1 data changed leading edge of QSPI_CLK, captured following edge. (7) 0 default is 1/2 QSPI_CLK or see MFCXXXX reference manual (8) 0 default is 8192/(system clock / 2) see MFCXXXX reference manual

Parameters

<i>baudRateInBps</i>	Maximum requested baud rate in bits per second. The maximum possible baud rate is determined by the system clock. The function will select the highest possible baud rate if the specified value cannot be achieved.
<i>transferSizeInBits</i>	Size of data values to be transferred. Values can be 8, 16 or 32 bits. Note that 16 and 32 bit size values must be word (16-bit) aligned (16-bit).
<i>peripheralChipSelects</i>	Peripheral chip select drive level. Used to select an external device for serial data transfer. More than one chip select may be active at once, and more than one device can be connected to each chip select. Bits 3-0 map directly to QSPI_CS[3:0], respectively. For each bit: • 0 = Chip select is 0 during a transfer. • 1 = Chip select is 1 during a transfer.
<i>chipSelectPolarity</i>	Peripheral chip select inactive level (no transfer in progress). Applies to all chip selects. • 0 = 0 when inactive • 1 = 1 when inactive
<i>clockPolarity</i>	Clock polarity: • 0 = The inactive state value of QSPI_CLK is logic level 0. • 1 = The inactive state value of QSPI_CLK is logic level 1.
<i>clockPhase</i>	Clock phase: • 0 = Data captured on the leading edge of QSPI_CLK and changed on the following edge of QSPI_CLK. • 1 = Data changed on the leading edge of QSPI_CLK and captured on the following edge of QSPI_CLK.
<i>doutHiz</i>	Data output high impedance enable. Selects QSPI_DOUT mode of operation. • 0 = Default value after reset. QSPI_DOUT is actively driven between transfers. • 1 = QSPI_DOUT is high impedance between transfers.

Parameters

<i>csToClockDelay</i>	QCD, QSPICLK delay. When the DSCK bit in the command RAM is set this field determines the length of the delay from assertion of the chip selects to valid QSPI_CLK transition.
<i>delayAfterTransfer</i>	Delay after transfer. When the DT bit in the command RAM is set this field determines the length of delay after the serial transfer.

Returns

groupQspiState

See also

[QSPInit\(\)](#)

[QSPiStart\(\)](#)

14.43.5.3.6 QSPiStart()

```
uint8_t QSPiStart (
    uint8_t transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    OS_SEM * finishedSem = NULL) [inline]
```

#include <dspi.h>

Start QSPI Data Transfer.

Parameters

<i>transmitBufferPtr</i>	Pointer to the buffer to use in the transfer. Specify NULL for receive only.
<i>receiveBufferPtr</i>	Pointer to buffer to store received data. NULL for transmit only.
<i>byteCount</i>	Number of bytes to send or receive. If the data size is greater than 8-bit, you must provide the total number of bytes.
<i>finishedSem</i>	Pointer to preinitialized semaphore to post to when transfer is complete. A value of NULL disables the semaphore function.

Returns

groupQspiState

[QSPIdone\(\)](#)

14.43.5.4 Variable Documentation

14.43.5.4.1 CHIP_SELECT_0

```
const uint8_t CHIP_SELECT_0 = 0
```

```
#include <dspi.h>
```

Chip select number.

If supported by the SPI peripheral, these values can be used to configure the chip select to be used during a SPI transfer. Configure the SPI peripheral to use chip select 0.

14.43.5.4.2 CHIP_SELECT_DISABLED

```
const uint8_t CHIP_SELECT_DISABLED = 0xFF
#include <dspi.h>
```

Or flag to set multi bit chipselect.
Configure the SPI peripheral to disable chip select.

14.43.6 SAME70 (QuadSPI)

QSPI for SAME70 (MODM7AE70, SBE70LC)

Classes

- class [SPI_QSPI](#)
The Single-Bit SPI mode QSPI Peripheral Class.

QuadSPI Peripheral Module Definitions

- #define **DEFAULT_QUADSPI_MODULE** 0
Default QUADSPI module.
- #define **QUADSPI_MODULE_COUNT** 1
Number of modules: 0, 1.

14.43.6.1 Detailed Description

QSPI for SAME70 (MODM7AE70, SBE70LC)

Supported Platforms:

- MODM7AE70
- SBE70LC

The NetBurner ARM SAME70 Quad SPI (QSPI) API. Note that there are 3 types of SPI peripherals:

- SPI using the SPI peripheral: Provides the most configuration options. Used in single data channel mode: SCLK, MISO, MOSI, Chip Selects.
- SPI using the QuadSPI peripheral: Single data channel as with SPI, but fewer configuration options.
- SPI using the USART peripheral: Single data channel as with SPI, but fewer configuration options.

14.43.7 SAME70 (USART)

USART for SAME70 (MODM7AE70, SBE70LC)

Topics

- [UsartModuleNumber](#)
USART Peripheral Module .

Classes

- class [SPI_USART](#)
USART in SPI mode Peripheral Module Class.

14.43.7.1 Detailed Description

USART for SAME70 (MODM7AE70, SBE70LC)

Supported Platforms:

- MODM7AE70
- SBE70LC

Note that for the ARM SAME70 there are 3 types of SPI peripherals:

- SPI using the SPI peripheral: Provides the most configuration options. Used in single data channel mode: SCLK, MISO, MOSI, Chip Selects.
- SPI using the QSPI peripheral: Single data channel as with SPI, but fewer configuration options.
- SPI using the USART peripheral: Single data channel as with SPI, but fewer configuration options.

14.43.7.2 UsartModuleNumber

USART Peripheral Module .

Macros

- #define **DEFAULT_USART_SPI_MODULE** 0
Default QUADSPI module.
- #define **USART_SPI_MODULE_COUNT** 2
Number of modules: 0, 1.

14.43.7.2.1 Detailed Description

USART Peripheral Module .

14.44 SSH

Topics

- [SSH Error Codes](#)

Typedefs

- typedef int(* [sshUserAuthenticateFn](#)) (const char *usernamePtr, const char *passwordPtr)
[DEPRECATED] User provided SSH username and password authenticate routine for a server. Please consider sshUserAuthenticateWithTypeFn.
- typedef int(* [sshUserAuthenticateWithTypeFn](#)) (const char *usernamePtr, const char *authValPtr, [AuthType](#) authType)
User provided SSH user authenticate routine for a server.
- typedef int(* [sshGetUserPwFn](#)) (const [NBString](#) &usernamePtr, [NBString](#) &passwordPtr)
User provided SSH user password authentication routine for clients.
- typedef int(* [sshGetUserKeyFn](#)) (const [NBString](#) &usernamePtr, [NBString](#) &publicKey, [NBString](#) &privateKey, [NBString](#) &keyType)
User provided SSH user key authenticate routine for clients.
- typedef int(* [sshUserGetKeyFn](#)) (int keyRequested, const unsigned char **keyBufferPtr, int *keyLengthPtr)
The user defined callback to get the server key used during the initial SSH negotiation.

Functions

- void [SshSetUserAuthenticate](#) ([sshUserAuthenticateFn](#) sshUserAuthenticateFnPtr)
[DEPRECATED] Sets the user defined server authentication function. Please consider [sshUserAuthenticateWithTypeFn](#).
- [sshUserAuthenticateFn](#) [SshGetUserAuthenticate](#) (void)
[DEPRECATED] Gets the user defined server authentication function. Please consider [SshGetUserAuthenticateWithType](#).
- void [SshSetUserAuthenticateWithType](#) ([sshUserAuthenticateWithTypeFn](#) sshUserAuthenticateFnPtr)
Sets the user defined server authentication function.
- [sshUserAuthenticateWithTypeFn](#) [SshGetUserAuthenticateWithType](#) (void)
Gets the user defined server authentication function..
- void [SshClientSetGetUserPasswordFn](#) ([sshGetUserPwFn](#) sshGetUserPwFnPtr)
Sets the user defined client authentication function for getting user passwords during SSH authentication.
- [sshGetUserPwFn](#) [SshClientGetUserPasswordFn](#) (void)
Gets the user defined client authentication function for getting a user password during authentication.
- void [SshClientSetGetUserKeyFn](#) ([sshGetUserKeyFn](#) sshGetUserKeyFnPtr)
Sets the user defined client authentication function for getting user keys during SSH authentication.
- [sshGetUserKeyFn](#) [SshClientGetUserKeyFn](#) (void)
Gets the user defined client authentication function for getting a user key during authentication.
- void [SshSetUserGetKey](#) ([sshUserGetKeyFn](#) sshUserGetKeyFnPtr)
Sets the user defined callback method to provide the server key.
- [sshUserGetKeyFn](#) [SshGetUserGetKey](#) (void)
Gets the user defined callback method to provide the server key.
- bool [SshValidateKey](#) (const char *candidateKey, int candidateKeySize, int *keyTypePtr, int keyFormat=WOLFSSH_FORMAT_ASN1)
Takes a key and returns if it's valid or not.
- bool [SshWritePublicKey](#) (int publicKeyFd, unsigned char *candidateKey, int candidateKeySize)
Write public key to file descriptor. Takes both PEM and ANS1 formats.
- int [NbSshInit](#) ()
Initializes the underlying SSH framework. This will start a background task used to handle negotiations and SSH traffic. This is automatically called by [SshAccept](#) and [SshConnect](#), and doesn't need to be called directly except in special circumstances.
- int [SshAccept](#) (int listenFd, [IPADDR](#) *clientAddress, uint16_t *securePort, uint16_t timeout)
Accepts and negotiates SSH session. Automatically calls [NbSshInit\(\)](#) if required.
- int [SshConnect](#) ([IPADDR](#) clientAddress, uint16_t securePort, uint16_t localPort, uint16_t timeout, const char *username)
Issues a connect request to negotiates an SSH session. Automatically calls [NbSshInit\(\)](#) if required.
- SshSocket * [SshNegotiateSession](#) (int fd)
Negotiates an SSH server session on an open file descriptor.
- SshSocket * [SshNegotiateSessionClient](#) (int secureFd, const char *username)
Negotiates an SSH client session on an open file descriptor.
- void [SshPrintStatistics](#) (int secureFd)
Negotiates an SSH client session on an open file descriptor.
- int [SshGetKeySize](#) ()
Determines and returns SSH's installed key size.
- int [SshSetBannerText](#) (const char *banner)
Sets the banner text displayed by the SSH server on connection.
- int [SshSetSockOption](#) (int fd, int option)
Set SSH TCP socket options.
- int [SshClrSockOption](#) (int fd, int option)
Clear SSH TCP socket options.
- int [SshGetSockOption](#) (int fd)
Returns the options for the specified SSH TCP socket.

14.44.1 Detailed Description

The NetBurner SSH Library

14.44.2 Typedef Documentation

14.44.2.1 sshGetUserKeyFn

```
typedef int(* sshGetUserKeyFn) (const NBString &usernamePtr, NBString &publicKey, NBString
&privateKey, NBString &keyType)
#include <NbWolfSsh.h>
```

User provided SSH user key authenticate routine for clients.

Parameters

	<i>usernamePtr</i>	Username in plain text
out	<i>publicKey</i>	Used to return the corresponding public key for the user
out	<i>privateKey</i>	Used to return the corresponding private key for the user
out	<i>keyType</i>	Used to return the corresponding key type (ECC or RSA) for the user

Return values

>0	Password available for the user
<=0	Authentication failed

14.44.2.2 sshGetUserPwFn

```
typedef int(* sshGetUserPwFn) (const NBString &usernamePtr, NBString &passwordPtr)
#include <NbWolfSsh.h>
```

User provided SSH user password authentication routine for clients.

Parameters

	<i>usernamePtr</i>	Username in plain text
out	<i>passwordPtr</i>	Used to return the corresponding password for the user

Return values

>0	Password available for the user
<=0	Authentication failed

14.44.2.3 sshUserAuthenticateFn

```
typedef int(* sshUserAuthenticateFn) (const char *usernamePtr, const char *passwordPtr)
#include <NbWolfSsh.h>
```

[DEPRECATED] User provided SSH username and password authenticate routine for a server. Please consider `sshUserAuthenticateWithTypeFn`.

Parameters

<i>usernamePtr</i>	Username in plain text
<i>passwordPtr</i>	Password in plain text

Return values

1	Authentication passed
!1	Authentication failed

14.44.2.4 sshUserAuthenticateWithTypeFn

```
typedef int(* sshUserAuthenticateWithTypeFn) (const char *usernamePtr, const char *authValPtr,  
AuthType authType)
```

```
#include <NbWolfSsh.h>
```

User provided SSH user authenticate routine for a server.

Parameters

<i>usernamePtr</i>	Username in plain text
<i>authValPtr</i>	The value that is being passed in for authentication
<i>authType</i>	Either a password or a key

Return values

1	Authentication passed
!1	Authentication failed

14.44.2.5 sshUserGetKeyFn

```
typedef int(* sshUserGetKeyFn) (int keyRequested, const unsigned char **keyBufferPtr, int *key↵  
LengthPtr)
```

```
#include <NbWolfSsh.h>
```

The user defined callback to get the server key used during the initial SSH negotiation.

Parameters

<i>keyRequested</i>	Type key requested (ECC or RSA)
<i>keyBufferPtr</i>	Buffer containing the key (ASN1 or PEM format supported)
<i>keyLengthPtr</i>	Size of the key in 8 bit bytes

Return values

0	Key and length are valid
-1	Key requested is not available

14.44.3 Function Documentation**14.44.3.1 NbSshInit()**

```
int NbSshInit ()
```

```
#include <NbWolfSsh.h>
```

Initializes the underlying SSH framework. This will start a background task used to handle negotiations and SSH traffic. This is automatically called by SshAccept and SshConnect, and doesn't need to be called directly except in special circumstances.

Return values

<i>SSH_SUCCESS</i>	if SSH system has been correctly initialized.
<i>Other</i>	SSH error code if initialization was unsuccessful.

See also

[SshAccept\(\)](#)[SshConnect\(\)](#)**14.44.3.2 SshAccept()**

```
int SshAccept (
    int listenFd,
    IPADDR * clientAddress,
    uint16_t * securePort,
    uint16_t timeout)
```

```
#include <NbWolfSsh.h>
```

Accepts and negotiates SSH session. Automatically calls [NbSshInit\(\)](#) if required.

Parameters

<i>listenFd</i>	File descriptor of listening socket
<i>clientAddress</i>	Address of client
<i>securePort</i>	Secure port of negotiated socket
<i>timeout</i>	Ticks to wait for connection, 0 is infinite

Return values

<i>>0</i>	The secure file descriptor if successful.
<i>Other</i>	A TCP or SSH error code, depending on the error..

See also

[NbSshInit\(\)](#)[SshConnect\(\)](#)**14.44.3.3 SshClientGetUserKeyFn()**

```
sshGetUserKeyFn SshClientGetUserKeyFn (
    void )
```

```
#include <NbWolfSsh.h>
```

Gets the user defined client authentication function for getting a user key during authentication.

Return values

<i>sshGetUserPwFnPtr</i>	Sets the user defined server authentication function.

See also

[SshClientSetGetUserPaswordFn\(\)](#)[SshClientGetUserPaswordFn\(\)](#)[SshClientSetGetUserKeyFn\(\)](#)

14.44.3.4 SshClientGetUserPaswordFn()

```
sshGetUserPwFn SshClientGetUserPaswordFn (
    void )
```

```
#include <NbWolfSsh.h>
```

Gets the user defined client authentication function for getting a user password during authentication.

Return values

A	pointer to the fuction that is currently set for passing in a user's password during authentication.

See also

[SshClientSetGetUserPaswordFn\(\)](#)

[SshClientSetGetUserKeyFn\(\)](#)

[SshClientGetUserKeyFn\(\)](#)

14.44.3.5 SshClientSetGetUserKeyFn()

```
void SshClientSetGetUserKeyFn (
    sshGetUserKeyFn sshGetUserKeyFnPtr)
```

```
#include <NbWolfSsh.h>
```

Sets the user defined client authentication function for getting user keys during SSH authentication.

Parameters

<i>sshGetUserKeyFnPtr</i>	Sets the user defined server authentication function.

See also

[SshClientSetGetUserPaswordFn\(\)](#)

[SshClientGetUserPaswordFn\(\)](#)

[SshClientGetUserKeyFn\(\)](#)

14.44.3.6 SshClientSetGetUserPaswordFn()

```
void SshClientSetGetUserPaswordFn (
    sshGetUserPwFn sshGetUserPwFnPtr)
```

```
#include <NbWolfSsh.h>
```

Sets the user defined client authentication function for getting user passwords during SSH authentication.

Parameters

<i>sshGetUserPwFnPtr</i>	Sets the user defined client authentication function.

See also

[SshClientGetUserPaswordFn\(\)](#)

[SshClientSetGetUserKeyFn\(\)](#)

[SshClientGetUserKeyFn\(\)](#)

14.44.3.7 SshClrSockOption()

```
int SshClrSockOption (
    int fd,
    int option)
```

```
#include <NbWolfSsh.h>
```

Clear SSH TCP socket options.

Parameters

<i>fd</i>	Socket file descriptor.
<i>option</i>	Socket option to clear: TCP Socket Options .

Returns

A bitmask of the options for the specified socket

See also

[SshSetSockOption\(\)](#)

[SshGetSockOption\(\)](#)

14.44.3.8 SshConnect()

```
int SshConnect (
    IPADDR clientAddress,
    uint16_t securePort,
    uint16_t localPort,
    uint16_t timeout,
    const char * username)
```

```
#include <NbWolfSsh.h>
```

Issues a connect request to negotiates an SSH session. Automatically calls [NbSshInit\(\)](#) if required.

Parameters

<i>clientAddress</i>	Address of client
<i>securePort</i>	Secure port of negotiated socket
<i>localPort</i>	Optional parameter to specify a Local port number. Recommend this always be set to a value of 0 so a random local port number is used.
<i>timeout</i>	Ticks to wait for connection, 0 is infinite
<i>username</i>	Username to use in negotiation process of secure connection

Return values

>0	The secure file descriptor if successful.
0	Request timed out.
<0	A TCP or SSH error code, depending on the error..

See also

[SshAccept\(\)](#)

[NbSshInit\(\)](#)

14.44.3.9 SshGetKeySize()

```
int SshGetKeySize ()
#include <NbWolfSsh.h>
```

Determines and returns SSH's installed key size.

Returns

The installed key's size

14.44.3.10 SshGetSockOption()

```
int SshGetSockOption (
    int fd)
#include <NbWolfSsh.h>
```

Returns the options for the specified SSH TCP socket.

Parameters

<i>fd</i>	Socket file descriptor.

Returns

A bitmask of the options for the specified socket

See also

[SshSetSockOption\(\)](#)
[SshClrSockOption\(\)](#)

14.44.3.11 SshGetUserAuthenticate()

```
sshUserAuthenticateFn SshGetUserAuthenticate (
    void )
#include <NbWolfSsh.h>
```

[DEPRECATED] Gets the user defined server authentication function. Please consider [SshGetUserAuthenticateWithType](#).

Return values

<i>Returns</i>	a pointer to the function that is currently set for server user authentication.

See also

[SshGetUserAuthenticateWithType](#)

14.44.3.12 SshGetUserAuthenticateWithType()

```
sshUserAuthenticateWithTypeFn SshGetUserAuthenticateWithType (
    void )
#include <NbWolfSsh.h>
```

Gets the user defined server authentication function..

Return values

<i>A</i>	pointer to the function that is currently set for server user authentication.

See also

[SshGetUserAuthenticateWithType\(\)](#)

14.44.3.13 SshGetUserGetKey()

```
sshUserGetKeyFn SshGetUserGetKey (
    void )
#include <NbWolfSsh.h>
```

Gets the user defined callback method to provide the server key.

Return values

<code>sshUserGetKeyFn</code>	The user defined callback

See also

[sshUserGetKeyFn\(\)](#)

[SshSetUserGetKey\(\)](#)

14.44.3.14 SshNegotiateSession()

```
SshSocket * SshNegotiateSession (
    int fd)
```

```
#include <NbWolfSsh.h>
```

Negotiates an SSH server session on an open file descriptor.

Parameters

<code>fd</code>	File descriptor to use in the SSN negotiation, usually obtained with a call to accept()

Returns

A pointer to the SSH socket created on a successfull connection, or a nullptr if not successful.

14.44.3.15 SshNegotiateSessionClient()

```
SshSocket * SshNegotiateSessionClient (
    int secureFd,
    const char * username)
```

```
#include <NbWolfSsh.h>
```

Negotiates an SSH client session on an open file descriptor.

Parameters

<code>secureFd</code>	File descriptor to use in the SSN negotiation
<code>username</code>	Username to use in negotiation process of secure connection

Returns

A pointer to the SSH socket created on a successfull connection, or a nullptr if not successful.

14.44.3.16 SshPrintStatistics()

```
void SshPrintStatistics (
    int secureFd)
```

```
#include <NbWolfSsh.h>
```

Negotiates an SSH client session on an open file descriptor.

Parameters

<code>secureFd</code>	Secure file descriptor

14.44.3.17 SshSetBannerText()

```
int SshSetBannerText (
    const char * banner)
```

```
#include <NbWolfSsh.h>
```

Sets the banner text displayed by the SSH server on connection.

Parameters

<i>banner</i>	The text to display to any connected clients

Return values

<i>SSH_SUCCESS</i>	If successful
<i><0</i>	Error code on failure

14.44.3.18 SshSetSockOption()

```
int SshSetSockOption (
    int fd,
    int option)
#include <NbWolfSsh.h>
Set SSH TCP socket options.
```

Parameters

<i>fd</i>	Socket file descriptor.
<i>option</i>	Socket option to set: TCP Socket Options .

Returns

A bitmask of the options for the specified socket

See also

[SshClrSockOption\(\)](#)

[SshGetSockOption\(\)](#)

14.44.3.19 SshSetUserAuthenticate()

```
void SshSetUserAuthenticate (
    sshUserAuthenticateFn sshUserAuthenticateFnPtr)
#include <NbWolfSsh.h>
[DEPRECATED] Sets the user defined server authentication function. Please consider sshUserAuthenticateWith↵
TypeFn.
```

Parameters

<i>sshUserAuthenticateFnPtr</i>	Fuction to set

See also

[SshSetUserAuthenticateWithType\(\)](#)

14.44.3.20 SshSetUserAuthenticateWithType()

```
void SshSetUserAuthenticateWithType (
    sshUserAuthenticateWithTypeFn sshUserAuthenticateFnPtr)
#include <NbWolfSsh.h>
Sets the user defined server authentication function.
```

Parameters

<code>sshUserAuthenticateFnPtr</code>	Fuction to set

See also

[SshSetUserAuthenticateWithType\(\)](#)

14.44.3.21 SshSetUserGetKey()

```
void SshSetUserGetKey (
    sshUserGetKeyFn sshUserGetKeyFnPtr)
#include <NbWolfSsh.h>
```

Sets the user defined callback method to provide the server key.

Parameters

<code>sshUserGetKeyFnPtr</code>	The user defined callback

See also

[sshUserGetKeyFn\(\)](#)

[SshGetUserGetKey\(\)](#)

14.44.3.22 SshValidateKey()

```
bool SshValidateKey (
    const char * candidateKey,
    int candidateKeySize,
    int * keyTypePtr,
    int keyFormat = WOLFSSH_FORMAT_ASN1)
#include <NbWolfSsh.h>
```

Takes a key and returns if it's valid or not.

Parameters

	<code>candidateKey</code>	A pointer to a buffer containing the key
	<code>candidateKeySize</code>	The size of the key in bytes
out	<code>keyTypePtr</code>	Is set to what kind of key is passed it (ECC and RSA are valid)
	<code>keyFormat</code>	The key format (ASN1 or PEM)

Return values

<code>true</code>	The key is valid
<code>false</code>	The key is not valid

14.44.3.23 SshWritePublicKey()

```
bool SshWritePublicKey (
    int publicKeyFd,
    unsigned char * candidateKey,
    int candidateKeySize)
#include <NbWolfSsh.h>
```

Write public key to file descriptor. Takes both PEM and ANS1 formats.

Parameters

<i>publicKeyFd</i>	Open target file descriptor
<i>candidateKey</i>	key in buffer
<i>candidateKeySize</i>	Size of key in bytes

Return values

<i>true</i>	A valid key was written to the file descriptor
<i>false</i>	An error occurred

14.44.4 SSH Error Codes

Macros

- **#define SSH_SUCCESS (0)**
The function completed successfully.
- **#define SSH_ERROR_FAILED_SESSION_FAILED (-300)**
Not currently used, kept for backward compatibility.
- **#define SSH_ERROR_FAILED_NEGOTIATION (-301)**
The connection failed the SSH negotiation.
- **#define SSH_ERROR_FAILED_INITIALIZATION (-302)**
The SSH system failed to initialize.
- **#define SSH_ERROR_FAILED_CONTEXT_INIT (-303)**
Unable to instantiate SSH client/server context.
- **#define SSH_ERROR_BAD_KEY (-304)**
The key provided was invalid.
- **#define SSH_ERROR_BAD_ARGUMENT (-305)**
A bad argument was provided to the function.
- **#define SSH_FAILED_KEY_CHECK (-306)**
There were no keys designated to use for the SSH library, .

14.44.4.1 Detailed Description

Error codes that can be returned by the NetBurner SSH functions.

14.45 SSL/TLS

The NetBurner SSL/TLS Library. See [SSL/TLS and Certificates](#) and examples in the examples/SSL folder.

Topics

- [ACME Certificate Generation](#)
Request valid public certificates from an ACME certificate authority for devices with a public IP and DNS.
- [Onboard Self-Signed Certificate Generation](#)
See [On-board Cert Generation - Simple](#) and other examples in the examples/SSL folder.
- [SSL Error Codes](#)

Enumerations

- enum class [ExpireRetCodes](#) : unsigned char { [ExpireRetCodes::E_CERT_VALID](#) = 0 , [ExpireRetCodes::E_CERT_EXPIRED](#) = 1 , [ExpireRetCodes::E_BAD_EXPIRATION_VALUE](#) = 2 , [ExpireRetCodes::E_NO_SYSTEM_TIME](#) = 3 }
- Return values for [SSL_IsCertExpired\(\)](#).*

Functions

- int **SSL_connect** (IPADDR ip, uint16_t remotePort, uint32_t timeout, const char *commonName, bool verifyPeer=false, bool waitForNegotiation=true, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM, int intf=-1)
SSL mirror of the TCP::connect() call.
- int **SSL_connect** (IPADDR ip, uint16_t localPort, uint16_t remotePort, uint32_t timeout, const char *commonName, bool verifyPeer=false, bool waitForNegotiation=true, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM, int intf=-1)
Old version of SSL_Connect with local port.
- int **SSL_makeSecure** (int tcpFd, const char *commonName, bool verifyPeer=false, bool waitForNegotiation=true, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM, bool blsClient=true, uint32_t timeout=WAIT_FOREVER)
SSL mirror of the TCP::connect() call, but uses an existing TCP file descriptor.
- int **SSL_negotiate** (int tcpFd, const char *common_name, bool reuseSessionPort=true, bool verifyPeer=false, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM, bool blsClient=true)
Executes the TLS negotiation over a given socket, to establish a secure communication channel through that socket.
- int **SSLReadWithTimeout** (int fd, char *cp, int size, uint32_t timeout)
SSL mirror of the ReadWithTiemout() function.
- uint32_t **SetMaxSessionReuseTime** (uint32_t newLifetimeTicks)
Allows one to specify at runtime what the longest duration that an established session can be used for before new connections must be fully renegotiated.
- bool **IsSSL_CertNKeyValid** (const char *keyPEM, ssize_t keylen, const char *certPEM, ssize_t certlen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Validate candidate certificate and private key.
- bool **SSL_AddCertToClientCaList** (const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Attempts to add a cert to the Certificate Authority List to the client SSL context.
- bool **SSL_AddCertToServerCaList** (const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Attempts to add a cert to the Certificate Authority List to the client SSL context.
- bool **SSL_ClearClientCaList** ()
Clears certs that have been added to the client's Certificate Authority list.
- bool **SSL_ClearServerCaList** ()
Clears certs that have been added to the server's Certificate Authority list.
- uint16_t **SSLGetRxBufferSpaceUsed** (int fd)
Returns the amount of data buffered to be read from the socket.
- uint16_t **SSLGetTxBufferAvailSpace** (int fd)
Returns the amount of data buffered to be read from the socket.
- void **SslInit** ()
This function initializes the SSL library.
- void **SSL_DumpSSLSockets** ()
Prints the current state of all used sockets to stdio.
- void **SSL_ClientReadyCert** (const unsigned char *cert, const unsigned char *key, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Add a key and certificate to the client.
- void **SSL_ServerReadyCert** (const unsigned char *cert, const unsigned char *key, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Add a key and certificate to the server.
- **ExpireRetCodes** **SSL_IsCertExpired** (unsigned char *certBuff, int certLen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Returns whether the given certificate has expired or not.

- bool [SSL_GetIssuerFromCert](#) (unsigned char *certBuff, int certLen, unsigned char *issBuf, int issBufLen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Returns the issuer from a certificate blob in the PEM format.
- bool [SSL_GetSubjectNameFromCert](#) (unsigned char *certBuff, int certLen, unsigned char *subNamBuf, int subNamBufLen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Returns the subject name from a certificate blob in the PEM format.
- bool [SSL_GetAltNameFromCert](#) (unsigned char *certBuff, int certLen, unsigned char *altNamBuf, int altNamBufLen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Returns an alternate name from a certificate blob in the PEM format.
- bool [SSL_GetExpirationDate](#) (unsigned char *certBuff, int certLen, unsigned char *expBuf, int expBufLen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Returns the expiration data of the certificate in question.
- bool [SSL_GetTimeToExpire](#) (unsigned char *certBuff, int certLen, uint16_t certBuffFormat, time_t &timeToExp)
Returns whether the given certificate has expired or not.
- bool [SSL_GetCnFromCert](#) (unsigned char *certBuff, int certLen, unsigned char *comNamBuf, int comNamBufLen, uint16_t certBuffFormat=SSL_FILETYPE_PEM)
Returns the common name from a certificate blob in the PEM format.
- const char * [GetCertificatePEM](#) ()
Function that returns a pointer to the compiled in server certificate.
- int [GetCertificateLen](#) ()
Function that returns the length of the compiled in server certificate.
- const char * [GetPrivateKeyPEM](#) ()
Function that returns a pointer to the compiled in server key.
- int [GetPrivateKeyLen](#) ()
Function that the length of the compiled in server key.
- void [SslSetVerifyPeerClient](#) (bool verifyPeer)
Sets whether or not verify peer should be enabled on the global SSL client context.
- void [SslSetVerifyPeerServer](#) (bool verifyPeer)
Sets whether or not verify peer should be enabled on the global SSL server context.
- bool [SSL_IsCertAddedToClientCaList](#) ()
Checks to see if any certificates have been added to the global SSL client context.
- bool [SSL_IsCertAddedToServerCaList](#) ()
Checks to see if any certificates have been added to the global SSL server context.

SSL Server Functions

- BOOL(* [IsSSLfd](#))(int fd)
Returns whether or not a file descriptor is an SSL file descriptor.
- int(* [SSL_GetRawSocket](#))(int sslSocketFd)
Returns the TCP file descriptor associated with an SSL socket file descriptor.
- int(* [SSL_setsockopt](#))(int fd, int option)
Set SSL TCP socket options.
- int(* [SSL_clrsockopt](#))(int fd, int option)
Clear SSL TCP socket options.
- int(* [SSL_getsockopt](#))(int fd)
Returns the options for the specified SSL TCP socket.
- int [SSL_accept](#) (int fdListen, [IPADDR](#) *address, uint16_t *port, uint16_t timeout, bool waitForNegotiation=true, bool verifyPeer=false, const unsigned char *certBuff=nullptr, uint32_t certBuffSize=0, uint16_t certBuffFormat=SSL_FILETYPE_PEM, const char *commonName=nullptr)
This call is a mirror of the TCP::accept() call.
- [IPADDR](#) [SSL_GetSocketRemoteAddr](#) (int fd)

- Returns the remote address of this connected socket.*
- uint16_t [SSL_GetSocketRemotePort](#) (int fd)
Returns the remote port of this connected socket.
- IPADDR [SSL_GetSocketLocalAddr](#) (int fd)
Returns the local address of this connected socket.
- uint16_t [SSL_GetSocketLocalPort](#) (int fd)
Returns the local port of this connected socket.
- int [SSL_GetSocketInterface](#) (int fd)
Return the network interface associated with an SSL TCP socket.
- uint16_t [SSL_GetTcpRtxCount](#) (int fd)
Returns the number of re-transmits that have occurred on the specified SSL connection.
- uint32_t [SSL_TcpGetLastRxTime](#) (int fd)
SSL mirror of [TcpGetLastRxTime\(\)](#).
- uint32_t [SSL_TcpGetLastRxInterval](#) (int fd)
SSL mirror of [TcpGetLastRxInterval\(\)](#).
- void [SSL_TcpSendKeepAlive](#) (int fd)
SSL mirror of [TcpSendKeepAlive\(\)](#).
- bool [SSLSocketsAvail](#) ()
Returns whether or not there are any sockets available.
- int [FreeSSLSockets](#) ()
Returns the number of currently free SSL sockets.

SSL socket option functions

- int [SSL_getsocketerror](#) (int fd)
Returns the socket error state for the specified SSL socket.

14.45.1 Detailed Description

The NetBurner SSL/TLS Library. See [SSL/TLS and Certificates](#) and examples in the examples/SSL folder.
`#include< ssl.h>`

14.45.2 Enumeration Type Documentation

14.45.2.1 ExpireRetCodes

```
enum class ExpireRetCodes : unsigned char [strong]
#include <ssl.h>
```

Return values for [SSL_IsCertExpired\(\)](#).

Enumerator

E_CERT_VALID	Certificate not expired.
E_CERT_EXPIRED	Certificate expired.
E_BAD_EXPIRATION_VALUE	Unable to read the expiration information from the certificate.
E_NO_SYSTEM_TIME	The system time has not been set.

14.45.3 Function Documentation

14.45.3.1 FreeSSLSockets()

```
int FreeSSLSockets ()  
#include <ssl.h>
```

Returns the number of currently free SSL sockets.

Returns

The number of free SSL sockets.

14.45.3.2 GetCertificateLen()

```
int GetCertificateLen ()  
#include <ssl.h>
```

Function that returns the length of the compiled in server certificate.

See the SSL documentation and examples for information on generating a self signed certificate and key. This function can be overridden to provide the ability to install uploaded certificates.

Returns

The length of the compiled in certificate.

See also

[GetCertificatePEM\(\)](#)

[GetPrivateKeyLen\(\)](#)

14.45.3.3 GetCertificatePEM()

```
const char * GetCertificatePEM ()  
#include <ssl.h>
```

Function that returns a pointer to the compiled in server certificate.

See the SSL documentation and examples for information on generating a self signed certificate and key.

Returns

A pointer to the compiled in certificate.

See also

[GetPrivateKeyPEM\(\)](#)

[GetCertificateLen\(\)](#)

14.45.3.4 GetPrivateKeyLen()

```
int GetPrivateKeyLen ()  
#include <ssl.h>
```

Function that the length of the compiled in server key.

See the SSL documentation and examples for information on generating a self signed certificate and key. This function can be overridden to provide the ability to install uploaded keys.

Returns

The length of the compiled in key.

See also

[GetPrivateKeyPEM\(\)](#)

[GetCertificateLen\(\)](#)

14.45.3.5 GetPrivateKeyPEM()

```
const char * GetPrivateKeyPEM ()
#include <ssl.h>
```

Function that returns a pointer to the compiled in server key.

See the SSL documentation and examples for information on generating a self signed certificate and key.

Returns

A pointer to the compiled in server key.

See also

[GetCertificatePEM\(\)](#)

[GetPrivateKeyLen\(\)](#)

14.45.3.6 IsSSL_CertNKeyValid()

```
bool IsSSL_CertNKeyValid (
    const char * keyPEM,
    ssize_t keylen,
    const char * certPEM,
    ssize_t certlen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)
#include <ssl.h>
```

Validate candidate certificate and private key.

Determines if the passed in certificate and private key are valid or not.

Parameters

<i>keyPEM</i>	A buffer containing the private key
<i>keylen</i>	The length of the buffer containing the private key
<i>certPEM</i>	A buffer containing the certificate
<i>certlen</i>	The length of the buffer containing the certificate
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>true</code></code>	Certificate and key passed in are valid
<code><code>false</code></code>	Certificate and/or key passed in are not valid

14.45.3.7 SetMaxSessionReuseTime()

```
uint32_t SetMaxSessionReuseTime (
    uint32_t newLifetimeTicks)
#include <ssl.h>
```

Allows one to specify at runtime what the longest duration that an established session can be used for before new connections must be fully renegotiated.

This is a security trade-off feature. It will negatively impact performance to decrease this value. To disable maximum reuse lifetime, pass the argument as 0. This will force a new negotiation on every connection. Calling this function will not affect sessions that are currently stored until they have been used to establish a new connection.

The default value used for this purpose on startup is defined in [predef.h](#) as the macro `SSL_DEFAULT_MAX_SESSION_AGE_TICKS` and is set to one hour.

Parameters

<i>newLifetimeTicks</i>	How long (in ticks) to allow an established session to be used.

Returns

Returns previously assigned reuse maximum.

14.45.3.8 SSL_accept()

```
int SSL_accept (
    int fdListen,
    IPADDR * address,
    uint16_t * port,
    uint16_t timeout,
    bool waitForNegotiation = true,
    bool verifyPeer = false,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM,
    const char * commonName = nullptr)
```

#include <ssl.h>

This call is a mirror of the TCP::accept() call.

Parameters

<i>fdListen</i>	File descriptor of the TCP listening socket.
<i>*address</i>	IPADDR variable to hold the address of the connecting computer.
<i>*port</i>	Variable to receive the remote port of this connection.
<i>timeout</i>	Number of system time ticks to wait for a connection (regular TCP::accept()).
<i>waitForNegotiation</i>	Wait for negotiation to complete. Default is true.
<i>verifyPeer</i>	Default is false. Set to true to verify the client certificate on connect.
<i>certBuff</i>	Buffer containing the certificate data. Default is null.
<i>certBuffSize</i>	Size of the buffer containing the certificate data. Default is 0.
<i>certBuffFormat</i>	Format of the certificate buffer. Default is SSL_FILETYPE_PEM.
<i>commonName</i>	Common name to use for checking certificate validity. Default is null, which will accept any connection.

Return values

>0	The file descriptor of the connected SSL socket
<0	The error code for the failure from SSL Error Codes or TCP Socket Status

See also

[SSL_connect\(\)](#)
[SSL_GetSocketRemoteAddr\(\)](#)
[SSL_GetSocketRemotePort\(\)](#)
[SSL_GetSocketLocalAddr\(\)](#)
[SSL_GetSocketLocalPort\(\)](#)
[IsSSLfd\(\)](#)
[SSL_setsockopt\(\)](#)
[SSL_clrsockopt\(\)](#)
[SSL_getsockopt\(\)](#)

14.45.3.9 SSL_AddCertToClientCaList()

```
bool SSL_AddCertToClientCaList (
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)
```

```
#include <ssl.h>
```

Attempts to add a cert to the Certificate Authority List to the client SSL context.

Parameters

<i>certBuff</i>	A buffer containing the certificate to add.
<i>certBuffSize</i>	The size of the cert being passed in.
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>true</code></code>	Successfully add the certificate to the CA List
<code><code>false</code></code>	Was not able to add the certificate to the CA List

14.45.3.10 SSL_AddCertToServerCaList()

```
bool SSL_AddCertToServerCaList (
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)
```

```
#include <ssl.h>
```

Attempts to add a cert to the Certificate Authority List to the client SSL context.

Parameters

<i>certBuff</i>	A buffer containing the certificate to add.
<i>certBuffSize</i>	The size of the cert being passed in.
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>true</code></code>	Successfully add the certificate to the CA List
<code><code>false</code></code>	Was not able to add the certificate to the CA List

14.45.3.11 SSL_ClearClientCaList()

```
bool SSL_ClearClientCaList ()
```

```
#include <ssl.h>
```

Clears certs that have been added to the client's Certificate Authority list.

Return values

<code><code>true</code></code>	Successfully cleared the Certificate Authority list
<code><code>false</code></code>	Failed to clear the Certificate Authority list

14.45.3.12 SSL_ClearServerCaList()

```
bool SSL_ClearServerCaList ()
#include <ssl.h>
```

Clears certs that have been added to the server's Certificate Authority list.

Return values

<code><code>true</code></code>	Successfully cleared the Certificate Authority list
<code><code>false</code></code>	Failed to clear the Certificate Authority list

14.45.3.13 SSL_ClientReadyCert()

```
void SSL_ClientReadyCert (
    const unsigned char * cert,
    const unsigned char * key,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)
#include <ssl.h>
```

Add a key and certificate to the client.

Parameters

<i>cert</i>	Pointer to the buffer holding the PEM certificate data
<i>key</i>	Pointer to the buffer holding the PEM key data
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

14.45.3.14 SSL_connect() [1/2]

```
int SSL_connect (
    IPADDR ip,
    uint16_t localPort,
    uint16_t remotePort,
    uint32_t timeout,
    const char * commonName,
    bool verifyPeer = false,
    bool waitForNegotiation = true,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM,
    int intf = -1)
#include <ssl.h>
```

Old version of SSL_Connect with local port.

Parameters

<i>ip</i>	The address to connect to.
<i>localPort</i>	The local port to use. 0 will pick one
<i>remotePort</i>	The remote port to connect to.
<i>timeout</i>	The number of ticks to wait for a connection.
<i>*commonName</i>	The common name to use for checking certificate validity passing in NULL will accept any connection.
<i>verifyPeer</i>	Should the client verify the server's certificate against a Certificate Authority list?
<i>waitForNegotiation</i>	Should the function wait until the negotiation is complete before returning?
<i>certBuff</i>	Buffer containing the certificate data

Parameters

<i>certBuffSize</i>	Size of the buffer containing the certificate data
<i>certBuffFormat</i>	The format of the certificate buffer
<i>intf</i>	Optional local interface number to use for connection

Return values

> 0	The file descriptor of the connected SSL socket
< 0	The error code for the failure from SSL Error Codes or TCP Socket Status

See also

14.45.3.15 SSL_connect() [2/2]

```

int SSL_connect (
    IPADDR ip,
    uint16_t remotePort,
    uint32_t timeout,
    const char * commonName,
    bool verifyPeer = false,
    bool waitForNegotiation = true,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM,
    int intf = -1)

```

```
#include <ssl.h>
```

SSL mirror of the TCP::connect() call.

Parameters

<i>ip</i>	The address to connect to.
<i>remotePort</i>	The remote port to connect to.
<i>timeout</i>	The number of ticks to wait for a connection.
<i>*commonName</i>	The common name to use for checking certificate validity passing in NULL will accept any connection.
<i>verifyPeer</i>	Should the client verify the server's certificate against a Certificate Authority list?
<i>waitForNegotiation</i>	Should the function wait until the negotiation is complete before returning?
<i>certBuff</i>	Buffer containing the certificate data
<i>certBuffSize</i>	Size of the buffer containing the certificate data
<i>certBuffFormat</i>	The format of the certificate buffer
<i>intf</i>	Optional local interface number to use for connection

Return values

>0	The file descriptor of the connected SSL socket
<0	The error code for the failure from SSL Error Codes or TCP Socket Status

14.45.3.16 SSL_GetAltNameFromCert()

```

bool SSL_GetAltNameFromCert (
    unsigned char * certBuff,
    int certLen,
    unsigned char * altNamBuf,
    int altNamBufLen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)

```

```
#include <ssl.h>
```

Returns an alternate name from a certificate blob in the PEM format.

Parameters

<i>certBuff</i>	The buffer containing the certificate data
<i>certLen</i>	The length of the certificate
<i>altNamBuf</i>	The buffer to store the alternate name in
<i>altNamBufLen</i>	The length of the buffer where the alternate name will be placed
<i>certBuffFormat</i>	The format of the cert being passed in. Either <code>SSL_FILETYPE_PEM</code> or <code>WOLFSSL_FILETYPE_ASN1</code> .

Return values

<code><code>true</code></code>	If successfully retrieved the alternate name from the cert
<code><code>false</code></code>	If unable to retrieved the alternate name from the cert

14.45.3.17 SSL_GetCnFromCert()

```

bool SSL_GetCnFromCert (
    unsigned char * certBuff,
    int certLen,
    unsigned char * comNamBuf,
    int comNamBufLen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)

```

```
#include <ssl.h>
```

Returns the common name from a certificate blob in the PEM format.

Parameters

<i>certBuff</i>	The buffer containing the certificate data
<i>certLen</i>	The length of the certificate
<i>comNamBuf</i>	The buffer to store the common name in
<i>comNamBufLen</i>	The length of the buffer where the common name will be placed
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>true</code></code>	If successfully retrieved the common name from the cert
<code><code>false</code></code>	If unable to retrieved the common name from the cert

14.45.3.18 SSL_GetExpirationDate()

```
bool SSL_GetExpirationDate (
    unsigned char * certBuff,
    int certLen,
    unsigned char * expBuf,
    int expBufLen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)
```

```
#include <ssl.h>
```

Returns the expiration data of the certificate in question.

Parameters

<i>certBuff</i>	The buffer containing the certificate data
<i>certLen</i>	The length of the certificate
<i>expBuf</i>	The buffer to store the expiration date in
<i>expBufLen</i>	The length of the buffer where the expiration date will be placed
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>true</code></code>	If successfully retrieved the alternate name from the cert
<code><code>false</code></code>	If unable to retrieved the alternate name from the cert

14.45.3.19 SSL_GetIssuerFromCert()

```
bool SSL_GetIssuerFromCert (
    unsigned char * certBuff,
    int certLen,
    unsigned char * issBuf,
    int issBufLen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)
```

```
#include <ssl.h>
```

Returns the issuer from a certificate blob in the PEM format.

Parameters

<i>certBuff</i>	The buffer containing the certificate data

Parameters

<i>certLen</i>	The length of the certificate
<i>issBuf</i>	The buffer to store the issuer in
<i>issBufLen</i>	The length of the buffer where the issuer will be placed
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>true</code></code>	If successfully retrieved the issuer from the cert
<code><code>false</code></code>	If unable to retrieved the issuer from the cert

14.45.3.20 SSL_getsocketerror()

```
int SSL_getsocketerror (
    int fd)
```

```
#include <ssl.h>
```

Returns the socket error state for the specified SSL socket.

Parameters

<i>fd</i>	Socket file descriptor.

Returns

The error state for the specified socket

14.45.3.21 SSL_GetSocketInterface()

```
int SSL_GetSocketInterface (
    int fd) [inline]
```

```
#include <ssl.h>
```

Return the network interface associated with an SSL TCP socket.

Parameters

<i>fd</i>	The socket file descriptor.

Returns

The network interface number (undefined for listening sockets)

See also

[TcpGetSocketInterface\(\)](#)

14.45.3.22 SSL_GetSocketLocalAddr()

```
IPADDR SSL_GetSocketLocalAddr (
    int fd) [inline]
```

```
#include <ssl.h>
```

Returns the local address of this connected socket.

This function is used to retrieve the local address of an SSL fd. This function will also work correctly if you pass in an fd that is a TCP connection. This allows you to use one set of code for both normal TCP and SSL connections.

Parameters

<i>fd</i>	The file descriptor to test.

Returns

The local IP address of the TCP or SSL connection, or 0 otherwise.

14.45.3.23 SSL_GetSocketLocalPort()

```
uint16_t SSL_GetSocketLocalPort (
    int fd) [inline]
#include <ssl.h>
```

Returns the local port of this connected socket.

This function is used to retrieve the local port of an SSL fd. This function will also work correctly if you pass in an fd that is a TCP connection. This allows you to use one set of code for both normal TCP and SSL connections.

Parameters

<i>fd</i>	The file descriptor to test.

Returns

The local port number of TCP or SSL connection, or 0 otherwise.

See also

[IsSSLfd\(\)](#)
[SSL_GetSocketRemoteAddr\(\)](#)
[SSL_GetSocketRemotePort\(\)](#)

14.45.3.24 SSL_GetSocketRemoteAddr()

```
IPADDR SSL_GetSocketRemoteAddr (
    int fd) [inline]
#include <ssl.h>
```

Returns the remote address of this connected socket.

This function is used to retrieve the remote address of an SSL fd. This function will also work correctly if you pass in an fd that is a TCP connection. This allows you to use one set of code for both normal TCP and SSL connections.

Parameters

<i>fd</i>	The file descriptor to test.

Returns

IP address of the TCP or SSL connection, or 0 otherwise.

14.45.3.25 SSL_GetSocketRemotePort()

```
uint16_t SSL_GetSocketRemotePort (
    int fd) [inline]
#include <ssl.h>
```

Returns the remote port of this connected socket.

This function is used to retrieve the remote port of an SSL fd. This function will also work correctly if you pass in an fd that is a TCP connection. This allows you to use one set of code for both normal TCP and SSL connections.

Parameters

<i>fd</i>	The file descriptor to test.

Returns

The remote port number of TCP or SSL connection, or 0 otherwise.

14.45.3.26 SSL_GetSubjectNameFromCert()

```
bool SSL_GetSubjectNameFromCert (
    unsigned char * certBuff,
    int certLen,
    unsigned char * subNamBuf,
    int subNamBufLen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)
#include <ssl.h>
```

Returns the subject name from a certificate blob in the PEM format.

Parameters

<i>certBuff</i>	The buffer containing the certificate data
<i>certLen</i>	The length of the certificate
<i>subNamBuf</i>	The buffer to store the subject name in
<i>subNamBufLen</i>	The length of the buffer where the subject name will be placed
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>true</code></code>	If successfully retrieved the subject name from the cert
<code><code>false</code></code>	If unable to retrieved the subject name from the cert

14.45.3.27 SSL_GetTcpRtxCount()

```
uint16_t SSL_GetTcpRtxCount (
    int fd) [inline]
```

```
#include <ssl.h>
```

Returns the number of re-transmits that have occurred on the specified SSL connection.

Parameters

<i>fd</i>	The socket file descriptor.

Returns

The number of system time ticks since the last packet was received on the connection.

See also

[GetTcpRtxCount\(\)](#);

14.45.3.28 SSL_GetTimeToExpire()

```
bool SSL_GetTimeToExpire (
    unsigned char * certBuff,
    int certLen,
    uint16_t certBuffFormat,
    time_t & timeToExp)
```

```
#include <ssl.h>
```

Returns whether the given certificate has expired or not.

Parameters

	<i>certBuff</i>	The buffer containing the certificate data
	<i>certLen</i>	The length of the certificate
	<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.
out	<i>timeToExp</i>	The time the certificate is set to expire

Return values

<code><code>true</code></code>	If the certificate expiration was found
<code><code>false</code></code>	If the certificate expiration was not found

14.45.3.29 SSL_IsCertAddedToClientCaList()

```
bool SSL_IsCertAddedToClientCaList ()
#include <ssl.h>
```

Checks to see if any certificates have been added to the global SSL client context.

Certificate Authority certificates can be added to the client context during calls to [SSL_connect\(\)](#) or with calls to [SSL_AddCertToClientCaList\(\)](#).

Returns

true If a certificate has been added to the certificate authority list.

false If a certificate has not been added to the certificate authority list.

14.45.3.30 SSL_IsCertAddedToServerCaList()

```
bool SSL_IsCertAddedToServerCaList ()
#include <ssl.h>
```

Checks to see if any certificates have been added to the global SSL server context.

Certificate Authority certificates can be added to the server context during calls to [SSL_connect\(\)](#) or with calls to [SSL_AddCertToServerCaList\(\)](#).

Returns

true If a certificate has been added to the certificate authority list.

false If a certificate has not been added to the certificate authority list.

14.45.3.31 SSL_IsCertExpired()

```
ExpireRetCodes SSL_IsCertExpired (
    unsigned char * certBuff,
    int certLen,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)
#include <ssl.h>
```

Returns whether the given certificate has expired or not.

Parameters

<i>certBuff</i>	The buffer containing the certificate data
<i>certLen</i>	The length of the certificate
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

Return values

<code><code>ExpireRetCodes::E_CERT_EXPIRED</code></code>	If the certificate has expired
<code><code>ExpireRetCodes::E_CERT_VALID</code></code>	If the certificate has not expired
<code><code>ExpireRetCodes::E_BAD_EXPIRATION_VALUE</code></code>	If unable to get the expiration data from the certificate
<code><code>ExpireRetCodes::E_NO_SYSTEM_TIME</code></code>	If the system time has not been set

14.45.3.32 SSL_makeSecure()

```
int SSL_makeSecure (
    int tcpFd,
    const char * commonName,
    bool verifyPeer = false,
    bool waitForNegotiation = true,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM,
    bool bIsClient = true,
    uint32_t timeout = WAIT_FOREVER)
#include <ssl.h>
```

SSL mirror of the TCP::connect() call, but uses an existing TCP file descriptor.

Parameters

<i>tcpFd</i>	The file descriptor for the socket to be secured.
<i>*commonName</i>	The common name to use for checking certificate validity passing in NULL will accept any connection.

Parameters

<i>verifyPeer</i>	Should the client verify the server's certificate against a Certificate Authority list?
<i>waitForNegotiation</i>	Should the function wait until the negotiation is complete before returning?
<i>certBuff</i>	Buffer containing the certificate data
<i>certBuffSize</i>	Size of the buffer containing the certificate data
<i>certBuffFormat</i>	The format of the certificate buffer
<i>bIsClient</i>	Perform the TLS negotiation as the Client and not the Server?
<i>timeout</i>	The number of timeticks to wait for completion

Return values

> 0	The file descriptor of the connected SSL socket
< 0	The error code for the failure from SSL Error Codes or TCP Socket Status

[SSL_setsockopt\(\)](#)
[SSL_clrsockopt\(\)](#)
[SSL_getsockopt\(\)](#)

14.45.3.33 SSL_negotiate()

```

int SSL_negotiate (
    int tcpFd,
    const char * common_name,
    bool reuseSessionPort = true,
    bool verifyPeer = false,
    const unsigned char * certBuff = nullptr,
    uint32_t certBuffSize = 0,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM,
    bool bIsClient = true)

```

```
#include <ssl.h>
```

Executes the TLS negotiation over a given socket, to establish a secure communication channel through that socket.

Parameters

<i>tcpFd</i>	The TCP file descriptor to associate the connection with.
<i>*common_name</i>	The common name to use for checking certificate validity passing in NULL will accept any connection.
<i>reuseSessionPort</i>	Should we look at the port for reuse lookup?
<i>verifyPeer</i>	Should the client verify the server's certificate against a Certificate Authority list?
<i>certBuff</i>	Buffer containing the certificate data
<i>certBuffSize</i>	Size of the buffer containing the certificate data
<i>certBuffFormat</i>	The format of the certificate buffer
<i>bIsClient</i>	Perform the TLS negotiation as the Client and not the Server?

Return values

>0	The file descriptor of the connected SSL socket
<0	The error code for the failure from SSL Error Codes or TCP Socket Status

14.45.3.34 SSL_ServerReadyCert()

```

void SSL_ServerReadyCert (
    const unsigned char * cert,
    const unsigned char * key,
    uint16_t certBuffFormat = SSL_FILETYPE_PEM)

```

#include <ssl.h>

Add a key and certificate to the server.

Parameters

<i>cert</i>	Pointer to the buffer holding the PEM certificate data
<i>key</i>	Pointer to the buffer holding the PEM key data
<i>certBuffFormat</i>	The format of the cert being passed in. Either SSL_FILETYPE_PEM or WOLFSSL_FILETYPE_ASN1.

14.45.3.35 SSL_TcpGetLastRxInterval()

```

uint32_t SSL_TcpGetLastRxInterval (
    int fd) [inline]

```

#include <ssl.h>

SSL mirror of [TcpGetLastRxInterval\(\)](#).

Parameters

<i>fd</i>	The socket file descriptor.

Returns

The number of system Time Ticks since the last packet was received on the connection.

See also

[SSL_TcpSendKeepAlive\(\)](#)
[TcpGetLastRxInterval\(\)](#)

14.45.3.36 SSL_TcpGetLastRxTime()

```
uint32_t SSL_TcpGetLastRxTime (
    int fd) [inline]
#include <ssl.h>
SSL mirror of TcpGetLastRxTime\(\).
```

Parameters

<i>fd</i>	The socket file descriptor.

Returns

The value of system Time Ticks when the last packet was received on the connection.

See also

[SSL_TcpSendKeepAlive\(\)](#)
[TcpGetLastRxTime\(\)](#)

14.45.3.37 SSL_TcpSendKeepAlive()

```
void SSL_TcpSendKeepAlive (
    int fd) [inline]
#include <ssl.h>
SSL mirror of TcpSendKeepAlive\(\).
```

Parameters

<i>fd</i>	The socket file descriptor.

See also

[SSL_TcpGetLastRxTime\(\)](#)
[TcpSendKeepAlive\(\)](#)

14.45.3.38 SSLGetRxBufferSpaceUsed()

```
uint16_t SSLGetRxBufferSpaceUsed (
    int fd)
#include <ssl.h>
Returns the amount of data buffered to be read from the socket.
```

Parameters

<i>fd</i>	The socket's file descriptor

Return values

≥ 0	The number of bytes available to be read
< 0	0 The requested socket does not exist

14.45.3.39 SSLGetTxBufferAvailSpace()

```
uint16_t SSLGetTxBufferAvailSpace (
    int fd)
#include <ssl.h>
Returns the amount of data buffered to be read from the socket.
```

Parameters

<i>fd</i>	The socket's file descriptor

Return values

≥ 0	The number of bytes available to be read
< 0	0 The requested socket does not exist

14.45.3.40 SslInit()

```
void SslInit ()
#include <ssl.h>
```

This function initializes the SSL library.

Note: It should only be called in the case that you want to verify peer certificates as a client and need to add the certificates individually. Otherwise, calls to [SSL_connect\(\)](#) will automatically call this function for you.

14.45.3.41 SSLReadWithTimeout()

```
int SSLReadWithTimeout (
    int fd,
    char * cp,
    int size,
    uint32_t timeout)
#include <ssl.h>
```

SSL mirror of the ReadWithTiemout() function.

This function will block until either the time-out expires or at least one byte is available to be read. This function can be used to read from stdio, TCP sockets, or Serial ports.

Important: This function operates like a read function in that it reads all available bytes and returns. The addition of a time-out does not cause the function to block until the maximum number of bytes specified in the function call is available. The application must use the return value of the function to determine how many bytes were read, and call the function again if necessary.

Parameters

<i>fd</i>	The file descriptor number.
<i>*cp</i>	A pointer to the read destination.
<i>size</i>	Maximum number of bytes to read.
<i>timeout</i>	The number of timer ticks to wait for data.

Return values

0	Invalid buf or size parameters were passed
> 0	The number of bytes read
<i>TCP_ERR_TIMEOUT</i>	No bytes were read before timeout
<i>TCP_ERR_CLOSING</i>	TCP connection is no longer valid, or the SSLSocket_Record no longer exists

See also

[ReadWithTimeout\(\)](#)

[SSL_negotiate\(\)](#)

14.45.3.42 SslSetVerifyPeerClient()

```
void SslSetVerifyPeerClient (
    bool verifyPeer)
```

```
#include <ssl.h>
```

Sets whether or not verify peer should be enabled on the global SSL client context.

Parameters

<i>verifyPeer</i>	True if verify should be enabled, or false otherwise.

14.45.3.43 SslSetVerifyPeerServer()

```
void SslSetVerifyPeerServer (
    bool verifyPeer)
```

```
#include <ssl.h>
```

Sets whether or not verify peer should be enabled on the global SSL server context.

Parameters

<i>verifyPeer</i>	True if verify should be enabled, or false otherwise.

14.45.3.44 SSLSocketsAvail()

```
bool SSLSocketsAvail ()
```

```
#include <ssl.h>
```

Returns whether or not there are any sockets available.

Return values

<i>true</i>	If there are sockets available.
<i>false</i>	If there are not any sockets available

See also

[FreeSSLSockets\(\)](#)

14.45.4 Variable Documentation**14.45.4.1 IsSSLfd**

```
BOOL(* IsSSLfd) (int fd) (
    int fd) [extern]
```

```
#include <ssl.h>
```

Returns whether or not a file descriptor is an SSL file descriptor.

This function is used to determine if the fd is an SSL connection. It can be used by things like the callback functions of the web server to determine how secure the fd is before sending sensitive information over it.

Parameters

<i>fd</i>	The file descriptor to test.

Return values

<i>TRUE</i>	If it is an SSL fd
<i>FALSE</i>	If it is not an SSL fd or if there was an error

See also

[SSL_GetSocketRemoteAddr\(\)](#)[SSL_GetSocketRemotePort\(\)](#)[SSL_GetSocketLocalAddr\(\)](#)[SSL_GetSocketLocalPort\(\)](#)**14.45.4.2 SSL_clrsocketoption**

```
int(* SSL_clrsocketoption) (int fd, int option) (  
    int fd,  
    int option) [extern]
```

#include <ssl.h>

Clear SSL TCP socket options.

Parameters

<i>fd</i>	Socket file descriptor.
<i>option</i>	Socket option to clear: TCP Socket Options .

Returns

A bitmask of the options for the specified socket

See also

[SSL_setsocketoption\(\)](#)[SSL_getsocketoption\(\)](#)**14.45.4.3 SSL_GetRawSocket**

```
int(* SSL_GetRawSocket) (int sslSocketFd) (  
    int sslSocketFd) [extern]
```

#include <ssl.h>

Returns the TCP file descriptor associated with an SSL socket file descriptor.

Parameters

<i>sslSocketFd</i>	The socket file descriptor.

Returns

The TCP file descriptor associated with the SSL socket.

See also

[SSL_GetSocketInterface\(\)](#)**14.45.4.4 SSL_getsocketoption**

```
int(* SSL_getsocketoption) (int fd) (  
    int fd) [extern]
```

#include <ssl.h>

Returns the options for the specified SSL TCP socket.

Parameters

<i>fd</i>	Socket file descriptor.

Returns

A bitmask of the options for the specified socket

See also

14.45.5 ACME Certificate Generation

Request valid public certificates from an ACME certificate authority for devices with a public IP and DNS.

Classes

- class [AcmeServletObject](#)
Main ACME Client Class.
- class [LetsEncryptAcmeServletObject](#)
ACME Client for Let's Encrypt.
- class [BuyPassAcmeServletObject](#)
ACME Client for BuyPass.

14.45.5.1 Detailed Description

Request valid public certificates from an ACME certificate authority for devices with a public IP and DNS.

To use, you can simply specify these constants, NTP, and the ACME Servlet in your program, editing as desired:

```
const char * DEFAULT_CERT_ALT_NAMES= "test.example.com,test2.example.com"; // alt name is required  
const char * DEFAULT_CERT_COM_NAME= "test.example.com";  
const char * DEFAULT_CERT_EMAIL= "changeme@example.com";  
NtpClientServlet ntp_client;
```

You have a choice of supported providers or a custom provider. Just add to your code:

- Let's Encrypt: `LetsEncryptAcmeServletObject acme_client;`
 - Let's Encrypt Staging (for testing, no rate limits): `LetsEncryptAcmeServletObject acme_client(true);`
- BuyPass: `BuyPassAcmeServletObject acme_client;`
- Custom: `AcmeServletObject acme_client("https://192.168.10.90:14000/dir");`

Then for debugging you can add `acme_client.SetDiag(true);` to your `UserMain()`

If your device is accessible on the Internet at those DNS names, Let's Encrypt should automatically issue you a certificate within about a minute of boot.

The NetBurner Config system accepts changing the certificate data under "CertData". You can also provide it in the constructor:

```
AcmeServletObject acme_client("https://acme.example.com/dir");
```

EAB (External Account Binding) support is planned for the future, which paid providers like ZeroSSL, SSL.com and Google require.

See the [ACME Certificate Generation \(Easy Servlet\)](#) example for more details.

14.45.6 Onboard Self-Signed Certificate Generation

See [On-board Cert Generation - Simple](#) and other examples in the examples/SSL folder.

Classes

- struct `CertGenData`

Used to store the information that is passed in when enabling onboard generated certificates, as well as the information needed to determine when they need to be regenerated.
- class `CertData`

Enumerations

- enum `SslKeyType_t` { }

Certificate Generation Key Types.
- enum `AltNameType_t` : char { `ALT_NAME_TYPE_NONE` = 0 , `ALT_NAME_TYPE_DNS` = (char)0x82 , `ALT_NAME_TYPE_IP` = (char)0x87 }

Certificate Generation Alternate Name Types.
- enum `CertGenReturnCode` : int {
`CERT_GEN_RETURN_SUCCESS` = 1 , `CERT_GEN_RETURN_NOT_REQUIRED` = 2 , `CERT_GEN_RETURN_INVALID_RANGE` = -1 , `CERT_GEN_RETURN_MALLOC_ERROR` = -2 , `CERT_GEN_RETURN_ECC_INIT_ERROR` = -3 , `CERT_GEN_RETURN_ECC_CREATE_ERROR` = -4 , `CERT_GEN_RETURN_RSA_INIT_ERROR` = -5 , `CERT_GEN_RETURN_RSA_CREATE_ERROR` = -6 , `CERT_GEN_RETURN_CERT_INIT_ERROR` = -7 , `CERT_GEN_RETURN_CERT_CREATE_ERROR` = -8 , `CERT_GEN_RETURN_CERT_SIGNING_ERROR` = -9 , `CERT_GEN_RETURN_CERT_SAVING_ERROR` = -10 , `CERT_GEN_RETURN_KEY_CONVERT_ERROR` = -11 , `CERT_GEN_RETURN_KEY_SAVING_ERROR` = -12 , `CERT_GEN_RETURN_SET_ISSUER_ERROR` = -13 }

Certificate Generation Function Return Codes.

Functions

- `CertGenReturnCode SSL_CreateNewSelfSignedCert (CertGenData &pGenData)`

Generates a new self-signed certificate that will be stored on the device.
- void `EnableOnboardCertificateCreation (CertGenReturnCode(*createCertFunc)(CertGenData &cGenData)=SSL_CreateNewSelfSignedCert)`

Enables the ability for the module to automatically generate self-signed certificates for use in SSL/TLS connections when acting as the server.
- void `FillInAltNamesASN1 (Cert &TheCert, NBString &altNameString)`

Helper function used to build ASN1 representation of alt names.

- [CertGenReturnCode](#) **CheckAndCreateHalCertAndKey** ()

Check for a valid SSL certificate and generate one if not found.

- [CertGenData](#) * [GetDataForCertGen](#) ()

A function to be overridden to pass certificate details to the certificate generator.

14.45.6.1 Detailed Description

See [On-board Cert Generation - Simple](#) and other examples in the examples/SSL folder.

14.45.6.2 Enumeration Type Documentation

14.45.6.2.1 AltNameType_t

```
enum AltNameType_t : char
#include <certgen.h>
```

Certificate Generation Alternate Name Types.

Enumerator

ALT_NAME_TYPE_NONE	None.
ALT_NAME_TYPE_DNS	DNS Name.
ALT_NAME_TYPE_IP	IP Address.

14.45.6.2.2 CertGenReturnCode

```
enum CertGenReturnCode : int
#include <certgen.h>
```

Certificate Generation Function Return Codes.

Enumerator

CERT_GEN_RETURN_SUCCESS	Returned when the certificate was successfully generated.
CERT_GEN_RETURN_NOT_REQUIRED	Returned when the a new certificate was not required to be generated.
CERT_GEN_RETURN_INVALID_RANDOM	Returned when the device was unable to generate a valid random number.
CERT_GEN_RETURN_MALLOC_ERROR	Returned when the device is unable to malloc enough space to generate the certificate.
CERT_GEN_RETURN_ECC_INIT_ERROR	Returned when the device was unable to initialize the required ECC object.
CERT_GEN_RETURN_ECC_CREATE_ERROR	Returned when the device was unable to create the ECC key.
CERT_GEN_RETURN_RSA_INIT_ERROR	Returned when the device was unable to initialize the required RSA object.
CERT_GEN_RETURN_RSA_CREATE_ERROR	Returned when the device was unable to create the RSA key.
CERT_GEN_RETURN_CERT_INIT_ERROR	Returned when the device was unable to initialize the required certificate object.
CERT_GEN_RETURN_CERT_CREATE_ERROR	Returned when the device was unable to create the certificate.
CERT_GEN_RETURN_CERT_SIGNING_ERROR	Returned when the device was unable to sign the created certificate.
CERT_GEN_RETURN_CERT_SAVING_ERROR	Returned when the device was unable to properly save the certificate.

Enumerator

CERT_GEN_RETURN_KEY_CONVERT_ERROR	Returned when the device was unable to convert the certificate from PEM to DER format.
CERT_GEN_RETURN_KEY_SAVING_ERROR	Returned when the device was unable to save the key.
CERT_GEN_RETURN_SET_ISSUER_ERROR	Returned when the device was unable to set the issuer if a CA was used.

14.45.6.2.3 SslKeyType_t

```
enum SslKeyType_t
```

```
#include <certgen.h>
```

Certificate Generation Key Types.

Enumerator

SSL_KEY_ECC_SECP192R1	Defined in wolfssl/wolfcrypt/ecc.h.
SSL_KEY_ECC_SECP224R1	Defined in wolfssl/wolfcrypt/ecc.h.
SSL_KEY_ECC_SECP256R1	Defined in wolfssl/wolfcrypt/ecc.h.
SSL_KEY_ECC_SECP384R1	Defined in wolfssl/wolfcrypt/ecc.h.
SSL_KEY_ECC_SECP521R1	Defined in wolfssl/wolfcrypt/ecc.h.
SSL_KEY_RSA_1024	RSA 1024.
SSL_KEY_RSA_2048	RSA 2048.
SSL_KEY_RSA_4096	RSA 4096.

14.45.6.3 Function Documentation

14.45.6.3.1 EnableOnboardCertificateCreation()

```
void EnableOnboardCertificateCreation (
```

```
    CertGenReturnCode (* createCertFunc ) (CertGenData &cGenData) = SSL_CreateNewSelfSignedCert)
```

```
#include <certgen.h>
```

Enables the ability for the module to automatically generate self-signed certificates for use in SSL/TLS connections when acting as the server.

If a certificate is manually loaded on the module prior to the SSL server being initialized, that certificate will be used and nothing will be generated. If a certificate had been previously generated and a new certificate is manually loaded on the device, the newly loaded certificate will be used in place of the automatically generated one, though the automatically generated one will still be available on the module.

Parameters

<i>createCertFunc</i>	Optional parameter to specify a custom create certificate function.

14.45.6.3.2 FillInAltNamesASN1()

```
void FillInAltNamesASN1 (
```

```
    Cert & TheCert,
```

```
    NBString & altNameString)
```

```
#include <certgen.h>
```

Helper function used to build ASN1 representation of alt names.

Parameters

<i>TheCert</i>	The WolfSSL Cert structure to put the altnames in/onto.
<i>altNameString</i>	a NBAStrng holding the comman seperated list of alt names. A single string, with possibly multiple altnames separated by a comma. You can either include a tag telling the system what kind of AltName it is... So say you wanted : IP:192.168.1.36 and DNS:demo.netburner.com The following strings would both work: "IP:192.168.1.36,DNS:demo.netburner.com" "192.168.1.36,demo.netburner.com"

or dual interface IP's...

"192.168.1.36,10.1.1.35"

or both V4 and V6.... "IP:fe80::203:f4ff:fe0a:447f,192.168.1.36"

14.45.6.3.3 GetDataForCertGen()

```
CertGenData * GetDataForCertGen () [extern]
#include <certgen.h>
```

A function to be overridden to pass certificate details to the certificate generator.

The library provides this function as a weak reference. The values returned by this weak reference are likely wrong for any real application and the user should provide their own function. Applicable for both self signed and ACME certificates generated onboard.

Returns

pointer to a [CertGenData](#) struct

14.45.6.3.4 SSL_CreateNewSelfSignedCert()

```
CertGenReturnCode SSL_CreateNewSelfSignedCert (
    CertGenData & pGenData)
#include <certgen.h>
```

Generates a new self-signed certificate that will be stored on the device.

The common name and alternative names used are taken from the parameters passed in.

By default, the certificate is generated using ECC with SECP384R1. This can be changed to an RSA key by undefining `ENABLE_ECCKEY_CREATE` in `<nndk_install>\libraries\crypto\platform\<module name>\user_settings.h`, and then rebuilding your application. To specify what curve or RSA key length is used in certificate generation, define `DEFAULT_KEY_TYPE` as one of the values defined by `SslKeyType_t`.

Parameters

<i>pGenData</i>	A pointer to structure used to hold data for certificate generation

Returns

[CertGenReturnCode](#)

14.45.7 SSL Error Codes

Macros

- `#define SSL_ERROR_FAILED_NEGOTIATION (-256)`
The SSL system failed to successfully negotiate a connection.
- `#define SSL_ERROR_CERTIFICATE_UNKNOWN (-258)`
The received certificate could not be decoded.
- `#define SSL_ERROR_CERTIFICATE_NAME_FAILED (-260)`
The connected name did not match common_name.
- `#define SSL_ERROR_CERTIFICATE_VERIFY_FAILED (-261)`

- The server returned a certificate that we did not trust.*
- #define **SSL_ERROR_NO_BUFFER** (-262)
Unable to get a buffer from the pool.
- #define **SSL_ERROR_HANDSHAKE_INCOMPLETE** (-265)
The SSL handshake is not complete yet.
- #define **SSL_ERROR_NO_SERVER_CERTIFICATE** (-257)
The server wasn't able to load the certificate.
- #define **SSL_ERROR_NO_SERVER_KEY** (-258)
The server wasn't able to load the key.
- #define **SSL_ERROR_UNABLE_TO_LOAD_CIPHERS** (-259)
The client was unable to load the cipher list.
- #define **SSL_ERROR_CERTIFICATE_CHECK** (-260)
The server was unable to check the certificate.

14.45.7.1 Detailed Description

Error codes that can be returned by the NetBurner SSL functions.

14.46 Serial Interfaces

Topics

- [Serial Port Error Codes](#)

Macros

- #define **ADDR_ESCAPE_CHAR** (0xFF)
Address escape character.
- #define [SimpleOpenSerial](#)(p, b) [OpenSerial](#)(p, b, 1, 8, [eParityNone](#))
Simple open a serial port.

Enumerations

- enum [parity_mode](#) {
 [eParityNone](#) , [eParityOdd](#) , [eParityEven](#) , [eParityMulti](#) ,
 [eParityMultiOdd](#) , [eParityMultiEven](#) }
Serial Parity Modes.

Functions

- int [OpenSerial](#) (int portnum, unsigned int baudrate, int stop_bits, int data_bits, [parity_mode](#) parity)
Open a serial port.
- int [OpenDefaultSerial](#) ()
Opens the Default serial port as defined by the Boot Config settings.
- void [SerialExpandRxBuffer](#) (int fd, int nb)
Expand the received serial buffer.
- int [SerialClose](#) (int portnum)
Close a serial port.
- void [SerialEnableTxFlow](#) (int port, int enab)
Enable transmit software flow control on the specified UART.
- void [SerialEnableRxFlow](#) (int port, int enab)
- void [SerialEnableHwTxFlow](#) (int port, int enab)

- BOOL [SerialSendComplete](#) (int fd)

14.46.1 Detailed Description

```
#include< serial.h>
```

The NetBurner Serial API

14.46.2 Macro Definition Documentation

14.46.2.1 SimpleOpenSerial

```
#define SimpleOpenSerial(  
    p,  
    b) OpenSerial(p, b, 1, 8, eParityNone)
```

```
#include <serial.h>
```

Simple open a serial port.

Select the UART number and baud rate, default parameters will be 1 stop bit, no parity, 8 data bits.

Parameters

<i>p</i>	The UART to open. First port is 0. The maximum number is platform dependent
<i>b</i>	The speed of the serial port in bits per second

See also

[OpenSerial\(\)](#)

14.46.3 Enumeration Type Documentation

14.46.3.1 parity_mode

```
enum parity\_mode  
#include <serial.h>  
Serial Parity Modes.
```

Enumerator

eParityNone	No parity.
eParityOdd	Odd parity.
eParityEven	Even parity.
eParityMulti	Multi parity.
eParityMultiOdd	Multi mode, Odd parity.
eParityMultiEven	Multi mode, Even parity.

14.46.4 Function Documentation

14.46.4.1 GetUartErrorReg()

```
int GetUartErrorReg (  
    int fd)
```

```
#include <serial.h>
```

Gets the UART error register. This is only applicable on select platforms. Any errors are added to this register in a logical OR operation. Calling this function to read the error status will clear the register.

Bit Description

3 Received break 2 Framing error 1 Parity error 0 Overrun error

fd - The file descriptor associated with the UART serial port whose error register is to be retrieved.

return - The value of the error register if successful (positive int - the bitwise values are represented by the UART_↵
_ERR_* definitions found near the top of this file); otherwise, one of the error codes is returned: SERIAL_ERR_↵
NOSUCH_PORT (-1) SERIAL_ERR_PORT_NOTOPEN (-2)

14.46.4.2 OpenDefaultSerial()

```
int OpenDefaultSerial ()
```

```
#include <serial.h>
```

Opens the Default serial port as defined by the Boot Config settings.

This function opens the Default serial port as defined by the Boot Config settings. It is called automatically by the system as part of the system initialization process. Unlike OpenSerial and SimpleOpenSerial, OpenDefaultSerial will configure the Tx and Rx pins to the Boot Config settings.

Returns

The file descriptor of the default serial port (> 0), or [Serial Port Error Codes](#)

See also

[OpenSerial\(\)](#)

14.46.4.3 OpenSerial()

```
int OpenSerial (
    int portnum,
    unsigned int baudrate,
    int stop_bits,
    int data_bits,
    parity_mode parity)
#include <serial.h>
```

Open a serial port.

This function opens a serial port. Note that functions to open a serial port, such as [OpenSerial\(\)](#) and [SimpleOpenSerial\(\)](#), must be called before any functions or pin assignments that configure the operation of the serial port. You must also configure all pins that have the same UART capability. For example, if UART 1 TX can be configured to come out on more than one pin (as a second or third alternate function), you must set those pins to some function other than UART 1 TX. This is because the functions that open a serial port will configure all serial port functions to default operation and default pins. For example, hardware flow control will be off, and the default pin assignments will be used on those platform that have multiple outputs.

Note

MODM7AE70 and SBE70LC platforms have two UART types: USART for serial ports 0 and 1, and two wire UART for serial ports 2 and above that only support RS-232, 1 stop bit , 8 data bits, no parity.

Parameters

<i>portnum</i>	The UART to open. First port is 0. The maximum number is platform dependent
<i>baudrate</i>	The speed of the serial port in bits per second
<i>stop_bits</i>	The number of stop bits, 1 or 2 (Hardware may not support all values)
<i>data_bits</i>	The number of data bits sent per character or frame: 5, 6, 7 or 8 (Hardware may not support all values)
<i>parity</i>	The type of parity checking to use: eParityNone, eParityEven, eParityOdd or eParityMulti

Returns

The file descriptor of the serial port (> 0), or [Serial Port Error Codes](#)

See also

[SimpleOpenSerial\(\)](#)

14.46.4.4 SendBreak()

```
void SendBreak (
    int port,
    uint32_t time)
#include <serial.h>
```

Sets a break in the UART transmission for a given period of time. The break starts when character transmission completes. The break is delayed until any character in the transmitter shift register is sent. Any character in the transmitter holding register is sent after the break.

Note: This feature may not be supported on all UART modules. Please refer to the processor's datasheet for details on supported features.

port - The UART whose transmitter will be forced low (start break). time - Specifies the amount of time in ticks that the break will hold; when time expires, the break will be stopped; 20 ticks equal 1 second by default.

return - Nothing to return.

14.46.4.5 Serial485HalfDupMode()

```
void Serial485HalfDupMode (
    int port,
    int enab)
#include <serial.h>
```

Enables or disables RS-485 half-duplex mode. Full-duplex mode is automatically enabled when half-duplex mode is disabled. This must be explicitly called before RS-485 functionality can be used. Jumpers may also be needed depending on the hardware device and/or development board used.

port - The UART port to use; the UART that can only be used for RS-485 depends on the platform (e.g., MOD52xx mounted on the MOD-DEV-100 development board use only UART 0 for RS-485, CB34-EX use only UART 1 for RS-485). enab - '0' disables half-duplex (enables full-duplex); '1' enables half- duplex (disables full-duplex)

return - Nothing to return.

14.46.4.6 SerialClose()

```
int SerialClose (
    int portnum)
#include <serial.h>
```

Close a serial port.

Parameters

<i>portnum</i>	The UART to close. First port is 0. The maximum number is platform dependent

Returns

0 if successful, otherwise [Serial Port Error Codes](#)

See also

[OpenSerial\(\)](#)

14.46.4.7 SerialEnableHwRxFlow()

```
void SerialEnableHwRxFlow (
    int port,
    int enab)
```

```
#include <serial.h>
```

Enables or disables request-to-send hardware flow control on receive (RxRTS). When enabled, receive throttles the transmitter on the other end. Jumpers may also be needed to enable the RxRTS line depending on the device and/or development board used.

(NB Device) Rx <--<--< Tx (Other Device) (NB Device) RxRTS >-->--> TxCTS (Other Device)

port - The UART whose flow control will be toggled. enab - '0' disables flow control; '1' (or any non-zero number) will enable it.

return - Nothing to return.

14.46.4.8 SerialEnableHwTxFlow()

```
void SerialEnableHwTxFlow (
    int port,
    int enab)
```

```
#include <serial.h>
```

Enables or disables clear-to-send hardware flow control on transmit (TxCTS). When enabled, transmit is throttled by the receiver on the other end. Jumpers may also be needed to enable the TxCTS line depending on the device and/or development board used.

(NB Device) Tx >-->--> Rx (Other Device) (NB Device) TxCTS <--<--< RxRTS (Other Device)

Note: Calling this function to disable Tx hardware flow control after enabling RS-485 full-duplex mode configures for RS-422 mode (Tx stays actively driven).

port - The UART whose flow control will be toggled. enab - '0' disables flow control; '1' (or any non-zero number) will enable it.

return - Nothing to return.

14.46.4.9 SerialEnableRxFlow()

```
void SerialEnableRxFlow (
    int port,
    int enab)
```

```
#include <serial.h>
```

Enables or disables software flow control (XON/XOFF) on receive. When enabled, the NetBurner device will send special XON and XOFF characters to another device in order to control the flow of incoming data.

port - The UART whose flow control will be toggled. enab - '0' disables flow control; '1' (or any non-zero number) will enable it.

return - Nothing to return.

14.46.4.10 SerialEnableTxFlow()

```
void SerialEnableTxFlow (
    int port,
    int enab)
```

```
#include <serial.h>
```

Enable transmit software flow control on the specified UART.

Enables or disables software flow control (XON/XOFF) on transmit. When enabled, the NetBurner device will recognize the special XON and XOFF characters being sent from another device in order to throttle the output.

Parameters

<i>port</i>	UART number
<i>enab</i>	0 disables flow control, 1 enables flow control

14.46.4.11 SerialExpandRxBuffer()

```
void SerialExpandRxBuffer (
    int fd,
    int nb)
```

```
#include <serial.h>
```

Expand the received serial buffer.

This function expands the number of buffer descriptors the specific serial port is allowed to use. Each buffer descriptor counts for 1500 bytes so setting this to 10 would make the serial Rx buffer 15000 bytes.

14.46.4.12 SerialSendComplete()

```
BOOL SerialSendComplete (
    int fd)
```

```
#include <serial.h>
```

Determines if data waiting in transmitter holding/shift registers are already sent out.

return - True if finished, false if data still sending

14.46.4.13 serwriteaddress()

```
int serwriteaddress (
    int fd,
    const char c)
```

```
#include <serial.h>
```

Sends an address character via the UART port number associated with the given file descriptor. This function can only be utilized if the UART is initialized in multidrop mode.

fd - The file descriptor associated with the UART serial port that will be used. c - The address character to be sent.

return - '1' if successful; otherwise, one of the error codes is returned (note that SERIAL_ERR_PORT_NOTOPEN is also returned if UART is not initialized to be in multidrop mode): SERIAL_ERR_NOSUCH_PORT (-1) SERIAL_ERR_PORT_NOTOPEN (-2)

14.46.4.14 SetRTS()

```
void SetRTS (
    int port,
    bool val)
```

```
#include <serial.h>
```

Sets or clears the Request To Send signal for the specified serial port.

port - The UART port whose RTS signal will be set or cleared. (0 or 1) val - The Boolean value to configure the signal; TRUE sets it, while FALSE clears it.

return - Nothing to return.

14.46.5 Serial Port Error Codes**Macros**

- **#define SERIAL_ERR_NOSUCH_PORT (-1)**
Port number does not exist.
- **#define SERIAL_ERR_PORT_NOTOPEN (-2)**
Port is not open.
- **#define SERIAL_ERR_PORT_ALREADYOPEN (-3)**
Port is already open.
- **#define SERIAL_ERR_PARAM_ERROR (-4)**
Parameter error.

14.46.5.1 Detailed Description

```
#include< serial.h>
```

14.47 Shutdown Notifications

Topics

- [ShutdownReasons](#)

Shutdown Reasons

```
#include< ShutDownNotifications.h>
```

Functions

- bool [NBApproveShutdown](#) (int reason)
Approve action that will result in a reboot.
- void [NBFaultNotify](#) ()
Emergency notification of a fault shutdown.

14.47.1 Detailed Description

```
#include< ShutDownNotifications.h>
```

The NBApproveShutdown callback function can be used by an application to put the system in a safe state before an application update, configuration update, or reboot event occurs. For example, closing active TCP sockets, ensuring Flash and/or file system write operations are complete, and putting critical peripherals in a safe state. The [NBApproveShutdown\(\)](#) function as a weak reference to a system function that always returns true by default. If an application creates its own function using the same signature, that function will be used instead.

A reason for the reboot request is passed to the function. The system will automatically call NBApproveShutdown() for the following reasons:

```
#define SHUTDOWN_CODEUPDATE (1) // A code update is requested
#define SHUTDOWN_CONFIGURE_REBOOT (2) // Configuration values have been modified with a requested reboot
```

An application can choose to ignore the parameters or add its own. For custom reasons, the application should call [NBApproveShutdown\(\)](#) with the appropriate reason:

```
// Custom reboot reason. System reasons start at 1, so pick something much larger
#define SHUTDOWN_CUSTOM_REBOOT 100

if ( NBApproveShutdown (SHUTDOWN_CUSTOM_REBOOT) )
{
    OSTimeDly (TICKS_PER_SECOND * 5);
    ForceReboot ();
}
```

14.47.2 Function Documentation

14.47.2.1 NBApproveShutdown()

```
bool NBApproveShutdown (
    int reason)
#include <ShutDownNotifications.h>
Approve action that will result in a reboot.
```

Note

Called for application updates or configuration changes that include the reboot option

This function will be called when the configuration values have changed with the option to reboot, or for an application update (always requires a reboot).

If the process fails at some time after this notification is approved, the system may not execute a reboot. This function is satisfied as a weak reference in the NetBurner library. In order to use it in your application, create a function of the same name (callback function).

Parameters

<i>reason</i>	The reason for the shutdown request (ShutdownReasons)

Return values

<i>true</i>	Ok to proceed with the modification and reboot
<i>false</i>	Abort the update

14.47.2.2 NBFaultNotify()

```
void NBFaultNotify ()  
#include <ShutDownNotifications.h>  
Emergency notification of a fault shutdown.
```

Note

Called after a critical error, such as a trap or memory fault before a reboot

If the system has a critical fault of some kind it will call this function before rebooting. Since this is a sever critical fault, the function is being called in an exception context with a very small stack. It should execute whatever is necessary and return immediately with a minimal number of variables. It is extremely limited in the actions it can perform. It cannot execute:

- Any RTOS functions
- printf family functions
- Writes to network sockets
- TCP or UDP functions
- Writes to serial ports
- RTOS delay functions
- Writes to Flash memory
- File system operations

Since this is a critical fault condition and the system is unstable, writing directly to I/O registers has the most chance of success.

14.47.3 ShutdownReasons

Shutdown Reasons

```
#include< ShutDownNotifications.h>
```

.

Macros

- **#define SHUTDOWN_CODEUPDATE (1)**
A code update is requested.
- **#define SHUTDOWN_CONFIGURE_REBOOT (2)**
Configuration values have been modified with a requested reboot.

14.47.3.1 Detailed Description

Shutdown Reasons

```
#include< ShutDownNotifications.h>
```

.

14.48 Signed Application Update

Topics

- [NBUpdate Function Return Values](#)

Functions

- void [RegisterAppSigningPublicKey](#) (const char *pKey)
Enable APP Signing by registering a RSA PEM or DER format public key.
- int [ProgramApplication](#) (uint32_t where, uint8_t *pAppImage)
Program an appliction image into Flash memory.
- int [UpdateFromStream](#) (int fd, AppUpdateRecord *&pu, uint32_t timeout)
Program/update an application image from a data stream.

14.48.1 Detailed Description

```
#include< nbupdate.h>
```

14.48.2 Function Documentation

14.48.2.1 ProgramApplication()

```
int ProgramApplication (
    uint32_t where,
    uint8_t * pAppImage)
```

```
#include <nbupdate.h>
```

Program an appliction image into Flash memory.

Parameters

<i>where</i>	Location in Flash memory
<i>pAppImage</i>	Pointer to the application image to program

Return values

0	Success
-1	Application image pointer invalid
-2	Invalid platform header

14.48.2.2 RegisterAppSigningPublicKey()

```
void RegisterAppSigningPublicKey (
    const char * pKey)
```

```
#include <nbupdate.h>
```

Enable APP Signing by registering a RSA PEM or DER format public key.

This function should be called BEFORE the [init\(\)](#) function if you want to guarantee security. It is ok to register a temporary text blob early, then overwrite it once the key via other means.

Parameters

<i>pKey</i>	Pointer to the public key to register

14.48.2.3 UpdateFromStream()

```
int UpdateFromStream (
    int fd,
    AppUpdateRecord *& pu,
    uint32_t timeout)
```

```
#include <nbupdate.h>
```

Program/update an application image from a data stream.

Parameters

<i>fd</i>	File descriptor of data stream
<i>pu</i>	Application record
<i>timeout</i>	Timeout value in system time ticks (eg TICKS_PER*SECOND * 10)

Return values

0	Success
-1	Application image pointer invalid
-2	Invalid platform header

14.48.3 NBUpdate Function Return Values

Macros

- **#define NBUP_ERR_NO_ERR 0**
No errors.
- **#define NBUP_ERR_BAD_SOCKET -1**
File descriptor socket is invlaid.
- **#define NBUP_ERR_TIMEOUT -2**
Timeout.
- **#define NBUP_ERR_TOO_LARGE -3**
Application update record is too large.
- **#define NBUP_ERR_WRONG_PLAT -4**
Device platform name does not match.
- **#define NBUP_ERR_BAD_PROG -5**
Programming failed, invalid checksum.
- **#define NBUP_ERR_BAD_AUTH -6**
Application update record authentication failed.

14.48.3.1 Detailed Description

```
#include< nbupdate.h>
```

14.49 Stream Update**Topics**

- [Stream Update Return Values](#)

Functions

- int [ReadBinaryApplicationCodeFromStream](#) (int fd)
Read a binary application image from an input stream and program flash memory.
- int [ReadS19ApplicationCodeFromStream](#) (int fd)
Read an ASCII application image in s-record .s19 format from an input stream and program flash memory.

14.49.1 Detailed Description

```
#include< StreamUpdate.h>
```

Functions to read an application form a source with a file descriptor. Useful for programming/updating an application image from sources such as flash memory cards, posts from other devices, and files received from FTP.

14.49.2 Function Documentation**14.49.2.1 ReadBinaryApplicationCodeFromStream()**

```
int ReadBinaryApplicationCodeFromStream (
    int fd)
```

```
#include <StreamUpdate.h>
```

Read a binary application image from an input stream and program flash memory.

Read a binary application image from an input stream and program the application image in flash memory. Flash memory will not be modified unless the entire application is received without error.

A reboot is required to run the new application. Before any reboot, the running application should free, close and clean up any items necessary to put the device in a safe state. For example, it would be better to close active TCP or FTP connections rather than just reset so that any connected clients can close normally. If you wish to reboot from a running application you can use the

```
void ForceReboot()
```

```
function ForceReboot().
```

Parameters

<i>fd</i>	The File Descriptor to read the input data stream from

Returns

[Stream Update Return Values](#)

14.49.2.2 ReadS19ApplicationCodeFromStream()

```
int ReadS19ApplicationCodeFromStream (
    int fd)
```

```
#include <StreamUpdate.h>
```

Read an ASCII application image in s-record .s19 format from an input stream and program flash memory.

Read a ASCII application image in s-record .s19 format from an input stream and program the application image in flash memory. Flash memory will not be modified unless the entire application is received without error.

A reboot is required to run the new application. Before any reboot, the running application should free, close and clean up any items necessary to put the device in a safe state. For example, it would be better to close active TCP or FTP connections rather than just reset so that any connected clients can close normally. If you wish to reboot from a running application you can use the

```
void ForceReboot()
```

```
function ForceReboot().
```

Parameters

<i>fd</i>	The File Descriptor to read the input data stream from

Returns

[Stream Update Return Values](#)

14.49.3 Stream Update Return Values

Macros

- `#define STREAM_UP_FAIL (0)`
Action failed.
- `#define STREAM_UP_OK (1)`
Action succeeded.

14.49.3.1 Detailed Description

```
#include< StreamUpdate.h>
```

14.50 Synchronous Audio Interface (SOMRT1061)

Topics

- [SAI Callback Types](#)
- [SAI Configuration Enumerations](#)
- [SAI Configuration Structures](#)
- [SAI Driver Class](#)
- [SAI Driver Constants](#)
- [SAI Predefined Configurations](#)

Files

- file [sai.h](#)
Synchronous Audio Interface (SAI/I2S) Driver for i.MX RT10xx.

Variables

- [SAICtx_t sai](#)
Global SAI driver instance.

14.50.1 Detailed Description

Note

Supported Platforms: SOMRT1061

14.50.2 Variable Documentation

14.50.2.1 sai

```
SAICtx_t sai [extern]
#include <sai.h>
```

Global SAI driver instance.

This is the main driver instance for SAI operations. Most applications will use this single global instance rather than creating their own.

```
extern SAICtx_t sai;
```

```
// Use the global instance
sai.Init(SAI_I2S_SLAVE_24_TXRX_RK);
```

14.50.3 SAI Callback Types

Typedefs

- typedef void(* [SAI_BufferDoneFn_t](#)) (void *buffer, int doneInvalid)

Callback function type for buffer completion notifications.

14.50.3.1 Detailed Description

14.50.3.2 Typedef Documentation

14.50.3.2.1 SAI_BufferDoneFn_t

```
typedef void(* SAI_BufferDoneFn_t) (void *buffer, int doneInvalid)
#include <sai.h>
```

Callback function type for buffer completion notifications.

This callback is invoked from interrupt context when a buffer transfer completes or encounters an error. The callback should return quickly and defer any lengthy processing to a task context.

Parameters

<i>buffer</i>	Pointer to the buffer that completed (same pointer passed to TransmitBuffer or ReadyReceiveBuffer)
<i>doneInvalid</i>	Status indicator for the buffer completion: • **< -1**: Channel error, buffer state unchanged (may be retried) • -1: Transfer error, buffer retired (do not reuse immediately) • 0: Half transfer complete (if half-notify enabled), second half still in progress • **> 0**: Buffer completely transferred successfully

Note

This callback executes in interrupt context. Keep processing minimal:

- Do NOT call blocking functions
- Do NOT perform long computations
- Use RTOS signaling (semaphores, flags) to defer work to tasks
- Avoid excessive printing

Warning

The buffer pointer is only valid if the completion status is non-negative. For error conditions (< 0), the buffer may be in an indeterminate state.

```
void myBufferCallback(void *buffer, int doneInvalid) {
    if (doneInvalid > 0) {
        // Success - buffer fully transferred
        OSSemPost(&bufferDoneSemaphore);
    } else if (doneInvalid == 0) {
        // Half complete - can start processing first half
        ProcessFirstHalf(buffer);
    } else {
        // Error condition
        iprintf("Buffer error: %d\n", doneInvalid);
    }
}
```

14.50.4 SAI Configuration Enumerations**Enumerations**

- enum `clkSrc_t` { `CLK_SRC_MCK` , `CLK_SRC_EXT` }
Clock source selection for SAI bit clock generation.
- enum `clkCh_t` { `CLK_CH_CH` , `CLK_CH_RK` , `CLK_CH_TK` }
Clock channel selection for determining which clock signal to use.
- enum `clkPol_t` { `CLK_ACTIVE_HIGH` , `CLK_ACTIVE_LOW` }
Clock polarity configuration.
- enum `frameSyncCh_t` { `SYNC_CH_CH` , `SYNC_CH_RX` , `SYNC_CH_TX` }
Frame synchronization channel selection.
- enum `startCond_t` {
 `START_CONTINUOUS` , `START_SYNC_RX_TX` , `START_FRAME_LOW` , `START_FRAME_HIGH` ,
 `START_FRAME_FALLING` , `START_FRAME_RISING` , `START_FRAME_LEVEL` , `START_FRAME_EDGE` ,
 `START_CMP_0` }
Starting conditions that trigger SAI data transfers.
- enum `clkGate_t` { `CLK_GATE_CONTINUOUS` , `CLK_GATE_FRAME_LOW` , `CLK_GATE_FRAME_HIGH` }
Clock gating mode for power optimization.
- enum `frameEdge_t` { `FRAME_SYNC_RISING` , `FRAME_SYNC_FALLING` }
Frame sync edge that indicates the start of a new frame.
- enum `clkOut_t` { `CLK_OUT_INPUT` , `CLK_OUT_CONTINUOUS` , `CLK_OUT_TRANSFER` }
Bit clock output mode configuration.
- enum `frameSyncOut_t` { `FRAME_SYNC_INPUT` , `FRAME_SYNC_NEGATIVE` , `FRAME_SYNC_POSITIVE` }
Frame synchronization signal output mode.
- enum `dataPacking_t` {
 `BUFFER_WORD8` , `BUFFER_WORD16_LEFT` , `BUFFER_WORD16_RIGHT` , `BUFFER_WORD32_LEFT` ,
 `BUFFER_WORD32_RIGHT` }
Buffer word format and data justification.
- enum `bitOrder_t` { `LEAST_SIG_FIRST` , `MOST_SIG_FIRST` }
Bit transmission order within each word.
- enum `bufferDepletionBehavior_t` { `DEPLETED_PAUSE` , `DEPLETED_REPEAT_LAST` }
DMA behavior when all queued buffers are exhausted.
- enum `rxTxSync_t` { `RXTX_ASYNC` , `RXTX_SYNC_RX` , `RXTX_SYNC_TX` }
Synchronization mode between RX and TX channels.

14.50.4.1 Detailed Description**14.50.4.2 Enumeration Type Documentation****14.50.4.2.1 bitOrder_t**

```
enum bitOrder_t
#include <sai.h>
```

Bit transmission order within each word.

Determines whether the least significant bit or most significant bit is transmitted first on the data line.

Enumerator

LEAST_SIG_FIRST	LSB transmitted first (uncommon for audio)
MOST_SIG_FIRST	MSB transmitted first (standard for I2S and most audio protocols)

14.50.4.2.2 bufferDepletionBehavior_t

```
enum bufferDepletionBehavior_t
#include <sai.h>
```

DMA behavior when all queued buffers are exhausted.

Defines what the DMA channel should do when it runs out of buffers to process. This is critical for preventing underruns/overruns.

Enumerator

DEPLETED_PAUSE	Pause transfers when buffers depleted (recommended for most uses)
DEPLETED_REPEAT_LAST	Continuously repeat the last buffer in the chain (useful for streaming)

14.50.4.2.3 clkCh_t

```
enum clkCh_t
#include <sai.h>
```

Clock channel selection for determining which clock signal to use.

Allows selection between transmit clock, receive clock, or channel default. Used for clock sharing between TX and RX channels.

Enumerator

CLK_CH_CH	Use the channel's default clock source
CLK_CH_RK	Use the receive clock (BCLK_RX) for this channel
CLK_CH_TK	Use the transmit clock (BCLK_TX) for this channel

14.50.4.2.4 clkGate_t

```
enum clkGate_t
#include <sai.h>
```

Clock gating mode for power optimization.

Controls when the bit clock is actively driven to reduce power consumption and EMI when no data transfer is occurring.

Enumerator

CLK_GATE_CONTINUOUS	Clock runs continuously (always enabled)
CLK_GATE_FRAME_LOW	Clock enabled only when frame sync is low
CLK_GATE_FRAME_HIGH	Clock enabled only when frame sync is high

14.50.4.2.5 clkOut_t

```
enum clkOut_t
#include <sai.h>
```

Bit clock output mode configuration.

Controls whether the bit clock is driven as an output (master mode) or used as an input (slave mode), and when it is active.

Enumerator

CLK_OUT_INPUT	Clock is an input; output driver is disabled (slave mode)
CLK_OUT_CONTINUOUS	Clock is continuously driven as output (master mode)
CLK_OUT_TRANSFER	Clock is driven only during active transfers (master mode with gating)

14.50.4.2.6 clkPol_t

```
enum clkPol_t
#include <sai.h>
```

Clock polarity configuration.

Determines the active edge of the bit clock for data sampling and driving.

Enumerator

CLK_ACTIVE_HIGH	Clock is active high: drive data on rising edge, sample on falling edge
CLK_ACTIVE_LOW	Clock is active low: drive data on falling edge, sample on rising edge

14.50.4.2.7 clkSrc_t

```
enum clkSrc_t
#include <sai.h>
```

Clock source selection for SAI bit clock generation.

The SAI can generate its bit clock from different sources depending on whether the device is operating as a master or slave.

Enumerator

CLK_SRC_MCK	Clock source is the divided peripheral master clock (for master mode)
CLK_SRC_EXT	Clock source is an external clock input (for slave mode or clock sharing)

14.50.4.2.8 dataPacking_t

```
enum dataPacking_t
#include <sai.h>
```

Buffer word format and data justification.

Defines how data is packed in memory buffers and whether it is left-justified or right-justified within the word. This affects how the DMA interprets the buffer data when moving it to/from the SAI FIFO.

Note

Left-justified packs MSBs at the upper bits of the word. Right-justified packs LSBs at the lower bits of the word.

Enumerator

BUFFER_WORD8	Each sample is 8 bits (1 byte per sample)

Enumerator

BUFFER_WORD16_LEFT	Each sample is 16 bits, left-justified in the word
BUFFER_WORD16_RIGHT	Each sample is 16 bits, right-justified in the word
BUFFER_WORD32_LEFT	Each sample is 32 bits, left-justified in the word
BUFFER_WORD32_RIGHT	Each sample is 32 bits, right-justified in the word

14.50.4.2.9 frameEdge_t

```
enum frameEdge_t
```

```
#include <sai.h>
```

Frame sync edge that indicates the start of a new frame.

Determines whether a rising or falling edge of the frame sync signal marks the beginning of a data frame.

Enumerator

FRAME_SYNC_RISING	New frame begins on rising edge of frame sync
FRAME_SYNC_FALLING	New frame begins on falling edge of frame sync

14.50.4.2.10 frameSyncCh_t

```
enum frameSyncCh_t
```

```
#include <sai.h>
```

Frame synchronization channel selection.

Determines which frame sync signal is used for synchronizing frame boundaries. Allows sharing of frame sync between TX and RX channels.

Enumerator

SYNC_CH_CH	Use the channel's default frame sync signal
SYNC_CH_RX	Use the receive frame sync (FRAME_SYNC_RX) for this channel
SYNC_CH_TX	Use the transmit frame sync (FRAME_SYNC_TX) for this channel

14.50.4.2.11 frameSyncOut_t

```
enum frameSyncOut_t
```

```
#include <sai.h>
```

Frame synchronization signal output mode.

Configures whether the frame sync is an input or output, and the polarity of the pulse when operating as an output.

Enumerator

FRAME_SYNC_INPUT	Frame sync is an input; output driver disabled (slave mode)
FRAME_SYNC_NEGATIVE	Frame sync driven with negative pulse at frame start (active low)
FRAME_SYNC_POSITIVE	Frame sync driven with positive pulse at frame start (active high)

14.50.4.2.12 rxTxSync_t

```
enum rxTxSync_t
```

```
#include <sai.h>
```

Synchronization mode between RX and TX channels.

Determines whether the receive and transmit channels operate independently or share clock and frame sync signals.

Enumerator

RXTX_ASYNC	RX and TX are completely independent (separate clocks and frame sync)
RXTX_SYNC_RX	TX synchronized to RX (both use RX clock and frame sync)
RXTX_SYNC_TX	RX synchronized to TX (both use TX clock and frame sync)

14.50.4.2.13 startCond_t

```
enum startCond_t
#include <sai.h>
```

Starting conditions that trigger SAI data transfers.

Defines when the SAI peripheral should begin transferring data. Different conditions are appropriate for different protocols and operating modes.

Enumerator

START_CONTINUOUS	Continuous operation: transfers start immediately when previous ends
START_SYNC_RX_TX	Synchronous start: transfers begin when opposite channel starts
START_FRAME_LOW	Start when frame sync signal is low
START_FRAME_HIGH	Start when frame sync signal is high
START_FRAME_FALLING	Start on falling edge of frame sync
START_FRAME_RISING	Start on rising edge of frame sync
START_FRAME_LEVEL	Start on any level change of frame sync
START_FRAME_EDGE	Start on any edge (rising or falling) of frame sync
START_CMP_0	Start when received data matches Compare 0 register value (RX only)

14.50.5 SAI Configuration Structures

Classes

- struct [SAI_rtx_cfg_t](#)
Configuration structure for one direction (TX or RX) of the SAI module.
- struct [SAI_cfg_t](#)
Complete configuration structure for the SAI driver.

14.50.5.1 Detailed Description**14.50.6 SAI Driver Class**

Classes

- class [SAICtx_t](#)
Main driver class for SAI peripheral operation.

14.50.6.1 Detailed Description**14.50.7 SAI Driver Constants**

Macros

- #define [SAI_HW_COUNT](#) 3
- #define [SAI_TXBD_COUNT](#) 4
- #define [SAI_RXBD_COUNT](#) 4

14.50.7.1 Detailed Description**14.50.7.2 Macro Definition Documentation****14.50.7.2.1 SAI_HW_COUNT**

```
#define SAI_HW_COUNT 3
#include <sai.h>
```

Number of SAI hardware instances available

14.50.7.2.2 SAI_RXBD_COUNT

```
#define SAI_RXBD_COUNT 4
#include <sai.h>
```

Number of receive buffer descriptors (maximum queued RX buffers)

14.50.7.2.3 SAI_TXBD_COUNT

```
#define SAI_TXBD_COUNT 4
#include <sai.h>
```

Number of transmit buffer descriptors (maximum queued TX buffers)

14.50.8 SAI Predefined Configurations**I2S Slave Mode Configurations**

These configurations set up the SAI as an I2S slave (receives clock from external master). Configurations are available for 8, 16, and 24-bit word widths, with various clock routing:

- `_RK`: Uses receive clock (BCLK from RX pins)
- `_TK`: Uses transmit clock (BCLK from TX pins)
- `_TKRK`: TX uses TX clock, RX uses RX clock (independent clocks)
- `const SAI_cfg_t SAI_I2S_SLAVE_24_TXRX_RK`
- `const SAI_cfg_t SAI_I2S_SLAVE_24_TXRX_TK`
- `const SAI_cfg_t SAI_I2S_SLAVE_24_TXRX_TKRK`
- `const SAI_cfg_t SAI_I2S_SLAVE_16_TXRX_RK`
- `const SAI_cfg_t SAI_I2S_SLAVE_16_TXRX_TK`
- `const SAI_cfg_t SAI_I2S_SLAVE_16_TXRX_TKRK`
- `const SAI_cfg_t SAI_I2S_SLAVE_8_TXRX_RK`
- `const SAI_cfg_t SAI_I2S_SLAVE_8_TXRX_TK`
- `const SAI_cfg_t SAI_I2S_SLAVE_8_TXRX_TKRK`

Left-Justified Slave Mode Configurations

These configurations set up the SAI for left-justified audio format (data starts immediately with frame sync, no delay). Available in 8, 16, and 24-bit variants.

- `const SAI_cfg_t SAI_LJUST_SLAVE_24_TXRX_RK`
- `const SAI_cfg_t SAI_LJUST_SLAVE_24_TXRX_TK`
- `const SAI_cfg_t SAI_LJUST_SLAVE_24_TXRX_TKRK`
- `const SAI_cfg_t SAI_LJUST_SLAVE_16_TXRX_RK`
- `const SAI_cfg_t SAI_LJUST_SLAVE_16_TXRX_TK`
- `const SAI_cfg_t SAI_LJUST_SLAVE_16_TXRX_TKRK`
- `const SAI_cfg_t SAI_LJUST_SLAVE_8_TXRX_RK`
- `const SAI_cfg_t SAI_LJUST_SLAVE_8_TXRX_TK`
- `const SAI_cfg_t SAI_LJUST_SLAVE_8_TXRX_TKRK`

```

14.51 Syslog

Functions

- int [SysLog](#) (const char *format,...)

Send a formatted log message to the syslog server.

- int [SysLogVia](#) (int interfaceNum, const char *format,...)

Send a formatted log message via a specific network interface.

Variables

- [IPADDR SysLogAddress](#)

Destination IP address for syslog messages.

14.51.1 Detailed Description

```
#include< syslog.h>
```

14.51.2 Function Documentation

14.51.2.1 SysLog()

```
int SysLog (  
    const char * format,  
    ...)
```

```
#include <syslog.h>
```

Send a formatted log message to the syslog server.

This function sends a formatted text message to the configured syslog destination using UDP. The message format follows printf() conventions with full support for format specifiers including floating-point numbers.

The function:

- Formats the message according to the format string and arguments
- Prepends a syslog header (priority and timestamp information)
- Sends the message via UDP to SysLogAddress on port 514
- Uses the default network interface for transmission
- Returns immediately without waiting for acknowledgment (UDP is connectionless)

Parameters

<i>format</i>	Printf-style format string supporting all standard format specifiers: • d, i - signed decimal integer • u - unsigned decimal integer • x, X - hexadecimal • f, e, g - floating-point (increases code size) • s - string • c - character • p - pointer • Plus width, precision, and length modifiers
...	Variable arguments corresponding to format specifiers in the format string

Returns

- Number of characters sent (positive value) on success
- Negative value on error (e.g., network unavailable, invalid parameters)
- 0 if SysLogAddress is not configured (0.0.0.0)

Note

This function includes floating-point formatting support which adds approximately 30-40KB to the application binary size. If code size is critical, consider alternatives for logging.

Messages are sent immediately without buffering. High-frequency logging can impact network performance.

Maximum message length is typically limited by the UDP packet size (approximately 1400 bytes for safe transmission).

Warning

Do not call this function from interrupt context or with interrupts disabled, as it performs network I/O operations.

Basic Usage Examples:

```
#include <syslog.h>

void BasicLogging() {
    // Simple text message
    SysLog("Application started");

    // Formatted with integers
    int temperature = 72;
    SysLog("Temperature: %d degrees", temperature);

    // Multiple values
    int sensor1 = 100, sensor2 = 200;
    SysLog("Sensors: S1=%d, S2=%d", sensor1, sensor2);

    // Floating-point values
    float voltage = 3.3f;
    SysLog("Supply voltage: %.2f V", voltage);

    // Hexadecimal output
    uint32_t address = 0x08000000;
    SysLog("Flash base address: 0x%08X", address);
}
```

Advanced Usage Examples:

```
// Error logging with context
void LogError(const char *function, int errorCode) {
    SysLog("ERROR in %s: code=%d", function, errorCode);
}

// Network event logging
void OnNetworkEvent(const char *event, IPADDR addr) {
    SysLog("Network: %s from %hI", event, addr);
}

// Performance monitoring
void LogPerformance(const char *operation, uint32_t ticks) {
    float milliseconds = (float)ticks / TICKS_PER_SECOND * 1000.0f;
    SysLog("PERF: %s took %.2f ms", operation, milliseconds);
}

// Structured logging with severity
#define LOG_ERROR(msg, ...) SysLog("ERROR: " msg, ##__VA_ARGS__)
#define LOG_WARN(msg, ...) SysLog("WARN: " msg, ##__VA_ARGS__)
#define LOG_INFO(msg, ...) SysLog("INFO: " msg, ##__VA_ARGS__)

void StructuredLogging() {
    LOG_ERROR("Connection failed to 192.168.1.100");
    LOG_WARN("Buffer usage at 90%%");
    LOG_INFO("Processing request #%d", requestCount);
}
```

Conditional Logging:

```
// Enable/disable logging at compile time
#ifdef DEBUG_LOGGING
    #define DEBUG_LOG(msg, ...) SysLog("DEBUG: " msg, ##__VA_ARGS__)
#else
    #define DEBUG_LOG(msg, ...) do {} while(0)
#endif

void ConditionalLogging() {
    DEBUG_LOG("Entering function");
    // ... function code ...
    DEBUG_LOG("Exiting function");
}
```

See also[SysLogVia\(\)](#)[SysLogAddress](#)**14.51.2.2 SysLogVia()**

```
int SysLogVia (
    int interfaceNum,
    const char * format,
    ...)
```

```
#include <syslog.h>
```

Send a formatted log message via a specific network interface.

This function is identical to SysLog() but allows explicit selection of the network interface to use for transmission.

This is primarily useful when:

- Logging from network driver code
- Multiple network interfaces are active
- Routing or interface-specific debugging is needed
- Sending logs on a specific VLAN or network segment

The function operates identically to SysLog() but routes the UDP packet through the specified interface rather than using the default routing table.

Parameters

<i>interfaceNum</i>	Zero-based index of the network interface to use for transmission: • 0: First network interface (usually primary Ethernet) • 1: Second network interface (if available) • etc. Invalid interface numbers will cause the message to be dropped.
<i>format</i>	Printf-style format string (same as SysLog())
...	Variable arguments corresponding to format specifiers

Returns

- Number of characters sent (positive value) on success
- Negative value on error (e.g., invalid interface, network unavailable)
- 0 if SysLogAddress is not configured (0.0.0.0)

Note

This function is typically only needed for specialized network driver development or multi-interface debugging scenarios.

The specified interface must be active and have a valid IP configuration for the message to be sent successfully.

Warning

Ensure the interfaceNum is valid for your hardware platform. Invalid interface numbers will fail silently or return an error code.

Usage Examples:

```
#include <syslog.h>
#include <netinterface.h>

// Log via specific interface
void LogViaInterface() {
    // Log via primary interface (eth0)
    SysLogVia(0, "Message from primary interface");

    // Log via secondary interface (eth1), if available
    if (GetNumberOfInterfaces() > 1) {
        SysLogVia(1, "Message from secondary interface");
    }
}

// Network driver debugging
void DriverLog(int ifNum, const char *event) {
    SysLogVia(ifNum, "IF%d: %s", ifNum, event);
}

// Multi-interface monitoring
void MonitorAllInterfaces() {
    int numInterfaces = GetNumberOfInterfaces();

    for (int i = 0; i < numInterfaces; i++) {
        InterfaceBlock *pifb = GetInterfaceBlock(i);
        if (pifb) {
            SysLogVia(i, "Interface %d: IP=%hI, Link=%s",
                i, pifb->ip_addr,
                pifb->IsLinkActive() ? "UP" : "DOWN");
        }
    }
}

// VLAN-specific logging
void LogToVLAN(int vlanInterface, const char *message) {
    SysLogVia(vlanInterface, "VLAN: %s", message);
}
```

Network Driver Usage:

```
// Typical use in network driver code
void NetworkDriverRx(int ifNum, PoolPtr pp, uint16_t size) {
    // Log received packet on specific interface
    SysLogVia(ifNum, "RX on IF%d: %d bytes", ifNum, size);

    // Process packet...
}

void NetworkDriverTx(int ifNum, uint16_t size) {
    // Log transmitted packet
    SysLogVia(ifNum, "TX on IF%d: %d bytes", ifNum, size);
}
```

14.51.3 Variable Documentation

14.51.3.1 SysLogAddress

`IPADDR SysLogAddress [extern]`

`#include <syslog.h>`

Destination IP address for syslog messages.

This global variable specifies the IP address of the host or server where syslog messages should be sent. The syslog protocol uses UDP port 514 by default (this is hardcoded and cannot be changed).

Default behavior:

- If set to `IPADDR(0,0,0,0)` or not initialized: Messages are sent to the UDP broadcast address 255.255.255.255
- If set to a specific IP address: Messages are sent directly to that host

Note

The destination address can be changed at any time during runtime to redirect logging to different hosts or servers.

Broadcast messages (255.255.255.255) may not cross router boundaries. For logging across subnets, specify an explicit unicast address.

Usage Examples:

```
#include <syslog.h>
#include <ipaddr.h>

void SetupSyslog() {
    // Send to specific syslog server
    SysLogAddress = IPADDR(192, 168, 1, 100);
    SysLog("Syslog initialized, sending to 192.168.1.100");

    // Send to broadcast (all hosts on local network)
    SysLogAddress = IPADDR(255, 255, 255, 255);
    SysLog("Broadcasting syslog messages");

    // Disable syslog by setting to zero
    SysLogAddress = IPADDR(0, 0, 0, 0);
}

// Dynamic syslog server selection
void SelectSyslogServer(const char *serverIP) {
    IPADDR addr;
    if (AsciiToIp(serverIP, &addr) {
        SysLogAddress = addr;
        SysLog("Syslog server changed to %s", serverIP);
    } else {
        fprintf("Invalid IP address: %s\r\n", serverIP);
    }
}
```

14.52 System Functions

NetBurner General System Functions.

Functions

- int `SaveUserParameters` (void *pCopyFrom, int len)
Save data to the on-chip flash memory User Parameter area.
- void * `GetUserParameters` (void)
Returns a void pointer to the user parameter area.
- const char * `GetReleaseTag` ()
Returns the NNDK release tag information.

14.52.1 Detailed Description

NetBurner General System Functions.

```
#include< system.h>
```

14.52.2 Function Documentation

14.52.2.1 GetReleaseTag()

```
const char * GetReleaseTag ()  
#include <system.h>
```

Returns the NNDK release tag information.

Returns

Pointer to a string representing the development tools release tag

14.52.2.2 GetUserParameters()

```
void * GetUserParameters (  
    void )  
#include <system.h>
```

Returns a void pointer to the user parameter area.

On most platforms the total amount of space is 8k bytes. Typically used to retrieve a structure.

This function is here for reverse compatibility with releases prior to NetBurner 3.0. Alternatives are to use the 3.0 configuration tree, or the EFFS STD file system.

Returns

Void pointer to the User Parameter area in flash memory

See also

[SaveUserParameters\(\)](#)

14.52.2.3 SaveUserParameters()

```
int SaveUserParameters (  
    void * pCopyFrom,  
    int len)  
#include <system.h>
```

Save data to the on-chip flash memory User Parameter area.

On most platforms the total amount of space is 8k bytes. Typically used to save a structure.

This function is here for reverse compatibility with releases prior to NetBurner 3.0. Alternatives are to use the 3.0 configuration tree, or the EFFS STD file system.

Parameters

<i>pCopyFrom</i>	Pointer to the data to copy and save
<i>len</i>	Length of data

Returns

The number of items copied, or <= 0 on failure

14.53 TCP

TCP socket programming interface.

Topics

- [TCP Notification System](#)
Advanced callback mechanism for asynchronous TCP socket event notification.
- [TCP Socket Options](#)
Configuration flags for TCP socket behavior.
- [TCP Socket State](#)
TCP connection state machine values (RFC 793)
- [TCP Socket Status](#)
Status codes and error values for TCP socket operations.

Functions

- `int accept (int listening_socket, IPADDR *address, uint16_t *port, uint16_t timeout)`
Accept an incoming connection on a listening socket.
- `int accept (int listening_socket, IPADDR *address, uint16_t *port, TickTimeout &timeout)`
Accept an incoming connection on a listening socket with timeout object.
- `int connect (const IPADDR &ipAddress, uint16_t remotePort, uint32_t timeout)`
Establish a TCP connection to a remote host.
- `int connectvia (const IPADDR &ipAddress, uint16_t remotePort, uint32_t timeout, const IPADDR &localIpAddress)`
Establish a TCP connection using a specific local interface IP address.
- `int connectvia (const IPADDR &ipAddress, uint16_t remotePort, uint32_t timeout, int ifnum)`
Establish a TCP connection using a specific local interface number.
- `int connectwlocal (const IPADDR &ipAddress, uint16_t localPort, uint16_t remotePort, uint32_t timeout, const IPADDR &localIpAddress=IPADDR::NullIP(), int intf=-1)`
Establish a TCP connection with full control over local parameters.
- `int connect (const IPADDR &ipAddress, uint16_t remotePort, TickTimeout &timeout)`
Establish a TCP connection to a remote host with TickTimeout object.
- `int connectvia (const IPADDR &ipAddress, uint16_t remotePort, TickTimeout &timeout, const IPADDR &localIpAddress)`
Establish a TCP connection using a specific local interface IP with TickTimeout.
- `int connectvia (const IPADDR &ipAddress, uint16_t remotePort, TickTimeout &timeout, int ifnum)`
Establish a TCP connection using a specific local interface number with TickTimeout.
- `int connectwlocal (const IPADDR &ipAddress, uint16_t localPort, uint16_t remotePort, TickTimeout timeout, const IPADDR &localIpAddress=IPADDR::NullIP(), int intf=-1)`
Establish a TCP connection with full control over local parameters and TickTimeout.
- `int listen (const IPADDR &addr, uint16_t port, uint8_t maxpend=5)`
Create a listening socket to accept incoming TCP connections.
- `int listenvia (const IPADDR &addr, uint16_t port, int ifn, uint8_t maxpend=5)`
Create a listening socket on a specific network interface.
- `int listenvia (const IPADDR &addr, uint16_t port, const IPADDR &localIpAddress, uint8_t maxpend=5)`
Create a listening socket bound to a specific interface IP address.
- `int NoBlockConnect (const IPADDR &ipAddress, uint16_t remotePort)`
Initiate a non-blocking TCP connection.
- `int NoBlockConnectVia (const IPADDR &ipAddress, uint16_t remotePort, const IPADDR &interfaceIpAddress=IPADDR::NullIP())`
Initiate a non-blocking TCP connection via a specific interface.
- `int NoBlockConnectVia (const IPADDR &ipAddress, uint16_t remotePort, int ifnum)`

- Initiate a non-blocking TCP connection via a specific interface number.*
- `int NoBlockConnectwlocal` (const `IPADDR` &ipAddress, `uint16_t` localPort, `uint16_t` remotePort, `IPADDR` interfaceIpAddress=IPADDR::NullIP(), `int` ifn=-1)
 - Initiate a non-blocking TCP connection with full local parameter control.*
- `int getsocketerror` (`int` fd)
 - Get the error status of a socket.*
- `IPADDR GetSocketRemoteAddr` (`int` fd)
 - Get the remote host IP address for a socket connection.*
- `IPADDR GetSocketLocalAddr` (`int` fd)
 - Get the local interface IP address for a socket connection.*
- `uint16_t GetSocketRemotePort` (`int` fd)
 - Get the remote host port number for a socket connection.*
- `uint16_t GetSocketLocalPort` (`int` fd)
 - Get the local port number for a socket connection.*
- `uint32_t TcpGetLastRxTime` (`int` fd)
 - Get the system tick count when the last packet was received.*
- `void TcpSendKeepAlive` (`int` fd)
 - Send a TCP keepalive probe packet.*
- `uint32_t TcpGetLastRxInterval` (`int` fd)
 - Get the time elapsed since the last received packet.*
- `int GetTcpRtxCount` (`int` fd)
 - Get the number of TCP retransmissions on a socket.*
- `uint8_t SetOutOfOrderBuffers` (`int` fd, `uint8_t` max)
 - Configure the maximum number of out-of-order buffers for a TCP socket.*
- `int setsockopt` (`int` fd, `int` option)
 - Enable TCP socket options.*
- `int clrsockopt` (`int` fd, `int` option)
 - Disable TCP socket options.*
- `int getsockopt` (`int` fd)
 - Query current TCP socket options.*
- `int SetSocketUnackBuffers` (`int` fd, `uint8_t` val)
 - Configure the maximum number of unacknowledged transmit buffers.*
- `int SetSocketRxBuffers` (`int` fd, `int` n)
 - Configure the number of TCP receive buffers.*
- `int SetSocketTxBuffers` (`int` fd, `int` n)
 - Configure the number of TCP transmit buffers.*
- `int abortsocket` (`int` fd)
 - Abort a TCP connection immediately.*
- `int SocketReadWithTimeout` (`int` fd, `char` *buf, `int` nbytes, `uint32_t` timeout)
 - Read from a TCP socket with a timeout.*
- `char SocketPeek` (`int` fd)
 - Peek at the next available byte without removing it from the receive buffer.*
- `void DumpTcpDebug` ()
 - Display current TCP debug information to the console.*
- `void EnableTcpDebug` (`uint16_t` dbFlags)
 - Enable TCP debug output with specified flags.*
- `int TcpGetSocketInterface` (`int` fd)
 - Get the network interface number associated with a TCP socket.*
- `uint8_t TcpGetSocketState` (`int` fd)
 - Get the current TCP state of a socket.*
- `uint16_t TcpGetRxBufferSpaceUsed` (`int` fd)

- Get the number of bytes currently in the receive buffer.*
- uint16_t [TcpGetTxBufferAvailSpace](#) (int fd)
- Get the available space in the transmit buffer.*
- uint16_t [TcpGetTxDataWaiting](#) (int fd)
- Get the number of bytes queued for transmission.*
- BOOL [TcpAllDataAked](#) (int socket)
- Check if all transmitted data has been acknowledged.*
- BOOL [WaitForSocketFlush](#) (int fd, uint32_t ticks)
- Wait for all transmitted data to be acknowledged.*

14.53.1 Detailed Description

TCP socket programming interface.

```
#include< tcp.h>
```

14.53.2 Overview

The NetBurner TCP API provides a robust, Berkeley-sockets-style interface for TCP/IP networking with support for both blocking and non-blocking operations. This API is designed specifically for embedded systems and real-time applications, offering fine-grained control over socket behavior, buffer management, and connection state.

Key Features:

- **Berkeley Sockets Compatibility:** Familiar API for developers with TCP/IP experience
- **IPv4 and IPv6 Support:** Conditional compilation for dual-stack or single-stack configurations
- **Blocking and Non-blocking Modes:** Choose between synchronous and asynchronous operation
- **Advanced Buffer Management:** Configurable TX/RX buffers and out-of-order packet handling
- **Connection Monitoring:** Real-time state tracking, keepalive probes, and connection diagnostics
- **Event-Driven Notifications:** Register callbacks for read/write events
- **Multi-Interface Support:** Control over which network interface to use for connections
- **TLS Ready:** Designed to work seamlessly with NetBurner's TLS implementation

14.53.3 Basic Usage Patterns

The TCP API supports three primary usage patterns:

14.53.3.1 Server Pattern (Listen/Accept)

Create a listening socket to accept incoming client connections:

1. Call [listen\(\)](#) to create a listening socket on a specific port
2. Call [accept\(\)](#) to wait for and accept incoming connections
3. Use [read\(\)](#) / [write\(\)](#) for data transfer on accepted connections
4. Call [close\(\)](#) when done with each connection

14.53.3.2 Client Pattern (Connect)

Establish an outbound connection to a remote server:

1. Call `connect()` to establish a connection to a remote host
2. Use `read()` / `write()` for data transfer
3. Call `close()` when done with the connection

14.53.3.3 Non-Blocking Pattern

For applications requiring immediate return without waiting:

1. Call `NoBlockConnect()` to initiate a connection
2. Poll connection state with `TcpGetSocketState()` or `writeavail()`
3. Once `TCP_STATE_ESTABLISHED`, use `read()` / `write()` for data transfer
4. Register read/write notification callbacks for event-driven operation

14.53.4 Important Concepts

14.53.4.1 Entry Point

NetBurner applications start in `UserMain()`, not `main()`. Always call `init()` at the beginning of `UserMain()` to initialize the network stack before using TCP functions.

14.53.4.2 Timeout Values

Many functions accept timeout parameters in system ticks. Use the `TICKS_PER_SECOND` constant for conversion:

- 5 second timeout: `TICKS_PER_SECOND * 5`
- 30 second timeout: `TICKS_PER_SECOND * 30`
- Wait forever: `0`

14.53.4.3 File Descriptors

TCP sockets are represented by integer file descriptors (fd). Functions that create sockets (`listen()`, `accept()`, `connect()`) return:

- **Positive value:** Valid file descriptor
- **Negative value:** Error code (see [TCP Socket Status](#))

Always check return values:

```
int fd = connect(serverAddr, 80, TICKS_PER_SECOND * 5);
if (fd < 0) {
    printf("Connection failed with error: %d\n", fd);
    return;
}
```

14.53.4.4 Buffer Management

TCP sockets use system buffer pools for transmit and receive operations. The default buffer allocation is conservative (5 buffers per socket) to support many simultaneous connections. For high-throughput applications, you can increase buffer allocations:

- `SetSocketRxBuffers()`: Increase receive buffer count
- `SetSocketTxBuffers()`: Increase transmit buffer count
- `SetSocketUnackBuffers()`: Increase unacknowledged buffer limit
- `SetOutOfOrderBuffers()`: Increase out-of-order packet handling

14.53.4.5 Socket States

TCP connections progress through well-defined states (RFC 793). Use [TcpGetSocketState\(\)](#) to query the current state:

- `TCP_STATE_CLOSED`: No connection
- `TCP_STATE_LISTEN`: Accepting connections
- `TCP_STATE_SYN_SENT`: Connection in progress
- `TCP_STATE_ESTABLISHED`: Connected and ready for data transfer
- `TCP_STATE_CLOSE_WAIT`: Remote closed, local close pending
- `TCP_STATE_CLOSING`: Connection closing

14.53.4.6 Resource Management

Always call [close\(\)](#) on sockets when finished to free system resources. This applies even if the socket enters an error state or `TCP_STATE_CLOSING`. Failing to close sockets will leak file descriptors and network buffers.

14.53.5 Function Categories

14.53.5.1 Connection Management

- [listen\(\)](#) / [listenvia\(\)](#): Create listening sockets for servers
- [accept\(\)](#): Accept incoming connections
- [connect\(\)](#) / [connectvia\(\)](#) / [connectwlocal\(\)](#): Establish outbound connections
- [NoBlockConnect\(\)](#) / [NoBlockConnectVia\(\)](#): Non-blocking connection initiation
- [close\(\)](#): Close connections and free resources
- [abortsocket\(\)](#): Forcefully terminate connection with RST packet

14.53.5.2 Data Transfer

- [read\(\)](#) / [write\(\)](#): Standard I/O operations (in `unistd.h`)
- [readall\(\)](#) / [writeall\(\)](#): Guaranteed complete transfers (in [utils.h](#))
- [SockReadWithTimeout\(\)](#): Read with explicit timeout
- [SocketPeek\(\)](#): Examine next byte without consuming it

14.53.5.3 Socket Query Functions

- [TcpGetSocketState\(\)](#): Get current TCP state
- [GetSocketRemoteAddr\(\)](#) / [GetSocketRemotePort\(\)](#): Remote endpoint information
- [GetSocketLocalAddr\(\)](#) / [GetSocketLocalPort\(\)](#): Local endpoint information
- [TcpGetSocketInterface\(\)](#): Get network interface number
- [dataavail\(\)](#) / [writeavail\(\)](#): Check buffer status (in [utils.h](#))
- [TcpGetRxBufferSpaceUsed\(\)](#): Bytes in receive buffer
- [TcpGetTxBufferAvailSpace\(\)](#): Available transmit space
- [TcpGetTxDataWaiting\(\)](#): Bytes queued for transmission

14.53.5.4 Configuration Functions

- [setsockopt\(\)](#) / [clrsockopt\(\)](#) / [getsockopt\(\)](#): Socket options (Nagle, PUSH)
- [SetSocketRxBuffers\(\)](#): Configure receive buffer count
- [SetSocketTxBuffers\(\)](#): Configure transmit buffer count
- [SetSocketUnackBuffers\(\)](#): Configure unacknowledged buffer limit
- [SetOutOfOrderBuffers\(\)](#): Configure out-of-order packet handling

14.53.5.5 Monitoring and Diagnostics

- [TcpGetLastRxTime\(\)](#) / [TcpGetLastRxInterval\(\)](#): Track connection activity
- [TcpSendKeepAlive\(\)](#): Send keepalive probe
- [GetTcpRtxCount\(\)](#): Get retransmission count
- [TcpAllDataAked\(\)](#): Check if all data acknowledged
- [WaitForSocketFlush\(\)](#): Wait for acknowledgments
- [getsocketerror\(\)](#): Get error code for socket

14.53.5.6 Event Notification

- [RegisterTCPReadNotify\(\)](#): Register callback for read events
- [RegisterTCPWriteNotify\(\)](#): Register callback for write events

14.53.5.7 Throughput Monitoring (#define TCP_THROUGHPUT_INFO)

- [TCPGetPayloadBytesSent\(\)](#): Payload bytes transmitted
- [TCPGetPayloadBytesReceived\(\)](#): Payload bytes received
- [TCPGetTotalBytesSent\(\)](#): Total bytes sent (including headers)
- [TCPGetTotalBytesReceived\(\)](#): Total bytes received (including headers)

14.53.6 Error Handling

TCP functions use negative return values to indicate errors. Always check return values and handle errors appropriately:

Common error codes (see [TCP Socket Status](#)):

- [TCP_ERR_TIMEOUT](#) (-1): Operation timed out
- [TCP_ERR_NOCON](#) (-2): No active connection
- [TCP_ERR_CLOSING](#) (-3): Socket is closing
- [TCP_ERR_NOSUCH_SOCKET](#) (-4): Invalid socket descriptor
- [TCP_ERR_NONE_AVAIL](#) (-5): No sockets available
- [TCP_ERR_CON_RESET](#) (-6): Connection reset by peer
- [TCP_ERR_CON_ABORT](#) (-7): Connection aborted

For detailed return code information, causes and solutions, see: [Programmers Guide TCP Error Codes](#)

14.53.7 Advanced Features

14.53.7.1 Multi-Interface Control

When multiple network interfaces are available, you can control which interface is used for connections:

- `connectvia(addr, port, timeout, localIpAddress)`: Use interface with specific IP
- `connectvia(addr, port, timeout, ifnum)`: Use interface by number
- `listenvia()`: Listen on specific interface

14.53.7.2 Keepalive Implementation

Detect stale connections using the keepalive mechanism:

1. Record lastRxTime with `TcpGetLastRxTime()`
2. Send keepalive probe with `TcpSendKeepAlive()`
3. Wait for response (2-3 seconds)
4. Check if lastRxTime changed
5. If unchanged, connection may be lost

14.53.7.3 Nagle Algorithm Control

The Nagle algorithm buffers small packets to improve efficiency but can add latency for interactive applications. Use `SO_NONAGLE` option to disable:

```
setsockopt(fd, SO_NONAGLE); // Disable Nagle, send immediately
```

14.53.7.4 Event-Driven Programming

For event-driven architectures, register notification callbacks instead of polling:

```
void OnDataReady(int fd) {  
    char buffer[1024];  
    int n = read(fd, buffer, sizeof(buffer));  
    // Process data...  
}
```

```
RegisterTCPReadNotify(fd, OnDataReady);
```

14.53.8 Best Practices

14.53.8.1 DO:

- Always call `init()` before using TCP functions
- Check return values from all TCP functions
- Use `TICKS_PER_SECOND` for timeout calculations
- Call `close()` on all sockets when finished
- Use `readall()` / `writeall()` for complete data transfers
- Implement timeouts for all blocking operations
- Use notification callbacks for event-driven designs
- Increase buffer allocations for high-throughput applications

14.53.8.2 DON'T:

- Don't forget to close sockets (causes resource leaks)
- Don't ignore negative return values (indicates errors)
- Don't assume `read()` / `write()` transfer all requested bytes
- Don't specify local port numbers unless absolutely necessary
- Don't use fixed buffer sizes without checking actual data size
- Don't block indefinitely without user approval
- Don't call `TcpGetLastRxTime()` more than once per second

14.53.9 IPv6 Support

The TCP API conditionally compiles for IPv4-only (IPV4ONLY) or dual-stack IPv6 support. When IPv6 is enabled:

- IPADDR type represents both IPv4 and IPv6 addresses
- Functions with '6' suffix operate on IPv6: `connect6()`, `listen6()`
- Functions with '4' suffix operate on IPv4: `connect4()`, `listen4()`
- Generic functions (`connect`, `listen`) use the default IP version

14.53.10 Performance Tuning

14.53.10.1 Bulk Data Transfer

For maximum throughput when transferring large amounts of data:

- Increase receive buffers: `SetSocketRxBuffers(fd, 43) // Maximum effective`
- Increase transmit buffers: `SetSocketTxBuffers(fd, 20)`
- Increase unack buffers: `SetSocketUnackBuffers(fd, 20)`
- Disable Nagle: `setsockopt(fd, SO_NONAGLE)`
- Use large `write()` calls (multiple KB per write)

14.53.10.2 Low Latency

For interactive or real-time applications requiring minimal latency:

- Disable Nagle: `setsockopt(fd, SO_NONAGLE)`
- Use small buffers (default 5 is fine)
- Use non-blocking mode with notification callbacks
- Process data immediately upon arrival

14.53.10.3 Many Simultaneous Connections

For servers handling many concurrent connections:

- Keep default buffer allocations (5 per socket)
- Use event-driven design with notification callbacks
- Implement connection timeouts to reclaim stale sockets
- Monitor system resource usage with `EnableSystemDiagnostics()`
- Consider increasing `SYSTEM_TCP_SOCKETS` in `predef.h`

14.53.11 Thread Safety

The NetBurner TCP implementation is designed for use in a multi-threaded RTOS environment. However, individual socket operations are not automatically thread-safe:

- **Single socket, single thread:** No synchronization needed
- **Single socket, multiple threads:** Application must provide synchronization
- **Multiple sockets, multiple threads:** Each socket can be used independently
- **Listening socket:** Can be shared by multiple threads calling [accept\(\)](#)
- **Notification callbacks:** Execute in TCP stack context, must be thread-safe

14.53.12 Related APIs

The TCP API works in conjunction with other NetBurner APIs:

- **utils.h:** [readall\(\)](#), [writeall\(\)](#), [dataavail\(\)](#), [writeavail\(\)](#)
- **unistd.h:** [read\(\)](#), [write\(\)](#), [close\(\)](#)
- **ip.h:** IPADDR class, [AsciiToIp\(\)](#), IP address utilities
- **dns.h:** [GetHostByName\(\)](#) for hostname resolution
- **ssl.h:** TLS encryption for secure connections
- **http.h:** High-level HTTP server built on TCP
- **websocket.h:** WebSocket protocol over TCP

14.53.13 Further Reading

- **NetBurner Documentation:** Comprehensive guides at docs.netburner.com
- **TCP/IP RFCs:** RFC 793 (TCP), RFC 1122 (Requirements)
- **Code Examples:** See NetBurner example applications in the SDK
- **API Reference:** Individual function documentation in this header

14.53.14 Function Documentation

14.53.14.1 abortsocket()

```
int abortsocket (
    int fd)
#include <tcp.h>
```

Abort a TCP connection immediately.

Forcefully terminates a TCP connection by sending a RST (reset) packet to the remote host. Unlike a normal [close\(\)](#), this does not perform a graceful shutdown and any pending data will be lost. Use this only when you need to terminate a connection immediately without the normal shutdown handshake.

Parameters

<i>fd</i>	Socket file descriptor

Returns

Status code: [TCP Socket Status](#)

See also

[close\(\)](#)

Expand for Example Usage

Examples

Basic Usage - Aborting a Connection

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

// Something went wrong, abort immediately
int result = abortsocket(fd);
if (result == TCP_ERR_NONE) {
    printf("Connection aborted\n");
}
```

Timeout Handler - Aborting Unresponsive Connection

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

uint32_t startTime = Secs;
char response[100];

while (Secs - startTime < 30) { // 30 second timeout
    int n = read(fd, response, sizeof(response));
    if (n > 0) {
        // Process response
        break;
    }
    OSTimeDly(TICKS_PER_SECOND);
}

if (Secs - startTime >= 30) {
    printf("Connection timeout, aborting...\n");
    abortsocket(fd); // Force immediate termination
} else {
    close(fd); // Normal graceful close
}
```

Error Recovery - Abort vs Close

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

if (write(fd, data, dataLen) < 0) {
    // Critical error occurred
    printf("Write failed, aborting connection\n");
    abortsocket(fd); // RST - immediate termination, no graceful shutdown
} else {
    // Normal operation complete
    close(fd); // FIN - graceful shutdown with handshake
}
```

Protocol Violation - Immediate Abort

```
void HandleConnection(int clientFd) {
    char buffer[256];
    int n = read(clientFd, buffer, sizeof(buffer));

    // Check for protocol violation
    if (n > 0 && !IsValidProtocolHeader(buffer)) {
        printf("Invalid protocol header detected\n");
        abortsocket(clientFd); // Immediate abort for security
        return;
    }

    // Normal processing...
    ProcessRequest(buffer, n);
    close(clientFd); // Graceful close for valid connections
}
```

14.53.14.2 accept() [1/2]

```
int accept (  
    int listening_socket,  
    IPADDR * address,  
    uint16_t * port,  
    TickTimeout & timeout)  
#include <tcp.h>
```

Accept an incoming connection on a listening socket with timeout object.

Accepts a pending connection request from the listen queue using a TickTimeout object for more flexible timeout management. The listening socket must have been created with [listen\(\)](#) before calling this function. Each successful accept frees one slot in the listen queue for additional incoming connections.

This overload of [accept\(\)](#) uses a TickTimeout object instead of a simple tick count, providing more sophisticated timeout behavior. The TickTimeout object can track elapsed time across multiple operations and provides precise timeout management for complex scenarios.

Parameters

<i>listening_socket</i>	File descriptor of the listening socket (obtained from listen())
<i>address</i>	Pointer to IPADDR to store the remote client's IP address. Pass NULL if you don't need the client's IP address
<i>port</i>	Pointer to uint16_t to store the remote client's port number. Pass NULL if you don't need the client's port
<i>timeout</i>	Reference to TickTimeout object specifying the maximum wait time. The TickTimeout tracks elapsed time and can be reused across multiple operations. Create with TickTimeout(ticks) where ticks is the total timeout period in system ticks

Returns

Positive file descriptor on success (use this for read/write with the client), negative [TCP Socket Status](#) error code on failure:

- TCP_ERR_TIMEOUT: No connection within timeout period
- TCP_ERR_NOSUCH_SOCKET: Invalid listening socket
- TCP_ERR_NONE_AVAIL: No available sockets in system pool

Notes:

- The TickTimeout object is updated by this function to reflect the remaining time. This allows multiple operations to share a common timeout budget.
- Always call [close\(\)](#) on the returned file descriptor when finished with the client connection to free system resources.
- TickTimeout provides more accurate timeout tracking than simple tick counts, especially when performing multiple sequential operations with a shared deadline.

Warning

The timeout parameter is passed by reference and will be modified by this function. If you need to preserve the original timeout value, create a copy.

Expand for Example Usage

Examples

Basic Accept with TickTimeout

```

#include <tcp.h>
#include <init.h>

void ServerWithTickTimeout(void *pd) {
    init();

    int fdListen = listen(INADDR_ANY, 8080, 5);
    printf("Server listening on port 8080\n");

    // Create TickTimeout object for 30 second timeout
    TickTimeout timeout(TICKS_PER_SECOND * 30);

    IPADDR clientAddr;
    uint16_t clientPort;

    int fdClient = accept(fdListen, &clientAddr, &clientPort, timeout);

    if (fdClient > 0) {
        printf("Client connected from %s:%d\n",
            clientAddr.print(), clientPort);

        // Check remaining time in timeout
        printf("Remaining timeout: %lu ticks\n", timeout.GetTimeLeft());

        // Use connection...
        close(fdClient);
    } else if (fdClient == TCP_ERR_TIMEOUT) {
        printf("No connection received within 30 seconds\n");
    } else {
        printf("Accept failed: %d\n", fdClient);
    }

    close(fdListen);
}

```

Shared Timeout Across Multiple Operations

```

#include <tcp.h>
#include <init.h>

// Accept connection and perform handshake within total time budget
bool AcceptAndHandshake(int fdListen, uint32_t totalTimeoutTicks) {
    // Create single TickTimeout for all operations
    TickTimeout timeout(totalTimeoutTicks);

    printf("Total timeout budget: %lu seconds\n", totalTimeoutTicks / TICKS_PER_SECOND);

    // Step 1: Accept connection (uses part of timeout)
    IPADDR clientAddr;
    uint16_t clientPort;
    int fdClient = accept(fdListen, &clientAddr, &clientPort, timeout);

    if (fdClient < 0) {
        printf("Accept failed: %d\n", fdClient);
        return false;
    }

    printf("Client connected, remaining time: %lu ticks\n", timeout.GetTimeLeft());

    // Step 2: Read handshake message (uses remaining timeout)
    char handshake[64];
    int n = ReadWithTimeout(fdClient, handshake, sizeof(handshake), timeout);

    if (n <= 0) {
        printf("Handshake read failed: %d\n", n);
        close(fdClient);
        return false;
    }

14.53.14.3 accept() [2/2]

```

int accept (
    int listening_socket,

```

```
IPADDR * address,
uint16_t * port,
uint16_t timeout)
```

```
#include <tcp.h>
```

Accept an incoming connection on a listening socket.

Accepts a pending connection request from the listen queue. The listening socket must have been created with [listen\(\)](#) before calling this function. Each successful accept frees one slot in the listen queue for additional incoming connections.

This function blocks until either a connection arrives or the timeout expires. When a client connects, [accept\(\)](#) returns a new socket file descriptor for communicating with that specific client. The original listening socket remains open and continues to accept new connections.

Parameters

<i>listening_socket</i>	File descriptor of the listening socket (obtained from listen())
<i>address</i>	Pointer to IPADDR to store the remote client's IP address. Pass NULL if you don't need the client's IP address
<i>port</i>	Pointer to uint16_t to store the remote client's port number. Pass NULL if you don't need the client's port
<i>timeout</i>	Maximum wait time in system ticks: • 0 = wait indefinitely until a connection arrives • Use TICKS_PER_SECOND * n for n second timeout • Example: TICKS_PER_SECOND * 5 for 5 second timeout • Example: TICKS_PER_SECOND * 30 for 30 second timeout

Returns

Positive file descriptor on success (use this for read/write with the client), negative [TCP Socket Status](#) error code on failure:

- TCP_ERR_TIMEOUT: No connection within timeout period
- TCP_ERR_NOSUCH_SOCKET: Invalid listening socket
- TCP_ERR_NONE_AVAIL: No available sockets in system pool

Notes:

- Always call [close\(\)](#) on the returned file descriptor when finished with the client connection to free system resources.
- The listening socket is not consumed by [accept\(\)](#) and can be used repeatedly to accept multiple client connections.
- If you pass NULL for both address and port parameters, the function still works but you won't know which client connected.

Warning

- When timeout is 0 (infinite wait), the calling task will block indefinitely until a connection arrives. Use finite timeouts in production code to prevent hanging tasks.
- If the system runs out of available sockets (TCP_ERR_NONE_AVAIL), you must close existing sockets before new connections can be accepted.

Examples

Basic Accept with Infinite Wait

```
#include <tcp.h>
#include <init.h>

void ServerTask(void *pd) {
    init();

    // Create listening socket on port 8080
    int fdListen = listen(INADDR_ANY, 8080, 5);
    if (fdListen < 0) {
        printf("Failed to create listening socket\n");
        return;
    }

    printf("Server listening on port 8080\n");

    // Accept connections (wait indefinitely)
    IPADDR clientAddr;
    uint16_t clientPort;
    int fdClient = accept(fdListen, &clientAddr, &clientPort, 0);

    if (fdClient > 0) {
        printf("Client connected from %s:%d\n",
            clientAddr.print(), clientPort);

        // Communicate with client...
        char buffer[256];
        int n = read(fdClient, buffer, sizeof(buffer));

        close(fdClient);
        printf("Client disconnected\n");
    }

    close(fdListen);
}
```

Accept with Timeout

```
#include <tcp.h>
#include <init.h>

void ServerWithTimeout(void *pd) {
    init();

    int fdListen = listen(INADDR_ANY, 9000, 5);
    printf("Waiting for connection (30 second timeout)...\n");

    IPADDR clientAddr;
    uint16_t clientPort;

    // Wait up to 30 seconds for a connection
    int fdClient = accept(fdListen, &clientAddr, &clientPort,
        TICKS_PER_SECOND * 30);

    if (fdClient == TCP_ERR_TIMEOUT) {
        printf("No connection received within timeout period\n");
    } else if (fdClient < 0) {
        printf("Accept failed with error: %d\n", fdClient);
    } else {
        printf("Client connected: %s:%d\n",
            clientAddr.print(), clientPort);

        // Handle client connection...
        close(fdClient);
    }

    close(fdListen);
}
```

Accept with Error Handling

```
#include <tcp.h>
#include <init.h>

void RobustAccept(int fdListen) {
    IPADDR clientAddr;
    uint16_t clientPort;

    int fdClient = accept(fdListen, &clientAddr, &clientPort,
        TICKS_PER_SECOND * 60);

    // Comprehensive error handling
    if (fdClient > 0) {
        printf("Connection accepted from %s:%d (fd=%d)\n",
            clientAddr.print(), clientPort, fdClient);
    }
}
```

```

        // Use connection...
        close(fdClient);

    } else {
        // Handle specific error codes
        switch (fdClient) {
            case TCP_ERR_TIMEOUT:
                printf("Accept timeout - no client connected within 60 seconds\n");
                break;

            case TCP_ERR_NOSUCH_SOCKET:
                printf("Invalid listening socket - was it closed?\n");
                break;

            case TCP_ERR_NONE_AVAIL:
                printf("No sockets available - too many open connections!\n");
                printf("Close unused sockets to free resources\n");
                break;

            case TCP_ERR_NOCON:
                printf("No connection on listening socket\n");
                break;

            default:
                printf("Accept failed with error code: %d\n", fdClient);
                break;
        }
    }
}

14.53.14.4 clrsockoption()

```

int clrsockoption (
    int fd,
    int option)
#include <tcp.h>

```

Disable TCP socket options.

Clears one or more option flags for the specified socket. Socket options control various aspects of TCP behavior such as the Nagle algorithm and PUSH flag handling. Multiple options can be combined using bitwise OR.

Parameters

<i>fd</i>	Socket file descriptor
<i>option</i>	Socket option flags to disable: TCP Socket Options

Returns

Bitmask of all currently enabled options for the socket, or negative value on error

Notes:

- This function does not affect options that are not specified in the parameter. Only the specified options are cleared.
- After clearing options, the return value shows the remaining enabled options.
- Multiple options can be cleared simultaneously using bitwise OR: `clrsockoption(fd, SO_NODELAY | SO_PUSH);`

14.53.14.5 connect() [1/2]

```

int connect (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    TickTimeout & timeout) [inline]
#include <tcp.h>

```

Establish a TCP connection to a remote host with TickTimeout object.

Creates a new TCP socket and attempts to connect to the specified remote IP address and port using a TickTimeout object for timeout management. This overload provides more sophisticated timeout tracking compared to the simple tick count version, allowing the timeout to be shared across multiple operations and providing precise elapsed time tracking.

The function automatically selects the local interface based on the routing table and assigns an available local port. The TickTimeout object is updated to reflect the remaining time after the connection attempt, enabling accurate timeout management across sequential operations.

Parameters

<i>ipAddress</i>	IP address of the remote host. Can be created using AsciiToIp() or obtained from DNS resolution. Example: AsciiToIp("192.168.1.100")
<i>remotePort</i>	Port number on the remote host (1-65535). Common ports include: • 80 for HTTP • 443 for HTTPS • 23 for Telnet • 22 for SSH
<i>timeout</i>	Reference to TickTimeout object specifying the maximum wait time. The TickTimeout tracks elapsed time and can be reused across multiple operations. Create with TickTimeout(ticks) where ticks is the total timeout period in system ticks. The object is updated by this function to reflect remaining time

Returns

Positive file descriptor on success (use for read/write operations), negative [TCP Socket Status](#) error code on failure:

- `TCP_ERR_TIMEOUT`: Connection not established within timeout period
- `TCP_ERR_NONE_AVAIL`: No available sockets in system pool
- `TCP_ERR_CON_RESET`: Connection was reset during establishment
- `TCP_ERR_CON_ABORT`: Connection was aborted

Notes:

- The `TickTimeout` object is updated by this function to reflect the remaining time. This allows multiple operations to share a common timeout budget.
- The local port number is automatically assigned from the ephemeral port range.
- The local network interface is automatically selected based on the routing table for the destination IP address.
- Always call [close\(\)](#) on the returned file descriptor when finished to free system resources, even if read/write operations fail.
- This function blocks the calling task until the connection is established or the timeout expires. For non-blocking connection attempts, use [NoBlockConnect\(\)](#).
- `TickTimeout` provides more accurate timeout tracking than simple tick counts, especially when performing multiple sequential operations with a shared deadline.

Warning

The timeout parameter is passed by reference and will be modified by this function. If you need to preserve the original timeout value, create a copy.

Connection timeouts that are too short (less than 3 seconds) may fail on networks with moderate latency. Use at least 5 seconds for reliable operation.

Expand for Example Usage

Examples

Basic Connection with `TickTimeout`

```
#include <tcp.h>
#include <init.h>

void ConnectWithTickTimeout(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");

    // Create TickTimeout for 15 second timeout
    TickTimeout timeout(TICKS_PER_SECOND * 15);

    printf("Connecting with 15 second timeout...\n");
    printf("Initial timeout: %lu ticks\n", timeout.GetTimeLeft());

    int fd = connect(serverAddr, 8080, timeout);

    if (fd > 0) {
        printf("Connected successfully!\n");
        printf("Connection time: %lu ticks\n", timeout.GetElapsedTime());
        printf("Remaining timeout: %lu ticks\n", timeout.GetTimeLeft());

        close(fd);
    } else {
        printf("Connection failed: %d\n", fd);
        printf("Time spent: %lu ticks\n", timeout.GetElapsedTime());
    }
}
```

Shared Timeout Across Multiple Operations

```

#include <tcp.h>
#include <init.h>
#include <utils.h>

// Connect and perform complete handshake within total time budget
bool ConnectAndHandshake(IPADDR serverAddr, uint16_t port,
                        uint32_t totalTimeoutTicks) {
    // Create single TickTimeout for entire operation sequence
    TickTimeout timeout(totalTimeoutTicks);

    printf("Total time budget: %lu seconds\n",
           totalTimeoutTicks / TICKS_PER_SECOND);

    // Step 1: Connect (uses part of timeout)
    printf("\nStep 1: Connecting...\n");
    int fd = connect(serverAddr, port, timeout);

    if (fd < 0) {
        printf("Connection failed: %d\n", fd);
        return false;
    }

    printf("Connected! Remaining time: %lu ticks\n", timeout.GetTimeLeft());

    // Step 2: Send handshake (uses remaining timeout)
    printf("\nStep 2: Sending handshake...\n");
    const char *handshake = "HELLO\r\n";
    int sent = WriteWithTimeout(fd, handshake, strlen(handshake), timeout);

    if (sent != strlen(handshake)) {
        printf("Handshake send failed\n");
        close(fd);
        return false;
    }

    printf("Handshake sent! Remaining time: %lu ticks\n", timeout.GetTimeLeft());

    // Step 3: Receive response (uses remaining timeout)
    printf("\nStep 3: Receiving response...\n");
    char response[64];
    int received = ReadWithTimeout(fd, response, sizeof(response), timeout);

    if (received <= 0) {
        printf("Response read failed\n");
        close(fd);
        return false;
    }

    response[received] = '\0';
    printf("Received: %s\n", response);
    printf("Remaining time: %lu ticks\n", timeout.GetTimeLeft());

    // Summary
    uint32_t totalUsed = timeout.GetElapsedTime();
    printf("\n=== Summary ===\n");
    printf("Total time used: %lu ticks (%.1f seconds)\n",
           totalUsed, (float)totalUsed / TICKS_PER_SECOND);
    printf("Time remaining: %lu ticks\n", timeout.GetTimeLeft());
    printf("Handshake successful!\n");

    close(fd);
    return true;
}

void UserMain(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");

    // Give entire sequence 20 seconds to complete
    bool success = ConnectAndHandshake(serverAddr, 8080, TICKS_PER_SECOND * 20);

    printf("\nOperation %s\n", success ? "SUCCEEDED" : "FAILED");

    while (1) {

14.53.14.6 connect() [2/2]

```

int connect (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    uint32_t timeout) [inline]

```

#include <tcp.h>

Establish a TCP connection to a remote host.

Creates a new TCP socket and attempts to connect to the specified remote IP address and port. This is a blocking call that waits up to the specified timeout period for the connection to be established. The function automatically selects the local interface based on the routing table and assigns an available local port.

This is the most commonly used function for establishing outbound TCP connections. The operating system automatically selects the appropriate local interface and port number based on the destination address and routing configuration.

Parameters

<i>ipAddress</i>	IP address of the remote host. Can be created using <code>AsciiToIp()</code> or obtained from DNS resolution. Example: <code>AsciiToIp("192.168.1.100")</code>
<i>remotePort</i>	Port number on the remote host (1-65535). Common ports include: • 80 for HTTP • 443 for HTTPS • 23 for Telnet • 22 for SSH
<i>timeout</i>	Maximum connection time in system ticks. Use <code>TICKS_PER_SECOND</code> macro: • <code>TICKS_PER_SECOND * 5</code> for 5 second timeout • <code>TICKS_PER_SECOND * 10</code> for 10 second timeout • <code>TICKS_PER_SECOND * 30</code> for 30 second timeout Typical timeout values are 5-30 seconds

Returns

Positive file descriptor on success (use for read/write operations), negative [TCP Socket Status](#) error code on failure:

- `TCP_ERR_TIMEOUT`: Connection not established within timeout period
- `TCP_ERR_NONE_AVAIL`: No available sockets in system pool
- `TCP_ERR_CON_RESET`: Connection was reset during establishment
- `TCP_ERR_CON_ABORT`: Connection was aborted

Notes:

- The local port number is automatically assigned from the ephemeral port range. You should not attempt to control the local port unless you have a specific protocol requirement (see [connectwlocal\(\)](#) for that use case).
- The local network interface is automatically selected based on the routing table for the destination IP address. For multi-homed systems where you need to control which interface is used, see [connectvia\(\)](#).
- Always call [close\(\)](#) on the returned file descriptor when finished to free system resources, even if read/write operations fail.
- This function blocks the calling task until the connection is established or the timeout expires. For non-blocking connection attempts, use [NoBlockConnect\(\)](#).

Warning

- Connection timeouts that are too short (less than 3 seconds) may fail on networks with moderate latency. Use at least 5 seconds for reliable operation.
- If the remote host is unreachable (network down, host down, firewall blocking), the function will wait the full timeout period before returning an error.

Examples

Basic HTTP Client Connection

```
#include <tcp.h>
#include <init.h>

void SimpleHttpClient(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Connect to web server
    IPADDR serverAddr = AsciiToIp("93.184.216.34"); // example.com
    int fd = connect(serverAddr, 80, TICKS_PER_SECOND * 10);

    if (fd < 0) {
        printf("Connection failed: %d\n", fd);
        return;
    }

    printf("Connected to server!\n");

    // Send HTTP GET request
    const char *request =
        "GET / HTTP/1.1\r\n"
        "Host: example.com\r\n"
        "Connection: close\r\n"
        "\r\n";

    writeall(fd, request, strlen(request));

    // Read response
    char buffer[512];
    int n = read(fd, buffer, sizeof(buffer) - 1);
    if (n > 0) {
        buffer[n] = '\0';
        printf("Received:\n%s\n", buffer);
    }

    close(fd);
    printf("Connection closed\n");
}
```

Connection with Error Handling

```
#include <tcp.h>
#include <init.h>

int ConnectWithRetry(IPADDR serverAddr, uint16_t port, int maxAttempts) {
    int attempt = 0;

    while (attempt < maxAttempts) {
        attempt++;
        printf("Connection attempt %d/%d to %s:%d\n",
            attempt, maxAttempts, serverAddr.print(), port);

        int fd = connect(serverAddr, port, TICKS_PER_SECOND * 10);

        if (fd > 0) {
            printf("Connection successful on attempt %d\n", attempt);
            return fd;
        }

        // Handle specific error codes
        switch (fd) {
            case TCP_ERR_TIMEOUT:
                printf(" Timeout - server not responding\n");
                break;

            case TCP_ERR_NONE_AVAIL:
                printf(" No sockets available - waiting for resources\n");
                OSTimeDly(TICKS_PER_SECOND * 5);
                break;

            case TCP_ERR_CON_RESET:
                printf(" Connection reset by server\n");
                break;

            case TCP_ERR_CON_ABORT:
                printf(" Connection aborted\n");
                break;

            default:
                printf(" Unknown error: %d\n", fd);
                break;
        }

        if (attempt < maxAttempts) {
            printf(" Retrying in 2 seconds...\n");
        }
    }
}
```

```

        OSTimeDly(TICKS_PER_SECOND * 2);
    }
}

printf("Failed to connect after %d attempts\n", maxAttempts);
return -1;
}

14.53.14.7 connectvia() [1/4]

```

int connectvia (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    TickTimeout & timeout,
    const IPADDR & localIpAddress) [inline]
#include <tcp.h>

```

Establish a TCP connection using a specific local interface IP with TickTimeout.

Creates a new TCP socket and connects to the remote host using the specified local network interface identified by its IP address, with TickTimeout object for sophisticated timeout management. This combines the benefits of explicit interface selection with precise timeout tracking across multiple operations.

This function is ideal for multi-homed systems where you need both controlled interface selection and the ability to share timeout budgets across sequential operations. The TickTimeout object is updated to reflect remaining time, enabling accurate timeout management for complex connection sequences.

Parameters

<i>ipAddress</i>	IP address of the remote host. Can be IPv4 or IPv6 depending on build configuration
<i>remotePort</i>	Port number on the remote host (1-65535)
<i>timeout</i>	Reference to TickTimeout object specifying the maximum wait time. The TickTimeout tracks elapsed time and can be reused across multiple operations. The object is updated by this function to reflect remaining time after the connection attempt
<i>localIpAddress</i>	IP address of the local interface to use for this connection. The system will select the network interface that has this IP address assigned. Use IPADDR::NullIP() to fall back to automatic interface selection based on routing table

Returns

Positive file descriptor on success (use for read/write operations), negative [TCP Socket Status](#) error code on failure:

- `TCP_ERR_TIMEOUT`: Connection not established within timeout period
- `TCP_ERR_NONE_AVAIL`: No available sockets in system pool
- `TCP_ERR_CON_RESET`: Connection was reset during establishment
- `TCP_ERR_CON_ABORT`: Connection was aborted

Notes:

- The TickTimeout object is updated by this function to reflect the remaining time. This allows multiple operations to share a common timeout budget.
- The local port is automatically assigned from the ephemeral port range.
- If the specified local IP address does not exist on any interface, the behavior depends on the network stack implementation. Generally, the connection will fail or fall back to the default interface.
- [GetInterfaceIP\(\)](#) to obtain the IP address of a specific interface number before calling this function.

- Always call `close()` on the returned file descriptor when finished to free system resources.

-is function blocks the calling task until the connection is established or the timeout expires. For non-blocking connection attempts, use `NoBlockConnectVia()`.

Warning

- The timeout parameter is passed by reference and will be modified by this function. If you need to preserve the original timeout value, create a copy.
- Ensure the specified local IP address is actually assigned to an interface before calling this function. Use `GetInterfaceIP()` to verify.

Examples

Basic Interface Selection with TickTimeout

```
#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

void ConnectViaInterfaceWithTimeout(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");
    IPADDR localIP = GetInterfaceIP(1); // Use interface 1

    printf("Connecting via interface %s\n", localIP.print());

    // Create TickTimeout for 15 seconds
    TickTimeout timeout(TICKS_PER_SECOND * 15);

    int fd = connectvia(serverAddr, 8080, timeout, localIP);

    if (fd > 0) {
        printf("Connected successfully!\n");
        printf("  Connection time: %.2f seconds\n",
            (float)timeout.GetElapsedTime() / TICKS_PER_SECOND);
        printf("  Remaining timeout: %.2f seconds\n",
            (float)timeout.GetTimeLeft() / TICKS_PER_SECOND);
        printf("  Local endpoint: %s:%d\n",
            GetSocketLocalAddr(fd).print(),
            GetSocketLocalPort(fd));

        // Verify correct interface
        if (GetSocketLocalAddr(fd) == localIP) {
            printf("  Verified: Using requested interface\n");
        }

        close(fd);
    } else {
        printf("Connection failed: %d\n", fd);
        printf("Time spent: %.2f seconds\n",
            (float)timeout.GetElapsedTime() / TICKS_PER_SECOND);
    }
}
```

Multi-Interface Connection with Shared Timeout

```
#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

// Try multiple interfaces within total time budget
int ConnectViaAnyInterface(IPADDR serverAddr, uint16_t port,
    uint32_t totalTimeoutTicks) {
    TickTimeout timeout(totalTimeoutTicks);
    int numInterfaces = GetNumberOfInterfaces();

    printf("Trying %d interfaces with %.1f second total budget\n\n",
        numInterfaces,
        (float)totalTimeoutTicks / TICKS_PER_SECOND);

    for (int i = 0; i < numInterfaces && !timeout.Expired(); i++) {
        IPADDR localIP = GetInterfaceIP(i);

        printf("Attempt %d via interface %d (%s)...\n",
            i + 1, i, localIP.print());
        printf("  Time remaining: %.1f seconds\n",
            (float)timeout.GetTimeLeft() / TICKS_PER_SECOND);

14.53.14.8 connectvia() [2/4]

```

int connectvia (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    TickTimeout & timeout,
    int ifnum) [inline]

```

#include <tcp.h>

Establish a TCP connection using a specific local interface number with TickTimeout.

Creates a new TCP socket and connects to the remote host using the specified local network interface number, with TickTimeout object for sophisticated timeout management. This provides the most direct interface control combined with precise timeout tracking, ideal for complex multi-homed systems requiring both explicit interface selection and accurate time budget management.

This function combines the unambiguous interface control of interface number selection with the advanced timeout capabilities of TickTimeout. The interface number takes precedence over all routing decisions, and the TickTimeout object tracks elapsed time for sharing timeout budgets across sequential operations.

Parameters

<i>ipAddress</i>	IP address of the remote host. Can be IPv4 or IPv6 depending on build configuration
<i>remotePort</i>	Port number on the remote host (1-65535)
<i>timeout</i>	Reference to TickTimeout object specifying the maximum wait time. The TickTimeout tracks elapsed time and can be reused across multiple operations. The object is updated by this function to reflect remaining time after the connection attempt
<i>ifnum</i>	Local interface number (0, 1, 2, etc.) to use for this connection. This overrides all routing decisions based on destination IP addresses. The interface number directly corresponds to the physical or logical network interface. Valid range is 0 to (number of interfaces - 1). Use GetNumberOfInterfaces() to determine valid range

Returns

Positive file descriptor on success (use for read/write operations), negative [TCP Socket Status](#) error code on failure:

- TCP_ERR_TIMEOUT: Connection not established within timeout period
- TCP_ERR_NONE_AVAIL: No available sockets in system pool
- TCP_ERR_CON_RESET: Connection was reset during establishment
- TCP_ERR_CON_ABORT: Connection was aborted

Notes:

- The TickTimeout object is updated by this function to reflect the remaining time. This allows multiple operations to share a common timeout budget.
- The local port is automatically assigned from the ephemeral port range.
- Interface numbers typically start at 0 and increment sequentially. Interface 0 is usually the primary Ethernet port, but this can vary by platform and configuration.
- This combination of interface number selection and TickTimeout provides the most control and precision for multi-homed systems with complex timing requirements.
- Always call [close\(\)](#) on the returned file descriptor when finished to free system resources.
- This function blocks the calling task until the connection is established or the timeout expires. For non-blocking connection attempts, use [NoBlockConnectVia\(\)](#).

Warning

- The timeout parameter is passed by reference and will be modified by this function. If you need to preserve the original timeout value, create a copy.
- Specifying an invalid interface number (negative or $\geq$ number of interfaces) may cause unpredictable behavior or connection failure. Always validate with GetNumberOfInterfaces() first.
- The specified interface must be in an "up" state with a valid IP address assigned for the connection to succeed.

Examples

Basic Interface Number Selection with TickTimeout

```

#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

void ConnectViaInterfaceWithTimeout(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");
    int interfaceNum = 1; // Use interface 1

    printf("Connecting via interface %d\n", interfaceNum);
    printf("Interface %d IP: %s\n",
        interfaceNum, GetInterfaceIP(interfaceNum).print());

    // Create TickTimeout for 15 seconds
    TickTimeout timeout(TICKS_PER_SECOND * 15);

    int fd = connectvia(serverAddr, 8080, timeout, interfaceNum);

    if (fd > 0) {
        printf("Connected successfully!\n");
        printf("  Connection time: %.2f seconds\n",
            (float)timeout.GetElapsedTime() / TICKS_PER_SECOND);
        printf("  Remaining timeout: %.2f seconds\n",
            (float)timeout.GetTimeLeft() / TICKS_PER_SECOND);
        printf("  Interface used: %d\n", TcpGetSocketInterface(fd));
        printf("  Local endpoint: %s:%d\n",
            GetSocketLocalAddr(fd).print(),
            GetSocketLocalPort(fd));

        close(fd);
    } else {
        printf("Connection failed: %d\n", fd);
        printf("Time spent: %.2f seconds\n",
            (float)timeout.GetElapsedTime() / TICKS_PER_SECOND);
        printf("Timeout expired: %s\n", timeout.Expired() ? "yes" : "no");
    }
}

```

Sequential Interface Attempts with Shared Timeout

```

#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

// Try each interface in sequence until success or timeout
int ConnectViaAnyInterface(IPADDR serverAddr, uint16_t port,
    uint32_t totalTimeoutTicks) {
    TickTimeout timeout(totalTimeoutTicks);
    int numInterfaces = GetNumberOfInterfaces();

    printf("Trying %d interfaces sequentially\n", numInterfaces);
    printf("Total timeout budget: %.1f seconds\n\n",
        (float)totalTimeoutTicks / TICKS_PER_SECOND);

    for (int i = 0; i < numInterfaces && !timeout.Expired(); i++) {
        printf("Attempt %d: Interface %d (%s)\n",
            i + 1, i, GetInterfaceIP(i).print());
        printf("  Time remaining: %.2f seconds\n",
            (float)timeout.GetTimeLeft() / TICKS_PER_SECOND);

        int fd = connectvia(serverAddr, port, timeout, i);

        if (fd > 0) {
            printf("  SUCCESS!\n");
            printf("  Total time: %.2f seconds\n",
                (float)timeout.GetElapsedTime() / TICKS_PER_SECOND);
            printf("  Unused time: %.2f seconds\n",
                (float)timeout.GetTimeLeft() / TICKS_PER_SECOND);
            return fd;
        }

        printf("  Failed: %d (%.2f sec used)\n",
            fd, (float)timeout.GetElapsedTime() / TICKS_PER_SECOND);
    }

    if (timeout.Expired()) {
        printf("\nTimeout budget exhausted (%.2f sec)\n",
            (float)timeout.GetElapsedTime() / TICKS_PER_SECOND);
    } else {
        printf("\nAll %d interfaces failed\n", numInterfaces);
    }

    return -1;
}

```

```

}

void UserMain(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");

14.53.14.9 connectvia() [3/4]

```

int connectvia (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    uint32_t timeout,
    const IPADDR & localIpAddress) [inline]

```

#include <tcp.h>

Establish a TCP connection using a specific local interface IP address.

Creates a new TCP socket and connects to the remote host using the specified local network interface identified by its IP address. This allows control over which interface is used when multiple network interfaces are available. The standard [connect\(\)](#) function uses the default interface selected by the routing table, while this function overrides that decision.

This is particularly useful in multi-homed systems where you need to ensure traffic uses a specific network path, such as separating control and data traffic, routing through different network segments, or implementing failover between interfaces.

Parameters

<i>ipAddress</i>	IP address of the remote host. Can be IPv4 or IPv6 depending on build configuration
<i>remotePort</i>	Port number on the remote host (1-65535)
<i>timeout</i>	Maximum connection time in system ticks: • Use <code>TICKS_PER_SECOND * n</code> for n second timeout • Example: <code>TICKS_PER_SECOND * 10</code> for 10 second timeout • Recommended: 5-30 seconds for most applications

Parameters

<i>localIpAddress</i>	IP address of the local interface to use for this connection. The system will select the network interface that has this IP address assigned. If multiple interfaces share the same IP (unusual configuration), the lower numbered interface is selected. Use IPADDR::NullIP() to fall back to automatic interface selection based on routing table (equivalent to calling connect())

Returns

Positive file descriptor on success (use for read/write operations), negative [TCP Socket Status](#) error code on failure:

- `TCP_ERR_TIMEOUT`: Connection not established within timeout period
- `TCP_ERR_NONE_AVAIL`: No available sockets in system pool
- `TCP_ERR_CON_RESET`: Connection was reset during establishment
- `TCP_ERR_CON_ABORT`: Connection was aborted

Notes:

- The local port is automatically assigned from the ephemeral port range. This function does not allow specification of the local port number.
- If the specified local IP address does not exist on any interface, the behavior depends on the network stack implementation. Generally, the connection will fail or fall back to the default interface.
- Use [GetInterfaceIP\(\)](#) to obtain the IP address of a specific interface number before calling this function.
- Always call [close\(\)](#) on the returned file descriptor when finished to free system resources.
- This function blocks the calling task until the connection is established or the timeout expires. For non-blocking connection attempts, use [NoBlockConnectVia\(\)](#).

Warning

Ensure the specified local IP address is actually assigned to an interface before calling this function. Use [GetInterfaceIP\(\)](#) to verify.

Expand for Example Usage

Examples

Basic Interface Selection

```
#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

void ConnectViaInterface(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Get IP address of interface 0
    IPADDR localIP = GetInterfaceIP(0);
    printf("Using local interface: %s\n", localIP.print());

    // Connect to server using specific interface
    IPADDR serverAddr = AsciiToIp("192.168.1.100");
    int fd = connectvia(serverAddr, 8080, TICKS_PER_SECOND * 10, localIP);

    if (fd > 0) {
        printf("Connected successfully!\n");
        printf("  Local endpoint: %s:%d\n",
            GetSocketLocalAddr(fd).print(),
            GetSocketLocalPort(fd));
        printf("  Remote endpoint: %s:%d\n",
            GetSocketRemoteAddr(fd).print(),
            GetSocketRemotePort(fd));

        // Verify we used the correct interface
        if (GetSocketLocalAddr(fd) == localIP) {
            printf("  Confirmed: Using requested interface\n");
        }
    }
}
```

```

    }

    close(fd);
} else {
    printf("Connection failed: %d\n", fd);
}
}

```

Dual-Homed System - Separate Control and Data Networks

```

#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

// System with two network interfaces:
// Interface 0: 192.168.1.x (Control network)
// Interface 1: 10.0.0.x (Data network)

void DualHomedExample(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Get interface IP addresses
    IPADDR controlIP = GetInterfaceIP(0); // Control network
    IPADDR dataIP = GetInterfaceIP(1);    // Data network

    printf("Control network IP: %s\n", controlIP.print());
    printf("Data network IP:    %s\n", dataIP.print());

    // Connect to control server via control network
    IPADDR controlServer = AsciiToIp("192.168.1.50");
    printf("\nConnecting to control server via control network...\n");

    int fdControl = connectvia(controlServer, 9000,
                               TICKS_PER_SECOND * 10,
                               controlIP);

    if (fdControl > 0) {
        printf("Control connection established via %s\n",
              GetSocketLocalAddr(fdControl).print());

        // Send control commands
        const char *cmd = "STATUS\r\n";
        write(fdControl, cmd, strlen(cmd));
    }

    // Connect to data server via data network
    IPADDR dataServer = AsciiToIp("10.0.0.50");
    printf("\nConnecting to data server via data network...\n");

    int fdData = connectvia(dataServer, 8080,
                           TICKS_PER_SECOND * 10,
                           dataIP);

    if (fdData > 0) {
        printf("Data connection established via %s\n",
              GetSocketLocalAddr(fdData).print());

        // Transfer bulk data
        char buffer[1024];
        // ... data transfer ...
    }

    // Clean up
    if (fdControl > 0) close(fdControl);
    if (fdData > 0)   close(fdData);

    printf("\nDual-homed operation complete\n");
}

```

Interface Failover

```

#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

// Try primary interface first, failover to backup if unavailable
int ConnectWithFailover(IPADDR serverAddr, uint16_t port) {
    // Try primary interface (interface 0)
    IPADDR primaryIP = GetInterfaceIP(0);
    printf("Attempting connection via primary interface %s...\n",
          primaryIP.print());

    int fd = connectvia(serverAddr, port, TICKS_PER_SECOND * 5, primaryIP);

    if (fd > 0) {
        printf("Connected via primary interface\n");
    }
}

```

```

        return fd;
    }

    printf("Primary interface failed: %d\n", fd);

    // Try backup interface (interface 1)
    IPADDR backupIP = GetInterfaceIP(1);
    printf("Attempting connection via backup interface %s...\n",
        backupIP.print());

    fd = connectvia(serverAddr, port, TICKS_PER_SECOND * 5, backupIP);

    if (fd > 0) {
        printf("Connected via backup interface\n");
        return fd;
    }

    printf("Backup interface also failed: %d\n", fd);
    printf("All interfaces exhausted\n");

    return fd;
}

void UserMain(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

14.53.14.10 connectvia() [4/4]

```

int connectvia (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    uint32_t timeout,
    int ifnum) [inline]

```

#include <tcp.h>

Establish a TCP connection using a specific local interface number.

Creates a new TCP socket and connects to the remote host using the specified local network interface number. This allows direct control over which interface is used, completely overriding the routing table. The interface number takes precedence over any IP-based routing decisions, providing the most explicit control over interface selection. This is the most direct way to control interface selection in multi-homed systems. Unlike selecting by IP address, specifying an interface number eliminates any ambiguity about which interface will be used, even if multiple interfaces share similar IP configurations.

Parameters

<i>ipAddress</i>	IP address of the remote host. Can be IPv4 or IPv6 depending on build configuration
<i>remotePort</i>	Port number on the remote host (1-65535)

Parameters

<i>timeout</i>	Maximum connection time in system ticks: • Use <code>TICKS_PER_SECOND * n</code> for n second timeout • Example: <code>TICKS_PER_SECOND * 10</code> for 10 second timeout • Recommended: 5-30 seconds for most applications
<i>ifnum</i>	Local interface number (0, 1, 2, etc.) to use for this connection. This overrides all routing decisions based on destination IP addresses. The interface number directly corresponds to the physical or logical network interface. Valid range is 0 to (number of interfaces - 1). Use <code>GetNumberOfInterfaces()</code> to determine valid range

Returns

Positive file descriptor on success (use for read/write operations), negative [TCP Socket Status](#) error code on failure:

- `TCP_ERR_TIMEOUT`: Connection not established within timeout period
- `TCP_ERR_NONE_AVAIL`: No available sockets in system pool
- `TCP_ERR_CON_RESET`: Connection was reset during establishment
- `TCP_ERR_CON_ABORT`: Connection was aborted

Notes:

- The local port is automatically assigned from the ephemeral port range. This function does not allow specification of the local port number.
- Interface numbers typically start at 0 and increment sequentially. Interface 0 is usually the primary Ethernet port, but this can vary by platform and configuration.
- If you specify an interface number that doesn't exist, the behavior is undefined. Always verify the interface count with `GetNumberOfInterfaces()` before using this function.
- This method of interface selection is preferred over IP-based selection when you need guaranteed, unambiguous interface control.
- Always call [close\(\)](#) on the returned file descriptor when finished to free system resources.
- This function blocks the calling task until the connection is established or the timeout expires. For non-blocking connection attempts, use [NoBlockConnectVia\(\)](#).

Warning

- Specifying an invalid interface number (negative or $\geq$ number of interfaces) may cause unpredictable behavior or connection failure.
- The specified interface must be in an "up" state with a valid IP address assigned for the connection to succeed.

Expand for Example Usage

Examples

Basic Interface Number Selection

```
#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

void ConnectViaInterfaceNumber(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Connect using interface 1
    int interfaceNum = 1;

    printf("Connecting via interface %d\n", interfaceNum);
    printf("Interface %d IP: %s\n",
        interfaceNum, GetInterfaceIP(interfaceNum).print());

    IPADDR serverAddr = AsciiToIp("192.168.1.100");
    int fd = connectvia(serverAddr, 8080, TICKS_PER_SECOND * 10, interfaceNum);

    if (fd > 0) {
        printf("Connected successfully!\n");
        printf(" Interface used: %d\n", TcpGetSocketInterface(fd));
        printf("  Local address: %s:%d\n",
            GetSocketLocalAddr(fd).print(),
            GetSocketLocalPort(fd));
        printf(" Remote address: %s:%d\n",
            GetSocketRemoteAddr(fd).print(),
            GetSocketRemotePort(fd));

        // Verify correct interface was used
        if (TcpGetSocketInterface(fd) == interfaceNum) {
            printf(" Verified: Correct interface selected\n");
        }

        close(fd);
    } else {
        printf("Connection failed: %d\n", fd);
    }
}
```

Iterating Through All Interfaces

```
#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

void TestAllInterfaces(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");
    int numInterfaces = GetNumberOfInterfaces();

    printf("System has %d network interfaces\n\n", numInterfaces);

    // Try connecting via each interface
    for (int i = 0; i < numInterfaces; i++) {
        IPADDR ifAddr = GetInterfaceIP(i);

        printf("Testing Interface %d (%s)...", i, ifAddr.print());

        uint32_t startTime = Secs;
        int fd = connectvia(serverAddr, 8080, TICKS_PER_SECOND * 5, i);
        uint32_t elapsed = Secs - startTime;

        if (fd > 0) {
            printf(" SUCCESS (%lu sec)\n", elapsed);
            printf(" Confirmed interface: %d\n", TcpGetSocketInterface(fd));
            printf(" Local endpoint: %s:%d\n",
                GetSocketLocalAddr(fd).print(),
                GetSocketLocalPort(fd));
            close(fd);
        } else {
            printf(" FAILED (error %d after %lu sec)\n", fd, elapsed);
        }

        printf("\n");
    }

    printf("Interface testing complete\n");
}
```

Primary and Backup Interface with Automatic Failover

```

#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

// Connect with automatic failover from primary to backup interface
int ConnectWithInterfaceFailover(IPADDR serverAddr, uint16_t port,
                                int primaryInterface, int backupInterface) {
    // Try primary interface first
    printf("Attempting connection via primary interface %d (%s)...\n",
           primaryInterface,
           GetInterfaceIP(primaryInterface).print());

    int fd = connectvia(serverAddr, port, TICKS_PER_SECOND * 5, primaryInterface);

    if (fd > 0) {
        printf("Connected via primary interface\n");
        return fd;
    }

    printf("Primary interface failed: %d\n", fd);
    printf("Failing over to backup interface %d (%s)...\n",
           backupInterface,
           GetInterfaceIP(backupInterface).print());

    fd = connectvia(serverAddr, port, TICKS_PER_SECOND * 5, backupInterface);

    if (fd > 0) {
        printf("Connected via backup interface\n");
        return fd;
    }

    printf("Backup interface also failed: %d\n", fd);
    printf("All interfaces exhausted\n");

    return fd;
}

void UserMain(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");

    // Try interface 0 first, failover to interface 1
    int fd = ConnectWithInterfaceFailover(serverAddr, 8080, 0, 1);

    if (fd > 0) {
        printf("Connection established via interface %d\n",
               TcpGetSocketInterface(fd));

        // Use connection...
        close(fd);
    }

    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

Interface Validation Before Connection

```

#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

// Safely connect via interface with validation
int SafeConnectViaInterface(IPADDR serverAddr, uint16_t port, int ifnum) {
    // Validate interface number
    int maxInterfaces = GetNumberOfInterfaces();

    if (ifnum < 0 || ifnum >= maxInterfaces) {
        printf("ERROR: Invalid interface number %d\n", ifnum);
        printf("Valid range is 0 to %d\n", maxInterfaces - 1);
        return -1;
    }

    // Get interface information
    IPADDR ifAddr = GetInterfaceIP(ifnum);

    // Check if interface has valid IP
    if (ifAddr == IPADDR::NullIP()) {
        printf("ERROR: Interface %d has no IP address assigned\n", ifnum);
        return -1;
    }
}

```

```

// Check if interface is up (platform-specific, may need additional checks)
printf("Interface %d status:\n", ifnum);
printf(" IP Address: %s\n", ifAddr.print());

// Proceed with connection

14.53.14.11 connectwlocal() [1/2]

```

int connectwlocal (
    const IPADDR & ipAddress,
    uint16_t localPort,
    uint16_t remotePort,
    TickTimeout timeout,
    const IPADDR & localIpAddress = IPADDR::NullIP(),
    int intf = -1) [inline]

#include <tcp.h>

```

Establish a TCP connection with full control over local parameters and TickTimeout.

Creates a new TCP socket with complete control over both local and remote connection parameters, using a Tick↔Timeout object for sophisticated timeout management. This function allows specification of the local port, interface IP address, or interface number, combined with precise timeout tracking for complex connection sequences.

This is the most advanced connection function, providing maximum control over all connection parameters plus the ability to track elapsed time and share timeout budgets. Most applications should use simpler connection functions unless they have specific requirements for local port control, explicit interface selection, and advanced timeout management.

Warning

Specifying a local port number is not recommended and should be avoided except in specialized cases. Using a fixed local port can cause connection failures when the remote host has a half-open socket remaining from a previous connection.

Parameters

<i>ipAddress</i>	IP address of the remote host. Can be IPv4 or IPv6 depending on build configuration
<i>localPort</i>	Local port number to bind (1-65535, or 0 for automatic assignment). Strongly recommend using 0 unless you have a specific protocol requirement (e.g., FTP active mode). Non-zero values can cause TCP_ERR_NOCON or connection failures when reconnecting if the previous connection is in TIME_WAIT state on the remote side
<i>remotePort</i>	Port number on the remote host (1-65535)
<i>timeout</i>	TickTimeout object specifying the maximum wait time. Unlike the reference version, this is passed by value, so the original timeout object is not modified. The function creates an internal copy for timeout tracking
<i>localIpAddress</i>	IP address of the local interface to use. Selects the network interface with this IP address. Use <code>IPADDR::NullIP()</code> if you want to specify interface by number instead (intf parameter). Default: <code>IPADDR::NullIP()</code> (automatic selection or use intf)
<i>intf</i>	Local interface number (0, 1, 2, etc.). Use -1 if you want to specify interface by IP address instead (localIpAddress parameter). Interface number takes precedence over IP-based routing. Default: -1 (use IP-based routing or localIpAddress)

Returns

Positive file descriptor on success (use for read/write operations), negative [TCP Socket Status](#) error code on failure:

- TCP_ERR_TIMEOUT: Connection not established within timeout period
- TCP_ERR_NONE_AVAIL: No available sockets in system pool
- TCP_ERR_NOCON: Local port is already in use or address binding failed
- TCP_ERR_CON_RESET: Connection was reset during establishment
- TCP_ERR_CON_ABORT: Connection was aborted

Notes:

- Unlike the reference version (`TickTimeout&`), this function accepts `TickTimeout` by value, so the caller's timeout object is not modified. This is useful when you want to preserve the original timeout state.
- Parameter Priority:
 - If `intf >= 0`: Uses the specified interface number, ignores `localIpAddress`
 - If `intf == -1` and `localIpAddress != NullIP()`: Uses interface with that IP
 - If `intf == -1` and `localIpAddress == NullIP()`: Uses routing table
- Local Port Behavior:
 - `localPort == 0`: System assigns available ephemeral port (recommended)
 - `localPort != 0`: Attempts to bind to specific port (can fail if in use)
- Always call [close\(\)](#) on the returned file descriptor when finished to free system resources and release the local port.
- This function blocks the calling task until the connection is established or the timeout expires. For non-blocking connection attempts, use [NoBlockConnectwlocal\(\)](#).

Warning

The combination of local port, interface IP, and interface number must be logically consistent. Specifying conflicting parameters will result in unpredictable behavior.

Expand for Example Usage**Examples****Basic Usage with Preserved Timeout Object**

```
#include <tcp.h>
#include <init.h>

void ConnectWithPreservedTimeout(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");

    // Create timeout that we want to preserve
    TickTimeout timeout(TICKS_PER_SECOND * 15);

    printf("Original timeout: %lu ticks\n", timeout.GetTimeLeft());

    // Connect using value semantics (timeout is copied, not modified)
    int fd = connectwlocal(serverAddr,
                          0, // Auto-assign local port
                          8080, // Remote port
                          timeout, // Passed by value
                          IPADDR::NullIP(),
                          -1);

    // Original timeout object is unchanged
    printf("After connect, original timeout still: %lu ticks\n",
          timeout.GetTimeLeft());

    if (fd > 0) {
        printf("Connected successfully!\n");
        printf("Can reuse original timeout for other operations\n");
        close(fd);
    }
}
```

Multiple Connections with Same Timeout Template

```
#include <tcp.h>
#include <init.h>

// Make multiple connections using the same timeout template
void MultipleConnectionsSameTimeout(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR servers[] = {
        AsciiToIp("192.168.1.10"),
        AsciiToIp("192.168.1.20"),
        AsciiToIp("192.168.1.30")
    };

    // Create timeout template
    TickTimeout timeoutTemplate(TICKS_PER_SECOND * 10);

    printf("Connecting to 3 servers, each with fresh 10 sec timeout\n\n");

    for (int i = 0; i < 3; i++) {
        printf("Server %d (%s)...", i + 1, servers[i].print());

        // Each connection gets a fresh copy of the timeout
        int fd = connectwlocal(servers[i],
                              0,
                              8080,
                              timeoutTemplate, // Copy for each connection
                              IPADDR::NullIP(),
                              -1);

        if (fd > 0) {
            printf(" Connected\n");
            close(fd);
        } else {
            printf(" Failed: %d\n", fd);
        }
    }

    // Verify template is unchanged
    printf(" Template timeout still: %lu ticks\n",
          timeoutTemplate.GetTimeLeft());
}
```

```
    printf("\nAll connections attempted with independent timeouts\n");
}
```

Interface Selection by IP with TickTimeout

```
#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

void ConnectViaSpecificInterface(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");
    IPADDR localIP = GetInterfaceIP(1); // Use interface 1

    printf("Connecting via interface %s\n", localIP.print());

    TickTimeout timeout(TICKS_PER_SECOND * 15);

    int fd = connectwlocal(serverAddr,
                           0, // Auto-assign port
                           8080, // Remote port
                           timeout, // By value
                           localIP, // Specific interface IP
                           -1); // Not using interface number

    if (fd > 0) {
        printf("Connected successfully!\n");
        printf("  Local: %s:%d\n",
               GetSocketLocalAddr(fd).print(),
               GetSocketLocalPort(fd));
        printf("  Remote: %s:%d\n",
               GetSocketRemoteAddr(fd).print(),
               GetSocketRemotePort(fd));

        // Verify correct interface used
        if (GetSocketLocalAddr(fd) == localIP) {
            printf("  Verified: Using requested interface\n");
        }

        close(fd);
    } else {
        printf("Connection failed: %d\n", fd);
    }
}
```

Interface Selection by Number with TickTimeout

```
#include <tcp.h>
#include <init.h>
#include <networkinterface.h>

void ConnectViaInterfaceNumber(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");
    int interfaceNum = 0;

    printf("Connecting via interface %d (%s)\n",
           interfaceNum, GetInterfaceIP(interfaceNum).print());

    TickTimeout timeout(TICKS_PER_SECOND * 15);

    int fd = connectwlocal(serverAddr,
                           0, // Auto-assign port
                           8080, // Remote port
                           timeout, // By value
                           IPADDR::NullIP(), // Not using IP selection
                           interfaceNum); // Specific interface number

    if (fd > 0) {
        printf("Connected successfully!\n");
        printf("  Interface used: %d\n", TcpGetSocketInterface(fd));
        printf("  Local IP: %s\n", GetSocketLocalAddr(fd).print());
        close(fd);
    } else {
        printf("Connection failed: %d\n", fd);
    }
}
```

FTP Active Mode with Fixed Port

```
#include <tcp.h>
#include <init.h>

// FTP active mode requires fixed local port for data connection
void FtpActiveModeConnection(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR ftpServer = AsciiToIp("192.168.1.10");

    // Step 1: Connect to FTP control port
    printf("Connecting to FTP control port...\n");
    TickTimeout controlTimeout(TICKS_PER_SECOND * 10);

    int fdControl = connectwlocal(ftpServer,
                                0, // Auto-assign
                                21, // FTP control
                                controlTimeout,
                                IPADDR::NullIP(),
                                -1);

    if (fdControl < 0) {
        printf("Control connection failed: %d\n", fdControl);
        return;
    }

    printf("FTP control connected\n");

    // Step 2: For FTP active mode, we need a listening socket
    // This is one of the few legitimate uses of fixed local port
    uint16_t dataPort = 2000;
    int fdDataListen = listen(INADDR_ANY, dataPort, 1);

    if (fdDataListen < 0) {
        printf("Data listen socket failed: %d\n", fdDataListen);
        close(fdControl);
        return;
    }

    printf("Data listen socket on port %d\n", dataPort);

    // Step 3: Tell server our IP and port
    IPADDR localIP = GetSocketLocalAddr(fdControl);

}

printf("\nTesting complete\n");
}

```

Timeout Template Library Pattern

```

#include <tcp.h>
#include <init.h>

// Create library of reusable timeout templates
namespace TimeoutTemplates {
    TickTimeout Quick(TICKS_PER_SECOND * 3);           // 3 seconds
    TickTimeout Normal(TICKS_PER_SECOND * 10);         // 10 seconds
    TickTimeout Patient(TICKS_PER_SECOND * 30);        // 30 seconds
    TickTimeout VeryPatient(TICKS_PER_SECOND * 60);    // 60 seconds
};

void UseTimeoutTemplates(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");

    // Quick attempt for high-priority connection
    printf("Quick attempt (3 sec timeout)...\n");
    int fd1 = connectwlocal(serverAddr, 0, 8080,
                           TimeoutTemplates::Quick,
                           IPADDR::NullIP(), -1);

    if (fd1 < 0) {
        printf("Quick failed, trying normal timeout...\n");

        // Fall back to normal timeout
        int fd2 = connectwlocal(serverAddr, 0, 8080,
                                TimeoutTemplates::Normal,
                                IPADDR::NullIP(), -1);

        if (fd2 < 0) {
            printf("Normal failed, using patient timeout...\n");

            // Last resort with patient timeout
            int fd3 = connectwlocal(serverAddr, 0, 8080,
                                    TimeoutTemplates::Patient,
                                    IPADDR::NullIP(), -1);

            if (fd3 > 0) {
                printf("Connected with patient timeout\n");
                close(fd3);
            }
        } else {
            printf("Connected with normal timeout\n");
            close(fd2);
        }
    } else {
        printf("Connected with quick timeout\n");
        close(fd1);
    }

    // Template objects are preserved for reuse
    printf("\nTimeout templates ready for next use\n");
}

```

}

14.53.14.12 connectwlocal() [2/2]

```
int connectwlocal (
    const IPADDR & ipAddress,
    uint16_t localPort,
    uint16_t remotePort,
    uint32_t timeout,
    const IPADDR & localIpAddress = IPADDR::NullIP(),
    int intf = -1) [inline]
#include <tcp.h>
```

Establish a TCP connection with full control over local parameters.

Creates a new TCP socket with complete control over both local and remote connection parameters. This function allows specification of the local port, interface IP address, or interface number. This is an advanced function intended for specialized use cases where standard [connect\(\)](#) or [connectvia\(\)](#) are insufficient.

Most applications should use [connect\(\)](#) or [connectvia\(\)](#) instead. This function is provided for protocols or scenarios that require specific local port numbers or explicit control over both the interface and local port simultaneously.

Warning

Specifying a local port number is not recommended and should be avoided except in specialized cases. Using a fixed local port can cause connection failures when the remote host has a half-open socket remaining from a previous connection. This is a common problem in client applications that reconnect frequently.

The combination of local port, interface IP, and interface number must be logically consistent. Specifying conflicting parameters will result in unpredictable behavior.

Parameters

<i>ipAddress</i>	IP address of the remote host. Can be IPv4 or IPv6 depending on build configuration
<i>localPort</i>	Local port number to bind (1-65535, or 0 for automatic assignment). Strongly recommend using 0 unless you have a specific protocol requirement. Non-zero values can cause TCP_ERR_NOCON or connection failures when reconnecting if the previous connection is in TIME_WAIT state on the remote side
<i>remotePort</i>	Port number on the remote host (1-65535)
<i>timeout</i>	Maximum connection time in system ticks: • Use TICKS_PER_SECOND * n for n second timeout • Example: TICKS_PER_SECOND * 10 for 10 second timeout • Recommended: 5-30 seconds for most applications
<i>localIpAddress</i>	IP address of the local interface to use. Selects the network interface with this IP address. Use IPADDR::NullIP() if you want to specify interface by number instead (intf parameter). Default: IPADDR::NullIP() (automatic selection)
<i>intf</i>	Local interface number (0, 1, 2, etc.). Use -1 if you want to specify interface by IP address instead (localIpAddress parameter). Interface number takes precedence over IP-based routing. Default: -1 (use IP-based routing or localIpAddress)

Returns

Positive file descriptor on success (use for read/write operations), negative [TCP Socket Status](#) error code on failure:

- TCP_ERR_TIMEOUT: Connection not established within timeout period
- TCP_ERR_NONE_AVAIL: No available sockets in system pool
- TCP_ERR_NOCON: Local port is already in use or address binding failed
- TCP_ERR_CON_RESET: Connection was reset during establishment
- TCP_ERR_CON_ABORT: Connection was aborted

Notes:

Parameter Priority:

- If intf $\geq$ 0: Uses the specified interface number, ignores localIpAddress
- If intf == -1 and localIpAddress != NullIP(): Uses interface with that IP
- If intf == -1 and localIpAddress == NullIP(): Uses routing table

Local Port Behavior:

- localPort == 0: System assigns available ephemeral port (recommended)
- localPort != 0: Attempts to bind to specific port (can fail if in use)

Common Use Cases:

- FTP active mode (requires specific local port for data connection)
- Protocol testing and debugging (need predictable source port)
- Load balancing across multiple interfaces
- Binding to specific interface when routing is ambiguous

Always call [close\(\)](#) on the returned file descriptor when finished to free system resources and release the local port.

Examples**Basic Usage - Interface Selection by IP**

```
#include <tcp.h>
#include <init.h>

void ConnectViaSpecificInterface(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");
    IPADDR localAddr = GetInterfaceIP(0); // Use interface 0's IP

    printf("Connecting to %s via local interface %s\n",
           serverAddr.print(), localAddr.print());

    // Connect using specific local interface, automatic port
    int fd = connectwlocal(serverAddr,
                           0, // Auto-assign local port
                           8080, // Remote port
                           TICKS_PER_SECOND * 10,
                           localAddr, // Specific interface IP
                           -1); // Not using interface number

    if (fd > 0) {
        printf("Connected!\n");
        printf("  Local: %s:%d\n",
               GetSocketLocalAddr(fd).print(),
               GetSocketLocalPort(fd));
        printf("  Remote: %s:%d\n",
               GetSocketRemoteAddr(fd).print(),
               GetSocketRemotePort(fd));

        close(fd);
    } else {
        printf("Connection failed: %d\n", fd);
    }
}
```

Interface Selection by Number

```
#include <tcp.h>
#include <init.h>

void ConnectViaInterfaceNumber(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("10.0.1.50");
    int interfaceNum = 1; // Use interface 1

    printf("Connecting via interface %d\n", interfaceNum);
    printf("Interface %d IP: %s\n",
           interfaceNum, GetInterfaceIP(interfaceNum).print());

    // Connect using interface number
    int fd = connectwlocal(serverAddr,
                           0, // Auto-assign local port
                           9000, // Remote port
                           TICKS_PER_SECOND * 10,
                           IPADDR::NullIP(), // Not using IP selection
                           interfaceNum); // Use interface 1

    if (fd > 0) {
        printf("Connected via interface %d\n", interfaceNum);
        printf("Actual local IP used: %s\n",
               GetSocketLocalAddr(fd).print());
        close(fd);
    } else {
        printf("Connection failed: %d\n", fd);
    }
}
```

Specifying Local Port (Not Recommended)

```
#include <tcp.h>
#include <init.h>

// Example showing why fixed local ports are problematic
void DemonstrateLocalPortProblem(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");
    uint16_t fixedLocalPort = 5000;

    printf("Attempting first connection with local port %d\n", fixedLocalPort);

    // First connection with fixed local port
    int fd1 = connectwlocal(serverAddr,
                           fixedLocalPort, // Fixed local port
                           8080,
                           TICKS_PER_SECOND * 10,
                           IPADDR::NullIP(),
                           -1);

    if (fd1 > 0) {
        printf("First connection succeeded\n");
        printf("  Local: %s:%d\n",
               GetSocketLocalAddr(fd1).print(),
               GetSocketLocalPort(fd1));

        // Simulate some work
        OSTimeDly(TICKS_PER_SECOND * 2);
        close(fd1);
        printf("First connection closed\n");
    }

    // Try to reconnect immediately with same local port
    printf("\nAttempting second connection with same local port %d\n",
           fixedLocalPort);

    int fd2 = connectwlocal(serverAddr,
                           fixedLocalPort, // Same fixed local port
                           8080,
                           TICKS_PER_SECOND * 10,
                           IPADDR::NullIP(),
                           -1);

    if (fd2 > 0) {
        printf("Second connection succeeded (lucky!)\n");
        close(fd2);
    } else {
        printf("Second connection FAILED: %d\n", fd2);
        printf("This is why fixed local ports are problematic!\n");
        printf("The local port may still be in TIME_WAIT state.\n");
    }
}
```

```

    }

    // Show the correct approach
    printf("\nCorrect approach - using automatic port assignment:\n");

    int fd3 = connectwlocal(serverAddr,
                           0, // Auto-assign port (RECOMMENDED)
                           8080,
                           TICKS_PER_SECOND * 10,
                           IPADDR::NullIP(),
                           -1);

    if (fd3 > 0) {
        printf("Connection with auto-assigned port succeeded\n");
        printf("  Assigned local port: %d\n", GetSocketLocalPort(fd3));
        close(fd3);
    }
}

```

Multi-Interface Load Balancing

```

#include <tcp.h>
#include <init.h>

// Distribute connections across multiple interfaces
void LoadBalancedConnections(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR serverAddr = AsciiToIp("192.168.1.100");
    int numInterfaces = 2; // Assume 2 network interfaces
    int connectionCount = 0;

    printf("Load balancing connections across %d interfaces\n", numInterfaces);

    for (int i = 0; i < 10; i++) { // Make 10 connections
        int interfaceNum = connectionCount % numInterfaces;

        printf("\nConnection %d using interface %d\n", i + 1, interfaceNum);

        int fd = connectwlocal(serverAddr,
                               0, // Auto port
                               8080,
                               TICKS_PER_SECOND * 10,
                               IPADDR::NullIP(),
                               interfaceNum);

        if (fd > 0) {
            printf("  Success - Local IP: %s, Port: %d\n",
                  GetSocketLocalAddr(fd).print(),
                  GetSocketLocalPort(fd));

            connectionCount++;

            // Do work...
            const char *msg = "Hello\r\n";
            write(fd, msg, strlen(msg));

            close(fd);
        } else {
            printf("  Failed: %d\n", fd);
        }

        OSTimeDly(TICKS_PER_SECOND);
    }

    printf("\nTotal successful connections: %d\n", connectionCount);
}

```

FTP Active Mode (Legitimate Fixed Port Use Case)

```

#include <tcp.h>
#include <init.h>

// FTP active mode requires server to connect back to specific client port
void FtpActiveMode(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    IPADDR ftpServer = AsciiToIp("192.168.1.10");

    // Step 1: Connect to FTP control port
    int fdControl = connect(ftpServer, 21, TICKS_PER_SECOND * 10);
    if (fdControl < 0) {
        printf("FTP control connection failed: %d\n", fdControl);
        return;
    }
}

```

```

    }

14.53.14.13 DumpTcpDebug()

```
void DumpTcpDebug ()
#include <tcp.h>
```

Display current TCP debug information to the console.

Outputs detailed TCP debug information to the console, including active connections, socket states, buffer usage, and other TCP stack diagnostics. The information displayed depends on which debug flags have been enabled via [EnableTcpDebug\(\)](#). This function is useful for troubleshooting network issues and monitoring TCP connection states.

[EnableTcpDebug\(\)](#)

Expand for Example Usage

Examples

Basic Usage - Dumping TCP Debug Info

```
// Enable TCP debugging
EnableTcpDebug(0xFFFF); // Enable all debug flags

// Perform some TCP operations
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

// Dump current TCP state
DumpTcpDebug();

close(fd);
```

Periodic Monitoring - Debug Output Every Second

```
void MonitoringTask(void *pd) {
    EnableTcpDebug(0x0001); // Enable basic debug info

    while (1) {
        printf("\n=== TCP Debug Info ===\n");
        DumpTcpDebug();
        printf("=====\n\n");

        OSTimeDly(TICKS_PER_SECOND);
    }
}

void UserMain(void *pd) {
    init();
    OSTaskCreate(MonitoringTask, NULL, &MonitorStack[USER_TASK_STK_SIZE],
                MonitorStack, MAIN_PRIO - 1);
}
```

Troubleshooting Connection Issues

```
int fd = socket(AF_INET, SOCK_STREAM, 0);

printf("Before connect:\n");
DumpTcpDebug();

int result = connect(fd, (struct sockaddr*)&addr, sizeof(addr));

if (result < 0) {
    printf("Connect failed! Debug info:\n");
    DumpTcpDebug(); // See what went wrong
} else {
    printf("After successful connect:\n");
    DumpTcpDebug(); // Verify connection state
}
```

Debug Snapshot on Error

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

char buffer[1024];
int n = read(fd, buffer, sizeof(buffer));

if (n < 0) {
    printf("Read error occurred! TCP state:\n");
    DumpTcpDebug(); // Capture state at error time

    printf("Error code: %d\n", n);
    abortsocket(fd);
}
```

14.53.14.14 EnableTcpDebug()

```
void EnableTcpDebug (
    uint16_t dbFlags)
```

```
#include <tcp.h>
```

Enable TCP debug output with specified flags.

Configures which types of TCP debug information should be tracked and displayed when [DumpTcpDebug\(\)](#) is called. The debug flags control the level of detail and which aspects of TCP operations are monitored. Use bitwise OR to combine multiple flags. Set to 0 to disable all TCP debugging.

Parameters

<i>dbFlags</i>	Debug flags to enable (bitwise OR of debug flag values) • 0x0000 = Disable all debugging • 0xFFFF = Enable all debugging • Individual flags control specific debug features (see TCP debug documentation)

See also

[DumpTcpDebug\(\)](#)

Expand for Example Usage

Examples

Basic Usage - Enable All Debug Output

```
void UserMain(void *pd) {
    init();

    // Enable all TCP debugging
    EnableTcpDebug(0xFFFF);

    // TCP operations will now generate debug output
    int fd = socket(AF_INET, SOCK_STREAM, 0);
    connect(fd, (struct sockaddr*)&addr, sizeof(addr));

    DumpTcpDebug(); // Display debug information
}
```

Selective Debug Output - Specific Flags

```
// Enable only specific debug features
#define TCP_DBG_CONNECTIONS 0x0001
#define TCP_DBG_BUFFERS 0x0002
#define TCP_DBG_RETRANSMIT 0x0004

// Enable connection and buffer debugging only
EnableTcpDebug(TCP_DBG_CONNECTIONS | TCP_DBG_BUFFERS);

DumpTcpDebug(); // Will show only connection and buffer info
```

Toggle Debug Mode

```
bool debugEnabled = false;

void ToggleDebugMode() {
    if (debugEnabled) {
        printf("Disabling TCP debug\n");
        EnableTcpDebug(0x0000); // Disable all debugging
        debugEnabled = false;
    } else {
        printf("Enabling TCP debug\n");
        EnableTcpDebug(0xFFFF); // Enable all debugging
        debugEnabled = true;
    }
}

void UserMain(void *pd) {
    init();

    // Start with debugging disabled
    EnableTcpDebug(0x0000);

    // Can be toggled during runtime via command or button press
    while (1) {
        if (CheckDebugButton()) {
            ToggleDebugMode();
        }
        OSTimeDly(TICKS_PER_SECOND / 10);
    }
}
```

Production vs Development Build

```
void UserMain(void *pd) {
    init();

#ifdef DEBUG_BUILD
    // Enable full debugging in development builds
    EnableTcpDebug(0xFFFF);
    printf("TCP debugging enabled (development build)\n");
#else
    // Disable debugging in production builds
    EnableTcpDebug(0x0000);
#endif

    StartHttp();

    while (1) {
#ifdef DEBUG_BUILD
        DumpTcpDebug(); // Periodic debug output in dev builds
#endif
        OSTimeDly(TICKS_PER_SECOND * 10);
    }
}
```

Conditional Debug Based on Connection Count

```
void MonitorConnections() {
    static int lastConnectionCount = 0;
    int currentConnections = GetActiveConnectionCount();

    if (currentConnections > 10 && lastConnectionCount <= 10) {
        // High connection count, enable detailed debugging
        printf("High connection count detected, enabling TCP debug\n");
        EnableTcpDebug(0xFFFF);
    } else if (currentConnections <= 10 && lastConnectionCount > 10) {
        // Connection count normalized, reduce debug output
        printf("Connection count normalized, reducing TCP debug\n");
        EnableTcpDebug(0x0001); // Basic info only
    }

    lastConnectionCount = currentConnections;
}
```

Debug On Demand via Network Command

```
void HandleDebugCommand(int clientFd, const char *cmd) {
    if (strcmp(cmd, "DEBUG ON") == 0) {
        EnableTcpDebug(0xFFFF);
        write(clientFd, "TCP debug enabled\n", 18);
        DumpTcpDebug();
    } else if (strcmp(cmd, "DEBUG OFF") == 0) {
        EnableTcpDebug(0x0000);
        write(clientFd, "TCP debug disabled\n", 19);
    } else if (strcmp(cmd, "DEBUG STATUS") == 0) {

```

```

        DumpTcpDebug();
    }
}

```

14.53.14.15 getsocketerror()

```

int getsocketerror (
    int fd)
#include <tcp.h>

```

Get the error status of a socket.

Retrieves the current error state of a socket file descriptor. This function is useful for diagnosing connection failures, especially with non-blocking sockets where errors may not be immediately apparent from the return value of [connect\(\)](#) or other operations.

Parameters

<i>fd</i>	File descriptor of the socket to query

Returns

0 if no error, positive error code if an error occurred, negative value on invalid fd

Notes:

- This function is particularly useful after a non-blocking connect operation to determine why a connection failed to establish.
- Common error codes include:
 - 0: No error (success)
 - ECONNREFUSED: Connection refused by remote host
 - ETIMEDOUT: Connection attempt timed out
 - ENETUNREACH: Network is unreachable
 - EHOSTUNREACH: Host is unreachable
 - ECONNRESET: Connection reset by peer
- After calling [getsocketerror\(\)](#), the error status is typically cleared.

            printf("Socket writable but not established (state: %d)\r\n", state);
        }
    }

    close(fd);
}

```

14.53.14.16 GetSocketLocalAddr()

```

IPADDR GetSocketLocalAddr (
    int fd) [inline]
#include <tcp.h>

```

Get the local interface IP address for a socket connection.

Retrieves the IP address of the local network interface used for the specified socket connection. This function works for both client connections and server sockets that have accepted a connection.

Parameters

<i>fd</i>	Socket file descriptor

Returns

IP address of the local interface, or [IPADDR::NullIP\(\)](#) if socket is not bound

Notes: For listening sockets, this returns the address the socket is bound to. If bound to `INADDR_ANY`, it returns `INADDR_ANY` rather than a specific interface IP.

- This function is useful for determining which network interface is being used when you have multiple interfaces (e.g., Ethernet and WiFi).
- This function supports both IPv4 and IPv6 addresses through the `IPADDR` class.

Examples

Basic Usage - Determine Connection Interface

```
#include <tcp.h>
#include <netinterface.h>
#include <nbrtos.h>

void DisplayConnectionDetails(void *pd)
{
    IPADDR serverIp = AsciiToIp("192.168.1.100");
    uint16_t serverPort = 8080;

    // Connect to server
    int fd = connect(serverIp, serverPort, TICKS_PER_SECOND * 10);

    if (fd < 0)
    {
        printf("Connection failed: %d\r\n", fd);
        return;
    }

    // Get local and remote addresses
    IPADDR localAddr = GetSocketLocalAddr(fd);
    IPADDR remoteAddr = GetSocketRemoteAddr(fd);
    uint16_t remotePort = GetSocketRemotePort(fd);

    printf("Connection established:\r\n");
    printf("  Local address: %I\r\n", localAddr);
    printf("  Remote address: %I:%d\r\n", remoteAddr, remotePort);

    // Determine which interface was used
    for (int i = 0; i < GetNumInterfaces(); i++)
    {

    close(fd);
}
```

14.53.14.17 GetSocketLocalPort()

```
uint16_t GetSocketLocalPort (
    int fd)
```

```
#include <tcp.h>
```

Get the local port number for a socket connection.

Retrieves the local port number assigned to the specified socket connection.

Parameters

<i>fd</i>	Socket file descriptor

Returns

Local port number

See also

[GetSocketRemotePort\(\)](#)

14.53.14.18 GetSocketRemoteAddr()

```
IPADDR GetSocketRemoteAddr (
    int fd) [inline]
```

```
#include <tcp.h>
```

Get the remote host IP address for a socket connection.

Retrieves the IP address of the remote host connected to the specified socket. This function works for both established connections and listening sockets that have accepted a client connection.

Parameters

<i>fd</i>	Socket file descriptor

Returns

IP address of the remote host, or `IPADDR::NullIP()` if socket is not connected

Notes:

- For listening sockets that have not accepted a connection, this function returns `IPADDR::NullIP()`. -note This function supports both IPv4 and IPv6 addresses through the `IPADDR` class.

Examples

Basic Usage - Get Remote Address After Connection

```
#include <tcp.h>
#include <nbrtos.h>

void DisplayConnectionInfo(void *pd)
{
    IPADDR serverIp = AsciiToIp("192.168.1.100");
    uint16_t serverPort = 8080;

    // Connect to server
    int fd = connect(serverIp, serverPort, TICKS_PER_SECOND * 10);

    if (fd < 0)
    {
        printf("Connection failed: %d\r\n", fd);
        return;
    }

    // Get remote address (should match serverIp)
    IPADDR remoteAddr = GetSocketRemoteAddr(fd);

    printf("Connected to remote host: %I\r\n", remoteAddr);
    printf("Remote port: %d\r\n", serverPort);

    // Send data
    const char *message = "Hello, Server!\r\n";
    write(fd, message, strlen(message));

    close(fd);
}
```

14.53.14.19 GetSocketRemotePort()

```
uint16_t GetSocketRemotePort (
    int fd)
```

```
#include <tcp.h>
```

Get the remote host port number for a socket connection.

Retrieves the port number being used by the remote host in the specified socket connection. This function works for both client connections and server sockets that have accepted a connection.

Parameters

<i>fd</i>	Socket file descriptor

Returns

Port number of the remote host, or 0 if socket is not connected

Notes:

- For listening sockets that have not accepted a connection, this function returns 0.
- The remote port is typically an ephemeral port (1024-65535) for client connections, or a well-known/registered port for server connections.

Expand for Example Usage**Examples****Basic Usage - Display Remote Connection Details**

```
#include <tcp.h>
#include <nbrtos.h>

void DisplayRemoteConnectionInfo(void *pd)
{
    IPADDR serverIp = AsciiToIp("192.168.1.100");
    uint16_t serverPort = 8080;

    // Connect to server
    int fd = connect(serverIp, serverPort, TICKS_PER_SECOND * 10);

    if (fd < 0)
    {
        printf("Connection failed: %d\r\n", fd);
        return;
    }

    // Get remote connection details
    IPADDR remoteAddr = GetSocketRemoteAddr(fd);
    uint16_t remotePort = GetSocketRemotePort(fd);

    printf("Connected to remote host:\r\n");
    printf("  IP address: %I\r\n", remoteAddr);
    printf("  Port:      %d\r\n", remotePort);

    // Verify it matches what we connected to
    if (remoteAddr == serverIp && remotePort == serverPort)
    {
        printf("  Connection verified!\r\n");
    }

    close(fd);
}
```

14.53.14.20 getsockopt()

```
int getsockopt (
    int fd)
#include <tcp.h>
```

Query current TCP socket options.

Retrieves the currently enabled option flags for the specified socket. The return value is a bitmask where each set bit represents an enabled option.

Parameters

<i>fd</i>	Socket file descriptor

Returns

Bitmask of all currently enabled options ([TCP Socket Options](#)), or negative value on error

Notes:

- The returned bitmask can be tested for specific options using bitwise AND: `if (getsockopt(fd) & SO_NODELAY) { ... }`
- A return value of 0 indicates no special options are enabled (all default behavior).
- This function is useful for checking socket configuration before making changes or for debugging connection behavior.

}
```

14.53.14.21 GetTcpRtxCount()

```
int GetTcpRtxCount (
    int fd)
#include <tcp.h>
```

Get the number of TCP retransmissions on a socket.

Returns the count of how many times TCP has retransmitted data on this connection. Retransmissions occur when acknowledgments are not received from the remote host within the expected timeout period. A high retransmission count may indicate network congestion, packet loss, or a slow/unstable connection.

Parameters

<i>fd</i>	Socket file descriptor

Returns

Number of retransmissions that have occurred on this connection, or -1 if socket is invalid

Notes:

- This counter is maintained for the lifetime of the connection and is reset when the socket is closed or reused.
- A small number of retransmissions is normal in most networks. However, a rapidly increasing count or very high values may indicate network problems.
- Each retransmitted segment increments this counter, so the same data being retransmitted multiple times will increment the counter each time.

}
```

14.53.14.22 listen()

```
int listen (  
    const IPADDR & addr,  
    uint16_t port,  
    uint8_t maxpend = 5) [inline]  
#include <tcp.h>
```

Create a listening socket to accept incoming TCP connections.

Creates a socket that listens for incoming connection requests on the specified port. This is the server-side counterpart to [connect\(\)](#), enabling your application to accept connections from remote clients. Incoming connections are placed in a pending queue until accepted with [accept\(\)](#). The maxpend parameter determines how many connections can wait in the queue before new connection attempts are rejected by the TCP stack.

The listening socket itself does not handle data transfer - it only accepts new connections. Each accepted connection returns a new socket file descriptor for communicating with that specific client. The listening socket remains open and continues accepting new connections.

Parameters

<i>addr</i>	IP address to bind to: • Use INADDR_ANY (or IPADDR::AnyIP()) to accept connections on all network interfaces. This is the most common usage for servers • Use a specific IP address to accept connections only on that interface • Example: INADDR_ANY for multi-homed systems
<i>port</i>	Port number to listen on (1-65535). Common server ports include: • 80 for HTTP • 443 for HTTPS • 23 for Telnet • Custom ports typically use values above 1024 Ports below 1024 are traditionally reserved for well-known services
<i>maxpend</i>	Maximum number of pending connections in the accept queue (default: 5). This is the maximum number of clients that can be waiting in the queue simultaneously. When this limit is reached, additional connection attempts will be refused by the TCP stack. Typical values are 5-20. Higher values consume more system resources but allow for burst connection handling

Returns

Positive file descriptor on success (use with [accept\(\)](#) to get client connections), negative [TCP Socket Status](#) error code on failure:

- TCP_ERR_NONE_AVAIL: No available sockets in system pool
- TCP_ERR_NOCON: Port already in use or binding failed

Notes:

- The listening socket uses one socket from the system pool. Each accepted connection uses an additional socket. Plan your maxpend value and system socket count accordingly.

- Always call `close()` on the listening socket when your server is shutting down to free the socket resource and release the port.
- The listening socket does not automatically close when the application exits. For clean shutdown, explicitly close all listening sockets.
- If you need to listen on a specific interface in a multi-homed system, use `listenvia()` instead for explicit interface control.
- Port numbers below 1024 may require special privileges on some systems, though this is typically not an issue on embedded NetBurner devices.

Warning

- If the port is already in use (by another listening socket or active connection), `listen()` will fail with `TCP_ERR_NOCON`. Ensure the port is available before calling.
- The `maxpend` parameter limits simultaneous pending connections, not total accepted connections. Once a connection is accepted with `accept()`, it no longer occupies a slot in the pending queue.

Examples

Basic Echo Server

```
#include <tcp.h>
#include <init.h>
#include <nbrtos.h>

void EchoServer(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Create listening socket on port 7 (echo port)
    int fdListen = listen(INADDR_ANY, 7, 5);

    if (fdListen < 0) {
        printf("Failed to create listening socket: %d\n", fdListen);
        return;
    }

    printf("Echo server listening on port 7\n");
    printf("Waiting for connections...\n\n");

    while (1) {
        // Accept incoming connection
        IPADDR clientAddr;
        uint16_t clientPort;
        int fdClient = accept(fdListen, &clientAddr, &clientPort, 0);

        if (fdClient > 0) {
            printf("Client connected: %s:%d\n",
                clientAddr.print(), clientPort);

            // Echo data back to client
            char buffer[512];
            while (1) {
                int n = read(fdClient, buffer, sizeof(buffer));
                if (n <= 0) break; // Connection closed

                writeall(fdClient, buffer, n); // Echo back
            }

            close(fdClient);
            printf("Client disconnected\n\n");
        }
    }

    close(fdListen);
}
```

HTTP Server Example

```
#include <tcp.h>
#include <init.h>
#include <nbrtos.h>

void SimpleHttpServer(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);
```

```

// Create listening socket on port 80 (HTTP)
int fdListen = listen(INADDR_ANY, 80, 10);

if (fdListen < 0) {
    printf("Failed to create HTTP listener: %d\n", fdListen);
    return;
}

printf("HTTP server listening on port 80\n");

while (1) {
    IPADDR clientAddr;
    uint16_t clientPort;
    int fdClient = accept(fdListen, &clientAddr, &clientPort, 0);

    if (fdClient > 0) {
        printf("HTTP request from %s:%d\n",
            clientAddr.print(), clientPort);

        // Read HTTP request (simplified)
        char request[1024];
        int n = read(fdClient, request, sizeof(request) - 1);

        if (n > 0) {
            request[n] = '\0';
            printf("Request: %s\n", request);

            // Send HTTP response
            const char *response =
                "HTTP/1.1 200 OK\r\n"
                "Content-Type: text/html\r\n"
                "Connection: close\r\n"
                "\r\n"
                "<html><body><h1>Hello from NetBurner!</h1></body></html>";

            writeall(fdClient, response, strlen(response));
        }

        close(fdClient);
    }
}

```

Server with Error Handling

```

#include <tcp.h>
#include <init.h>

int CreateServer(uint16_t port, uint8_t backlog) {
    int fdListen = listen(INADDR_ANY, port, backlog);

    if (fdListen < 0) {
        // Handle specific error cases
        switch (fdListen) {
            case TCP_ERR_NONE_AVAIL:

14.53.14.23 listenvia() [1/2]

```

int listenvia (
    const IPADDR & addr,
    uint16_t port,
    const IPADDR & localIpAddress,
    uint8_t maxpend = 5) [inline]
#include <tcp.h>

```

Create a listening socket bound to a specific interface IP address.

Creates a socket that listens for incoming connection requests on the specified port using the network interface with the given IP address. If multiple interfaces share the same IP address, the lower numbered interface is selected. Incoming connections are placed in a pending queue until accepted with [accept\(\)](#).

Parameters

<i>addr</i>	IP address to bind to (use INADDR_ANY to accept connections on any interface)
<i>port</i>	Port number to listen on
<i>localIpAddress</i>	IP address of the local interface to use. Selects the interface with this IP address (lower numbered interface if multiple match)
<i>maxpend</i>	Maximum number of pending connections in the accept queue (default: 5)

Returns

Positive file descriptor on success, negative [TCP Socket Status](#) error code on failure

Note

This function is useful when you have multiple network interfaces and need to ensure the listening socket binds to a specific interface rather than all interfaces.

Warning

If multiple interfaces have the same IP address, the behavior is deterministic but may not match expectations - the lower numbered interface will be selected.

Examples

Basic Usage - Listen on Specific Interface

```

#include <tcp.h>
#include <nbrtos.h>

void ServerTask(void *pd)
{
    // Get the IP address of interface 0
    IPADDR localIp = GetIPAddress(0);

    // Create a listening socket on port 8080 bound to interface 0
    int listenFd = listenvia(INADDR_ANY, 8080, localIp);

    if (listenFd < 0)
    {
        printf("Failed to create listening socket: %d\r\n", listenFd);
        return;
    }

    printf("Listening on %I:8080 via interface IP %I\r\n", INADDR_ANY, localIp);

    while (1)
    {
        IPADDR clientAddr;
        uint16_t clientPort;

        // Accept incoming connections
        int clientFd = accept(listenFd, &clientAddr, &clientPort, 0);

        if (clientFd > 0)
        {
            printf("Client connected from %I:%d\r\n", clientAddr, clientPort);

            // Handle client connection
            // ... your code here ...

            close(clientFd);
        }

        close(listenFd);
    }
}

```

Multi-Interface Server - Listen on Both Ethernet and WiFi

```

#include <tcp.h>
#include <nbrtos.h>

void MultiInterfaceServer(void *pd)
{
    const uint16_t SERVER_PORT = 8080;

    // Get IP addresses for Ethernet (interface 0) and WiFi (interface 1)
    IPADDR ethernetIp = GetIPAddress(0);

        FD_SET(ethernetFd, &read_fds);
        FD_SET(wifiFd, &read_fds);

        int maxFd = (ethernetFd > wifiFd) ? ethernetFd : wifiFd;
    }
}

```

```

    if (select(maxFd + 1, &read_fds, NULL, NULL, TICKS_PER_SECOND * 5) > 0)
    {
        IPADDR clientAddr;
        uint16_t clientPort;

        if (FD_ISSET(ethernetFd, &read_fds))
        {
            int clientFd = accept(ethernetFd, &clientAddr, &clientPort, 0);
            if (clientFd > 0)
            {
                printf("Client connected via Ethernet from %I:%d\r\n",
                    clientAddr, clientPort);
                // Handle client...
                close(clientFd);
            }
        }

        if (FD_ISSET(wifiFd, &read_fds))
        {
            int clientFd = accept(wifiFd, &clientAddr, &clientPort, 0);
            if (clientFd > 0)
            {
                printf("Client connected via WiFi from %I:%d\r\n",
                    clientAddr, clientPort);
                // Handle client...
                close(clientFd);
            }
        }
    }

    close(ethernetFd);
    close(wifiFd);
}

```

Error Handling and Interface Validation

```

#include <tcp.h>
#include <netinterface.h>

int CreateInterfaceListener(int interfaceNum, uint16_t port)
{
    // Validate interface exists and is active
    if (interfaceNum < 0 || interfaceNum >= GetNumInterfaces())
    {
        printf("Invalid interface number: %d\r\n", interfaceNum);
        return -1;
    }

    // Get interface IP address
    IPADDR localIp = GetIPAddress(interfaceNum);

    if (localIp == IPADDR_ANY)
    {
        printf("Interface %d has no IP address assigned\r\n", interfaceNum);
        return -1;
    }

    // Create listening socket with custom queue size
    int listenFd = listenvia(INADDR_ANY, port, localIp, 20);

    if (listenFd < 0)
    {
        // Handle specific error codes
        switch (listenFd)
        {
            case TCP_ERR_NOSOCKETS:
                printf("No socket resources available\r\n");
                break;
            case TCP_ERR_PORT_IN_USE:
                printf("Port %d already in use on interface\r\n", port);
                break;
            default:
                printf("Failed to create listener: error %d\r\n", listenFd);
                break;
        }
        return listenFd;
    }

    printf("Successfully listening on %I:%d (interface %d)\r\n",
        localIp, port, interfaceNum);

    return listenFd;
}

```

14.53.14.24 listenvia() [2/2]

```
int listenvia (
    const IPADDR & addr,
    uint16_t port,
    int ifn,
    uint8_t maxpend = 5) [inline]
#include <tcp.h>
```

Create a listening socket on a specific network interface.

Creates a socket that listens for incoming connection requests on the specified port and network interface. This provides direct control over which interface accepts connections when multiple interfaces are available, useful in multi-homed systems where you need to segregate traffic by interface or ensure connections arrive on a specific network path.

This function is the interface-specific version of [listen\(\)](#). While [listen\(\)](#) accepts connections on all interfaces (when using INADDR_ANY) or relies on IP routing, this function gives explicit control by interface number. Incoming connections are placed in a pending queue until accepted with [accept\(\)](#).

Parameters

<i>addr</i>	IP address to bind to: • Use INADDR_ANY (or IPADDR::AnyIP()) to accept connections on any IP address assigned to the specified interface • Use a specific IP address to accept only on that address (the IP must be assigned to the specified interface) • INADDR_ANY is the most common usage for interface-specific servers
<i>port</i>	Port number to listen on (1-65535). The port must not already be in use on any interface
<i>ifn</i>	Network interface number (0, 1, 2, etc.) to bind to. This forces the listening socket to accept connections only through this specific interface, regardless of routing table or IP address configuration. Valid range is 0 to (number of interfaces - 1). Use GetNumberOfInterfaces() to determine valid range
<i>maxpend</i>	Maximum number of pending connections in the accept queue (default: 5). This is the maximum number of clients that can be waiting simultaneously. When this limit is reached, additional connection attempts will be refused

Returns

Positive file descriptor on success (use with [accept\(\)](#) to get client connections), negative [TCP Socket Status](#) error code on failure:

- TCP_ERR_NONE_AVAIL: No available sockets in system pool
- TCP_ERR_NOCON: Port already in use or binding failed

Notes

- The listening socket uses one socket from the system pool. Each accepted connection uses an additional socket.
- Interface numbers typically start at 0 and increment sequentially. Interface 0 is usually the primary Ethernet port, but this can vary by platform.
- If you specify an invalid interface number (negative or $\geq$ number of interfaces), the behavior is undefined. Always validate with GetNumberOfInterfaces() first.
- The specified interface must be in an "up" state with a valid IP address assigned for connections to be accepted successfully.
- Always call [close\(\)](#) on the listening socket when shutting down to free the socket resource and release the port.

- This function provides the most direct interface control for server applications. For interface selection by IP address, see the other [listenvia\(\)](#) overload.

Warning

Specifying an invalid interface number may cause the listen to fail or bind to an unexpected interface. Always validate interface numbers before use.

The port is global across all interfaces - you cannot listen on the same port on multiple interfaces simultaneously. Each port can only have one listener.

14.53.14.25 NoBlockConnect()

```
int NoBlockConnect (
    const IPADDR & ipAddress,
    uint16_t remotePort) [inline]
#include <tcp.h>
```

Initiate a non-blocking TCP connection.

Creates a TCP socket and initiates a connection to the remote host, returning immediately without waiting for the connection to complete. The application must poll the socket state using [TcpGetSocketState\(\)](#) to determine when the connection is established (TCP_STATE_ESTABLISHED). The connection status can also be checked using [writeavail\(\)](#).

Parameters

<i>ipAddress</i>	IP address of the remote host
<i>remotePort</i>	Port number on the remote host

Returns

Positive file descriptor on success, negative [TCP Socket Status](#) error code on failure

Notes:

- This function returns immediately and does not block waiting for the connection to establish. The socket will be in a connecting state, and the application must poll its state to determine when it becomes ready for data transfer.
- The system will automatically select the local interface and port for the connection. Use [NoBlockConnectVia\(\)](#) if you need control over which interface is used.

Warning

Always call [close\(\)](#) to free system resources, even if the socket enters the TCP_STATE_CLOSING state. Failure to close will cause a resource leak.

    }
}

close(fd);
}

```

14.53.14.26 NoBlockConnectVia() [1/2]

```

int NoBlockConnectVia (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    const IPADDR & interfaceIpAddress = IPADDR::NullIP()) [inline]
#include <tcp.h>

```

Initiate a non-blocking TCP connection via a specific interface.

Creates a TCP socket and initiates a connection to the remote host using the specified local interface IP address. The function returns immediately without waiting for the connection to complete. The application must poll the socket state using [TcpGetSocketState\(\)](#) to determine when the connection is established (TCP_STATE_ESTABLISHED).

Warning

Always call [close\(\)](#) to free system resources, even if the socket enters the TCP_STATE_CLOSING state. Failure to close will cause a resource leak.

Parameters

<i>ipAddress</i>	IP address of the remote host
<i>remotePort</i>	Port number on the remote host
<i>interfaceIpAddress</i>	IP address of the local interface to use (default: IPADDR::NullIP() for automatic selection based on routing)

Returns

Positive file descriptor on success, negative [TCP Socket Status](#) error code on failure

See also

[NoBlockConnect\(\)](#), [TcpGetSocketState\(\)](#), [writeavail\(\)](#), [connect\(\)](#), [connectvia\(\)](#), [connectwlocal\(\)](#)

14.53.14.27 NoBlockConnectVia() [2/2]

```

int NoBlockConnectVia (
    const IPADDR & ipAddress,
    uint16_t remotePort,
    int ifnum) [inline]
#include <tcp.h>

```

Initiate a non-blocking TCP connection via a specific interface number.

Creates a TCP socket and initiates a connection to the remote host using the specified local interface number. The function returns immediately without waiting for the connection to complete. The interface number overrides routing decisions based on destination IP address. The application must poll the socket state using [TcpGetSocketState\(\)](#) to determine when the connection is established (TCP_STATE_ESTABLISHED).

Parameters

<i>ipAddress</i>	IP address of the remote host
<i>remotePort</i>	Port number on the remote host
<i>ifnum</i>	Network interface number to use. Overrides all routing decisions

Returns

Positive file descriptor on success, negative [TCP Socket Status](#) error code on failure

Notes:

- This function is useful when you have multiple network interfaces (e.g., Ethernet and WiFi) and need to force the connection through a specific interface regardless of routing tables.
- Interface numbers are zero-based. Use [GetNumInterfaces\(\)](#) to determine the total number of available interfaces and [GetIPAddress\(ifnum\)](#) to verify the interface has a valid IP.

Warning

- Always call [close\(\)](#) to free system resources, even if the socket enters the TCP_STATE_CLOSING state. Failure to close will cause a resource leak.
- If the specified interface is not active or does not have a valid IP address, the connection will fail. Always validate the interface before use.

14.53.14.28 NoBlockConnectwlocal()

```

int NoBlockConnectwlocal (
    const IPADDR & ipAddress,
    uint16_t localPort,
    uint16_t remotePort,
    IPADDR interfaceIpAddress = IPADDR::NullIP(),
    int ifn = -1) [inline]

```

#include <tcp.h>

Initiate a non-blocking TCP connection with full local parameter control.

Creates a TCP socket with complete control over connection parameters and initiates a connection to the remote host. The function returns immediately without waiting for the connection to complete. The application must poll the socket state using [TcpGetSocketState\(\)](#) to determine when the connection is established (TCP_STATE_↵ESTABLISHED).

Parameters

<i>ipAddress</i>	IP address of the remote host

Parameters

<i>localPort</i>	Local port number to bind (recommend 0 for automatic assignment). Warning: Non-zero values can cause connection failures with half-open sockets on the remote side
<i>remotePort</i>	Port number on the remote host
<i>interfaceIpAddress</i>	IP address of local interface (use <code>IPADDR::NullIP()</code> if using <i>ifn</i>)
<i>ifn</i>	Network interface number (use -1 if using <i>interfaceIpAddress</i>)

Returns

Positive file descriptor on success, negative [TCP Socket Status](#) error code on failure

Notes: This function provides the most control over connection parameters but is rarely needed. For most applications, use [NoBlockConnect\(\)](#) or [NoBlockConnectVia\(\)](#) instead.

- You can specify the interface either by IP address (*interfaceIpAddress*) or by interface number (*ifn*), but not both. If both are specified, the interface number takes precedence.

Warning

- Always call [close\(\)](#) to free system resources, even if the socket enters the `TCP_STATE_CLOSING` state. Failure to close will cause a resource leak.
- Specifying a local port number is not recommended. Using a fixed local port can cause connection failures when the remote host has a half-open socket remaining from a previous connection. Always use 0 for automatic port assignment unless you have a specific protocol requirement.

Expand for Example Usage

Examples

Basic Usage - Let System Assign Local Port (Recommended)

```
#include <tcp.h>
#include <netinterface.h>
#include <nbrtos.h>

void RecommendedUsageTask(void *pd)
{
    IPADDR serverIp = AsciiToIp("192.168.1.100");
    uint16_t remotePort = 8080;

    // Get local interface IP
    IPADDR localIp = GetIPAddress(0);

    // Connect with automatic local port assignment (recommended)
    // localPort = 0 means system will choose an available ephemeral port
    int fd = NoBlockConnectwlocal(serverIp, 0, remotePort, localIp);

    if (fd < 0)
    {
        printf("Connection initiation failed: %d\r\n", fd);
        return;
    }

    printf("Connecting to %I:%d from %I:<auto>\r\n",
        serverIp, remotePort, localIp);

    // Wait for connection to establish
    uint32_t startTime = Secs;
    bool connected = false;

    while ((Secs - startTime) < 10)
    {
        TcpState state = TcpGetSocketState(fd);

        if (state == TCP_STATE_ESTABLISHED)
        {
            connected = true;
            printf("Connection established!\r\n");
            break;
        }
    }
}
```

```

    }
    else if (state == TCP_STATE_CLOSED || state == TCP_STATE_CLOSING)
    {
        printf("Connection failed (state: %d)\r\n", state);
        break;
    }

    OSTimeDly(TICKS_PER_SECOND / 10);
}

if (connected)
{
    const char *message = "Hello, Server!\r\n";
    write(fd, message, strlen(message));
}

close(fd);
}

```

Using Interface Number Instead of IP Address

```

#include <tcp.h>
#include <netinterface.h>
#include <nbrtos.h>

void ConnectViaInterfaceNumberTask(void *pd)
{
    IPADDR serverIp = AsciiToIp("192.168.1.100");
    uint16_t remotePort = 8080;
    const int ETHERNET_IF = 0;

    // Verify interface exists
    if (ETHERNET_IF >= GetNumInterfaces())
    {
        printf("Interface %d does not exist\r\n", ETHERNET_IF);
        return;
    }

    // Connect using interface number instead of IP address
    // Pass IPADDR::NullIP() for interfaceIpAddress when using ifn
    int fd = NoBlockConnectwlocal(serverIp, 0, remotePort,
                                  IPADDR::NullIP(), ETHERNET_IF);

    if (fd < 0)
    {
        printf("Connection initiation failed: %d\r\n", fd);
        return;
    }

    IPADDR localIp = GetIPAddress(ETHERNET_IF);
    printf("Connecting to %I:%d via interface %d (%I)\r\n",
           serverIp, remotePort, ETHERNET_IF, localIp);

    // Wait for connection
    uint32_t startTime = Secs;
    while ((Secs - startTime) < 10)
    {
        TcpState state = TcpGetSocketState(fd);

        if (state == TCP_STATE_ESTABLISHED)
        {
            printf("Connected via interface %d!\r\n", ETHERNET_IF);

            const char *msg = "Hello from specific interface!\r\n";
            write(fd, msg, strlen(msg));
            break;
        }
        else if (state == TCP_STATE_CLOSED || state == TCP_STATE_CLOSING)
        {
            printf("Connection failed\r\n");
            break;
        }

        OSTimeDly(TICKS_PER_SECOND / 10);
    }

    close(fd);
}

```

Fixed Local Port (Not Recommended - Shows Potential Issues)

```

#include <tcp.h>
#include <netinterface.h>
#include <nbrtos.h>

void FixedLocalPortExample(void *pd)

}

```

Protocol Requiring Specific Local Port (Rare Use Case)

```

#include <tcp.h>
#include <netinterface.h>
#include <nbrtos.h>

// Example: Some legacy protocols require client to use specific port
void LegacyProtocolClient(void *pd)
{
    IPADDR serverIp = AsciiToIp("192.168.1.100");
    uint16_t remotePort = 8080;
    uint16_t requiredLocalPort = 6000; // Protocol requirement

    IPADDR localIp = GetIPAddress(0);

    printf("Legacy protocol requires local port %d\r\n", requiredLocalPort);

    // First, ensure port is not already in use

```

```

// In production, implement proper port cleanup and retry logic

int fd = NoBlockConnectwlocal(serverIp, requiredLocalPort, remotePort, localIp);

if (fd < 0)
{
    if (fd == TCP_ERR_PORT_IN_USE)
    {
        printf("Required port %d is in use. Wait for TIME_WAIT...\r\n",
            requiredLocalPort);

        // In real application, you might:
        // 1. Wait for TIME_WAIT to expire (typically 2*MSL = 240s)
        // 2. Use SO_REUSEADDR if available
        // 3. Inform user of the conflict
        return;
    }
    else
    {
        printf("Connection failed: %d\r\n", fd);
        return;
    }
}

printf("Initiated connection from %I:%d to %I:%d\r\n",
    localIp, requiredLocalPort, serverIp, remotePort);

// Wait for connection with timeout
uint32_t startTime = Secs;
bool connected = false;

14.53.14.29 SetOutOfOrderBuffers()

```

uint8_t SetOutOfOrderBuffers (
    int fd,
    uint8_t max) [inline]
#include <tcp.h>

```

Configure the maximum number of out-of-order buffers for a TCP socket.

Sets the maximum number of out-of-order TCP receive buffers for the socket. TCP may receive packets out of sequence, which must be stored until earlier packets arrive to maintain correct data ordering. Each buffer is approximately 1500 bytes.

The default value is 5 buffers. The maximum is 43 buffers. Increasing this value can improve bulk data throughput on fast networks but may increase TCP latency if connection problems (such as resets) occur.

Parameters

<i>fd</i>	Socket file descriptor
<i>max</i>	Maximum number of out-of-order buffers (1-43, default: 5)

Returns

Status code: 0 on success, negative [TCP Socket Status](#) error code on failure

Notes:

- This setting should be configured before significant data transfer begins, ideally right after the connection is established.
- Higher values improve performance on high-bandwidth, high-latency networks where packet reordering is common, but consume more memory.
- Lower values reduce memory usage but may cause TCP to request retransmissions more frequently when packets arrive out of order.

Warning

Setting this value too high may waste system resources. Setting it too low may reduce throughput on networks with significant packet reordering.

}

```

14.53.14.30 SetSocketRxBuffers()

```

int SetSocketRxBuffers (
    int fd,
    int n)

```

#include <tcp.h>

Configure the number of TCP receive buffers.

Sets the maximum number of receive buffers allocated to the socket. Each buffer is approximately 1548 bytes. The available space in these buffers determines the TCP window size advertised to the remote host, which controls how much data they can send.

As data is read from the socket, buffer space is freed, allowing the remote host to send more data. Since the maximum TCP window size is 65536 bytes, increasing this value beyond 43 buffers (approximately 66KB) provides no additional benefit.

The system default is 5 buffers (defined in [constants.h](#)) to conserve network buffer resources. This default is sufficient for most applications unless transferring large amounts of bulk data.

Parameters

<i>fd</i>	Socket file descriptor
<i>n</i>	Number of receive buffers to allocate

Returns

Status code: [TCP Socket Status](#)

See also

[setsockopt\(\)](#), [getsockopt\(\)](#), [clrsockopt\(\)](#), [SetSocketUnackBuffers\(\)](#), [SetSocketTxBuffers\(\)](#)

Expand for Example Usage

Examples

Basic Usage - Setting Receive Buffers

```

int fd = socket(AF_INET, SOCK_STREAM, 0);
if (fd > 0) {
    // Allocate 10 receive buffers (~15KB window)
    int result = SetSocketRxBuffers(fd, 10);
    if (result == TCP_ERR_NONE) {
        printf("Receive buffers configured successfully\n");
    }
}

```

Maximum Window Size Configuration

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
if (fd > 0) {
    // Set to maximum useful value (43 buffers equals approx. 66KB)
    // Beyond this provides no benefit due to 64KB TCP window limit
    SetSocketRxBuffers(fd, 43);

    bind(fd, ...);
    listen(fd, 5);
}
```

Server Socket with Custom Receive Buffer

```
int listenFd = socket(AF_INET, SOCK_STREAM, 0);
SetSocketRxBuffers(listenFd, 20); // Configure before accepting connections

bind(listenFd, (struct sockaddr*)&addr, sizeof(addr));
listen(listenFd, 5);

int clientFd = accept(listenFd, NULL, NULL);
// clientFd inherits the buffer settings from listenFd
```

Memory-Constrained Application

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
if (fd > 0) {
    // Use minimal buffers to conserve memory
    SetSocketRxBuffers(fd, 3); // ~4.6KB receive window
}
```

14.53.14.31 SetSocketTxBuffers()

```
int SetSocketTxBuffers (
    int fd,
    int n)
#include <tcp.h>
```

Configure the number of TCP transmit buffers.

Sets the maximum number of buffers allocated to the transmit queue. Each buffer is approximately 1548 bytes. The transmit queue accumulates outgoing data up to this limit regardless of the current state of unacknowledged buffers or the remote host's window size. This value effectively sets the maximum size for a single [write\(\)](#) operation.

Note

Always check the return value of write functions to determine how many bytes were actually written to the transmit queue.

Parameters

<i>fd</i>	Socket file descriptor
<i>n</i>	Number of transmit buffers to allocate

Returns

Status code: [TCP Socket Status](#)

See also

[setsockopt\(\)](#), [getsockopt\(\)](#), [clrsockopt\(\)](#), [SetSocketRxBuffers\(\)](#), [SetSocketUnackBuffers\(\)](#), [write\(\)](#), [writeall\(\)](#)

Expand for Example Usage

Examples

Basic Usage - Setting Transmit Buffers

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
if (fd > 0) {
    // Allocate 15 transmit buffers (~23KB queue)
    int result = SetSocketTxBuffers(fd, 15);
    if (result == TCP_ERR_NONE) {
        printf("Transmit buffers configured successfully\n");
    }
}
```

Large Data Transfer Setup

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
if (fd > 0) {
    // Configure for sending large chunks of data
    SetSocketTxBuffers(fd, 30); // ~46KB transmit queue

    connect(fd, (struct sockaddr*)&serverAddr, sizeof(serverAddr));

    // Now we can write larger amounts in a single call
    char largeBuffer[40000];
    int bytesWritten = write(fd, largeBuffer, sizeof(largeBuffer));
    printf("Wrote %d bytes\n", bytesWritten);
}
```

Checking Write Return Values

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
SetSocketTxBuffers(fd, 10); // ~15KB transmit queue
connect(fd, ...);

char data[20000];
int bytesWritten = write(fd, data, sizeof(data));

if (bytesWritten < sizeof(data)) {
    printf("Warning: Only wrote %d of %d bytes\n",
           bytesWritten, sizeof(data));
    // Transmit queue is full, need to wait or use writeall()
}
```

Complete Socket Configuration

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
if (fd > 0) {
    // Configure all buffer settings for optimal performance
    SetSocketTxBuffers(fd, 20); // Transmit queue: ~31KB
    SetSocketRxBuffers(fd, 15); // Receive window: ~23KB
    SetSocketUnackBuffers(fd, 10); // Unacknowledged: 10 buffers

    // Socket is now ready for high-performance communication
    connect(fd, (struct sockaddr*)&addr, sizeof(addr));
}
```

14.53.14.32 SetSocketUnackBuffers()

```
int SetSocketUnackBuffers (
    int fd,
    uint8_t val) [inline]
#include <tcp.h>
```

Configure the maximum number of unacknowledged transmit buffers.

Sets the maximum number of TCP transmit buffers that can remain unacknowledged by the remote host. When data is sent, it moves from the transmit queue to the unacknowledged list. Buffers remain in this list until the remote host sends an acknowledgment (ACK), at which point they are freed. The actual number of unacknowledged buffers is also limited by the remote host's TCP window size.

Increasing this value can improve bulk data throughput on fast networks. However, on lossy networks without selective acknowledgment (SACK), higher values may reduce performance. Note: Most modern PCs support SACK, but many NAT routers do not.

Parameters

<i>fd</i>	Socket file descriptor
<i>val</i>	Maximum number of unacknowledged buffers

Returns

Status code: [TCP Socket Status](#)

See also

Expand for Example Usage**Examples****Basic Usage - Setting Unacknowledged Buffers**

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
if (fd > 0) {
    // Set to 10 unacknowledged buffers for better throughput
    int result = SetSocketUnackBuffers(fd, 10);
    if (result == TCP_ERR_NONE) {
        printf("Successfully configured unack buffers\n");
    }
}
```

Optimizing for High-Speed Bulk Transfer

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
if (fd > 0) {
    // Configure socket for high-throughput data transfer
    SetSocketTxBuffers(fd, 20);           // Large transmit queue
    SetSocketUnackBuffers(fd, 15);       // Allow more unacknowledged data

    // Now ready for bulk transfer
    connect(fd, ...);
    write(fd, largeDataBuffer, largeDataSize);
}
```

Conservative Setting for Lossy Networks

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
if (fd > 0) {
    // Lower value for networks with packet loss
    SetSocketUnackBuffers(fd, 3); // Conservative for lossy/NAT environments
}
```

14.53.14.33 setsockopt()

```
int setsockopt (
    int fd,
    int option)
```

```
#include <tcp.h>
```

Enable TCP socket options.

Sets one or more option flags for the specified socket. Socket options control various aspects of TCP behavior such as the Nagle algorithm and PUSH flag handling. Multiple options can be combined using bitwise OR.

Parameters

<i>fd</i>	Socket file descriptor
<i>option</i>	Socket option flags to enable: TCP Socket Options

Returns

Bitmask of all currently enabled options for the socket, or negative value on error

Notes:

- Common options include:
 - SO_NODELAY: Disable Nagle algorithm for low-latency transmission
 - SO_PUSH: Set TCP PUSH flag on transmitted data
 - SO_KEEPALIVE: Enable TCP keepalive probes

- Multiple options can be set simultaneously using bitwise OR: `setsockopt(fd, SO_NODELAY | SO_PUSH)` ;
- This function does not clear existing options - it only adds new ones. Use `clrsockopt()` to disable options.

Examples

Disable Nagle Algorithm for Low Latency

```
#include <tcp.h>
#include <nbrtos.h>

void LowLatencyClient(void *pd)
{
    IPADDR serverIp = AsciiToIp("192.168.1.100");
    uint16_t serverPort = 8080;

    int fd = connect(serverIp, serverPort, TICKS_PER_SECOND * 10);

    if (fd < 0)
    {
        printf("Connection failed: %d\r\n", fd);
        return;
    }

    // Disable Nagle algorithm for immediate transmission
    int result = setsockopt(fd, SO_NODELAY);

    if (result >= 0)
    {
        printf("SO_NODELAY enabled - options mask: 0x%X\r\n", result);
    }
    else
    {
        printf("Failed to set SO_NODELAY: %d\r\n", result);
    }

    // Send small messages that will be transmitted immediately
    const char *msg1 = "A";
    const char *msg2 = "B";
    const char *msg3 = "C";

    write(fd, msg1, 1); // Sent immediately (no Nagle delay)
    write(fd, msg2, 1); // Sent immediately
    write(fd, msg3, 1); // Sent immediately

    printf("Small messages sent without Nagle delay\r\n");

    close(fd);
}
```

Enable Multiple Options

```
#include <tcp.h>
#include <nbrtos.h>

void ConfigureOptimalSocket(void *pd)
{
    IPADDR serverIp = AsciiToIp("192.168.1.100");
    uint16_t serverPort = 8080;

    int fd = connect(serverIp, serverPort, TICKS_PER_SECOND * 10);

    if (fd < 0)
    {
        printf("Connection failed: %d\r\n", fd);
        return;
    }

    // Enable multiple options for optimal real-time performance
    int options = SO_NODELAY | SO_PUSH;
    int result = setsockopt(fd, options);

    if (result >= 0)
    {
        printf("Socket configured for low-latency:\r\n");
        printf("  SO_NODELAY: %s\r\n", (result & SO_NODELAY) ? "ON" : "OFF");
        printf("  SO_PUSH:    %s\r\n", (result & SO_PUSH) ? "ON" : "OFF");
    }
}
```

```

    else
    {
        printf("Failed to configure socket: %d\r\n", result);
    }

    // Send time-critical data
    const char *message = "Real-time control command\r\n";
    write(fd, message, strlen(message));

    close(fd);
}

```

Interactive Terminal Application

```

#include <tcp.h>
#include <nbrtos.h>

void InteractiveTerminal(void *pd)
{
    IPADDR serverIp = AsciiToIp("192.168.1.100");

```

Server-Side Socket Configuration

```

#include <tcp.h>
#include <nbrtos.h>

void ConfiguredServerTask(void *pd)
{
    const uint16_t SERVER_PORT = 8080;

    int listenFd = listen(INADDR_ANY, SERVER_PORT, 5);

    if (listenFd < 0)
    {
        printf("Failed to create listening socket: %d\r\n", listenFd);
        return;
    }

    printf("Server listening on port %d\r\n", SERVER_PORT);

    while (1)
    {
        IPADDR clientAddr;
        uint16_t clientPort;

        int clientFd = accept(listenFd, &clientAddr, &clientPort, 0);

        if (clientFd > 0)
        {
            printf("Client connected: %I:%d\r\n", clientAddr, clientPort);

            // Configure client socket for optimal performance
            int options = SO_NODELAY | SO_PUSH;
            int result = setsockopt(clientFd, options);

            if (result >= 0)
            {
                printf("Client socket configured: 0x%X\r\n", result);
            }

            // Handle client with optimized socket

```

```

char buffer[256];
int bytesRead = read(clientFd, buffer, sizeof(buffer) - 1,
                    Ticks_Per_Second * 5);

if (bytesRead > 0)
{
    buffer[bytesRead] = '\0';

    // Echo response will be sent immediately due to SO_NODELAY
    write(clientFd, buffer, bytesRead);
}

close(clientFd);
}

close(listenFd);
}

```

14.53.14.34 SocketPeek()

```

char SocketPeek (
    int fd)
#include <tcp.h>

```

Peek at the next available byte without removing it from the receive buffer.

Examines the next byte that would be read from the socket without actually removing it from the receive buffer. The byte remains available for subsequent read operations. If no data is available, returns 0.

Parameters

<i>fd</i>	Socket file descriptor

Returns

The next byte that would be read, or 0 if no data is available

See also

[read\(\)](#), [dataavail\(\)](#)

Expand for Example Usage

Examples

Basic Usage - Peeking at Next Byte

```

int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

char nextByte = SocketPeek(fd);
if (nextByte != 0) {
    printf("Next byte is: 0x%02X ('%c')\n", nextByte,
        isprint(nextByte) ? nextByte : '.');

    // Byte is still in buffer, can read it normally
    char actualByte;
    read(fd, &actualByte, 1);
    // actualByte == nextByte
}

```

Protocol Detection - Checking Message Type

```

int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

// Peek at message type without consuming it
char msgType = SocketPeek(fd);

if (msgType == 0x01) {
    HandleDataMessage(fd);
} else if (msgType == 0x02) {
    HandleControlMessage(fd);
} else if (msgType == 0x03) {
    HandleErrorMessage(fd);
} else if (msgType == 0) {
    printf("No data available\n");
} else {
    printf("Unknown message type: 0x%02X\n", msgType);
    abortsocket(fd);
}

```

Waiting for Specific Start Byte

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

const char START_MARKER = 0xAA;

// Wait for start marker
while (1) {
    char nextByte = SocketPeek(fd);

    if (nextByte == START_MARKER) {
        // Found start marker, now read the full message
        char buffer[256];
        int n = read(fd, buffer, sizeof(buffer));
        ProcessMessage(buffer, n);
        break;
    } else if (nextByte != 0) {
        // Discard unexpected byte
        char discard;
        read(fd, &discard, 1);
        printf("Discarded unexpected byte: 0x%02X\n", discard);
    } else {
        // No data yet, wait
        OSTimeDly(TICKS_PER_SECOND / 10);
    }
}
```

Non-Destructive Buffer Inspection

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

// Check if data looks like ASCII text or binary
char firstByte = SocketPeek(fd);

if (firstByte == 0) {
    printf("No data available\n");
} else if (isprint(firstByte) || firstByte == '\n' || firstByte == '\r') {
    printf("Data appears to be ASCII text\n");
    // Process as text
    char textBuffer[512];
    int n = read(fd, textBuffer, sizeof(textBuffer) - 1);
    textBuffer[n] = '\0';
    printf("Text: %s\n", textBuffer);
} else {
    printf("Data appears to be binary (first byte: 0x%02X)\n", firstByte);
    // Process as binary
    uint8_t binaryBuffer[512];
    int n = read(fd, binaryBuffer, sizeof(binaryBuffer));
    ProcessBinaryData(binaryBuffer, n);
}
```

Checking Data Availability Before Blocking Read

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

// Use peek to check if data is available before potentially blocking
if (SocketPeek(fd) != 0) {
    char buffer[256];
    int n = read(fd, buffer, sizeof(buffer));
    printf("Read %d bytes\n", n);
} else {
    printf("No data available, skipping read\n");
}
```

14.53.14.35 SockReadWithTimeout()

```
int SockReadWithTimeout (
    int fd,
    char * buf,
    int nbytes,
    uint32_t timeout)
```

#include <tcp.h>

Read from a TCP socket with a timeout.

Attempts to read data from a TCP socket, waiting up to the specified timeout period. The function returns when at least 1 byte of data becomes available or the timeout expires. The nbytes parameter specifies the maximum number

of bytes to read, but the actual number read may be less. Always check the return value to determine how many bytes were actually read.

Note

This function works with standard TCP sockets only; it does not work with TLS sockets.

Parameters

<i>fd</i>	Socket file descriptor
<i>buf</i>	Buffer to store received data
<i>nbytes</i>	Maximum number of bytes to read
<i>timeout</i>	Timeout duration in system ticks. Recommended usage: TICKS_PER_SECOND * n where n is the number of seconds. For example: TICKS_PER_SECOND * 5 for a 5 second timeout

Returns

Number of bytes read on success, negative [TCP Socket Status](#) error code on failure

See also

[ReadWithTimeout\(\)](#)

Expand for Example Usage

Examples

Basic Usage - Read with 5 Second Timeout

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

char buffer[256];
int bytesRead = SockReadWithTimeout(fd, buffer, sizeof(buffer), TICKS_PER_SECOND * 5);

if (bytesRead > 0) {
    printf("Received %d bytes: %.s\n", bytesRead, bytesRead, buffer);
} else if (bytesRead == TCP_ERR_TIMEOUT) {
    printf("Read timeout after 5 seconds\n");
} else {
    printf("Read error: %d\n", bytesRead);
}
```

Request-Response Pattern with Timeout

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

// Send request
const char *request = "GET /data HTTP/1.1\r\n\r\n";
write(fd, request, strlen(request));

// Wait up to 10 seconds for response
char response[1024];
int n = SockReadWithTimeout(fd, response, sizeof(response), TICKS_PER_SECOND * 10);

if (n > 0) {
    response[n] = '\0';
    printf("Server response: %s\n", response);
} else if (n == TCP_ERR_TIMEOUT) {
    printf("Server did not respond within 10 seconds\n");
    abortsocket(fd);
}
```

Multiple Read Attempts with Variable Timeout

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

char buffer[512];
int totalBytes = 0;
int attempts = 0;
const int maxAttempts = 3;

while (attempts < maxAttempts) {
    int n = SockReadWithTimeout(fd, buffer + totalBytes,
```

```

        sizeof(buffer) - totalBytes,
        TICKS_PER_SECOND * 2);

    if (n > 0) {
        totalBytes += n;
        printf("Attempt %d: read %d bytes (total: %d)\n",
            attempts + 1, n, totalBytes);
        break; // Success
    } else if (n == TCP_ERR_TIMEOUT) {
        attempts++;
        printf("Timeout on attempt %d\n", attempts);
    } else {
        printf("Read error: %d\n", n);
        break;
    }
}

if (attempts >= maxAttempts) {
    printf("Failed after %d attempts\n", maxAttempts);
}

```

Polling Loop with Short Timeout

```

int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

bool running = true;
char data[128];

while (running) {
    // Short timeout allows checking other conditions frequently
    int n = SocketReadWithTimeout(fd, data, sizeof(data), TICKS_PER_SECOND / 2);

    if (n > 0) {
        ProcessData(data, n);
    } else if (n == TCP_ERR_TIMEOUT) {
        // No data yet, check other conditions
        if (ShouldShutdown()) {
            running = false;
        }
    } else {
        printf("Socket error, exiting\n");
        running = false;
    }
}

```

14.53.14.36 TcpAllDataAcked()

```

BOOL TcpAllDataAcked (
    int socket)

```

```

#include <tcp.h>

```

Check if all transmitted data has been acknowledged.

Determines whether all data sent on this socket has been acknowledged by the remote host. This is useful for ensuring data has been successfully delivered before closing a connection or performing other operations.

Parameters

<i>socket</i>	Socket file descriptor

Return values

<i>TRUE</i>	All sent data has been acknowledged by the remote host
<i>FALSE</i>	Some data remains unacknowledged

See also

[WaitForSocketFlush\(\)](#)

14.53.14.37 TcpGetLastRxInterval()

```
uint32_t TcpGetLastRxInterval (
    int fd)
```

```
#include <tcp.h>
```

Get the time elapsed since the last received packet.

Calculates the number of system ticks that have elapsed between the current time and when the last packet was received on this socket. This is a convenience function that computes the difference between the current system time (TimeTick) and the socket's lastRxTime value.

Parameters

<i>fd</i>	Socket file descriptor

Returns

Number of system ticks since the last packet was received, or 0 if socket is invalid

Notes:

- This function handles one rollover of the system tick counter (approximately 6 years of uptime at typical tick rates) but not multiple rollovers. Given typical usage patterns and connection lifetimes, this limitation should not present problems in practice.
- The returned value is in system ticks. Use TICKS_PER_SECOND to convert to seconds: `uint32_t seconds = TcpGetLastRxInterval(fd) / TICKS_PER_SECOND;`
- This function is useful for detecting idle connections or implementing timeout logic without needing to manually track timestamps.

```

14.53.14.38 TcpGetLastRxTime()

```
uint32_t TcpGetLastRxTime (
    int fd)
```

```
#include <tcp.h>
```

Get the system tick count when the last packet was received.

Returns the timestamp (in system ticks) of the last received packet on this connection. Each TCP socket maintains a lastRxTime value that is updated whenever a packet arrives. This function is primarily used with [TcpSendKeepAlive\(\)](#) to implement TCP keepalive functionality and detect stale connections.

To detect a lost connection:

1. Record lastRxTime before sending a keepalive packet
2. Send the keepalive packet with [TcpSendKeepAlive\(\)](#)
3. Wait sufficient time for a response
4. Check if lastRxTime has changed
5. If unchanged, the remote host has not responded and the connection may be lost

Parameters

<i>fd</i>	Socket file descriptor

Returns

System tick count when the last packet was received, or 0 if socket is invalid

Notes:

- The returned value is in system ticks. Use TICKS_PER_SECOND to convert to seconds.
- This timestamp is updated on any received packet, including ACKs, data packets, and keepalive responses.

Warning

Do not call this function more frequently than once per second to avoid unnecessary overhead.

14.53.14.39 TcpGetRxBufferSpaceUsed()

```
uint16_t TcpGetRxBufferSpaceUsed (
    int fd)
```

```
#include <tcp.h>
```

Get the number of bytes currently in the receive buffer.

Returns the amount of received data waiting to be read from the socket's receive buffer.

Parameters

<i>fd</i>	Socket file descriptor

Returns

Number of bytes available to read

See also

[TcpGetTxBufferAvailSpace\(\)](#), [TcpGetTxDataWaiting\(\)](#)

14.53.14.40 TcpGetSocketInterface()

```
int TcpGetSocketInterface (
    int fd)
```

```
#include <tcp.h>
```

Get the network interface number associated with a TCP socket.

Retrieves the network interface number being used by an established TCP connection.

Note

The return value is undefined for listening sockets.

Parameters

<i>fd</i>	Socket file descriptor

Returns

Network interface number

Expand for Example Usage

Examples

Basic Usage - Getting Socket Interface

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

int ifNum = TcpGetSocketInterface(fd);
printf("Socket is using interface number: %d\n", ifNum);

close(fd);
```

Multi-Interface System - Identifying Active Interface

```
int fd = socket(AF_INET, SOCK_STREAM, 0);

struct sockaddr_in serverAddr;
serverAddr.sin_family = AF_INET;
serverAddr.sin_port = htons(8080);
serverAddr.sin_addr.s_addr = inet_addr("192.168.1.100");

if (connect(fd, (struct sockaddr*)&serverAddr, sizeof(serverAddr)) == 0) {
    int ifNum = TcpGetSocketInterface(fd);
    InterfaceBlock *pIfBlock = GetInterfaceBlock(ifNum);

    if (pIfBlock != NULL) {
        printf("Connected via interface %d\n", ifNum);
        printf("Interface IP: %I\n", pIfBlock->ip4.cur_addr.i4);
        printf("Interface name: %s\n", pIfBlock->GetInterfaceName());
    }
}

close(fd);
```

Routing Verification - Check Expected Interface

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
connect(fd, (struct sockaddr*)&addr, sizeof(addr));

int actualInterface = TcpGetSocketInterface(fd);
int expectedInterface = 0; // Expected to use eth0

if (actualInterface == expectedInterface) {
    printf("Connection using correct interface\n");
} else {
    printf("Warning: Using interface %d, expected %d\n",
        actualInterface, expectedInterface);
}

close(fd);
```

Server Connection Logging

```
void HandleClient(int clientFd) {
    int ifNum = TcpGetSocketInterface(clientFd);
    InterfaceBlock *pIfBlock = GetInterfaceBlock(ifNum);

    struct sockaddr_in clientAddr;
    socklen_t addrLen = sizeof(clientAddr);
    getpeername(clientFd, (struct sockaddr*)&clientAddr, &addrLen);

    printf("Client %I connected via interface %d (%s)\n",
        clientAddr.sin_addr.s_addr,
        ifNum,
        pIfBlock ? pIfBlock->GetInterfaceName() : "unknown");

    // Process client request...

    close(clientFd);
}
```

Load Balancing - Track Interface Usage

```
struct InterfaceStats {
    int connectionCount;
    uint32_t bytesTransferred;
};

InterfaceStats ifStats[2] = {0}; // Track 2 interfaces

void TrackConnection(int fd, int bytesTransferred) {
    int ifNum = TcpGetSocketInterface(fd);

    if (ifNum >= 0 && ifNum < 2) {
        ifStats[ifNum].connectionCount++;
        ifStats[ifNum].bytesTransferred += bytesTransferred;

        printf("Interface %d stats: %d connections, %lu bytes\n",
            ifNum,
            ifStats[ifNum].connectionCount,
            ifStats[ifNum].bytesTransferred);
    }
}
```

Failover Detection

```
int fd = socket(AF_INET, SOCK_STREAM, 0);
int primaryInterface = 0;

connect(fd, (struct sockaddr*)&addr, sizeof(addr));

int activeInterface = TcpGetSocketInterface(fd);

if (activeInterface != primaryInterface) {
    printf("WARNING: Connection failed over to backup interface %d\n",
        activeInterface);
    // Log failover event
    LogFailoverEvent(primaryInterface, activeInterface);
} else {
    printf("Connection established on primary interface %d\n",
        primaryInterface);
}
```

Diagnostic Output for All Connections

```
void DiagnoseConnections(int *fdArray, int fdCount) {
    printf("\n=== Connection Diagnostics ===\n");

    for (int i = 0; i < fdCount; i++) {
        int fd = fdArray[i];
        int ifNum = TcpGetSocketInterface(fd);

        struct sockaddr_in peerAddr;
        socklen_t addrLen = sizeof(peerAddr);
        getpeername(fd, (struct sockaddr*)&peerAddr, &addrLen);

        printf("FD %d: Peer %I via interface %d\n",
            fd, peerAddr.sin_addr.s_addr, ifNum);
    }

    printf("=====\n\n");
}
```

14.53.14.41 TcpGetSocketState()

```
uint8_t TcpGetSocketState (  
    int fd)
```

```
#include <tcp.h>
```

Get the current TCP state of a socket.

Queries the current state of a TCP socket connection. The returned value corresponds to one of the states in the TCP state machine as defined in RFC 793.

Parameters

<i>fd</i>	Socket file descriptor

Returns

Current socket state: [TCP Socket State](#)

14.53.14.42 TcpGetTxBufferAvailSpace()

```
uint16_t TcpGetTxBufferAvailSpace (  
    int fd)
```

```
#include <tcp.h>
```

Get the available space in the transmit buffer.

Returns the number of bytes that can be written to the socket's transmit buffer before it becomes full.

Parameters

<i>fd</i>	Socket file descriptor

Returns

Number of bytes available for writing

See also

[TcpGetRxBufferSpaceUsed\(\)](#), [TcpGetTxDataWaiting\(\)](#)

14.53.14.43 TcpGetTxDataWaiting()

```
uint16_t TcpGetTxDataWaiting (  
    int fd)
```

```
#include <tcp.h>
```

Get the number of bytes queued for transmission.

Returns the number of bytes currently in the transmit buffer waiting to be sent to the remote host. This includes both data that has not yet been transmitted and data that has been transmitted but not yet acknowledged.

Parameters

<i>fd</i>	Socket file descriptor

Returns

Number of bytes queued for transmission

See also

[TcpGetTxBufferAvailSpace\(\)](#), [TcpGetRxBufferSpaceUsed\(\)](#)

14.53.14.44 TcpSendKeepAlive()

```
void TcpSendKeepAlive (
    int fd)
```

```
#include <tcp.h>
```

Send a TCP keepalive probe packet.

Transmits a TCP keepalive packet to the remote host to verify the connection is still active. The keepalive packet is an empty segment with a sequence number one less than the last sent packet. If the remote host is still connected, it will respond with a TCP ACK packet, which will update the socket's lastRxTime.

This function is used with [TcpGetLastRxTime\(\)](#) to implement TCP keepalive functionality and detect stale or dead connections.

Parameters

<i>fd</i>	Socket file descriptor

Notes:

- The keepalive probe does not contain any data - it's purely a mechanism to elicit an ACK response from the remote host.
- If the remote host is unreachable or the connection is dead, no response will be received and the lastRxTime will not change.
- This is a lightweight operation that generates minimal network traffic (typically just the TCP header with no payload).

Examples

Basic Keepalive Usage

```
#include <tcp.h>
#include <nbrtos.h>

void SimpleKeepaliveExample(void *pd)
{
    IPADDR serverIp = AsciiToIp("192.168.1.100");
    uint16_t serverPort = 8080;

    int fd = connect(serverIp, serverPort, TICKS_PER_SECOND * 10);

    if (fd < 0)
    {
        printf("Connection failed: %d\r\n", fd);
        return;
    }

    printf("Connected - sending keepalive every 30 seconds\r\n");

    while (1)
    {
        // Wait 30 seconds
        OSTimeDly(TICKS_PER_SECOND * 30);

        // Send keepalive
        TcpSendKeepAlive(fd);
        printf("Keepalive sent at %lu seconds\r\n", Secs);

        // Check if connection is still valid
        TcpState state = TcpGetSocketState(fd);
        if (state != TCP_STATE_ESTABLISHED)
        {
            printf("Connection lost (state: %d)\r\n", state);
            break;
        }
    }

    close(fd);
}
```

Keepalive with Response Verification

```
#include <tcp.h>
#include <nbrtos.h>

void VerifiedKeepaliveExample(void *pd)
{
    IPADDR serverIp = AsciiToIp("192.168.1.100");
    uint16_t serverPort = 8080;

    int fd = connect(serverIp, serverPort, TICKS_PER_SECOND * 10);

    if (fd < 0)
    {
        printf("Connection failed: %d\r\n", fd);
        return;
    }

    printf("Connected - monitoring with keepalives\r\n");

    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND * 30);

        // Get RX time before keepalive
        uint32_t rxBefore = TcpGetLastRxTime(fd);

        // Send keepalive
        TcpSendKeepAlive(fd);
        printf("Keepalive sent, waiting for ACK...\r\n");

        // Wait for response (typically very quick)
        OSTimeDly(TICKS_PER_SECOND * 3);

        // Check if we got a response
        uint32_t rxAfter = TcpGetLastRxTime(fd);

        if (rxAfter != rxBefore)
        {
            uint32_t responseTimeMs = ((rxAfter - rxBefore) * 1000) / TICKS_PER_SECOND;
            printf("Keepalive ACK received (RTT: %lu ms)\r\n", responseTimeMs);
        }
        else
        {
            printf("WARNING: No response to keepalive!\r\n");

            // Retry once more
            rxBefore = TcpGetLastRxTime(fd);
            TcpSendKeepAlive(fd);
            OSTimeDly(TICKS_PER_SECOND * 5);
            rxAfter = TcpGetLastRxTime(fd);

            if (rxAfter == rxBefore)
            {
                printf("Connection dead - no response to keepalive retry\r\n");
                break;
            }
        }
    }

    close(fd);
}
```

Multiple Connections with Coordinated Keepalives

```
#include <tcp.h>
#include <nbrtos.h>

#define MAX_CONNECTIONS 5

struct ManagedConnection
{
    int fd;
    IPADDR serverIp;
    uint32_t lastKeepaliveTime;
    bool alive;
};

        }
    }
}

```

14.53.14.45 WaitForSocketFlush()

```

BOOL WaitForSocketFlush (
    int fd,
    uint32_t ticks)

```

```
#include <tcp.h>
```

Wait for all transmitted data to be acknowledged.

Blocks until all data sent on the socket has been acknowledged by the remote host or until the specified timeout expires. A socket is considered "flushed" when all transmitted data has been acknowledged.

Parameters

<i>fd</i>	Socket file descriptor
<i>ticks</i>	Maximum wait time in system ticks

Return values

<i>TRUE</i>	All sent data has been acknowledged
<i>FALSE</i>	Timeout occurred before all data was acknowledged

14.53.15 TCP Notification System

Advanced callback mechanism for asynchronous TCP socket event notification.

Typedefs

- typedef void [tcp_notify_handler](#)(int tcpFd)
TCP notification callback function type.

Functions

- void [RegisterTCPReadNotify](#) (int tcpFd, [tcp_notify_handler](#) *notifyHandler)
Register a callback for read event notifications.
- void [RegisterTCPWriteNotify](#) (int tcpFd, [tcp_notify_handler](#) *notifyHandler)
Register a callback for write event notifications.

14.53.15.1 Detailed Description

Advanced callback mechanism for asynchronous TCP socket event notification.

```
#include< tcp.h>
```

The TCP notification system provides an event-driven approach to handling TCP socket activity. Instead of polling sockets for read/write availability, applications can register callback functions that are automatically invoked when:

- Data arrives and is ready to be read (read notification)
- Buffer space becomes available for writing (write notification)

Callback functions have full access to normal TCP socket operations and can perform any standard read/write operations during notification handling.

14.53.15.2 Typedef Documentation

14.53.15.2.1 tcp_notify_handler

```
typedef void tcp_notify_handler(int tcpFd)
#include <tcp.h>
```

TCP notification callback function type.

Applications implement callback functions of this type to handle TCP socket notifications. The callback is invoked from the TCP stack when the registered event occurs (data available for reading or buffer space available for writing).

Parameters

<i>tcpFd</i>	File descriptor of the socket that triggered the notification

Examples

Basic Read Callback Implementation

```
void MyReadHandler(int tcpFd) {
    char buffer[256];
    int bytesRead = read(tcpFd, buffer, sizeof(buffer));

    if (bytesRead > 0) {
        printf("Received %d bytes via callback\n", bytesRead);
        buffer[bytesRead] = '\0';
        printf("Data: %s\n", buffer);
    }
}
```

Basic Write Callback Implementation

```
void MyWriteHandler(int tcpFd) {
    const char *data = "Response from write callback\n";
    int bytesWritten = write(tcpFd, data, strlen(data));

    if (bytesWritten > 0) {
        printf("Wrote %d bytes via callback\n", bytesWritten);
    }
}
```

State Machine Callback

```
enum ConnectionState { WAITING_HEADER, WAITING_DATA, PROCESSING };

struct ClientContext {
    ConnectionState state;
    int expectedBytes;
    char buffer[1024];
    int bufferPos;
};

ClientContext contexts[10]; // Support up to 10 clients

void StateMachineHandler(int tcpFd) {
    ClientContext *ctx = &contexts[tcpFd % 10];

    switch (ctx->state) {
        case WAITING_HEADER:
            if (dataavail(tcpFd) >= 4) {
                read(tcpFd, &ctx->expectedBytes, 4);
                ctx->state = WAITING_DATA;
                ctx->bufferPos = 0;
            }
            break;

        case WAITING_DATA:
            int available = dataavail(tcpFd);
            int toRead = (ctx->expectedBytes - ctx->bufferPos);
            if (toRead > available) toRead = available;

            int n = read(tcpFd, ctx->buffer + ctx->bufferPos, toRead);
            ctx->bufferPos += n;

            if (ctx->bufferPos >= ctx->expectedBytes) {
                ctx->state = PROCESSING;
                ProcessData(ctx->buffer, ctx->expectedBytes);
                ctx->state = WAITING_HEADER;
            }
            break;
    }
}
```

Multiple Socket Handler with Context

```

struct SocketData {
    int fd;
    char name[32];
    uint32_t bytesReceived;
};

SocketData socketContexts[5];

void UniversalReadHandler(int tcpFd) {
    // Find context for this socket
    SocketData *ctx = NULL;
    for (int i = 0; i < 5; i++) {
        if (socketContexts[i].fd == tcpFd) {
            ctx = &socketContexts[i];
            break;
        }
    }

    if (ctx != NULL) {
        char buffer[128];
        int n = read(tcpFd, buffer, sizeof(buffer));
        ctx->bytesReceived += n;

        printf("[%s] Received %d bytes (total: %lu)\n",
            ctx->name, n, ctx->bytesReceived);
    }
}

```

14.53.15.3 Function Documentation

14.53.15.3.1 RegisterTCPReadNotify()

```

void RegisterTCPReadNotify (
    int tcpFd,
    tcp_notify_handler * notifyHandler)

```

#include <tcp.h>

Register a callback for read event notifications.

Registers a callback function to be invoked whenever data becomes available for reading on the specified TCP socket. The callback is called automatically by the TCP stack when new data arrives.

Parameters

<i>tcpFd</i>	File descriptor of the socket to monitor
<i>notifyHandler</i>	Pointer to the callback function

Examples

Basic Registration - Echo Server

```

void EchoHandler(int tcpFd) {
    char buffer[256];
    int n = read(tcpFd, buffer, sizeof(buffer));
    if (n > 0) {
        write(tcpFd, buffer, n); // Echo back
    }
}

void UserMain(void *pd) {
    init();

    int listenFd = socket(AF_INET, SOCK_STREAM, 0);
    // ... bind and listen ...

    int clientFd = accept(listenFd, NULL, NULL);

    // Register read notification
    RegisterTCPReadNotify(clientFd, EchoHandler);

    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

```
    }
}
```

Multiple Client Handler

```
void ClientReadHandler(int tcpFd) {
    char buffer[512];
    int n = read(tcpFd, buffer, sizeof(buffer));

    if (n > 0) {
        buffer[n] = '\0';
        printf("Client FD %d: %s\n", tcpFd, buffer);
        ProcessCommand(tcpFd, buffer);
    } else if (n < 0) {
        printf("Client FD %d disconnected\n", tcpFd);
        close(tcpFd);
    }
}

void ServerTask(void *pd) {
    int listenFd = socket(AF_INET, SOCK_STREAM, 0);
    // ... bind and listen ...

    while (1) {
        int clientFd = accept(listenFd, NULL, NULL);
        if (clientFd > 0) {
            printf("New client connected, FD: %d\n", clientFd);
            RegisterTCPReadNotify(clientFd, ClientReadHandler);
        }
        OSTimeDly(TICKS_PER_SECOND / 10);
    }
}
```

Event-Driven HTTP Server

```
void HttpReadHandler(int tcpFd) {
    static char requestBuffer[2048];
    static int bufferPos = 0;

    int n = read(tcpFd, requestBuffer + bufferPos,
        sizeof(requestBuffer) - bufferPos - 1);

    if (n > 0) {
        bufferPos += n;
        requestBuffer[bufferPos] = '\0';

        // Check for end of HTTP headers
        if (strstr(requestBuffer, "\r\n\r\n") != NULL) {
            ProcessHttpRequest(tcpFd, requestBuffer);
            bufferPos = 0; // Reset for next request
        }
    }
}

void StartEventDrivenHttpServer() {
    int listenFd = socket(AF_INET, SOCK_STREAM, 0);
    // ... bind to port 80 and listen ...

    while (1) {
        int clientFd = accept(listenFd, NULL, NULL);
        if (clientFd > 0) {
            RegisterTCPReadNotify(clientFd, HttpReadHandler);
        }
    }
}
```

Removing Notification (Unregister)

```
void TemporaryReadHandler(int tcpFd) {
    char buffer[128];
    int n = read(tcpFd, buffer, sizeof(buffer));

    if (n > 0) {
        printf("Received: %.*s\n", n, buffer);

        // Unregister after first read
        RegisterTCPReadNotify(tcpFd, NULL);
        printf("Read notification removed\n");
    }
}

void UserMain(void *pd) {
    init();
    int fd = socket(AF_INET, SOCK_STREAM, 0);
    connect(fd, ...);
}
```

```

    RegisterTCPReadNotify(fd, TemporaryReadHandler);

    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

Protocol Parser with Notification

```

#define PROTO_START_BYTE 0xAA
#define PROTO_END_BYTE 0x55

void ProtocolReadHandler(int tcpFd) {
    static char msgBuffer[256];
    static int msgPos = 0;
    static bool inMessage = false;

    while (dataavail(tcpFd) > 0) {
        char byte;
        read(tcpFd, &byte, 1);

        if (byte == PROTO_START_BYTE) {
            inMessage = true;
            msgPos = 0;
        } else if (byte == PROTO_END_BYTE && inMessage) {
            ProcessProtocolMessage(msgBuffer, msgPos);
            inMessage = false;
            msgPos = 0;
        } else if (inMessage) {
            if (msgPos < sizeof(msgBuffer)) {
                msgBuffer[msgPos++] = byte;
            }
        }
    }
}

```

14.53.15.3.2 RegisterTCPWriteNotify()

```

void RegisterTCPWriteNotify (
    int tcpFd,
    tcp_notify_handler * notifyHandler)

```

#include <tcp.h>

Register a callback for write event notifications.

Registers a callback function to be invoked whenever buffer space becomes available for writing on the specified TCP socket. The callback is called automatically by the TCP stack when the transmit buffer has space available.

Parameters

<i>tcpFd</i>	File descriptor of the socket to monitor
<i>notifyHandler</i>	Pointer to the callback function

Examples

Basic Write Notification - Queued Data Transfer

```

struct DataQueue {
    char buffer[4096];
    int size;
    int sent;
} dataQueue;

void WriteNotifyHandler(int tcpFd) {
    if (dataQueue.sent < dataQueue.size) {
        int remaining = dataQueue.size - dataQueue.sent;
        int n = write(tcpFd, dataQueue.buffer + dataQueue.sent, remaining);

        if (n > 0) {
            dataQueue.sent += n;
            printf("Sent %d bytes, %d remaining\n", n,
                dataQueue.size - dataQueue.sent);
        }
    }
}

```

```

        if (dataQueue.sent >= dataQueue.size) {
            // All data sent, unregister
            RegisterTCPWriteNotify(tcpFd, NULL);
            printf("Transfer complete\n");
        }
    }
}

void QueueDataForSend(int fd, const char *data, int len) {
    memcpy(dataQueue.buffer, data, len);
    dataQueue.size = len;
    dataQueue.sent = 0;

    RegisterTCPWriteNotify(fd, WriteNotifyHandler);
}

```

Large File Transfer with Write Notifications

```

struct FileTransfer {
    int fd;
    FILE *file;
    uint32_t totalBytes;
    uint32_t sentBytes;
};

FileTransfer transfer;

void FileWriteHandler(int tcpFd) {
    char buffer[1024];
    size_t bytesRead = fread(buffer, 1, sizeof(buffer), transfer.file);

    if (bytesRead > 0) {
        int n = write(tcpFd, buffer, bytesRead);
        if (n > 0) {
            transfer.sentBytes += n;
            printf("Progress: %lu / %lu bytes (%.1f%%)\n",
                transfer.sentBytes, transfer.totalBytes,
                (float)transfer.sentBytes / transfer.totalBytes * 100);
        }
    }

    if (feof(transfer.file)) {
        fclose(transfer.file);
        RegisterTCPWriteNotify(tcpFd, NULL);
        printf("File transfer complete\n");
    }
}

        transfer.fd = tcpFd;

        RegisterTCPWriteNotify(tcpFd, FileWriteHandler);
    }
}

```

Periodic Data Streaming

```

struct StreamContext {
    uint32_t sequenceNumber;
    bool streaming;
} stream = {0, true};

void StreamWriteHandler(int tcpFd) {
    if (stream.streaming) {
        char packet[64];
        int len = snprintf(packet, sizeof(packet),
            "STREAM:%lu:%lu\n",
            stream.sequenceNumber++, Secs);

        int n = write(tcpFd, packet, len);
        if (n > 0) {
            printf("Streamed packet #%lu\n", stream.sequenceNumber - 1);
        }

        // Continue streaming (notification will fire when space available)
    } else {
        // Stop streaming, unregister
        RegisterTCPWriteNotify(tcpFd, NULL);
    }
}

```

```

    }

    void StartStreaming(int fd) {
        stream.sequenceNumber = 0;
        stream.streaming = true;
        RegisterTCPWriteNotify(fd, StreamWriteHandler);
    }

    void StopStreaming() {
        stream.streaming = false;
    }

```

Write Notification for Flow Control

```

volatile bool canWrite = true;

void FlowControlWriteHandler(int tcpFd) {
    // Buffer space available, we can write again
    canWrite = true;

    // Unregister until we need it again
    RegisterTCPWriteNotify(tcpFd, NULL);
    printf("Write buffer available\n");
}

void SendDataWithFlowControl(int tcpFd, const char *data, int len) {
    int n = write(tcpFd, data, len);

    if (n < len) {
        // Couldn't send all data, buffer is full
        printf("Buffer full, sent only %d of %d bytes\n", n, len);
        canWrite = false;

        // Register for notification when space becomes available
        RegisterTCPWriteNotify(tcpFd, FlowControlWriteHandler);

        // Wait for space
        while (!canWrite) {
            OSTimeDly(TICKS_PER_SECOND / 100);
        }

        // Retry sending remaining data
        SendDataWithFlowControl(tcpFd, data + n, len - n);
    }
}

```

Combined Read and Write Notifications

```

void CombinedReadHandler(int tcpFd) {
    char buffer[256];
    int n = read(tcpFd, buffer, sizeof(buffer));

    if (n > 0) {
        printf("Read %d bytes\n", n);
        ProcessAndQueueResponse(tcpFd, buffer, n);
    }
}

void CombinedWriteHandler(int tcpFd) {
    if (HasQueuedResponse()) {
        char *response = GetQueuedResponse();
        int len = strlen(response);
        int n = write(tcpFd, response, len);

        if (n == len) {
            // All sent, unregister write notify
            RegisterTCPWriteNotify(tcpFd, NULL);
        }
    }
}

void SetupConnection(int tcpFd) {
    RegisterTCPReadNotify(tcpFd, CombinedReadHandler);
    RegisterTCPWriteNotify(tcpFd, CombinedWriteHandler);
}

```

14.53.16 TCP Socket Options

Configuration flags for TCP socket behavior.

Macros

- #define SO_DEBUG 1

Reserved for debugging purposes.

- **#define SO_NONAGLE 2**
Disable Nagle's algorithm (send data immediately without delay)
- **#define SO_NOPUSH 4**
Disable TCP PUSH flag (buffer data before sending)

14.53.16.1 Detailed Description

Configuration flags for TCP socket behavior.

```
#include< tcp.h>
```

Socket options for use with [setsockopt\(\)](#), [clrsockopt\(\)](#), and [getsockopt\(\)](#).

14.53.17 TCP Socket State

TCP connection state machine values (RFC 793)

Macros

- **#define TCP_STATE_CLOSED (0)**
Socket is closed, no connection exists.
- **#define TCP_STATE_LISTEN (1)**
Socket is listening for incoming connections.
- **#define TCP_STATE_SYN_SENT (2)**
SYN packet sent, waiting for SYN-ACK.
- **#define TCP_STATE_SYN_RCVD (3)**
SYN received, SYN-ACK sent.
- **#define TCP_STATE_WAIT_FOR_ACCEPT (4)**
Connection pending, waiting for [accept\(\)](#) call.
- **#define TCP_STATE_ESTABLISHED (5)**
Connection established, data transfer possible.
- **#define TCP_STATE_CLOSE_WAIT (6)**
FIN received from remote host, local close pending.
- **#define TCP_STATE_LAST_ACK (7)**
FIN sent, waiting for final ACK.
- **#define TCP_STATE_FIN_WAIT_1 (8)**
Local FIN sent, waiting for ACK.
- **#define TCP_STATE_FIN_WAIT_2 (9)**
Local FIN acknowledged, waiting for remote FIN.
- **#define TCP_STATE_CLOSING (10)**
Both sides closing simultaneously.
- **#define TCP_STATE_TIME_WAIT (11)**
Connection closed, waiting to ensure remote received final ACK.

14.53.17.1 Detailed Description

TCP connection state machine values (RFC 793)

```
#include< tcp.h>
```

These constants represent the current state of a TCP connection according to the TCP state machine defined in RFC 793. These values should not be modified as they correspond to the TCP protocol specification.

14.53.18 TCP Socket Status

Status codes and error values for TCP socket operations.

Macros

- `#define TCP_ERR_NORMAL (0)`
Operation completed successfully with no errors.
- `#define TCP_ERR_TIMEOUT (-1)`
Operation timed out before completion.
- `#define TCP_ERR_NOCON (-2)`
No active connection exists on this socket.
- `#define TCP_ERR_CLOSING (-3)`
Socket is currently in the closing state.
- `#define TCP_ERR_NOSUCH_SOCKET (-4)`
The specified socket does not exist.
- `#define TCP_ERR_NONE_AVAIL (-5)`
No sockets available in the system pool.
- `#define TCP_ERR_CON_RESET (-6)`
Connection was reset by remote host.
- `#define TCP_ERR_CON_ABORT (-7)`
Connection was aborted.

14.53.18.1 Detailed Description

Status codes and error values for TCP socket operations.

```
#include< tcp.h>
```

When calling API functions that return a file descriptor (such as [listen\(\)](#), [accept\(\)](#), [connect\(\)](#)), a negative value indicates an error condition, while a positive value represents a valid file descriptor number.

Note

See detailed return code information, causes and solutions at: [Programmers Guide TCP Error Codes](#)

14.54.2.2 Function Documentation

14.54.2.2.1 GetTFTP()

```
int GetTFTP (
    PCSTR fileName,
    PCSTR mode,
    puint8_t buffer,
    int & len,
    uint32_t timeout,
    IPADDR4 server,
    uint16_t port = IANA_TFTP_PORT)
```

```
#include <tftp.h>
```

Get a file from a TFTP server.

Parameters

<i>fileName</i>	Name of file to retrieve
<i>mode</i>	Transfer mode. 'b' = binary, 't' = text
<i>buffer</i>	Data destination buffer
<i>len</i>	Maximum length when function is called, bytes read upon function return.
<i>timeout</i>	Total amount of time for file transfer, in system TimeTicks
<i>server</i>	IPv4 address of TFTP server
<i>port</i>	Optional TFTP server port number. If not specified the default TFTP port number 69 will be used.

Returns

    uint32_t timeout,
    uint32_t packetTimeout,
```

```

        IPADDR4 server,
        uint16_t port = IANA_TFTP_PORT)
#include <tftp.h>
Send a file to a TFTP server.

```

Parameters

<i>fileName</i>	Name of file to retrieve
<i>mode</i>	Transfer mode. 'b' = binary, 't' = text
<i>buffer</i>	Data destination buffer
<i>len</i>	Length of file to transfer, in bytes
<i>timeout</i>	Total amount of time for file transfer, in system TimeTicks
<i>packetTimeout</i>	Timeout for any single UDP packet to successfully transfer and be acknowledged, in system Time Ticks
<i>server</i>	IPv4 address of TFTP server
<i>port</i>	Optional TFTP server port number. If not specified the default TFTP port number 69 will be used.

14.55 Time

Time management functions including time zones, NTP, and system clock.

Classes

- struct [TimeZoneRecord](#)
Time zone record structure containing complete time zone information.

Functions

- time_t [time](#) (time_t *pt)
Gets the current system GMT time.
- time_t [set_time](#) (time_t time_to_set, uint32_t fraction=0)
Set the system time to the value passed in the time_t parameter.
- time_t [timegm](#) (struct tm *bts)
Converts a tm structure to time_t in GMT.
- void [tzsetchar](#) (const char *tzenv)
Set the system local time.

Variables

- const [TimeZoneRecord](#) * [TZRecords](#)
Global array of time zone records.

14.55.1 Detailed Description

Time management functions including time zones, NTP, and system clock.

```
#include< nbttime.h>
```

The NBTime library provides methods to set and read the system time. The system time will reset whenever power is lost or the system is reset. On power-up, system time can be set:

- With a NTP server (most common)
- From a real time clock (RTC)
- Manually

Examples are provided in the example section for each of these methods.

Time is always stored as GMT. If you are using an internal or external real-time clock, it should also be set to GMT. Example application function calls are shown below. Refer to the examples for your specific NetBurner platform for RTC functions. Functions with an "_r" are reentrant.

A partial list of common standard Time library functions include:

- time_t [time](#) (time_t* timeT) Returns current system GMT time as a time_t, either as an argument or return value. (Provide NULL as an argument to just return a time_t)
- time_t [mktime](#) (tm* time) Converts local given time in struct tm format to GMT time as a time_t. Also validates and modifies the time struct to their proper ranges.
- size_t [strftime](#) (char* str, size_t count, const char* format, const tm* tp) Creates a formatted time string from the tm struct tp and stores it in a buffer str.
- tm* [gmtime](#) (time_t &timeT) Converts given time since epoch (a time_t value pointed to by timeT) to calendar time, expressed in Coordinated Universal Time (UTC) in the struct tm format.

- `tm* gmtime_r(time_t &timeT, tm &stmUTC)` Converts given time since epoch (a `time_t` value pointed to by `timeT`) to calendar time, expressed in Coordinated Universal Time (UTC) in the struct `tm` format. The result is stored in the struct `tm` pointed to by `stmUTC`.
- `tm* localtime(time_t &tv)` Converts given time since epoch (`time_t`) to calendar time, expressed in local time, in the struct `tm` format.
- `tm* localtime_r(time_t &tv, tm &tm_struct)` Converts given time since epoch (`time_t`) to calendar time, expressed in local time, in the struct `tm` format. The result is stored in the `tm` struct.
- `size_t strftime(char* str, size_t count, const char* format, const struct tm* tp)` Creates a formatted time string and stores it in a buffer.
- `double difftime(time_t t1, time_t t2)` Returns the difference between two `time_t` values.

For example, to get local time:

```
char buf[80];
time_t RawTime;
struct tm *TimeInfo;

time(&RawTime);           // Get system time in time_t format
TimeInfo = localtime(&RawTime); // Convert to struct tm format
strftime(buf, 79, "%l:%M:%S %p", TimeInfo);
printf("Formatted time string: %s\r\n", buf);
#include< timezones.h>
```

The `NBTime` module provides comprehensive time management capabilities:

- Time zone database with daylight saving time support
- NTP client for network time synchronization
- System clock management and conversions
- Local time calculations with automatic DST adjustments

14.55.2 Function Documentation

14.55.2.1 set_time()

```
time_t set_time (
    time_t time_to_set,
    uint32_t fraction = 0)
#include <nbtime.h>
```

Set the system time to the value passed in the `time_t` parameter.

Parameters

<i>time_to_set</i>	<code>time_t</code> value to set the system time.
<i>fraction</i>	the fraction (in $1/(2^{32})$ of the second)

Returns

The system time `time_t` value

14.55.2.2 time()

```
time_t time (
    time_t * pt)
#include <nbtime.h>
```

Gets the current system GMT time.

Parameters

<i>pt</i>	Optional pointer to a <code>time_t</code> to fill with the current time (may be NULL)

Returns

The system time `time_t` value

14.55.2.3 timegm()

```
time_t timegm (
    struct tm * bts)
```

```
#include <nbtime.h>
```

Converts a `tm` structure to `time_t` in GMT.

Performs the reverse translation that is done by `gmtime()`. This is not to be confused with the `mktime()` function, which performs the reverse conversion of the `localtime()` function.

Parameters

<i>bts</i>	Pointer to a <code>tm</code> structure

Returns

`time_t` value of `tm`

14.55.2.4 tzsetchar()

```
void tzsetchar (
    const char * tzenv)
```

```
#include <nbtime.h>
```

Set the system local time.

This function initializes the TZ environment variable to contain the local time zone offset information from the standard time (UTC) and, if applicable, daylight saving time (DST). This does not overwrite the system time to the local time. The TZ environment variable is used by the `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions of the standard `time.h` library to calculate the local time.

Once the TZ variable is set, the time library functions use it to determine when DST is in effect, when type conversions are made, or what time zone string is provided in the case of the `strftime()` function.

The system provides time zones around the world that can be referenced in the `TZRecords` variable in [timezones.h](#). The time zone strings are located in `timezones.cpp`. Please refer to the `timezones` and `RTC` example programs for methods on utilizing these time zone settings.

Parameters

<i>tzenv</i>	The time zone string. For example: <code>tzsetchar("EST5EDT4,M3.2.0/02:00:00,M11.1.0/02:00:00");</code> Eastern

14.55.3 Variable Documentation**14.55.3.1 TZRecords**

```
const TimeZoneRecord* TZRecords [extern]
#include <timezones.h>
```

Global array of time zone records.

This constant array contains over 75 time zone definitions covering all major regions worldwide. The array is NULL-terminated (the last record has `Posix = NULL`) to allow iteration through all available time zones.

The array is defined in `nbrtos/source/timezones.cpp` and includes time zones sorted by GMT offset and then alphabetically by region.

Accessing Time Zones:

Time zones can be accessed by:

- Iterating through the array until Posix == NULL
- Searching by description string
- Filtering by bUsCanada flag
- Matching against known POSIX strings

Complete Usage Example:

```
#include <timezones.h>
#include <ntp.h>
#include <string.h>

// List all available time zones
void ListTimeZones() {
    iprintf("Available Time Zones:\r\n");
    const TimeZoneRecord *tz = TZRecords;
    int index = 0;

    while (tz->Posix != NULL) {
        iprintf("%3d: %s\r\n", index, tz->Description);
        tz++;
        index++;
    }
}

// Find and set a specific time zone
bool SetTimeZoneByDescription(const char *searchStr) {
    const TimeZoneRecord *tz = TZRecords;

    while (tz->Posix != NULL) {
        if (strstr(tz->Description, searchStr) != NULL) {
            // Found matching time zone
            tzset(tz->Posix);
            iprintf("Time zone set to: %s\r\n", tz->Description);
            return true;
        }
        tz++;
    }

    iprintf("Time zone not found: %s\r\n", searchStr);
    return false;
}

// Get only US/Canada time zones
void ListUSTimeZones() {
    iprintf("US/Canada Time Zones:\r\n");
    const TimeZoneRecord *tz = TZRecords;

    while (tz->Posix != NULL) {
        if (tz->bUsCanada) {
            iprintf("  %s (%s)\r\n", tz->Short_name, tz->Description);
        }
        tz++;
    }
}

// Complete NTP + Time Zone setup
void SetupNetworkTime() {
    // Start NTP client
    if (SetTimeNTPServer("pool.ntp.org")) {
        iprintf("NTP synchronization started\r\n");

        // Wait for time sync
        while (!GetTimeNTPStatus()) {
            OSTimeDly(TICKS_PER_SECOND);
        }

        // Set time zone
        SetTimeZoneByDescription("Pacific Time");

        // Display current local time
        time_t now = time(NULL);
        struct tm *local = localtime(&now);
        iprintf("Current time: %02d:%02d:%02d\r\n",
            local->tm_hour, local->tm_min, local->tm_sec);
    }
}
```

Note

The array is const and should not be modified at runtime

Always check for NULL termination when iterating

Time zone data is stored in flash/ROM and does not consume RAM

14.56 Timers

Topics

- [High Resolution Delay Timer](#)
High-precision microsecond delay functionality.
- [Interval Timer](#)
- [Stopwatch Timer](#)

14.56.1 Detailed Description

Hardware based high resolution timers:

- [StopWatch](#) to time events
- Interval Timer for periodic semaphore posts or interrupts
- HiResDelay ([DelayObject](#)) providing microsecond delay functions

14.56.2 High Resolution Delay Timer

High-precision microsecond delay functionality.

Classes

- class [DelayObject](#)
High-resolution microsecond delay timer class.

14.56.2.1 Detailed Description

High-precision microsecond delay functionality.

```
#include< HiResDelay.h>
```

The High Resolution Delay Timer provides microsecond-precision timing by utilizing hardware system timers. This is ideal for applications requiring precise timing control such as:

- Protocol timing requirements
- Sensor polling with specific intervals
- Hardware interface timing
- Signal generation

14.56.2.2 Usage Overview

When a [DelayObject](#) is created, it automatically allocates an available hardware system timer from the processor's timer pool. The timer remains allocated for the lifetime of the object and is automatically freed when the object goes out of scope or is destroyed.

14.56.2.3 Timing Precision

- **Minimum delay:** Platform-dependent, typically ~ 1 -10 microseconds
- **Maximum delay:** Limited by 32-bit counter (up to $\sim 4,294$ seconds)
- **Precision:** Hardware timer precision (typically sub-microsecond)
- **Accuracy:** Depends on system load and interrupt latency

14.56.2.4 Example Usage

```
#include <HiResDelay.h>

void performPreciseTiming() {
    // Create delay object - allocates hardware timer
    static DelayObject myHiResDelay;

    // Verify timer was successfully allocated
    if (!myHiResDelay.valid()) {
        iprintf("Error: No free timers available\n");
        return;
    }

    // Perform precise delays
    myHiResDelay.DelayUsec(100); // Delay 100 microseconds
    myHiResDelay.DelayUsec(200); // Delay 200 microseconds
    myHiResDelay.DelayUsec(1000); // Delay 1 millisecond
}

// Timer is automatically freed when object goes out of scope
```

14.56.2.5 Important Notes

- Hardware timers are a limited resource - check valid() after construction
- Delays block the calling task (use RTOS tasks for concurrent operations)
- Very short delays ($< 10\mu s$) may have reduced accuracy due to overhead
- For non-blocking timing, consider using the Interval Timer classes
- Static or global DelayObjects prevent timer reallocation overhead

14.56.2.6 Comparison with Other Timing Methods

Method	Resolution	Blocking	Use Case
OSTimeDly()	20ms (1 tick)	Yes	General delays
DelayObject	Microseconds	Yes	Precise hardware timing
IntervalTimer	Microseconds	No	Periodic callbacks
Stopwatch	Microseconds	No	Time measurement

See also

[Interval Timer](#) Interval Timer for non-blocking periodic operations

[Stopwatch Timer](#) Stopwatch for time measurement

OSTimeDly() Standard RTOS delay function

14.56.3 Interval Timer

Functions

- int [IntervalOSSem](#) (OS_SEM *p_toSem, int num_per_sec, int timer=FIRST_UNUSED_TIMER)
Create a periodic timer that posts to an RTOS semaphore.
- int [IntervalOSFlag](#) (OS_FLAGS *p_toFlag, uint32_t flag_value, int num_per_sec, int timer=FIRST_UNUSED_TIMER)

Create a periodic timer that sets RTOS flags.

- int [IntervalInterruptCallback](#) (void(*p_toCallbackFunc)(), int num_per_sec, int timer=FIRST_UNUSED_TIMER)

Create a periodic timer that calls a function from interrupt context.

- void [IntervalStop](#) (int timer_number)

Stop and release an interval timer.

14.56.3.1 Detailed Description

```
#include< IntervalTimer.h>
```

The Interval Timer API provides hardware-based periodic interrupts for real-time applications. Unlike software timers, these use dedicated hardware timer peripherals to generate precise, low-jitter periodic events.

14.56.3.1.1 Features

- Periodic interrupt generation with configurable frequency (minimum 20 Hz)
- Direct callback execution from interrupt context (for immediate response)
- RTOS semaphore posting (for task synchronization)
- RTOS flag setting (for event notification)
- Multiple independent timers (platform-dependent)
- Automatic timer allocation or manual timer selection
- Microsecond-level precision and consistency

14.56.3.1.2 Use Cases

- **Periodic sampling:** ADC reads, sensor polling at fixed intervals
- **Real-time control:** PID loops, motor control updates
- **Task synchronization:** Waking tasks at precise intervals
- **Time-critical events:** Watchdog servicing, status updates
- **Signal generation:** PWM, timing signals for external devices
- **Rate limiting:** Throttling operations to specific frequencies

14.56.3.1.3 Basic Usage - Semaphore Posting

```
// Create and initialize a semaphore
OS_SEM timerSem;
timerSem.Init();

// Create interval timer that posts 20 times per second
int timerNumber = IntervalOSSem(&timerSem, 20);
if (timerNumber < 0)
{
    iprintf("Error creating interval timer: %d\r\n", timerNumber);
}
else
{
    iprintf("Timer %d created successfully\r\n", timerNumber);
}

// Task waits for periodic semaphore posts
while (running)
{
    timerSem.Pend(); // Blocks until timer posts (50ms intervals)
    ProcessPeriodicData();
}

// Clean up when done
IntervalStop(timerNumber);
```

14.56.3.1.4 Advanced Usage - Multiple Timers with Different Rates

```

OS_SEM fastSem, slowSem;
fastSem.Init();
slowSem.Init();

// Fast sampling at 1000 Hz
int fastTimer = IntervalOSSem(&fastSem, 1000);

// Slow processing at 10 Hz
int slowTimer = IntervalOSSem(&slowSem, 10);

// Fast task
DWORD FastTask(void *pd)
{
    while (1)
    {
        fastSem.Pend(); // Every 1ms
        ReadSensors();
    }
}

// Slow task
DWORD SlowTask(void *pd)
{
    while (1)
    {
        slowSem.Pend(); // Every 100ms
        UpdateDisplay();
    }
}

// Cleanup
IntervalStop(fastTimer);
IntervalStop(slowTimer);

```

14.56.3.1.5 Interrupt Callback Usage

```

volatile uint32_t interruptCount = 0;

// Callback runs in interrupt context - keep it fast!
void TimerCallback()
{
    interruptCount++;
    // Toggle a GPIO pin
    Pins[42].toggle();
}

// Setup 100 Hz callback
int timer = IntervalInterruptCallback(TimerCallback, 100);

// Main loop can monitor interrupt count
while (1)
{
    OSTimeDly(TICKS_PER_SECOND);
    iprintf("Interrupts per second: %lu\n", interruptCount);
    interruptCount = 0;
}

IntervalStop(timer);

```

14.56.3.1.6 OS Flag Usage

```

OS_FLAGS controlFlags;
const uint32_t TIMER_EVENT = 0x0001;
const uint32_t OTHER_EVENT = 0x0002;

// Setup 50 Hz flag posting
int timer = IntervalOSFlag(&controlFlags, TIMER_EVENT, 50);

// Task waits for flags
while (running)
{
    uint32_t flags = controlFlags.PendAll(TIMER_EVENT | OTHER_EVENT,
                                           TICKS_PER_SECOND);

    if (flags & TIMER_EVENT)
        HandlePeriodicEvent();
    if (flags & OTHER_EVENT)
        HandleOtherEvent();
}

IntervalStop(timer);

```

14.56.3.1.7 Important Considerations

14.56.3.1.7.1 Interrupt Context (for `IntervalInterruptCallback`)

Callback functions execute in interrupt context with the following restrictions:

- **Keep callbacks short:** Long execution blocks other interrupts
- **No blocking calls:** Cannot call `Pend()`, `OSTimeDly()`, or other blocking functions
- **Be careful with shared data:** Use volatile and appropriate synchronization
- **Limited stack space:** Interrupt stacks are smaller than task stacks
- **Higher priority:** Interrupts preempt all tasks

14.56.3.1.7.2 Frequency Limitations

- **Minimum frequency:** 20 Hz (50ms period)
- **Maximum frequency:** Platform and system load dependent
- **CPU overhead:** Higher frequencies consume more CPU time
- **Jitter:** Very high frequencies may experience more timing variation

14.56.3.1.7.3 Timer Resources

- Hardware timers are limited (typically 4-8 per platform)
- Each `IntervalOSSem/Flag/Callback` call uses one timer
- Always call `IntervalStop()` to free timers when done
- Use `FIRST_UNUSED_TIMER` for automatic allocation

14.56.3.1.7.4 Thread Safety

- Timer setup/teardown is not automatically synchronized
- Protect timer creation/destruction with mutexes if called from multiple tasks
- Callbacks and posts are inherently thread-safe (interrupt-driven)

14.56.3.1.8 Performance Guidelines

Frequency	Use Case	Callback Execution Time
20-100 Hz	Display updates, slow sensors	< 100 us
100-1000 Hz	Control loops, fast sampling	< 10 us
1000+ Hz	High-speed I/O, signal generation	< 1 us

14.56.3.1.9 Error Codes

- **-1:** No hardware timer available (all timers in use)
- **-2:** Invalid frequency (`num_per_sec < 20`)
- **Positive value:** Timer number (success)

14.56.3.1.10 Best Practices

1. **Always check return values** from Interval functions
2. **Call [IntervalStop\(\)](#)** when timer no longer needed to free resources
3. **Use semaphores for task sync** rather than callbacks when possible
4. **Profile callback execution time** to ensure it doesn't exceed period
5. **Avoid dynamic memory allocation** in interrupt callbacks
6. **Use volatile** for variables shared between interrupts and tasks
7. **Document timer usage** in your code to track resource allocation

14.56.3.1.11 Common Pitfalls

- Forgetting to call [IntervalStop\(\)](#) causes timer leaks
- Callbacks that take too long can cause system instability
- Using blocking functions in callbacks causes crashes
- Not checking return values leads to silent failures
- Excessive interrupt frequency can starve normal tasks

14.56.3.2 Function Documentation

14.56.3.2.1 IntervalInterruptCallback()

```
int IntervalInterruptCallback (
    void(* p_toCallbackFunc )(),
    int num_per_sec,
    int timer = FIRST_UNUSED_TIMER)
```

```
#include <IntervalTimer.h>
```

Create a periodic timer that calls a function from interrupt context.

Creates a hardware interval timer that calls the specified callback function at the requested frequency. The callback executes in interrupt context, providing the lowest possible latency and jitter for time-critical operations.

Use with extreme caution. Interrupt callbacks have strict requirements and restrictions. They are appropriate for simple, fast operations like toggling GPIO pins, reading sensors, or updating counters. For most periodic tasks, [IntervalOSSem\(\)](#) or [IntervalOSFlag\(\)](#) are safer and more appropriate choices.

14.56.3.2.2 When to Use Interrupt Callbacks

- Time-critical operations requiring sub-millisecond response
- Simple hardware I/O that must occur at precise intervals
- Generating timing signals or PWM-like patterns
- High-frequency data acquisition where task overhead is too high

14.56.3.2.3 When NOT to Use Interrupt Callbacks

- Any operation that can be done from a task (use IntervalOSSem instead)
- Operations requiring significant processing time
- Code that needs to call blocking functions
- Complex logic with multiple decision points

14.56.3.2.4 Interrupt Context Restrictions

Your callback function **MUST NOT**:

- Call blocking functions (Pend(), OSTimeDly(), etc.)
- Perform long computations (keep under 10 us at typical frequencies)
- Call printf() or iprintf() (extremely slow)
- Perform dynamic memory allocation
- Access non-volatile shared data without proper synchronization
- Call non-reentrant library functions

Your callback function **SHOULD**:

- Complete as quickly as possible (microseconds, not milliseconds)
- Use volatile for variables shared with tasks
- Be reentrant and thread-safe
- Use atomic operations for counters if possible
- Post to semaphores/flags if triggering task work

Parameters

<i>p_toCallbackFunc</i>	Pointer to the callback function. Must have signature: void MyCallback(void). The function will be called from interrupt context at the specified frequency. Must remain valid (not be deleted) while timer is active.
<i>num_per_sec</i>	Callback frequency in Hz (calls per second). Valid range is 20 to platform-dependent maximum. Consider: • 20-100 Hz: Low-frequency periodic tasks • 100-1000 Hz: Control loops, moderate-speed sampling • 1000-10000 Hz: High-speed I/O, signal generation Higher frequencies require shorter execution times.
<i>timer</i>	Hardware timer number to use. Options: • FIRST_UNUSED_TIMER (default, -1): Automatically selects the first available hardware timer • 0, 1, 2, etc.: Specific timer number (platform-dependent) Use default unless you need specific timer for hardware reasons.

Returns

On success: Non-negative timer number (0, 1, 2, etc.) that identifies this interval timer. Save this value to pass to [IntervalStop\(\)](#). On failure:

- -1: No hardware timer available (all timers in use)
- -2: Invalid num_per_sec (less than 20 Hz)

Note

The callback executes at higher priority than all tasks and most interrupts.

Long callbacks can cause system instability by blocking other interrupts.

If callback execution time exceeds the timer period, interrupts will be missed.

Always call [IntervalStop\(\)](#) when done to free the hardware timer resource.

Warning

Callbacks run with interrupts disabled for their priority level. Keep execution time minimal to avoid blocking other system functions.

Do not call any RTOS blocking functions from the callback. This will cause system crashes or undefined behavior.

The callback function pointer must remain valid. Do not use member functions or lambdas unless you understand their lifetime implications.

Example - Simple counter increment (safe):

```
volatile uint32_t interruptCount = 0;

void CounterCallback()
{
    interruptCount++; // Fast, atomic on most platforms
}

void UserMain(void *pd)
{
    init();

    // Increment counter 1000 times per second
    int timer = IntervalInterruptCallback(CounterCallback, 1000);
    if (timer < 0)
    {
        iprintf("Timer creation failed: %d\n", timer);
        return;
    }

    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND);
        uint32_t count = interruptCount; // Read volatile
        iprintf("Interrupts per second: %lu\n", count);
        interruptCount = 0;
    }
}
```

Example - GPIO toggling for timing signal (safe):

```
void TogglePin()
{
    Pins[42].toggle(); // Fast GPIO operation
}

// Create 1 kHz square wave on pin 42
int timer = IntervalInterruptCallback(TogglePin, 2000); // 2000 Hz = 1 kHz square wave
```

Example - ADC sampling with semaphore post (safe):

```
volatile uint16_t adcValue = 0;
OS_SEM processSem;

void SampleADC()
{
    adcValue = ReadADCRegister(); // Fast hardware read
    processSem.Post(); // Wake processing task
}

void Setup()
{
    processSem.Init();
    int timer = IntervalInterruptCallback(SampleADC, 1000); // 1 kHz sampling
}
```

```

}

void ProcessTask(void *pd)
{
    while (1)
    {
        processSem.Pend();
        uint16_t value = adcValue; // Read volatile
        ProcessSample(value);      // Complex processing in task context
    }
}

```

Example - WRONG - Do not do this (unsafe):

```

void BadCallback()
{
    // WRONG: printf is extremely slow (milliseconds)
    iprintf("Timer fired\n"); // DON'T DO THIS!

    // WRONG: Blocking call in interrupt context
    OSTimeDly(1); // DON'T DO THIS!

    // WRONG: Complex processing taking too long
    for (int i = 0; i < 10000; i++)
        ProcessData(); // DON'T DO THIS!

    // WRONG: Dynamic memory allocation
    char *buffer = new char[100]; // DON'T DO THIS!
}

```

Example - Measuring callback overhead:

```

volatile uint32_t maxCallbackTime = 0;

void MonitoredCallback()
{
    uint32_t start = GetHighResTimer(); // Platform-specific

    // Your time-critical code here
    DoFastOperation();

    uint32_t elapsed = GetHighResTimer() - start;
    if (elapsed > maxCallbackTime)
        maxCallbackTime = elapsed;
}

// In main loop, check maxCallbackTime to ensure it's acceptable

```

Example - Proper synchronization with tasks:

```

volatile uint32_t sensorValue = 0;
volatile bool newDataReady = false;
OS_SEM dataSem;

void SensorCallback()
{
    // Read sensor quickly
    sensorValue = ReadSensor();
    newDataReady = true;
    dataSem.Post(); // Signal task
}

void SensorTask(void *pd)
{
    while (1)
    {
        dataSem.Pend();
        if (newDataReady)
        {
            uint32_t value = sensorValue;
            newDataReady = false;

            // Process in task context (can be slow)
            ProcessSensorData(value);
        }
    }
}

```

[IntervalStop\(\)](#)
[IntervalOSSem\(\)](#)
[IntervalOSFlag\(\)](#)

14.56.3.2.5 IntervalOSFlag()

```

int IntervalOSFlag (

```

```
OS_FLAGS * p_toFlag,
uint32_t flag_value,
int num_per_sec,
int timer = FIRST_UNUSED_TIMER)
```

```
#include <IntervalTimer.h>
```

Create a periodic timer that sets RTOS flags.

Creates a hardware interval timer that sets the specified flag bit(s) in an OS_FLAGS object at the requested frequency. This is ideal for event notification where multiple event sources need to signal a single task, or when you need to distinguish between different types of periodic events.

Unlike semaphores which simply count posts, flags maintain distinct bit states allowing a task to wait on multiple different events simultaneously and determine which event(s) occurred.

14.56.3.2.6 Typical Usage Pattern

1. Create an OS_FLAGS object
2. Define flag bit values for different events
3. Call [IntervalOSFlag\(\)](#) to set specific flag bit(s) periodically
4. Task(s) wait on flags using [PendAll\(\)](#), [PendAny\(\)](#), etc.
5. Call [IntervalStop\(\)](#) when timer is no longer needed

Parameters

<i>p_toFlag</i>	Pointer to an OS_FLAGS object. The flags object need not be initialized before use (has no Init() method). Must remain valid for the lifetime of the interval timer.
<i>flag_value</i>	The flag bit(s) to set on each timer period. Can be a single bit (e.g., 0x0001) or multiple bits (e.g., 0x0003). Use bitwise OR to combine multiple flags. Bits are set, not toggled. Common patterns: • Single bit: 0x0001, 0x0002, 0x0004, 0x0008, etc. • Multiple bits: 0x0003 (bits 0 and 1), 0x000F (bits 0-3)
<i>num_per_sec</i>	Flag setting frequency in Hz (sets per second). Valid range is 20 to platform-dependent maximum (typically 10,000+). Higher frequencies increase CPU overhead. Common values: • 20-50 Hz: UI updates, slow polling • 100-500 Hz: Control system events • 1000+ Hz: High-speed event signaling
<i>timer</i>	Hardware timer number to use. Options: • FIRST_UNUSED_TIMER (default, -1): Automatically selects the first available hardware timer • 0, 1, 2, etc.: Specific timer number (platform-dependent) Use default unless you need specific timer for hardware reasons.

Returns

On success: Non-negative timer number (0, 1, 2, etc.) that identifies this interval timer. Save this value to pass to [IntervalStop\(\)](#). On failure:

- -1: No hardware timer available (all timers in use)
- -2: Invalid num_per_sec (less than 20 Hz)

Note

Flags are set (ORed), not cleared. If no task is pending on the flags, they will remain set until a task checks them.

Multiple interval timers can set different flags in the same OS_FLAGS object.

Use flag consumption mode (OSFlagPend with consume option) if you need to clear flags after reading.

Always call [IntervalStop\(\)](#) when done to free the hardware timer resource.

Warning

Do not delete or let the flags object go out of scope while the timer is active. Call [IntervalStop\(\)](#) first.

Example - Basic flag-based periodic event:

```
OS_FLAGS eventFlags;
const uint32_t TIMER_EVENT = 0x0001;
int timerNum;

void EventTask(void *pd)
{
    // Set flag 50 times per second (20ms period)
    timerNum = IntervalOSFlag(&eventFlags, TIMER_EVENT, 50);
    if (timerNum < 0)
    {
        iprintf("Failed to create timer: %d\n", timerNum);
        return;
    }

    while (1)
    {
        // Wait for timer flag, auto-clear on return
        uint32_t flags = eventFlags.Pend(TIMER_EVENT, OS_FLAG_WAIT_SET_ALL);

        // This runs exactly 50 times per second
        PeriodicProcessing();
    }
}
```

Example - Multiple periodic events with different rates:

```
OS_FLAGS systemFlags;
const uint32_t FAST_EVENT = 0x0001; // Bit 0
const uint32_t SLOW_EVENT = 0x0002; // Bit 1

int fastTimer, slowTimer;

void Setup()
{
    // Fast event: 100 Hz
    fastTimer = IntervalOSFlag(&systemFlags, FAST_EVENT, 100);

    // Slow event: 10 Hz
    slowTimer = IntervalOSFlag(&systemFlags, SLOW_EVENT, 10);
}

void ControlTask(void *pd)
{
    while (1)
    {
        // Wait for either event
        uint32_t flags = systemFlags.Pend(FAST_EVENT | SLOW_EVENT,
                                         OS_FLAG_WAIT_SET_ANY |
                                         OS_FLAG_CONSUME);

        if (flags & FAST_EVENT)
        {
            FastProcessing(); // Runs every 10ms
        }

        if (flags & SLOW_EVENT)
        {
            SlowProcessing(); // Runs every 100ms
        }
    }
}

void Cleanup()
{
    IntervalStop(fastTimer);
    IntervalStop(slowTimer);
}
```

Example - Combining timer events with other events:

```
OS_FLAGS controlFlags;
```

```

const uint32_t TIMER_EVENT      = 0x0001;
const uint32_t BUTTON_EVENT    = 0x0002;
const uint32_t NETWORK_EVENT    = 0x0004;

int timer = IntervalOSFlag(&controlFlags, TIMER_EVENT, 20);

// Other parts of code can set BUTTON_EVENT or NETWORK_EVENT
void ButtonISR()
{
    controlFlags.Post(BUTTON_EVENT);
}

void StateMachine(void *pd)
{
    while (1)
    {
        // Wait for any event
        uint32_t events = controlFlags.Pend(TIMER_EVENT |
                                           BUTTON_EVENT |
                                           NETWORK_EVENT,
                                           OS_FLAG_WAIT_SET_ANY |
                                           OS_FLAG_CONSUME);

        // Handle each event type
        if (events & TIMER_EVENT)
            HandlePeriodicUpdate();

        if (events & BUTTON_EVENT)
            HandleButtonPress();

        if (events & NETWORK_EVENT)
            HandleNetworkData();
    }
}

```

Example - Watchdog pattern:

```

OS_FLAGS watchdogFlags;
const uint32_t WATCHDOG_FLAG = 0x0001;
const uint32_t TASK_ALIVE_FLAG = 0x0002;

int watchdogTimer = IntervalOSFlag(&watchdogFlags, WATCHDOG_FLAG, 1); // 1 Hz

void WatchdogTask(void *pd)
{
    while (1)
    {
        uint32_t flags = watchdogFlags.Pend(WATCHDOG_FLAG,
                                           OS_FLAG_WAIT_SET_ALL |
                                           OS_FLAG_CONSUME,
                                           TICKS_PER_SECOND * 2);

        if (flags & WATCHDOG_FLAG)
        {
            // Check if monitored task is alive
            uint32_t status = watchdogFlags.Pend(TASK_ALIVE_FLAG,
                                                OS_FLAG_WAIT_SET_ALL |
                                                OS_FLAG_CONSUME,
                                                0); // No wait

            if (!(status & TASK_ALIVE_FLAG))
            {
                iprintf("ERROR: Monitored task not responding!\n");
                HandleTaskFailure();
            }
        }
    }
}

// Monitored task periodically sets its alive flag
void MonitoredTask(void *pd)
{
    while (1)
    {
        DoWork();
        watchdogFlags.Post(TASK_ALIVE_FLAG);
        OSTimeDly(TICKS_PER_SECOND / 2);
    }
}

```

[IntervalStop\(\)](#)
[IntervalOSSem\(\)](#)
[IntervalInterruptCallback\(\)](#)
[OS_FLAGS](#)

14.56.3.2.7 IntervalOSSem()

```
int IntervalOSSem (
    OS_SEM * p_toSem,
    int num_per_sec,
    int timer = FIRST_UNUSED_TIMER)
```

```
#include <IntervalTimer.h>
```

Create a periodic timer that posts to an RTOS semaphore.

Creates a hardware interval timer that posts to the specified semaphore at the requested frequency. This is the preferred method for periodic task synchronization, as it allows tasks to block efficiently on the semaphore while the hardware timer ensures precise timing.

The timer uses a hardware peripheral to generate periodic interrupts. Each interrupt posts to the semaphore, waking any task waiting on it. This provides low-jitter, precise periodic events for time-critical operations.

14.56.3.2.8 Typical Usage Pattern

1. Create and initialize an OS_SEM
2. Call [IntervalOSSem\(\)](#) to start periodic posting
3. Task(s) call [Pend\(\)](#) on the semaphore to wait for each period
4. Call [IntervalStop\(\)](#) when timer is no longer needed

Parameters

<i>p_toSem</i>	Pointer to an initialized OS_SEM object. The semaphore must be initialized with Init() before passing to this function. Must remain valid for the lifetime of the interval timer.
<i>num_per_sec</i>	Posting frequency in Hz (posts per second). Valid range is 20 to platform-dependent maximum (typically 10,000+). Higher frequencies increase CPU overhead. Common values: • 20-50 Hz: UI updates, slow sensors • 100-500 Hz: Control loops, moderate sampling • 1000+ Hz: High-speed data acquisition
<i>timer</i>	Hardware timer number to use. Options: • FIRST_UNUSED_TIMER (default, -1): Automatically selects the first available hardware timer • 0, 1, 2, etc.: Specific timer number (platform-dependent) Use default unless you need specific timer for hardware reasons.

Returns

On success: Non-negative timer number (0, 1, 2, etc.) that identifies this interval timer. Save this value to pass to [IntervalStop\(\)](#). On failure:

- -1: No hardware timer available (all timers in use)
- -2: Invalid num_per_sec (less than 20 Hz)

Note

The semaphore counter will increment each period until a task calls [Pend\(\)](#). If no task is pending, posts accumulate (up to semaphore max count).

Multiple tasks can wait on the same semaphore. The RTOS will wake them according to priority and FIFO order.

Always call [IntervalStop\(\)](#) when done to free the hardware timer resource.

Warning

Do not delete or let the semaphore go out of scope while the timer is active. Call [IntervalStop\(\)](#) first.

Frequencies above 1000 Hz may consume significant CPU time. Profile your system to ensure adequate CPU remains for other tasks.

Example - Basic periodic task:

```
OS_SEM periodicSem;
int timerNum;

void PeriodicTask(void *pd)
{
    periodicSem.Init();

    // Post 100 times per second (10ms period)
    timerNum = IntervalOSSem(&periodicSem, 100);
    if (timerNum < 0)
    {
        iprintf("Failed to create timer: %d\n", timerNum);
        return;
    }

    while (1)
    {
        // Wait for next period
        periodicSem.Pend();

        // This runs exactly 100 times per second
        ProcessData();
    }
}

// Cleanup function
void StopPeriodicTask()
{
    if (timerNum >= 0)
        IntervalStop(timerNum);
}
```

Example - Multiple tasks synchronized to one timer:

```
OS_SEM syncSem;
int timer;

void TaskA(void *pd)
{
    while (1)
    {
        syncSem.Pend();
        DoTaskAWork(); // Runs every 50ms
    }
}

void TaskB(void *pd)
{
    while (1)
    {
        syncSem.Pend();
        DoTaskBWork(); // Also runs every 50ms
    }
}

void UserMain(void *pd)
{
    init();
    syncSem.Init(0, 100); // Init with count 0, max 100

    // 20 Hz timer (50ms period)
    timer = IntervalOSSem(&syncSem, 20);

    OSTaskCreate(TaskA, ...);
    OSTaskCreate(TaskB, ...);

    // Both tasks wake on each timer period
}
```

Example - Error handling:

```
OS_SEM sem;
sem.Init();

int timer = IntervalOSSem(&sem, 500);
switch (timer)
{
    case -1:
        iprintf("ERROR: No hardware timers available\n");
        iprintf("Check for timer leaks - are you calling IntervalStop()?\n");
        break;
}
```

```

    case -2:
        iprintf("ERROR: Invalid frequency (minimum 20 Hz)\n");
        break;
    default:
        iprintf("Timer %d created successfully at 500 Hz\n", timer);
        break;
}

```

Example - Timeout with periodic check:

```

OS_SEM checkSem;
checkSem.Init();

int timer = IntervalOSSem(&checkSem, 10); // Check 10 times/second

bool WaitForConditionWithTimeout(int timeoutSeconds)
{
    int checks = timeoutSeconds * 10; // 10 checks per second

    for (int i = 0; i < checks; i++)
    {
        checkSem.Pend();
        if (ConditionMet())
        {
            IntervalStop(timer);
            return true;
        }
    }

    IntervalStop(timer);
    return false; // Timeout
}

```

[IntervalInterruptCallback\(\)](#)
[OS_SEM](#)

14.56.3.2.9 IntervalStop()

```

void IntervalStop (
    int timer_number)
#include <IntervalTimer.h>

```

Stop and release an interval timer.

Stops the specified interval timer and frees the associated hardware timer resource, making it available for reuse. After calling this function, the timer will no longer generate interrupts, post to semaphores, set flags, or call callbacks.

Always call this function when you no longer need an interval timer. Failing to stop timers causes resource leaks, eventually exhausting the limited number of hardware timers available on the platform.

This function is safe to call from any context (task or interrupt) and is safe to call multiple times on the same timer number (subsequent calls have no effect).

14.56.3.2.10 When to Call IntervalStop()

- When your application no longer needs periodic events
- Before re-configuring a timer with different parameters
- In cleanup code before task termination
- When switching between different operational modes
- Before system shutdown or reset

14.56.3.2.11 Resource Management Pattern

```

// Setup
int timer = IntervalOSSem(...);
if (timer >= 0)
{
    // Use timer
    ...
}

```

```

    // Cleanup
    IntervalStop(timer);
}

```

Parameters

<i>timer_number</i>	The timer number returned by IntervalOSSem() , IntervalOSFlag() , or IntervalInterruptCallback() . Valid timer numbers are non-negative integers (0, 1, 2, etc.). Negative values are ignored (function returns immediately).

Note

After stopping, the timer number becomes invalid and should not be reused.

For [IntervalOSSem\(\)](#), pending semaphore posts are preserved - the semaphore counter is not cleared by stopping the timer.

For [IntervalOSFlag\(\)](#), flags remain in their current state - they are not cleared by stopping the timer.

For [IntervalInterruptCallback\(\)](#), the callback will not be called again after this function returns, but you must ensure the callback function itself remains valid if it was mid-execution.

This function is thread-safe and can be called from any task or interrupt.

It is safe to call [IntervalStop\(\)](#) with an invalid or already-stopped timer number - the function will simply return without error.

Example - Basic cleanup:

```

OS_SEM timerSem;
int timer;

void StartPeriodicTask()
{
    timerSem.Init();
    timer = IntervalOSSem(&timerSem, 100);
}

void StopPeriodicTask()
{
    if (timer >= 0)
    {
        IntervalStop(timer);
        timer = -1; // Mark as stopped
    }
}

```

Example - RAIL-style resource management:

```

class PeriodicTask
{
private:
    OS_SEM sem;
    int timerNum;

public:
    PeriodicTask(int hz) : timerNum(-1)
    {
        sem.Init();
        timerNum = IntervalOSSem(&sem, hz);
    }

    ~PeriodicTask()
    {
        if (timerNum >= 0)
            IntervalStop(timerNum);
    }

    void WaitForPeriod()
    {
        sem.Pend();
    }
};

void UsePeriodicTask()
{
    PeriodicTask task(50); // 50 Hz

    while (running)
    {
        task.WaitForPeriod();
    }
}

```

```

        DoWork();
    }

    // Timer automatically stopped when task goes out of scope
}

```

Example - Multiple timers management:

```

#define MAX_TIMERS 4
int activeTimers[MAX_TIMERS];
int timerCount = 0;

int CreateTimer(...)
{
    int timer = IntervalOSSem(...);
    if (timer >= 0 && timerCount < MAX_TIMERS)
    {
        activeTimers[timerCount++] = timer;
    }
    return timer;
}

void StopAllTimers()
{
    for (int i = 0; i < timerCount; i++)
    {
        IntervalStop(activeTimers[i]);
    }
    timerCount = 0;
}

```

Example - Mode switching:

```

int currentTimer = -1;

void SwitchToFastMode()
{
    // Stop old timer if active
    if (currentTimer >= 0)
        IntervalStop(currentTimer);

    // Start new timer at higher frequency
    currentTimer = IntervalOSSem(&sem, 1000); // 1 kHz
}

void SwitchToSlowMode()
{
    if (currentTimer >= 0)
        IntervalStop(currentTimer);

    currentTimer = IntervalOSSem(&sem, 10); // 10 Hz
}

```

Example - Safe shutdown:

```

volatile bool shutdownRequested = false;
int timer = -1;

void PeriodicTask(void *pd)
{
    OS_SEM sem;
    sem.Init();

    timer = IntervalOSSem(&sem, 100);
    if (timer < 0)
    {
        iprintf("Timer creation failed\n");
        return;
    }

    while (!shutdownRequested)
    {
        sem.Pend();
        DoWork();
    }

    // Clean shutdown
    IntervalStop(timer);
    timer = -1;
    iprintf("Task shutdown complete\n");
}

void RequestShutdown()
{
    shutdownRequested = true;
    // Timer will be stopped by the task itself
}

```

Example - Error recovery:

```

int timer = -1;

bool RecoverFromError()

```

```

{
    // Stop old timer if it exists
    if (timer >= 0)
    {
        IntervalStop(timer);
        timer = -1;
    }

    // Try to restart
    timer = IntervalOSSem(&sem, 100);
    if (timer < 0)
    {
        iprintf("Recovery failed - no timers available\n");
        return false;
    }

    iprintf("Recovery successful - timer %d\n", timer);
    return true;
}

```

14.56.4 Stopwatch Timer

Classes

- class [StopWatch](#)

High-resolution stopwatch timer for precise event timing and performance measurement.

14.56.4.1 Detailed Description

```
#include< stopwatch.h>
```

The [StopWatch](#) class provides high-resolution timing capabilities for measuring code execution time, profiling performance, and timing events with precision beyond the standard RTOS tick resolution.

14.56.4.1.1 Features

- High-resolution timing using hardware timers
- Start/Stop functionality with cumulative timing
- Clear and reset capabilities
- Time reading without stopping the timer
- Platform-independent API with automatic timer allocation

14.56.4.1.2 Basic Usage

```

StopWatch myStopwatch;

myStopwatch.Start();
for (volatile int i = 0; i < numLoop; i++)
{
    count++;
}
myStopwatch.Stop();

unsigned long long elapsed = myStopwatch.GetTime();
double seconds = myStopwatch.Convert(elapsed);
printf("Elapsed time: %f seconds\n", seconds);

```

14.56.4.1.3 Advanced Usage - Cumulative Timing

```
StopWatch timer;

// Time multiple operations cumulatively
timer.Start();
DoOperation1();
timer.Stop();

// Continue timing without clearing
timer.Start(); // Continues from previous elapsed time
DoOperation2();
timer.Stop();

double totalTime = timer.Convert(timer.GetTime());
printf("Total time for both operations: %f seconds\n", totalTime);
```

14.56.4.1.4 Timing Without Stopping

```
StopWatch timer;
timer.Start();

while (processing)
{
    DoWork();

    // Check elapsed time without stopping
    unsigned long long current = timer.GetTime();
    if (current > MAX_ALLOWED_TIME)
    {
        printf("Warning: Operation taking too long!\n");
        break;
    }
}
timer.Stop();
```

14.56.4.1.5 Timer Resolution

```
StopWatch timer;
double resolution = timer.CountResolution();
printf("Timer resolution: %f seconds per tick\n", resolution);
```

Note

On platforms with dedicated RTOS timers, the `timer_number` parameter in the constructor can be omitted and the system will automatically allocate an appropriate timer.

The [StopWatch](#) maintains cumulative time across Start/Stop cycles unless explicitly cleared with `Clear()` or `Start(true)`.

14.57 UDP

NetBurner User Datagram Protocol (UDP) Implementation.

Topics

- [UDP Error Codes](#)
- [UDP Packet API](#)
- [UDP Socket API](#)

BSD-style socket functions for UDP communication.

Classes

- class [UDPPacket](#)

UDP Packet Class - Complete UDP packet management.

Typedefs

- typedef void [udp_data_notify](#)(OS_FIFO *pfifo, uint16_t port)
UDP packet arrival notification callback function type.

Functions

- bool [RegisterUDPFifo](#) (uint16_t listenPort, OS_FIFO *pFifo)
Register FIFO to receive UDP packets on specified port.
- bool [RegisterUDPFifoVia](#) (uint16_t listenPort, OS_FIFO *pFifo, int interface)
Register FIFO to receive UDP packets on specified port via specific network interface.
- uint16_t [RegisterEphemeralFifo](#) (OS_FIFO *pfifo, int ifn=-1)
Register UDP FIFO on a random unused ephemeral port.
- bool [RegisterUDPFifoWithNotify](#) (uint16_t listenPort, OS_FIFO *pFifo, [udp_data_notify](#) *pNotifyFunction)
Register UDP FIFO with callback notification on packet arrival.
- bool [RegisterUDPFifoWithNotifyVia](#) (uint16_t listenPort, OS_FIFO *pFifo, [udp_data_notify](#) *pNotifyFunction, int interface)
Register UDP FIFO with callback notification on specific network interface.
- void [UnregisterUDPFifo](#) (uint16_t listenPort, bool drain=false)
Unregister UDP FIFO and stop receiving packets on specified port.

14.57.1 Detailed Description

NetBurner User Datagram Protocol (UDP) Implementation.

```
#include< udp.h>
```

Complete UDP protocol implementation providing both object-oriented C++ interface ([UDPPacket](#) class) and BSD-style socket functions for flexible network communication.

14.57.1.1 Features

- **Dual API Design:** Choose between OOP [UDPPacket](#) class or familiar BSD sockets
- **IPv4 and IPv6 Support:** Full dual-stack networking capabilities
- **Zero-Copy Operations:** Direct buffer access for maximum efficiency
- **Quality of Service (QoS):** DSCP marking for traffic prioritization
- **Multi-Interface Routing:** Send packets via specific network interfaces
- **Automatic Memory Management:** RAII-based resource cleanup in C++ API
- **Fragment Handling:** Support for large datagrams exceeding MTU
- **FIFO-Based Reception:** Non-blocking packet queue management

14.57.1.2 When to Use UDP

UDP is ideal for applications requiring:

- **Low latency:** No connection overhead or retransmission delays
- **Broadcast/Multicast:** One-to-many communication patterns
- **Real-time data:** Streaming sensor data, video, audio, gaming
- **Simple request/response:** DNS, SNMP, NTP, TFTP protocols
- **Custom protocols:** Where application handles reliability

Not suitable for: File transfers, critical data, ordered delivery requirements (use TCP for these scenarios)

14.57.1.3 API Selection Guide

14.57.1.3.1 Use UDPPacket Class When:

- Writing new C++ code
- Need automatic memory management
- Sending to multiple destinations
- Require direct buffer manipulation
- Working with NetBurner-specific features (OS_FIFO integration)

14.57.1.3.2 Use BSD Socket Functions When:

- Porting existing socket code
- Compatibility with standard POSIX code
- Integration with [select\(\)/poll\(\)](#) event loops
- Writing in C (not C++)
- Familiarity with Berkeley sockets

14.57.1.4 Quick Start Examples

Examples

Example 1: Simple UDP Echo Server (UDPPacket)

```
#include <ucos.h>
#include <udp.h>

const char *AppName = "UDP Echo Server";

void UserMain(void *pd) {
    init();
    StartHttp();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Create FIFO for receiving packets
    OS_FIFO udpFifo;
    OSFifoInit(&udpFifo);
    RegisterUDPFifo(5000, &udpFifo); // Listen on port 5000

    printf("UDP Echo Server listening on port 5000\r\n");

    while (1) {
        UDPPacket pkt(&udpFifo, TICKS_PER_SECOND * 60);

        if (pkt.Validate()) {
            IPADDR srcIP = pkt.GetSourceAddress();
            uint16_t srcPort = pkt.GetSourcePort();
            uint16_t dataLen = pkt.GetDataSize();

            printf("Received %d bytes from %s:%d\r\n",
                  dataLen, AsciiIP(srcIP).c_str(), srcPort);

            // Echo back to sender
            pkt.SetDestinationPort(srcPort);
            pkt.Send(srcIP);
        }
    }
}
```

Example 2: UDP Sensor Client (UDPPacket)

```
#include <ucos.h>
#include <udp.h>

void SendSensorData(IPADDR serverIP, uint16_t serverPort, int sensorValue) {
    UDPPacket pkt;

    pkt.SetSourcePort(0); // Auto-assign ephemeral port
    pkt.SetDestinationPort(serverPort);
    pkt.SetDSCP(46); // Mark as high-priority (VoIP class)

    // Format message directly into packet buffer
```

```

uint16_t len = sprintf(pkt.GetDataBuffer(),
                      "SENSOR:%d,TEMP:%d",
                      GetDeviceID(), sensorValue);

pkt.SetDataSize(len);

pkt.Send(serverIP); // Send and auto-free buffer
}

```

Example 3: UDP Server with BSD Sockets

```

#include <ucos.h>
#include <udp.h>

void UserMain(void *pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    int sock = CreateRxUdpSocket(8080);
    if (sock < 0) {
        printf("Failed to create socket\r\n");
        return;
    }

    uint8_t buffer[1024];
    IPADDR clientIP;
    uint16_t localPort, remotePort;

    while (1) {
        int n = recvfrom(sock, buffer, sizeof(buffer),
                        &clientIP, &localPort, &remotePort);

        if (n > 0) {
            buffer[n] = '\0'; // Null-terminate for printing
            printf("Received: %s from %s:%d\r\n",
                  buffer, AsciiIP(clientIP).c_str(), remotePort);

            // Echo back
            sendto(sock, buffer, n, clientIP, remotePort);
        }
    }
}

```

Example 4: Multi-Interface UDP Routing

```

// Send packet via specific network interface
UDPPacket pkt;
pkt.SetSourcePort(3000);
pkt.SetDestinationPort(4000);
pkt.AddData("Hello from interface 1");

// Send via interface 1 (e.g., second Ethernet port)
pkt.SendViaInterfaceNum(destIP, 1);

```

Example 5: Broadcast UDP Discovery

```

void SendDiscoveryBroadcast() {
    UDPPacket pkt;
    pkt.SetSourcePort(5555);
    pkt.SetDestinationPort(5555);
    pkt.AddData("DISCOVER:NetBurner");

    // Broadcast to local subnet
    IPADDR broadcastAddr = AsciiToIp("255.255.255.255");
    pkt.Send(broadcastAddr);
}

```

14.57.1.5 Memory Management

14.57.1.5.1 UDPPacket Automatic Cleanup

The `UDPPacket` class uses RAIL (Resource Acquisition Is Initialization):

- Constructor allocates buffer from pool
- Destructor automatically returns buffer to pool
- `Send()` frees buffer after transmission
- `SendAndKeep()` retains buffer for multiple sends

14.57.1.5.2 Buffer Lifecycle Example

```
void SendToMultipleHosts() {
    UDPPacket pkt;
    pkt.SetSourcePort(1000);
    pkt.SetDestinationPort(2000);
    pkt.AddData("Broadcast message");

    // Send copies to multiple destinations
    pkt.SendAndKeep(host1IP); // Sends copy, keeps buffer
    pkt.SendAndKeep(host2IP); // Sends copy, keeps buffer
    pkt.Send(host3IP);        // Sends and frees buffer

    // pkt destructor runs here, but buffer already freed by Send()
}
```

14.57.1.6 Port Number Guidelines

- **0**: Auto-assign ephemeral port (49152-65535 range)
- **1-1023**: Well-known ports (requires root on some systems)
- **1024-49151**: Registered ports for applications
- **49152-65535**: Dynamic/private ports

Common UDP Ports:

- 53: DNS
- 67/68: [DHCP](#)
- 123: NTP (Network Time Protocol)
- 161/162: SNMP
- 514: Syslog
- 5353: mDNS
- 1900: SSDP (UPnP)

14.57.1.7 Quality of Service (QoS)

Use `SetDSCP()` to prioritize traffic in QoS-enabled networks:

DSCP Value | Traffic Class | Use Case

- 0 (CS0): Best Effort - Normal traffic
- 8 (CS1): Bulk Data - Background transfers
- 10 (AF11): High-throughput data
- 18 (AF21): Low-latency data
- 26 (AF31): Multimedia streaming
- 34 (AF41): Multimedia conferencing
- 46 (EF): Expedited Forwarding - VoIP, real-time gaming
- 48 (CS6): Network control traffic

```
UDPPacket voipPacket;
voipPacket.SetDSCP(46); // Mark as VoIP for low latency
```

14.57.1.8 Performance Considerations

14.57.1.8.1 Buffer Size Limits

- **IPv4 MTU:** 1500 bytes (typical Ethernet)
- **UDP Header:** 8 bytes
- **IP Header:** 20 bytes (IPv4), 40 bytes (IPv6)
- **Maximum Safe Payload:** ~1472 bytes (IPv4), ~1452 bytes (IPv6)
- **Fragmentation:** Available for larger packets (use [SendFragmentedUdpPacket\(\)](#))

14.57.1.8.2 Optimization Tips

1. Use appropriate data insertion method:

- `GetDataBuffer()` + `SetDataSize()`: Best for `sprintf`/binary writes
- `AddData()`: Best for incremental assembly

2. Minimize packet sends:

- Batch data when possible
- Use `SendAndKeep()` only when necessary

3. FIFO sizing:

- Size FIFO based on expected burst traffic
- Monitor FIFO with `GetFifoMessageCount()`

4. Interface binding:

- Bind sockets to specific interfaces in multi-homed systems
- Reduces routing overhead

14.57.1.9 Error Handling

14.57.1.9.1 UDPPacket Validation

```
UDPPacket pkt(&fifo, timeout);

if (!pkt.Validate()) {
    // Could be timeout, checksum error, or invalid packet
    printf("Packet validation failed\r\n");
    return;
}

// Safe to access packet data
puint8_t data = pkt.GetDataBuffer();
```

14.57.1.9.2 Socket Error Codes

```
int sock = CreateRxUdpSocket(port);
if (sock < 0) {
    switch (sock) {
        case UDP_ERR_NOSUCH_SOCKET:
            printf("Socket does not exist\r\n");
            break;
        case UDP_ERR_NOTOPEN_TO_WRITE:
            printf("Socket not open for writing\r\n");
            break;
        case UDP_ERR_NOTOPEN_TO_READ:
            printf("Socket not open for reading\r\n");
            break;
    }
}
```

14.57.1.10 Thread Safety

- **UDPPacket**: Each packet object should be used by single task
- **OS_FIFO**: Thread-safe for multiple consumers/producers
- **BSD Sockets**: Each socket should be accessed by single task
- **Multiple packets**: Create separate **UDPPacket** for each task

14.57.1.11 Advanced Features

14.57.1.11.1 IPv6 Dual-Stack

```
#ifdef IPV6
// Code automatically handles both IPv4 and IPv6
IPADDR destIP = AsciiToIp("2001:db8::1"); // IPv6
// or
IPADDR destIP = AsciiToIp("192.168.1.100"); // IPv4-mapped

UDPPacket pkt;
pkt.Send(destIP); // Works for both
#endif
```

14.57.1.11.2 Fragment Handling

```
// Send large packet (>MTU) with automatic fragmentation
uint8_t largeData[8000];
// ... fill largeData ...

int result = SendFragmentedUdpPacket(
    destIP,
    5000, // source port (0 = auto)
    6000, // dest port
    largeData,
    sizeof(largeData)
);

if (result != sizeof(largeData)) {
    printf("Fragmented send failed\r\n");
}
```

14.57.1.11.3 MAC Address Access

```
UDPPacket pkt(&fifo, timeout);
if (pkt.Validate()) {
    MACADDR srcMAC = pkt.GetMacSource();
    printf("From MAC: %02X:%02X:%02X:%02X:%02X\r\n",
        srcMAC.bytes[0], srcMAC.bytes[1], srcMAC.bytes[2],
        srcMAC.bytes[3], srcMAC.bytes[4], srcMAC.bytes[5]);
}
```

14.57.1.12 Debugging Tips

1. Use **EnableSystemDiagnostics()**: Monitor system resources
2. **Check FIFO overflow**: Increase FIFO size if packets dropped
3. **Validate packets**: Always call Validate() after receiving
4. **Monitor port conflicts**: Ensure unique port assignments
5. **Network tools**: Use Wireshark to capture actual packets

14.57.1.13 Common Pitfalls

14.57.1.13.1 [NO] Forgetting to set data size

```
UDPPacket pkt;
sprintf(pkt.GetDataBuffer(), "Hello");
pkt.Send(ip); // BUG: Size not set!
```

14.57.1.13.2 [YES] Correct approach

```
UDPPacket pkt;
uint16_t len = sprintf(pkt.GetDataBuffer(), "Hello");
pkt.SetDataSize(len); // REQUIRED!
pkt.Send(ip);
```

14.57.1.13.3 [NO] Using packet after Send()

```
UDPPacket pkt;
pkt.AddData("Hello");
pkt.Send(ip);
pkt.Send(ip2); // BUG: Buffer freed by first Send()!
```

14.57.1.13.4 [YES] Use SendAndKeep() for multiple sends

```
UDPPacket pkt;
pkt.AddData("Hello");
pkt.SendAndKeep(ip);
pkt.Send(ip2); // OK: Buffer kept until last Send()
```

14.57.1.13.5 [NO] Not validating received packets

```
UDPPacket pkt(&fifo, timeout);
uint8_t data = pkt.GetDataBuffer(); // BUG: Might be null!
```

14.57.1.13.6 [YES] Always validate

```
UDPPacket pkt(&fifo, timeout);
if (pkt.Validate()) {
    uint8_t data = pkt.GetDataBuffer(); // Safe
}
```

14.57.2 Typedef Documentation**14.57.2.1 udp_data_notify**

```
typedef void udp_data_notify(OS_FIFO *pfifo, uint16_t port)
#include <udp.h>
```

UDP packet arrival notification callback function type.

Defines the function signature for callbacks that are invoked when a UDP packet arrives on a registered port. The callback is executed in interrupt context, allowing immediate notification of packet arrival without polling.

Use this callback type when registering a UDP FIFO with notification functions like [RegisterUDPFifoWithNotify\(\)](#) or [RegisterUDPFifoWithNotifyVia\(\)](#).

Parameters

<i>pfifo</i>	Pointer to the OS_FIFO where the packet will be queued. This is the same FIFO that was registered with the port.
<i>port</i>	The UDP port number on which the packet was received. Useful when the same callback handles multiple ports.

Note

This callback is invoked from interrupt context - keep processing minimal and fast

Do not perform blocking operations, lengthy calculations, or printf statements

The callback is invoked before the packet is queued to the FIFO

You can use OSFifoPost() or other RTOS primitives to signal tasks

Warning

Never call blocking functions or perform long operations in this callback

Do not call [UnregisterUDPFifo\(\)](#) from within this callback

Avoid dynamic memory allocation in interrupt context

Expand for Example Usage**Examples**

Example implementation:

```
// Simple notification - just count packets
void MyUdpNotify(OS_FIFO *pfifo, uint16_t port) {
    static volatile uint32_t packetCount = 0;
    packetCount++; // Fast operation only
}
```

Example with task notification:

```
OS_SEM udpSemaphore;

// Callback signals a semaphore to wake processing task
void UdpArrivalNotify(OS_FIFO *pfifo, uint16_t port) {
    OSSemPost(&udpSemaphore); // Wake up processing task
}

// In task context
void ProcessingTask(void *pdata) {
    while (1) {
        OSSemPend(&udpSemaphore, 0); // Wait for packet arrival

        // Now safe to do full packet processing
        UDPPacket packet;
        if (ReadUDPPacket(&packet, myPort, 0)) {
            ProcessPacket(&packet);
            ReleaseUDPPacket(packet);
        }
    }
}
```

Example with multiple ports:

```
// Single callback handles multiple ports
void MultiPortNotify(OS_FIFO *pfifo, uint16_t port) {
    switch (port) {
        case 5000:
            controlPacketFlag = true;
            break;
        case 5001:
            dataPacketFlag = true;
            break;
        default:
            unknownPacketFlag = true;
            break;
    }
}
```

[RegisterUDPFifoWithNotifyVia\(\)](#)

14.57.3 Function Documentation**14.57.3.1 RegisterEphemeralFifo()**

```
uint16_t RegisterEphemeralFifo (
    OS_FIFO * pfifo,
    int ifn = -1)
```

```
#include <udp.h>
```

Register UDP FIFO on a random unused ephemeral port.

Automatically selects and registers an available UDP port from the ephemeral port range (typically 49152-65535). This is particularly useful for client applications that need a source port for receiving replies but don't require a specific port number.

The function ensures the selected port is not already in use and associates it with the provided FIFO for packet queuing. This is the recommended approach for client-side UDP communication where the remote server will reply to the source port.

Parameters

<i>pfifo</i>	Pointer to an OS_FIFO structure for queuing received packets. The FIFO must be initialized before calling this function. Recommended queue depth: 5-20 packets depending on traffic volume.
<i>ifn</i>	Network interface number to bind to. Use -1 for default interface (recommended). Specify a specific interface (0, 1, 2, etc.) to receive only on that interface.

Returns

The assigned ephemeral port number (49152-65535) on success, or 0 on failure (e.g., no ports available, invalid FIFO, or interface doesn't exist)

Note

The assigned port remains registered until [UnregisterUDPFifo\(\)](#) is called
 Ephemeral ports are typically in the range 49152-65535 (IANA recommended)
 You must call [UnregisterUDPFifo\(\)](#) when done to free the port and resources

Warning

The FIFO must remain valid for the lifetime of the port registration
 Multiple calls will allocate multiple ephemeral ports - track and unregister all of them

Expand for Example Usage

Examples

Example (client sending request and receiving reply):

```
OS_FIFO udpFifo;
OSFifoInit(&udpFifo);

// Get an ephemeral port for receiving replies
uint16_t myPort = RegisterEphemeralFifo(&udpFifo);
if (myPort == 0) {
    printf("Failed to register ephemeral port\n");
    return;
}

printf("Listening on ephemeral port %d\n", myPort);

// Send request to server (server will reply to myPort)
IPADDR server = AsciiToIp("192.168.1.100");
SendUdpPacket(server, myPort, 8000, (uint8_t*)"REQUEST", 7);

// Wait for reply
UDPPacket reply;
if (ReadUDPPacket(&reply, myPort, TICKS_PER_SECOND * 5)) {
    printf("Got reply from %s\n", reply.sourceIpAddr.toString());
    ReleaseUDPPacket(reply);
}

// Cleanup
UnregisterUDPFifo(myPort, true);
```

Example (multiple concurrent requests):

```
struct ClientConnection {
    OS_FIFO fifo;
    uint16_t port;
};

ClientConnection connections[5];

// Create multiple ephemeral ports for parallel requests
for (int i = 0; i < 5; i++) {
    OSFifoInit(&connections[i].fifo);
    connections[i].port = RegisterEphemeralFifo(&connections[i].fifo);
    if (connections[i].port == 0) {
        printf("Failed to register port for connection %d\n", i);
    }
}

// ... use connections ...

// Cleanup all ports
for (int i = 0; i < 5; i++) {
    if (connections[i].port != 0) {
        UnregisterUDPFifo(connections[i].port, true);
    }
}
```

See also

[RegisterUDPFifo\(\)](#) to register a specific port number
[UnregisterUDPFifo\(\)](#) to release the ephemeral port when done
[ReadUDPPacket\(\)](#) to [read](#) packets from the FIFO

14.57.3.2 RegisterUDPFifo()

```
bool RegisterUDPFifo (  
    uint16_t listenPort,  
    OS_FIFO * pFifo)
```

```
#include <udp.h>
```

Register FIFO to receive UDP packets on specified port.

Registers a UDP port for receiving packets and associates it with a FIFO queue for packet buffering. This is the standard method for setting up UDP reception on NetBurner devices. Incoming packets are automatically queued to the FIFO and can be retrieved using [ReadUDPPacket\(\)](#).

The FIFO depth determines how many packets can be buffered before new packets are dropped. Choose a depth based on your expected traffic volume and processing speed. A depth of 5-10 is typical for low-traffic applications, while 20+ may be needed for high-traffic scenarios.

Parameters

<i>listenPort</i>	UDP port number to register (1-65535). Common ports: 80 (HTTP), 443 (HTTPS), 161 (SNMP), etc. Must not already be registered. Port becomes unavailable to other applications.
<i>pFifo</i>	Pointer to an initialized OS_FIFO structure for queuing received packets. Must be initialized with OSFifoInit() before calling this function. The FIFO depth should match your traffic expectations (typically 5-20). The FIFO must remain valid until UnregisterUDPFifo() is called.

Returns

true if port successfully registered, false on failure (e.g., port already in use, invalid FIFO pointer, or out of resources)

Note

The port remains registered until explicitly unregistered with [UnregisterUDPFifo\(\)](#)

Packets exceeding the FIFO depth will be silently dropped

This function registers on all active network interfaces (use [RegisterUDPFifoVia](#) for specific interface)

Well-known ports (1-1023) may require special privileges depending on the system

Warning

The FIFO must remain valid for the entire time the port is registered

Always call [UnregisterUDPFifo\(\)](#) before destroying or deallocating the FIFO

Port numbers must be unique - attempting to register an in-use port will fail

Expand for Example Usage**Examples**

Basic example:

```
OS_FIFO udpFifo;  
OSFifoInit(&udpFifo); // Initialize with default depth  
  
if (RegisterUDPFifo(1234, &udpFifo)) {  
    printf("UDP port 1234 registered successfully\n");  
} else {  
    printf("Failed to register port 1234\n");  
}
```

Example with custom FIFO depth:

```
OS_FIFO highTrafficFifo;
```

```

OSFifoInit(&highTrafficFifo, 20); // Deep queue for high traffic

if (RegisterUDPFifo(5000, &highTrafficFifo)) {
    printf("High-traffic port 5000 registered with 20 packet buffer\n");

    // Process packets in a loop
    UDPPacket packet;
    while (true) {
        if (ReadUDPPacket(&packet, 5000, TICKS_PER_SECOND)) {
            printf("Received %d bytes from %s:%d\n",
                packet.receivedDataLen,
                packet.sourceIpAddr.toString(),
                packet.sourcePort);
            ProcessPacket(&packet);
            ReleaseUDPPacket(packet);
        }
    }
}

```

Example with proper cleanup:

```

OS_FIFO myFifo;
OSFifoInit(&myFifo);

if (RegisterUDPFifo(8000, &myFifo)) {
    // ... do work ...

    // Clean shutdown
    UnregisterUDPFifo(8000, true); // Drain queued packets
    printf("Port 8000 unregistered\n");
}

```

Example - multiple ports:

```

OS_FIFO controlFifo, dataFifo, statusFifo;
OSFifoInit(&controlFifo);
OSFifoInit(&dataFifo);
OSFifoInit(&statusFifo);

// Register multiple ports for different purposes
RegisterUDPFifo(5000, &controlFifo); // Control channel
RegisterUDPFifo(5001, &dataFifo);    // Data channel
RegisterUDPFifo(5002, &statusFifo);  // Status channel

// Each port has its own FIFO and can be read independently
UDPPacket controlPacket;
if (ReadUDPPacket(&controlPacket, 5000, 0)) {
    HandleControl(&controlPacket);
    ReleaseUDPPacket(controlPacket);
}

```

Example - error handling:

```

OS_FIFO myFifo;
OSFifoInit(&myFifo);

const uint16_t PORT = 9000;

if (!RegisterUDPFifo(PORT, &myFifo)) {
    printf("ERROR: Failed to register port %d\n", PORT);
    printf("Possible causes:\n");
    printf(" - Port already in use\n");
    printf(" - Invalid FIFO pointer\n");
    printf(" - Out of system resources\n");
    return -1;
}

printf("Port %d ready to receive packets\n", PORT);

```

14.57.3.3 RegisterUDPFifoVia()

```

bool RegisterUDPFifoVia (
    uint16_t listenPort,

```

```

    OS_FIFO * pFifo,
    int interface)
#include <udp.h>

```

Register FIFO to receive UDP packets on specified port via specific network interface.

Similar to [RegisterUDPFifo\(\)](#), but allows explicit selection of which network interface to listen on. This is essential for multi-homed systems (devices with multiple network connections) where you need to receive UDP packets on a specific interface only, such as separating management traffic from data traffic, or implementing failover systems. Use this function when your device has multiple active network interfaces (Ethernet, WiFi, cellular, etc.) and you need to control which interface receives UDP traffic on a given port. The same port number can be registered on different interfaces simultaneously.

Parameters

<i>listenPort</i>	UDP port number to register (1-65535). Must not already be registered on the specified interface. The same port can be registered on different interfaces.
<i>pFifo</i>	Pointer to an initialized OS_FIFO structure for queuing received packets. Must be initialized with OSFifoInit() before calling. Recommended depth: 5-20 packets depending on traffic. The FIFO must remain valid until UnregisterUDPFifo() is called.
<i>interface</i>	Network interface number (0-based index): • 0 = First/primary interface (typically Ethernet) • 1 = Second interface (WiFi, secondary Ethernet, etc.) • 2+ = Additional interfaces if present The interface must be active and properly configured. Use GetInterfaceCount() to determine available interfaces.

Returns

true if port successfully registered on the specified interface, false on failure (e.g., port already in use on this interface, interface doesn't exist, invalid FIFO)

Note

Only packets arriving on the specified interface will be received

The same port can be registered on multiple interfaces with different FIFOs

Interface numbers are platform and configuration specific

The interface must remain active while the port is registered

Warning

Verify the interface exists and is active before registering

The FIFO must remain valid until [UnregisterUDPFifo\(\)](#) is called

If an interface goes down, registered ports on that interface stop receiving packets

Expand for Example Usage

Examples

Example (dual-homed device - management on eth0, data on eth1):

```

OS_FIFO mgmtFifo, dataFifo;
OSFifoInit(&mgmtFifo);
OSFifoInit(&dataFifo);

// Management interface (interface 0 - secure network)
if (RegisterUDPFifoVia(161, &mgmtFifo, 0)) { // SNMP on eth0
    printf("Management port 161 registered on interface 0\n");
}

// Data interface (interface 1 - production network)
if (RegisterUDPFifoVia(5000, &dataFifo, 1)) {
    printf("Data port 5000 registered on interface 1\n");
}

// Each interface receives independently

```

```

UDPPacket mgmtPacket;
if (ReadUDPPacket(&mgmtPacket, 161, 0)) {
    printf("Management packet from secure network\n");
    ReleaseUDPPacket(mgmtPacket);
}

```

Example (same port on multiple interfaces):

```

OS_FIFO primaryFifo, backupFifo;
OSFifoInit(&primaryFifo);
OSFifoInit(&backupFifo);

// Listen on port 8000 on both interfaces
RegisterUDPFifoVia(8000, &primaryFifo, 0); // Primary Ethernet
RegisterUDPFifoVia(8000, &backupFifo, 1);  // Backup WiFi

// Can distinguish which interface received packet by which FIFO
UDPPacket packet;
if (ReadUDPPacket(&packet, 8000, 0)) {
    // Check which FIFO had data to know which interface
    printf("Packet received on one of the interfaces\n");
    ReleaseUDPPacket(packet);
}

```

Example (interface availability checking):

```

int targetInterface = 1;

// Verify interface exists before attempting registration
if (GetInterfaceCount() > targetInterface) {
    if (InterfaceActive(targetInterface)) {
        OS_FIFO myFifo;
        OSFifoInit(&myFifo);

        if (RegisterUDPFifoVia(7000, &myFifo, targetInterface)) {
            printf("Port 7000 registered on interface %d\n", targetInterface);
        } else {
            printf("Failed to register on interface %d\n", targetInterface);
        }
    } else {
        printf("Interface %d exists but is not active\n", targetInterface);
    }
} else {
    printf("Interface %d does not exist\n", targetInterface);
}

```

Example (failover system):

```

OS_FIFO primaryFifo, failoverFifo;
OSFifoInit(&primaryFifo, 10);
OSFifoInit(&failoverFifo, 10);

const uint16_t SERVICE_PORT = 9000;
const int PRIMARY_IF = 0;
const int FAILOVER_IF = 1;

// Register on both interfaces
bool primaryOk = RegisterUDPFifoVia(SERVICE_PORT, &primaryFifo, PRIMARY_IF);
bool failoverOk = RegisterUDPFifoVia(SERVICE_PORT, &failoverFifo, FAILOVER_IF);

if (primaryOk && failoverOk) {
    printf("Failover system ready on port %d\n", SERVICE_PORT);

    while (true) {
        UDPPacket packet;

        // Check primary interface first
        if (ReadUDPPacket(&packet, SERVICE_PORT, 0)) {
            // Determine which interface by checking both FIFOs
            printf("Packet received - processing\n");
            ProcessPacket(&packet);
            ReleaseUDPPacket(packet);
        }

        OSTimeDly(TICKS_PER_SECOND / 10);
    }
}

```

Example (WiFi vs Ethernet separation):

```

#define ETH_INTERFACE 0
#define WIFI_INTERFACE 1

OS_FIFO ethernetFifo, wifiFifo;
OSFifoInit(&ethernetFifo);
OSFifoInit(&wifiFifo);

// Register different services on different interfaces
RegisterUDPFifoVia(80, &ethernetFifo, ETH_INTERFACE); // HTTP on wired only
RegisterUDPFifoVia(53, &wifiFifo, WIFI_INTERFACE);    // DNS on WiFi only

printf("HTTP on Ethernet, DNS on WiFi\n");

```

See also

[RegisterUDPFifo\(\)](#) for registration on all interfaces (simpler, most common)
[GetInterfaceCount\(\)](#) to determine number of available interfaces
[InterfaceActive\(\)](#) to check if an interface is active
[GetInterfaceIP\(\)](#) to get interface IP address
[UnregisterUDPFifo\(\)](#) to unregister the port
[RegisterUDPFifoWithNotifyVia\(\)](#) to add notification callback on specific interface

14.57.3.4 RegisterUDPFifoWithNotify()

```

bool RegisterUDPFifoWithNotify (
    uint16_t listenPort,
    OS_FIFO * pFifo,
    udp_data_notify * pNotifyFunction)
#include <udp.h>

```

Register UDP FIFO with callback notification on packet arrival.

Registers a UDP port for receiving packets and associates it with both a FIFO queue and a notification callback function. When a packet arrives, the callback is invoked immediately (typically from an interrupt context), allowing for prompt handling of time-sensitive data without polling.

The notification function is called before the packet is queued to the FIFO, enabling priority processing or filtering. This is useful for protocols requiring immediate response or for implementing custom packet filtering logic.

Parameters

<i>listenPort</i>	UDP port number to register (1-65535). Must not already be registered.
<i>pFifo</i>	Pointer to an OS_FIFO structure for queuing packets. The FIFO must be initialized before calling this function. Can be NULL if you only want notification callbacks.
<i>pNotifyFunction</i>	Pointer to callback function invoked when packet arrives. Function signature: void callback(uint16_t port, uint8_t* data, int len, IPADDR& srcAddr) Called in interrupt context - keep processing minimal and fast. Can be NULL if you only want FIFO queuing without notification.

Returns

true if port successfully registered with notification, false on failure (e.g., port already in use, invalid parameters)

Note

The notification callback is invoked from interrupt context - keep it fast and minimal

Do not perform blocking operations or lengthy processing in the callback

Both pFifo and pNotifyFunction can be provided, or just one (the other can be NULL)

Packets are queued to FIFO after the notification callback returns

Warning

The callback executes in interrupt context - avoid blocking calls, printf, or long operations

The FIFO and callback function must remain valid until [UnregisterUDPFifo\(\)](#) is called

Do not call [UnregisterUDPFifo\(\)](#) from within the notification callback

Expand for Example Usage**Examples**

Example (immediate response protocol):

```
OS_FIFO pingFifo;
OSFifoInit(&pingFifo);

// Notification callback - responds immediately to ping requests
void PingNotify(uint16_t port, uint8_t* data, int len, IPADDR& srcAddr) {
    if (len >= 4 && memcmp(data, "PING", 4) == 0) {
        // Immediate pong response
        SendUdpPacket(srcAddr, port, port, (uint8_t*)"PONG", 4);
    }
}

// Register with notification
if (RegisterUDPFifoWithNotify(9000, &pingFifo, PingNotify)) {
    printf("Ping responder registered on port 9000\n");
}

// Packets are also queued for later processing if needed
UDP_PACKET packet;
while (ReadUDPPacket(&packet, 9000, 0)) {
    printf("Logged ping from %s\n", packet.sourceIpAddr.toString());
    ReleaseUDPPacket(packet);
}
```

Example (packet filtering and statistics):

```
OS_FIFO datagramFifo;
OSFifoInit(&datagramFifo);

volatile uint32_t packetCount = 0;
volatile uint32_t filteredCount = 0;

// Notification for statistics and filtering
void DatagramNotify(uint16_t port, uint8_t* data, int len, IPADDR& srcAddr) {
    packetCount++;

    // Filter packets - could modify data or reject certain sources
    if (len < 10) {
        filteredCount++;
        // Packet still gets queued to FIFO
    }
}

RegisterUDPFifoWithNotify(5000, &datagramFifo, DatagramNotify);

// Main loop can check statistics
printf("Received: %lu, Filtered: %lu\n", packetCount, filteredCount);

Example (notification only, no FIFO):
// Just count packets, don't queue them
volatile uint32_t statsPackets = 0;

void StatsOnlyNotify(uint16_t port, uint8_t* data, int len, IPADDR& srcAddr) {
    statsPackets++;
}

// NULL FIFO - only notification callback
RegisterUDPFifoWithNotify(6000, NULL, StatsOnlyNotify);
```

See also

[RegisterUDPFifo\(\)](#) for registration without notification callback

[RegisterUDPFifoWithNotifyVia\(\)](#) to specify network interface

[UnregisterUDPFifo\(\)](#) to unregister the port

14.57.3.5 RegisterUDPFifoWithNotifyVia()

```
bool RegisterUDPFifoWithNotifyVia (
    uint16_t listenPort,
    OS_FIFO * pFifo,
    udp_data_notify * pNotifyFunction,
    int interface)

#include <udp.h>
```

Register UDP FIFO with callback notification on specific network interface.

Similar to [RegisterUDPFifoWithNotify\(\)](#), but allows explicit selection of which network interface to listen on. This is essential for multi-homed systems (devices with multiple network connections) where you need to receive UDP packets on a specific interface only.

Use this function when your device has multiple network interfaces (Ethernet, WiFi, etc.) and you need to isolate UDP traffic by interface. For example, listening for management traffic only on the Ethernet interface while ignoring

similar packets from WiFi.

Parameters

<i>listenPort</i>	UDP port number to register (1-65535). Must not already be registered on the specified interface.
<i>pFifo</i>	Pointer to an OS_FIFO structure for queuing packets. Must be initialized before calling. Can be NULL for notification-only.
<i>pNotifyFunction</i>	Pointer to callback function invoked when packet arrives. Function signature: void callback(uint16_t port, uint8_t* data, int len, IPADDR& srcAddr) Called in interrupt context. Can be NULL for FIFO-only operation.
<i>interface</i>	Network interface number (0-based): • 0 = First interface (typically primary Ethernet) • 1 = Second interface (WiFi, secondary Ethernet, etc.) • 2+ = Additional interfaces if present The interface must be active and configured.

Returns

true if port successfully registered on the specified interface, false on failure (e.g., port already in use on this interface, interface doesn't exist, invalid parameters)

Note

Only packets arriving on the specified interface will be received

The same port can be registered on different interfaces simultaneously

The notification callback is invoked from interrupt context - keep it minimal

Interface numbers are system-specific - check your platform documentation

Warning

The callback executes in interrupt context - avoid blocking operations

The FIFO and callback must remain valid until [UnregisterUDPFifo\(\)](#) is called

Verify the interface exists and is active before registering

Expand for Example Usage

Examples

Example (dual-homed device - different ports per interface):

```
OS_FIFO ethernetFifo, wifiFifo;
OSFifoInit(&ethernetFifo);
OSFifoInit(&wifiFifo);

// Listen on port 8000 on Ethernet interface only
if (RegisterUDPFifoWithNotifyVia(8000, &ethernetFifo, NULL, 0)) {
    printf("Registered on Ethernet (interface 0)\n");
}

// Listen on port 8000 on WiFi interface only (same port, different interface)
if (RegisterUDPFifoWithNotifyVia(8000, &wifiFifo, NULL, 1)) {
    printf("Registered on WiFi (interface 1)\n");
}

// Now we can distinguish packets by which FIFO they arrive on
```

Example (management vs. data network separation):

```
OS_FIFO mgmtFifo, dataFifo;
OSFifoInit(&mgmtFifo);
OSFifoInit(&dataFifo);

// Management traffic on dedicated Ethernet interface
RegisterUDPFifoWithNotifyVia(161, &mgmtFifo, NULL, 0); // SNMP on eth0

// High-speed data on separate interface
```

```

RegisterUDPFifoWithNotifyVia(5000, &dataFifo, NULL, 1); // Data on eth1

// Process management packets
UDPPacket mgmtPacket;
if (ReadUDPPacket(&mgmtPacket, 161, 0)) {
    printf("Management packet from secure network\n");
    ReleaseUDPPacket(mgmtPacket);
}

Example (interface-specific notification):
OS_FIFO primaryFifo, backupFifo;
OSFifoInit(&primaryFifo);
OSFifoInit(&backupFifo);

void PrimaryNotify(uint16_t port, uint8_t* data, int len, IPADDR& srcAddr) {
    // Log that primary interface received packet
    primaryPacketCount++;
}

void BackupNotify(uint16_t port, uint8_t* data, int len, IPADDR& srcAddr) {
    // Alert if backup interface is receiving traffic
    backupPacketCount++;
    TriggerFailoverAlert();
}

// Same port, different interfaces with different callbacks
RegisterUDPFifoWithNotifyVia(9000, &primaryFifo, PrimaryNotify, 0);
RegisterUDPFifoWithNotifyVia(9000, &backupFifo, BackupNotify, 1);

Example (checking interface availability first):
int targetInterface = 1;

// Verify interface exists and is active
if (GetInterfaceCount() > targetInterface && InterfaceActive(targetInterface)) {
    OS_FIFO myFifo;
    OSFifoInit(&myFifo);

    if (RegisterUDPFifoWithNotifyVia(7000, &myFifo, NULL, targetInterface)) {
        printf("Successfully registered on interface %d\n", targetInterface);
    } else {
        printf("Failed to register on interface %d\n", targetInterface);
    }
} else {
    printf("Interface %d not available\n", targetInterface);
}

```

See also

[RegisterUDPFifoWithNotify\(\)](#) for default interface registration
[RegisterUDPFifo\(\)](#) for basic registration without notification
[GetInterfaceCount\(\)](#) to determine available interfaces
[InterfaceActive\(\)](#) to check if an interface is active
[UnregisterUDPFifo\(\)](#) to unregister the port

14.57.3.6 UnregisterUDPFifo()

```

void UnregisterUDPFifo (
    uint16_t listenPort,
    bool drain = false)

```

```
#include <udp.h>
```

Unregister UDP FIFO and stop receiving packets on specified port.

Stops listening for UDP packets on the specified port and removes the associated FIFO queue from the system.

This function should be called when a UDP port is no longer needed to free system resources.

If the FIFO has queued packets waiting to be processed, the drain parameter controls whether these packets are discarded or left in the queue. Typically, you should drain the queue unless you have already processed all packets.

Parameters

<i>listenPort</i>	The UDP port number to unregister (must match a previously registered port)
<i>drain</i>	If true, frees all queued packets in the FIFO and releases their memory. If false, leaves queued packets in memory (default: false). In most cases, you should set this to true to prevent memory leaks.

Note

After calling this function, the port becomes available for other applications
 Any subsequent packets arriving on this port will be ignored until re-registered
 If drain is false and packets remain queued, you may have a memory leak

Warning

Always drain the FIFO (drain=true) unless you have a specific reason not to
 Unregistering a port that was never registered has no effect but is safe

Expand for Example Usage**Examples**

Example (typical cleanup):

```
// Registered earlier
RegisterUDPFifo(5000, 10); // Port 5000 with queue depth 10

// ... process packets ...
```

```
// Clean shutdown - drain all remaining packets
UnregisterUDPFifo(5000, true);
```

Example (graceful shutdown - process remaining packets first):

```
// Process all remaining packets before unregistering
UDPPacket packet;
while (ReadUDPPacket(&packet, 5000, 0)) { // 0 = non-blocking
    ProcessPacket(packet);
    ReleaseUDPPacket(packet);
}
```

```
// Now safe to unregister without drain since we processed everything
UnregisterUDPFifo(5000, false);
```

Example (application shutdown):

```
void ShutdownNetworking() {
    // Unregister all UDP ports and free resources
    UnregisterUDPFifo(5000, true); // Control port
    UnregisterUDPFifo(5001, true); // Data port
    UnregisterUDPFifo(5002, true); // Status port
}
```

[ReleaseUDPPacket\(\)](#) to free individual packet buffers

14.57.4 UDP Error Codes**Macros**

- **#define UDP_ERR_NOSUCH_SOCKET (-1)**
Socket does not exist.
- **#define UDP_ERR_NOTOPEN_TO_WRITE (-2)**
Socket not open for write.
- **#define UDP_ERR_NOTOPEN_TO_READ (-3)**
Socket not open for read.

14.57.4.1 Detailed Description

These negative values are returned by UDP socket creation and operation functions to indicate specific error conditions. All successful operations return non-negative values (valid file descriptors ≥ 0 or byte counts ≥ 0).

Note

See detailed return code information, causes and solutions at:
[Programmers Guide UDP Error Codes](#)

14.57.5 UDP Packet API

Refer to UDP Packet Class and API: [UDPPacket](#)

14.57.6 UDP Socket API

BSD-style socket functions for UDP communication.

Functions

- int [CreateRxUdpSocket](#) (uint16_t listening_port)
Create receive-only UDP socket bound to specified port.
- int [CreateTxUdpSocket](#) (const [IPADDR](#) &send_to_addr, uint16_t remote_port, uint16_t local_port)
Create transmit-only UDP socket for sending to specified destination.
- int [CreateRxTxUdpSocket](#) (const [IPADDR](#) &send_to_addr, uint16_t send_to_remote_port, uint16_t local_port)
Create bidirectional UDP socket for both sending and receiving.
- int [sendto](#) (int sock, uint8_t what_to_send, int len_to_send, const [IPADDR](#) &to_addr, uint16_t remote_port)
Send UDP packet through socket to specified destination.
- int [sendtovia](#) (int sock, uint8_t what_to_send, int len_to_send, const [IPADDR](#) &to_addr, uint16_t remote_port, int intfnum)
Send via specific interface.
- int [recvfrom](#) (int sock, uint8_t buffer, int len, [IPADDR](#) *pAddr, uint16_t *pLocal_port, uint16_t *pRemote_port)
Receive UDP packet from socket with sender information.
- int [SendFragmentedUdpPacket](#) (const [IPADDR](#) &to, uint16_t source_port, uint16_t dest_port, uint8_t data, int length)
Send large UDP packet (>MTU) with IP fragmentation.

14.57.6.1 Detailed Description

BSD-style socket functions for UDP communication.

Provides familiar Berkeley Sockets (BSD) style interface for UDP networking. These functions offer an alternative to the [UDPPacket](#) class for developers who prefer traditional socket programming or are porting existing code.

14.57.6.1.1 Overview

The UDP Socket API provides three main operation types:

- **Receive-only sockets:** Listen for incoming packets on a specific port
- **Transmit-only sockets:** Send packets to a specific destination
- **Bidirectional sockets:** Combined receive and transmit capabilities

14.57.6.1.2 Key Concepts

14.57.6.1.2.1 Socket Types

1. Receive-Only Socket (Server/Listener)

- Created with [CreateRxUdpSocket\(\)](#)
- Binds to local port to receive packets
- Can receive from any sender
- Typical use: Servers, listeners, broadcast receivers

2. Transmit-Only Socket (Client/Sender)

- Created with [CreateTxUdpSocket\(\)](#)
- Optionally binds to specific local port
- Sends to predefined destination
- Typical use: Clients, sensors, periodic transmitters

3. Bidirectional Socket (Request/Response)

- Created with [CreateRxTxUdpSocket\(\)](#)
- Combines both receive and transmit
- Binds local port and sets remote endpoint
- Typical use: Client-server patterns, RPC-style communication

14.57.6.1.2.2 Port Number Selection

Local Port (Binding)

- **0**: System assigns ephemeral port (49152-65535) - recommended for clients
- **1-1023**: Well-known ports (e.g., 53=DNS, 123=NTP) - requires privileges
- **1024-49151**: Registered ports - typical for custom servers
- **49152-65535**: Dynamic/private ports - ephemeral port range

Remote Port (Destination)

- Specify the destination service port
- Must match the listening port on remote system

```
// Server pattern - fixed local port
int serverSock = CreateRxUdpSocket(8080);

// Client pattern - auto-assign local port
int clientSock = CreateTxUdpSocket(serverIP, 8080, 0);
```

14.57.6.1.3 Common Usage Patterns

Examples

Pattern 1: Simple UDP Server

```
#include <udp.h>
#include <init.h>

void UdpServerTask(void* pd) {
    int sock = CreateRxUdpSocket(5000);
    if (sock < 0) {
        printf("Failed to create socket: %d\r\n", sock);
        return;
    }

    uint8_t buffer[1024];
    IPADDR clientIP;
    uint16_t localPort, remotePort;

    while (1) {
        int n = recvfrom(sock, buffer, sizeof(buffer),
                        &clientIP, &localPort, &remotePort);

        if (n > 0) {
            printf("Received %d bytes from %s:%d\r\n",
                  n, AsciiIP(clientIP).c_str(), remotePort);

            // Echo back to sender
            sendto(sock, buffer, n, clientIP, remotePort);
        }
    }
}
```

Pattern 2: UDP Client (One-Way Sender)

```

void SendSensorData(IPADDR serverIP, int sensorValue) {
    // Create socket with auto-assigned local port (0)
    int sock = CreateTxUdpSocket(serverIP, 5000, 0);
    if (sock < 0) {
        printf("Socket creation failed\r\n");
        return;
    }

    char msg[64];
    int len = sprintf(msg, "SENSOR:%d,VALUE:%d",
                      GetDeviceID(), sensorValue);

    sendto(sock, (uint8_t*)msg, len, serverIP, 5000);

    close(sock);
}

```

Pattern 3: Request/Response (Bidirectional)

```

int QueryServer(IPADDR serverIP, const char* request,
                char* response, int maxLen) {
    // Create bidirectional socket
    int sock = CreateRxTxUdpSocket(serverIP, 6000, 0);
    if (sock < 0) return -1;

    // Send request
    sendto(sock, (uint8_t*)request, strlen(request), serverIP, 6000);

    // Wait for response with timeout
    fd_set readfds;
    struct timeval tv = {5, 0}; // 5 second timeout
    FD_ZERO(&readfds);
    FD_SET(sock, &readfds);

    if (select(sock + 1, &readfds, NULL, NULL, &tv) > 0) {
        IPADDR srcIP;
        uint16_t localPort, remotePort;
        int n = recvfrom(sock, (uint8_t*)response, maxLen,
                        &srcIP, &localPort, &remotePort);

        close(sock);
        return n;
    }

    close(sock);
    return 0; // Timeout
}

```

Pattern 4: Multi-Interface Routing

```

// Send via specific network interface (multi-homed device)
void SendViaInterface(IPADDR destIP, int interfaceNum) {
    int sock = CreateTxUdpSocketVia(destIP, 8080, 0, interfaceNum);
    if (sock >= 0) {
        uint8_t data[] = "Hello from specific interface";
        sendto(sock, data, sizeof(data), destIP, 8080, interfaceNum);
        close(sock);
    }
}

```

Pattern 5: Broadcast Discovery

```

void DiscoverDevices() {
    IPADDR broadcastAddr = AsciiToIp("255.255.255.255");
    int sock = CreateTxUdpSocket(broadcastAddr, 9999, 0);

    if (sock >= 0) {
        uint8_t discover[] = "DISCOVER:NetBurner";
        sendto(sock, discover, sizeof(discover), broadcastAddr, 9999);

        // Listen for responses
        uint8_t buf[256];
        IPADDR responderIP;
        uint16_t lp, rp;

        while (recvfrom(sock, buf, sizeof(buf), &responderIP, &lp, &rp) > 0) {
            printf("Found device at %s\r\n", AsciiIP(responderIP).c_str());
        }

        close(sock);
    }
}

```

Pattern 6: Using select() for Multiple Sockets

```
void MultiSocketHandler() {
    int sock1 = CreateRxUdpSocket(5000);
    int sock2 = CreateRxUdpSocket(5001);
    int maxfd = (sock1 > sock2) ? sock1 : sock2;

    fd_set readfds;
    uint8_t buffer[512];
    IPADDR srcIP;
    uint16_t lp, rp;

    while (1) {
        FD_ZERO(&readfds);
        FD_SET(sock1, &readfds);
        FD_SET(sock2, &readfds);

        if (select(maxfd + 1, &readfds, NULL, NULL, NULL) > 0) {
            if (FD_ISSET(sock1, &readfds)) {
                int n = recvfrom(sock1, buffer, sizeof(buffer),
                                &srcIP, &lp, &rp);
                printf("Port 5000: %d bytes\r\n", n);
            }

            if (FD_ISSET(sock2, &readfds)) {
                int n = recvfrom(sock2, buffer, sizeof(buffer),
                                &srcIP, &lp, &rp);
                printf("Port 5001: %d bytes\r\n", n);
            }
        }
    }
}
```

14.57.6.1.4 Error Handling

All socket creation functions return:

- `**>= 0**`: Valid socket file descriptor
- `**< 0**`: Error code (see `UDP_ERR_*` constants)

Common error codes:

- `UDP_ERR_NOSUCH_SOCKET (-1)`: Socket does not exist or was closed
- `UDP_ERR_NOTOPEN_TO_WRITE (-2)`: Socket not configured for sending
- `UDP_ERR_NOTOPEN_TO_READ (-3)`: Socket not configured for receiving

```
int sock = CreateRxUdpSocket(port);
if (sock < 0) {
    switch (sock) {
        case UDP_ERR_NOSUCH_SOCKET:
            printf("Socket does not exist\r\n");
            break;
        case UDP_ERR_NOTOPEN_TO_WRITE:
            printf("Cannot write to socket\r\n");
            break;
        case UDP_ERR_NOTOPEN_TO_READ:
            printf("Cannot read from socket\r\n");
            break;
        default:
            printf("Unknown error: %d\r\n", sock);
    }
    return;
}
```

14.57.6.1.5 Thread Safety

- Each socket should be used by a single task
- Multiple tasks can use different sockets
- Sockets are NOT thread-safe for concurrent access
- Use separate sockets per task for parallel operations

```
// Good: Each task uses its own socket
void Task1(void* pd) {
    int sock = CreateRxUdpSocket(5000);
    // ... use sock ...
}

void Task2(void* pd) {
    int sock = CreateRxUdpSocket(5001);
    // ... use sock ...
}
```

14.57.6.1.6 Performance Considerations

14.57.6.1.6.1 Buffer Sizing

- **Typical MTU:** 1500 bytes (Ethernet)
- **UDP header overhead:** 8 bytes
- **IP header overhead:** 20 bytes (IPv4), 40 bytes (IPv6)
- **Safe payload size:** 1472 bytes (IPv4), 1452 bytes (IPv6)
- **Larger packets:** Use [SendFragmentedUdpPacket\(\)](#) for automatic fragmentation

14.57.6.1.6.2 Optimization Tips

1. **Reuse sockets:** Create once, use many times
2. **Batch operations:** Send multiple packets before context switch
3. **Appropriate buffer sizes:** Match expected packet sizes
4. **Interface binding:** Reduce routing overhead in multi-homed systems
5. **Port reuse:** Close sockets when no longer needed

14.57.6.1.7 IPv4 vs IPv6

The API automatically handles both IPv4 and IPv6 based on IPADDR type:

```
#ifdef IPV6
// Dual-stack - works with both IPv4 and IPv6
IPADDR destIP = AsciiToIp("2001:db8::1"); // IPv6
// or
IPADDR destIP = AsciiToIp("192.168.1.100"); // IPv4-mapped

int sock = CreateTxUdpSocket(destIP, 8080, 0);
#else
// IPv4 only
IPADDR4 destIP = AsciiToIp4("192.168.1.100");
int sock = CreateTxUdpSocket(destIP, 8080, 0);
#endif
```

14.57.6.1.8 Multi-Homed Systems

For devices with multiple network interfaces:

14.57.6.1.8.1 Interface Number (Preferred)

```
// Send via interface 1 (second Ethernet, Wi-Fi, etc.)
int sock = CreateTxUdpSocketVia(destIP, 8080, 0, 1);
sendtovia(sock, data, len, destIP, 8080, 1);
```

14.57.6.1.8.2 Interface IP Address (Alternative)

```
// Send via specific interface IP
IPADDR myInterfaceIP = GetInterfaceIP(1);
int sock = CreateTxUdpSocketVia(destIP, 8080, 0, myInterfaceIP);
```

14.57.6.1.9 Comparison with UDPPacket Class

Feature	BSD Sockets	UDPPacket Class
API Style	Familiar C functions	C++ object-oriented
Memory Management	Manual	Automatic (RAII)
Buffer Access	Copy-based	Zero-copy available
Multi-destination	Multiple sends	SendAndKeep() support
Integration	select() / poll()	OS_FIFO queues
Portability	Standard POSIX	NetBurner-specific
Best For	Porting code, C code	New C++ projects

14.57.6.1.9.1 When to Use BSD Sockets:

- Porting existing socket-based code
- Writing in C (not C++)
- Need [select\(\)](#)/[poll\(\)](#) integration
- Familiar with Berkeley sockets
- Simple send/receive patterns

14.57.6.1.9.2 When to Use UDPPacket:

- New C++ development
- Need automatic memory management
- Direct buffer manipulation
- Multiple destination sends
- OS_FIFO-based architectures

14.57.6.1.10 Advanced Features

14.57.6.1.10.1 Large Packet Transmission (Fragmentation)

For packets exceeding MTU, use [SendFragmentedUdpPacket\(\)](#):

```
uint8_t largeData[5000];
// ... fill largeData ...

int result = SendFragmentedUdpPacket(
    destIP,
    0,      // source port (0 = auto-assign)
    8080,   // destination port
    largeData,
    sizeof(largeData)
);

if (result == sizeof(largeData)) {
    printf("Successfully sent %d bytes\r\n", result);
} else {
    printf("Send failed or partial: %d/%d bytes\r\n",
        result, sizeof(largeData));
}
```

Note: Fragmentation should be avoided when possible due to:

- Increased packet loss risk (one fragment lost = entire packet lost)
- Additional processing overhead
- Potential firewall/router issues
- Better to design protocol with smaller messages when feasible

14.57.6.1.10.2 Socket Lifecycle Management

```
// Create socket
int sock = CreateRxTxUdpSocket(serverIP, 8080, 0);
if (sock < 0) {
    // Handle error
    return;
}

// Use socket for communication
// ...

// Close socket when done
close(sock);

// Socket descriptor is now invalid
```

14.57.6.1.11 Common Pitfalls

14.57.6.1.11.1 [NO] Not checking return values

```
int sock = CreateRxUdpSocket(5000);
recvfrom(sock, buf, len, &ip, &lp, &rp); // BUG: sock might be negative!
```

14.57.6.1.11.2 [YES] Always validate

```
int sock = CreateRxUdpSocket(5000);
if (sock < 0) {
    printf("Socket creation failed: %d\r\n", sock);
    return;
}
recvfrom(sock, buf, len, &ip, &lp, &rp);
```

14.57.6.1.11.3 [NO] Buffer overflow

```
uint8_t buf[100];
recvfrom(sock, buf, 1000, &ip, &lp, &rp); // BUG: Buffer too small!
```

14.57.6.1.11.4 [YES] Match buffer size

```
uint8_t buf[1500];
int n = recvfrom(sock, buf, sizeof(buf), &ip, &lp, &rp);
if (n > 0 && n < sizeof(buf)) {
    // Process n bytes safely
}
```

14.57.6.1.11.5 [NO] Ignoring recvfrom() return value

```
uint8_t buf[512];
recvfrom(sock, buf, sizeof(buf), &ip, &lp, &rp);
printf("%s", buf); // BUG: Might print garbage or crash!
```

14.57.6.1.11.6 [YES] Check bytes received

```
uint8_t buf[512];
int n = recvfrom(sock, buf, sizeof(buf), &ip, &lp, &rp);
if (n > 0) {
    buf[n] = '\0'; // Safe null-termination
    printf("%s", buf);
}
```

14.57.6.1.11.7 [NO] Port conflicts

```
int sock1 = CreateRxUdpSocket(8080);
int sock2 = CreateRxUdpSocket(8080); // BUG: Port already in use!
```

14.57.6.1.11.8 [YES] Unique ports or reuse pattern

```
int sock1 = CreateRxUdpSocket(8080);
// ... use sock1 ...
close(sock1);

// Now safe to reuse port
int sock2 = CreateRxUdpSocket(8080);
```

14.57.6.1.12 Debugging Tips

1. **Enable diagnostics:** Call [EnableSystemDiagnostics\(\)](#) in UserMain()
2. **Check socket descriptor:** Valid sockets are ≥ 0
3. **Verify network connectivity:** Ensure interface is up and configured
4. **Monitor packet capture:** Use Wireshark to inspect actual traffic
5. **Test with known tools:** Use netcat (nc) for quick testing: ``bash

14.57.6.2 Send UDP packet from command line

```
echo "test" | nc -u 192.168.1.100 8080
```

14.57.6.3 Listen for UDP packets

```
nc -ul 8080 ``
```

1. **Check firewall rules:** Ensure UDP traffic is not blocked
2. **Validate addresses:** Use [AsciiIP\(\)](#) to print addresses for debugging

14.57.6.4 Function Documentation

14.57.6.4.1 CreateRxTxUdpSocket()

```
int CreateRxTxUdpSocket (
    const IPADDR & send_to_addr,
    uint16_t send_to_remote_port,
    uint16_t local_port) [inline]
```

```
#include <udp.h>
```

Create bidirectional UDP socket for both sending and receiving.

Creates a UDP socket that can both send packets to a specified destination and receive packets on a local port. This combines the functionality of [CreateTxUdpSocket\(\)](#) and [CreateRxUdpSocket\(\)](#) into a single socket, ideal for request/response patterns and client-server communication.

Socket Characteristics:

- Can send to pre-configured destination
- Can receive on bound local port
- Single socket for bidirectional communication
- Efficient for request/response protocols

Common Use Cases:

- Client applications expecting replies (DNS queries, SNMP, RPC)
- Request/response protocols
- Duplex communication patterns
- Protocols requiring both send and receive on same endpoint

Parameters

<i>send_to_addr</i>	Destination IP address for sending packets Use <code>AsciiToIp()</code> or <code>AsciiToIp4()</code> to convert from string
<i>send_to_remote_port</i>	Destination port number for sending (1-65535)
<i>local_port</i>	Local port to bind for receiving (0-65535) • 0: Auto-assign ephemeral port (common for clients) • 1-65535: Specific port (required if server must reply to known port)

Returns

Socket file descriptor (≥ 0) on success, negative error code on failure:

- `UDP_ERR_NOSUCH_SOCKET` (-1): Socket creation failed
- `UDP_ERR_NOTOPEN_TO_WRITE` (-2): Socket not writable
- `UDP_ERR_NOTOPEN_TO_READ` (-3): Socket not readable

Note

Port Selection: Use 0 for `local_port` if server response port doesn't matter. Use specific port only when protocol requires clients to listen on fixed ports.

Response Handling: Responses will arrive on the `local_port`. Use `recvfrom()` to receive them. The remote source may be different from `send_to_addr`.

Warning

Thread Safety: Socket should be used by single task. Do not call `sendto()` and `recvfrom()` concurrently from multiple tasks on same socket.

Expand for Example Usage

Examples

Example 1: DNS Query (Request/Response Pattern)

```
#include <udp.h>

bool DnsQuery(const char* hostname, IPADDR* result) {
    IPADDR dnsServer = AsciiToIp("8.8.8.8");

    // Create bidirectional socket for DNS query and response
    int sock = CreateRxTxUdpSocket(dnsServer, 53, 0);
    if (sock < 0) return false;

    // Build DNS query packet
    uint8_t query[512];
    int queryLen = BuildDnsQuery(query, hostname);

    // Send query
    sendto(sock, query, queryLen, dnsServer, 53);

    // Wait for response with timeout
    fd_set readfds;
    struct timeval tv = {5, 0}; // 5 second timeout
    FD_ZERO(&readfds);
    FD_SET(sock, &readfds);

    if (select(sock + 1, &readfds, NULL, NULL, &tv) > 0) {
        uint8_t response[512];
        IPADDR srcIP;
        uint16_t lp, rp;
        int n = recvfrom(sock, response, sizeof(response),
                        &srcIP, &lp, &rp);

        if (n > 0) {
            *result = ParseDnsResponse(response, n);
            close(sock);
            return true;
        }
    }
}
```

```

    close(sock);
    return false; // Timeout or error
}

```

Example 2: Echo Client with Response

```

void EchoClientTest() {
    IPADDR serverIP = AsciiToIp("192.168.1.100");

    // Create bidirectional socket
    int sock = CreateRxTxUdpSocket(serverIP, 5000, 0);
    if (sock < 0) {
        printf("Socket creation failed\r\n");
        return;
    }

    // Send message
    const char* msg = "Hello, Server!";
    sendto(sock, (uint8_t*)msg, strlen(msg), serverIP, 5000);
    printf("Sent: %s\r\n", msg);

    // Wait for echo response
    uint8_t buf[256];
    IPADDR respIP;
    uint16_t lp, rp;

    int n = recvfrom(sock, buf, sizeof(buf), &respIP, &lp, &rp);
    if (n > 0) {
        buf[n] = '\0';
        printf("Received echo: %s\r\n", buf);
    }

    close(sock);
}

```

Example 3: Persistent Connection Pattern

```

void RequestResponseLoop() {
    IPADDR serverIP = AsciiToIp("10.0.0.50");

    // Create persistent bidirectional socket
    int sock = CreateRxTxUdpSocket(serverIP, 6000, 0);
    if (sock < 0) return;

    uint8_t request[64];
    uint8_t response[256];
    IPADDR respIP;
    uint16_t lp, rp;

    for (int i = 0; i < 10; i++) {
        // Send request
        int reqLen = sprintf((char*)request, "REQ:%d", i);
        sendto(sock, request, reqLen, serverIP, 6000);

        // Wait for response
        int n = recvfrom(sock, response, sizeof(response),
                        &respIP, &lp, &rp);

        if (n > 0) {
            response[n] = '\0';
            printf("Response %d: %s\r\n", i, response);
        }

        OSTimeDly(TICKS_PER_SECOND);
    }

    close(sock);
}

```

14.57.6.4.2 CreateRxUdpSocket()

```

int CreateRxUdpSocket (

```

```
uint16_t listening_port)
#include <udp.h>
```

Create receive-only UDP socket bound to specified port.

Creates a UDP socket configured only for receiving packets. The socket is bound to the specified local port and can receive UDP packets from any source. This is the standard function for creating UDP server/listener sockets.

Socket Characteristics:

- Bound to specified local port
- Receives from any source IP/port
- Cannot send packets (receive-only)
- Suitable for servers and broadcast receivers

Common Use Cases:

- UDP servers listening for client requests
- Broadcast/multicast receivers
- Service discovery listeners
- Logging/monitoring receivers

Parameters

<i>listening_port</i>	Local port number to bind (1-65535) • Well-known ports (1-1023): Standard services (use with caution) • Registered ports (1024-49151): Custom applications (recommended) • Dynamic ports (49152-65535): Temporary/ephemeral use

Returns

Socket file descriptor (≥ 0) on success, negative error code on failure:

- `UDP_ERR_NOSUCH_SOCKET` (-1): Socket creation failed
- `UDP_ERR_NOTOPEN_TO_READ` (-3): Internal error - socket not readable

Note

Port Availability: The port must not already be in use by another socket. Use [UnregisterUDPFifo\(\)](#) or [close\(\)](#) existing sockets before reusing ports.

Thread Safety: The returned socket should only be used by a single task. For multi-task reception, create separate sockets on different ports or use the [UDPPacket](#) class with `OS_FIFO` for thread-safe queue-based reception.

Warning

Error Checking Required: Always check return value before using socket. Attempting to use a negative file descriptor will cause undefined behavior.

Expand for Example Usage

Examples

Example 1: Simple UDP Server

```
#include <udp.h>
#include <init.h>

void UdpServerTask(void* pd) {
    // Create receive-only socket on port 8080
    int sock = CreateRxUdpSocket(8080);
    if (sock < 0) {
        printf("Failed to create socket: error %d\r\n", sock);
        return;
    }

    printf("UDP server listening on port 8080\r\n");

    uint8_t buffer[1024];
    IPADDR clientIP;
    uint16_t localPort, remotePort;

    while (1) {
        // Wait for incoming packet
        int n = recvfrom(sock, buffer, sizeof(buffer),
                        &clientIP, &localPort, &remotePort);

        if (n > 0) {
            buffer[n] = '\0'; // Null-terminate for printing
            printf("Received %d bytes from %s:%d: %s\r\n",
                  n, AsciiIP(clientIP).c_str(), remotePort, buffer);
        }

        // Clean up (typically never reached in server loop)
        close(sock);
    }
}
```

Example 2: Echo Server

```
void UdpEchoServer() {
    int sock = CreateRxUdpSocket(5000);
    if (sock < 0) return;

    uint8_t buf[512];
    IPADDR srcIP;
    uint16_t lp, rp;

    while (1) {
        int n = recvfrom(sock, buf, sizeof(buf), &srcIP, &lp, &rp);
        if (n > 0) {
            // Note: Cannot echo back using this socket - it's receive-only!
            // Need CreateRxTxUdpSocket() for bidirectional operation
            printf("Echo server received: %d bytes\r\n", n);
        }
    }
}
```

Example 3: Broadcast Receiver

```
void BroadcastListener() {
    int sock = CreateRxUdpSocket(9999);
    if (sock < 0) {
        printf("Cannot create broadcast listener\r\n");
        return;
    }

    printf("Listening for broadcast packets on port 9999\r\n");

    uint8_t buf[256];
    IPADDR senderIP;
    uint16_t lp, rp;

    while (1) {
        int n = recvfrom(sock, buf, sizeof(buf), &senderIP, &lp, &rp);
        if (n > 0) {
            buf[n] = '\0';
            printf("Broadcast from %s: %s\r\n",
                  AsciiIP(senderIP).c_str(), buf);
        }
    }
}
```

[RegisterUDPFifo\(\)](#) - Alternative using [UDPPacket](#) class with OS_FIFO

[close\(\)](#) - Close socket when finished

14.57.6.4.3 CreateTxUdpSocket()

```
int CreateTxUdpSocket (
    const IPADDR & send_to_addr,
    uint16_t remote_port,
    uint16_t local_port) [inline]
#include <udp.h>
```

Create transmit-only UDP socket for sending to specified destination.

Creates a UDP socket configured only for sending packets to a specific remote address and port. The socket can optionally be bound to a specific local port, or use 0 to auto-assign an ephemeral port (recommended for most clients).

Socket Characteristics:

- Send-only (cannot receive packets)
- Pre-configured with destination address and port
- Optional local port binding (0=auto-assign)
- Suitable for client applications and sensors

Common Use Cases:

- UDP clients sending requests to servers
- Sensor data transmission
- Logging to remote syslog servers
- Periodic status updates to monitoring systems

Parameters

<i>send_to_addr</i>	Destination IP address (IPv4 or IPv6 depending on build config) Use AsciiToIp() or AsciiToIp4() to convert from string
<i>remote_port</i>	Destination port number (1-65535) Must match the listening port on remote system
<i>local_port</i>	Local port to bind (0-65535) • 0: Auto-assign ephemeral port (RECOMMENDED for clients) • 1-65535: Specific port (use only if required by protocol)

Returns

Socket file descriptor (≥ 0) on success, negative error code on failure:

- `UDP_ERR_NOSUCH_SOCKET` (-1): Socket creation failed
- `UDP_ERR_NOTOPEN_TO_WRITE` (-2): Internal error - socket not writable

Note

Local Port Recommendation: Use 0 for automatic port assignment unless your protocol specifically requires a fixed source port. Auto-assignment prevents port conflicts and is standard practice for UDP clients.

Destination Changes: This socket is bound to the specified destination. To send to different destinations, use [sendto\(\)](#) or create multiple sockets.

Warning

Send-Only: This socket cannot receive packets. For bidirectional communication (request/response patterns), use [CreateRxTxUdpSocket\(\)](#).

Expand for Example Usage**Examples****Example 1: Simple UDP Client**

```
#include <udp.h>

void SendMessage(const char* message) {
    IPADDR serverIP = AsciiToIp("192.168.1.100");

    // Create socket with auto-assigned local port (0)
    int sock = CreateTxUdpSocket(serverIP, 8080, 0);
    if (sock < 0) {
        printf("Failed to create socket\r\n");
        return;
    }

    // Send message
    int sent = sendto(sock, (uint8_t*)message, strlen(message),
                     serverIP, 8080);

    if (sent > 0) {
        printf("Sent %d bytes\r\n", sent);
    }

    close(sock);
}
```

Example 2: Periodic Sensor Data Transmission

```
void SensorTransmitTask(void* pd) {
    IPADDR serverIP = AsciiToIp("10.0.1.50");

    // Create persistent socket (reuse for efficiency)
    int sock = CreateTxUdpSocket(serverIP, 5000, 0);
    if (sock < 0) return;

    char msgBuf[64];

    while (1) {
        // Read sensor
        int temperature = ReadTemperatureSensor();
        int humidity = ReadHumiditySensor();

        // Format message
        int len = sprintf(msgBuf, "TEMP:%d,HUM:%d",
                          temperature, humidity);

        // Send to server
        sendto(sock, (uint8_t*)msgBuf, len, serverIP, 5000);

        // Wait before next transmission
        OSTimeDly(TICKS_PER_SECOND * 10); // Every 10 seconds
    }
}
```

Example 3: Syslog Client

```
void SendSyslogMessage(const char* msg, int severity) {
    IPADDR syslogServer = AsciiToIp("192.168.1.10");
    int sock = CreateTxUdpSocket(syslogServer, 514, 0); // Syslog port

    if (sock >= 0) {
        char syslogMsg[512];
        int len = sprintf(syslogMsg, "<%d>%s", severity, msg);
        sendto(sock, (uint8_t*)syslogMsg, len, syslogServer, 514);
        close(sock);
    }
}
```

Example 4: Multiple Destinations (Create Multiple Sockets)

```
void SendToMultipleServers() {
    IPADDR server1 = AsciiToIp("192.168.1.10");
    IPADDR server2 = AsciiToIp("192.168.1.20");

    int sock1 = CreateTxUdpSocket(server1, 8080, 0);
    int sock2 = CreateTxUdpSocket(server2, 8080, 0);

    uint8_t data[] = "Status update";

    if (sock1 >= 0) {
        sendto(sock1, data, sizeof(data), server1, 8080);
        close(sock1);
    }

    if (sock2 >= 0) {
```

```

        sendto(sock2, data, sizeof(data), server2, 8080);
        close(sock2);
    }
}

```

[sendto\(\)](#) - Send data through socket

[close\(\)](#) - Close socket when finished

14.57.6.4.4 recvfrom()

```

int recvfrom (
    int sock,
    uint8_t buffer,
    int len,
    IPADDR * pAddr,
    uint16_t * pLocal_port,
    uint16_t * pRemote_port) [inline]

```

#include <udp.h>

Receive UDP packet from socket with sender information.

Receives a UDP datagram from the specified socket and returns the sender's IP address and port. This is the standard BSD socket function for receiving UDP data. Works with sockets created by [CreateRxUdpSocket\(\)](#) or [CreateRxTxUdpSocket\(\)](#). Blocks until data arrives.

Parameters

<i>sock</i>	Socket file descriptor from CreateRxUdpSocket() or CreateRxTxUdpSocket()
<i>buffer</i>	Destination buffer for received data
<i>len</i>	Maximum bytes to read (buffer size, recommend 1500+ bytes)
<i>pAddr</i>	[OUT] Sender's IP address (can be NULL)
<i>pLocal_port</i>	[OUT] Local port packet arrived on (can be NULL)
<i>pRemote_port</i>	[OUT] Sender's port number (can be NULL)

Returns

Bytes received (0 to len), or negative error code:

- UDP_ERR_NOTOPEN_TO_READ (-3): Socket not configured for receiving
- UDP_ERR_NOSUCH_SOCKET (-1): Invalid socket

Note

Blocking: Waits indefinitely for data. Use [select\(\)](#) for timeout.

Datagram Boundaries: Each call returns one complete datagram.

Truncation: If datagram > buffer, excess data is discarded.

Warning

Buffer Size: Ensure buffer has at least len bytes.

Example: Echo Server

```
int sock = CreateRxUdpSocket(5000);
uint8_t buf[1500];
IPADDR clientIP;
uint16_t lp, rp;

while (1) {
    int n = recvfrom(sock, buf, sizeof(buf), &clientIP, &lp, &rp);
    if (n > 0) {
        printf("Received %d bytes from %s:%d\r\n",
            n, AsciiIP(clientIP).c_str(), rp);
        sendto(sock, buf, n, clientIP, rp); // Echo back
    }
}
```

See also

[CreateRxUdpSocket\(\)](#), [CreateRxTxUdpSocket\(\)](#), [sendto\(\)](#), [select\(\)](#)

14.57.6.4.5 SendFragmentedUdpPacket()

```
int SendFragmentedUdpPacket (
    const IPADDR & to,
    uint16_t source_port,
    uint16_t dest_port,
    uint8_t data,
    int length) [inline]
```

#include <udp.h>

Send large UDP packet (>MTU) with IP fragmentation.

Sends a UDP packet that exceeds the Maximum Transmission Unit (MTU) by automatically fragmenting it at the IP layer. The function handles both IPv4 and IPv6 addressing and reassembly is handled by the receiving host.

This is useful for sending large datagrams without implementing application-level fragmentation. However, note that IP fragmentation can reduce reliability since loss of any fragment requires retransmission of the entire datagram.

Parameters

<i>to</i>	Destination IP address (IPv4 or IPv6)
<i>source_port</i>	Source UDP port number. Use 0 for automatic port assignment (recommended)
<i>dest_port</i>	Destination UDP port number
<i>data</i>	Pointer to data buffer to send
<i>length</i>	Length of data in bytes (can exceed MTU)

Returns

Number of bytes sent on success, 0 on failure

Note

IP fragmentation may be blocked by some firewalls and routers

For maximum reliability, consider keeping packets under MTU size (typically 1500 bytes for Ethernet)

This function wraps `SendFragmentedUdpPacket6()` which handles both IPv4 and IPv6

Warning

Fragmented packets are more susceptible to loss and can impact performance

Example:

```
IPADDR destination = AsciiToIp("192.168.1.100");
uint8_t largeData[8000]; // Larger than typical MTU
// ... fill largeData ...

int result = SendFragmentedUdpPacket(destination, 0, 5000, largeData, sizeof(largeData));
if (result > 0) {
    printf("Sent %d bytes\n", result);
} else {
    printf("Send failed\n");
}
```

See also

[SendFragmentedUdpPacket6\(\)](#)

[SendUdpPacket\(\)](#) for non-fragmented sending

14.57.6.4.6 sendto()

```
int sendto (
    int sock,
    puint8_t what_to_send,
    int len_to_send,
    const IPADDR & to_addr,
    uint16_t remote_port) [inline]
```

```
#include <udp.h>
```

Send UDP packet through socket to specified destination.

Transmits a UDP datagram through the specified socket to the given IP address and port. This is the standard BSD socket function for sending UDP data. Works with sockets created by [CreateTxUdpSocket\(\)](#) or [CreateRxTxUdpSocket\(\)](#).

Operation:

- Sends datagram immediately (non-blocking)
- No connection establishment required
- No delivery guarantee (UDP is unreliable)
- Each call creates a new independent datagram

Parameters

<i>sock</i>	Socket file descriptor from CreateTxUdpSocket() or CreateRxTxUdpSocket() Must be a valid socket (≥ 0) or behavior is undefined
<i>what_to_send</i>	Pointer to data buffer to transmit Buffer content is copied during transmission
<i>len_to_send</i>	Number of bytes to send from buffer • Maximum practical size: 1472 bytes (IPv4) or 1452 bytes (IPv6) • Larger sizes may cause IP fragmentation (avoid if possible) • Use SendFragmentedUdpPacket() for data $>$ MTU
<i>to_addr</i>	Destination IP address (IPv4 or IPv6 based on build configuration) Use AsciiToIp() or AsciiToIp4() to convert from string format
<i>remote_port</i>	Destination port number (1-65535) Must match listening port on remote system

Returns

Number of bytes successfully queued for transmission (should equal `len_to_send`), or negative error code on failure:

- `UDP_ERR_NOTOPEN_TO_WRITE` (-2): Socket not configured for sending
- `UDP_ERR_NOSUCH_SOCKET` (-1): Invalid socket descriptor
- Other negative values: System-specific errors

Note

Non-Blocking: This function returns immediately after queuing data. The datagram may not have been physically transmitted yet.

No Delivery Confirmation: UDP provides no acknowledgment. Successfully sending does NOT mean the remote host received the packet. For reliable delivery, implement application-level acknowledgments or use TCP.

Maximum Transfer Unit (MTU): Ethernet MTU is typically 1500 bytes. After UDP (8 bytes) and IP headers (20-40 bytes), safe payload is ~1472 bytes. Exceeding this causes fragmentation, increasing packet loss risk.

Warning

Buffer Validity: Ensure `what_to_send` buffer remains valid and contains at least `len_to_send` bytes. Buffer overruns cause undefined behavior.

Socket Type: Using [sendto\(\)](#) on receive-only socket ([CreateRxUdpSocket\(\)](#)) will fail with `UDP_ERR_NOTOPEN_TO_WRITE`.

Expand for Example Usage

Examples

Example 1: Simple Send

```
IPADDR serverIP = AsciiToIp("192.168.1.100");
int sock = CreateTxUdpSocket(serverIP, 8080, 0);

if (sock >= 0) {
    const char* msg = "Hello, Server!";
    int sent = sendto(sock, (uint8_t*)msg, strlen(msg), serverIP, 8080);

    if (sent == strlen(msg)) {
        printf("Successfully sent %d bytes\r\n", sent);
    } else if (sent < 0) {
        printf("Send failed: error %d\r\n", sent);
    }
    close(sock);
}
```

Example 2: Send Binary Data

```
struct SensorData {
    uint32_t timestamp;
    int16_t temperature;
    int16_t humidity;
} data;

data.timestamp = Secs;
data.temperature = ReadTemperature();
data.humidity = ReadHumidity();

IPADDR collector = AsciiToIp("10.0.1.50");
int sock = CreateTxUdpSocket(collector, 5000, 0);

if (sock >= 0) {
    int result = sendto(sock, (uint8_t*)&data, sizeof(data),
                        collector, 5000);
    if (result != sizeof(data)) {
        printf("Warning: Send incomplete\r\n");
    }
    close(sock);
}
```

14.58 User Authorization Manager

Topics

- [Authorization Responses](#)
- [Authorization Types](#)

Classes

- struct [UserAuthRecord](#)
A stored record of a user's authorization credentials. The value is hashed when saved so it can't be read directly. User's can currently only have one authorization record per user name.
- class [UserAuthManager](#)
The user authorization manager class allows application developers the ability to manage user authorization records. The can be loaded and saved to any storage space, including the config system or UserParams. Authorization values are hashed before being saved. Validation compares both the hash as well as the authorization type. Adding, updating, and removing records will automatically call the user devined save functions. For usage, please see the example found in `examples/SSH/sshServerUserAuth`.

Typedefs

- typedef int(* [SaveAuthRecordsFn](#)) (const [UserAuthRecord](#) *authRec)
User provided function for saving user authorization records. This allows the users to dictate where their authorization records are stored.
- typedef int(* [LoadAuthRecordsFn](#)) ([UserAuthRecord](#) *authRec)
User provided function for loading user authorization records. This allows the users to dictate where their authorization records are stored.

14.58.1 Detailed Description

The NetBurner User Authorization Manager

14.58.2 Typedef Documentation

14.58.2.1 LoadAuthRecordsFn

```
typedef int (* LoadAuthRecordsFn) (UserAuthRecord *authRec)
#include <UserAuthManager.h>
```

User provided function for loading user authorization records. This allows the users to dictate where their authorization records are stored.

Parameters

<i>authRec</i>	A pointer to an array of UserAuthRecords where the data will be loaded.

Return values

0	If the authorization records were loaded correctly.
!0	If there was an error loading the authorization records. Error codes are left to application developers to define.

14.58.2.2 SaveAuthRecordsFn

```
typedef int (* SaveAuthRecordsFn) (const UserAuthRecord *authRec)
#include <UserAuthManager.h>
```

User provided function for saving user authorization records. This allows the users to dictate where their authorization records are stored.

Parameters

<i>authRec</i>	A pointer to an array of UserAuthRecords that should be saved.

Return values

0	If the authorization records were saved correctly.
/0	If there was an error saving the authorization records. Error codes are left to application developers to define.

14.58.3 Authorization Responses

Enumerations

- enum `AuthResponse` : `int16_t` {
`eAuthSuccess` = 1 , `eAuthErrorUserExists` = -1 , `eAuthErrorUserDoesNotExist` = -2 , `eAuthErrorNoEmptyUserAuthRecords` = -3 ,
`eAuthErrorUnableToCreateHash` = -4 , `eAuthErrorAuthCheckFailed` = -5 , `eAuthErrorAuthTypeMismatch` = -6
, `eAuthErrorFailedRecordUpdate` = -7 ,
`eAuthErrorUnableToAddUser` = -8 , `eAuthErrorSaveFailed` = -9 }

Response return codes when checking for the authorization status of a user.

14.58.3.1 Detailed Description

14.58.3.2 Enumeration Type Documentation

14.58.3.2.1 AuthResponse

```
enum AuthResponse : int16_t
```

```
#include <UserAuthManager.h>
```

Response return codes when checking for the authorization status of a user.

Enumerator

<code>eAuthSuccess</code>	The authorization request or function was successful.
<code>eAuthErrorUserExists</code>	The user already exists.
<code>eAuthErrorUserDoesNotExist</code>	The user does not exist.
<code>eAuthErrorNoEmptyUserAuthRecords</code>	The authorization records are full.
<code>eAuthErrorUnableToCreateHash</code>	There was an error hashing the authorization value.
<code>eAuthErrorAuthCheckFailed</code>	The authorization check failed.
<code>eAuthErrorAuthTypeMismatch</code>	The authorization type didn't match the request.
<code>eAuthErrorFailedRecordUpdate</code>	The record update failed.
<code>eAuthErrorUnableToAddUser</code>	The user was not added successfully.
<code>eAuthErrorSaveFailed</code>	Unable to save user authorization records.

14.58.4 Authorization Types

Enumerations

- enum `AuthType` : `int8_t` { `eAuthTypeDefault` = 0 , `eAuthTypePassword` = 1 , `eAuthTypeKey` = 2 }

The types of authorization requests that are managed. These just indicate what the has value is, and don't provide any specific processing logic.

14.58.4.1 Detailed Description

14.58.4.2 Enumeration Type Documentation

14.58.4.2.1 AuthType

```
enum AuthType : int8_t
#include <UserAuthManager.h>
```

The types of authorization requests that are managed. These just indicate what the has value is, and don't provide any specific processing logic.

Enumerator

eAuthTypeDefault	Default value, should be considered an invalid type.
eAuthTypePassword	Password.
eAuthTypeKey	Key.

IPv6 error debug messages.

Functions

- [IPADDR AsciiToIp6](#) (const char *p)
Convert an ASCII IPv6 string to an IP address.
- void **ShowCounters** ()
Dump all system counters to stdio.
- void [sShowCounters](#) (char *buffer, int slen)
Dump all system counters to a memory buffer.
- void [FdShowRingData](#) (int fd, const uint8_t *ringBuf, uint32_t bufLen, uint32_t start, uint32_t end, const char *indent=NULL)
Dump part of a ring buffer to file descriptor.
- void [ShowRingData](#) (const uint8_t *ringBuf, uint32_t bufLen, uint32_t start, uint32_t end, const char *indent=NULL)
Dump part of a ring buffer to stdio.
- void [FdShowData](#) (int fd, const uint8_t *fromptr, uint16_t len)
Dump a block of data to file descriptor and show in ASCII and hex.
- void [ShowData](#) (const uint8_t *fromptr, uint16_t len)
Dump a block of data to stdio and show in ASCII and hex.
- void [ShowMac](#) (const [MACADR](#) *ma)
Dump a MAC address to stdio.
- void [fdShowMac](#) (int fd, const [MACADR](#) *ma)
Dump a MAC address to file descriptor.
- void [ShowMac](#) (const [MACADR](#) &ma)
Dump a MAC address to stdio (reference version)
- void [snShowMac](#) (char *buf, size_t maxlen, const [MACADR](#) *ma)
Dump a MAC address to character buffer.
- void [snShowMac](#) (char *buf, size_t maxlen, const [MACADR](#) &ma)
Dump a MAC address to character buffer (reference version)
- void [MacToId](#) ([MACADR](#) *ma, char *IDBuf)
Write 6 character ID string based on unique portion of MAC.
- void [outbyte](#) (char c)
Write out a single, unbuffered byte to stdio.
- void [print](#) (const char *str)
Write out a zero-terminated, unbuffered string.
- void [putnum](#) (int i)
Write out a hexadecimal, unbuffered number to stdio.
- void [putbytenum](#) (unsigned char c)
Write out a hexadecimal, unbuffered byte to stdio.
- [IPADDR4 AsciiToIp4](#) (const char *p)
Convert an ASCII IPv4 string to an IP address.
- [MACADR AsciiToMac](#) (const char *p)
Convert an ASCII MAC address string to a MAC address.
- BOOL [ValidIPv4](#) (const char *p)
Validate if a string contains a valid IPv4 address.
- void [ShowIP4](#) (const [IPADDR4](#) ia)
Dump an IPv4 address in ASCII IP string format to stdio.
- int [snShowIP4](#) (char *buf, size_t maxlen, const [IPADDR4](#) ia)
Dump an IPv4 address in ASCII IP string format to character buffer.
- void [ShowIP6](#) (const [IPADDR](#) &ia)
Dump an IPv6 address in ASCII IP string format to stdio.
- int [snShowIP6](#) (char *buf, size_t maxlen, const [IPADDR](#) &ia)

- Dump an IPv6 address in ASCII IP string format to character buffer.*

 - uint32_t `GetPreciseTime` (void)

Gets the time tick since system start at a higher resolution.
- unsigned long long `Get_msec` ()

Returns the number of milliseconds as a 64-bit value.
- int `kill` (int pid, int sig)

Send a signal to a process.
- void `_exit` (int i)

Terminate the calling process.
- int `_fini` (void)

Finalization function.
- unsigned char * `convertBinaryToHexAscii` (unsigned char *fromBufferPtr, unsigned int fromByteCount, unsigned char *toBufferPtr, unsigned int toByteCount)

Convert binary data to hexadecimal ASCII representation.
- unsigned char * `convertHexAsciiToBinary` (unsigned char *fromBufferPtr, unsigned int fromByteCount, unsigned char *toBufferPtr, unsigned int toByteCount)

Convert hexadecimal ASCII string to binary data.
- const char * `bfnstr` (const char *search, const char *target, size_t len)

Search for a C string in an arbitrary memory blob that may contain NULL chars.

14.59.1 Detailed Description

```
#include< utils.h>
```

14.59.2 Macro Definition Documentation

14.59.2.1 DB_TCPIP

```
#define DB_TCPIP (1)
```

```
#include <utils.h>
```

Debug output control flags for NetBurner system components.

These flags control diagnostic output from various NetBurner subsystems. Set the global DB_FLAGS variable to enable debug messages from specific components. Flags can be combined using bitwise OR to enable multiple debug outputs simultaneously.

Use requires the declaration of unsigned int DB_FLAGS = NB_SSL, usually in main.cpp. At least one flag or a value of 0 must be set in the DB_FLAGS declaration.

Note

Debug output should be disabled in production code as it adds overhead and can flood the console with messages.

```
#include <utils.h>
```

```
void UserMain(void *pd) {
    init();
```

```
    // Enable TCP/IP debug messages only
    unsigned int DB_FLAGS = DB_TCPIP | DB_SSL;
```

```
    // Now you'll see TCP/IP and SSL related debug output in the console
```

```
    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

TCP/IP debug messages

14.59.3 Function Documentation

14.59.3.1 `_exit()`

```
void _exit (
    int i)
#include <utils.h>
Terminate the calling process.
```

Parameters

<i>i</i>	Exit status

14.59.3.2 `_fini()`

```
int _fini (
    void )
#include <utils.h>
Finalization function.
```

Returns

Status code

14.59.3.3 `AsciiToIp4()`

```
IPADDR4 AsciiToIp4 (
    const char * p)
#include <utils.h>
Convert an ASCII IPv4 string to an IP address.
```

Parameters

<i>p</i>	Pointer to null-terminated ASCII IPv4 string

Returns

[IPADDR4](#) object containing the converted IPv4 address

14.59.3.4 `AsciiToIp6()`

```
IPADDR AsciiToIp6 (
    const char * p)
#include <utils.h>
Convert an ASCII IPv6 string to an IP address.
```

Parameters

<i>p</i>	Pointer to null-terminated ASCII IPv6 string

Returns

IPADDR object containing the converted IPv6 address

14.59.3.5 `AsciiToMac()`

```
MACADR AsciiToMac (
    const char * p)
#include <utils.h>
Convert an ASCII MAC address string to a MAC address.
```

Parameters

<i>p</i>	Pointer to null-terminated ASCII MAC address string

Returns

MACADR object containing the converted MAC address

14.59.3.6 bufnstr()

```
const char * bufnstr (
    const char * search,
    const char * target,
    size_t len)
```

```
#include <utils.h>
```

Search for a C string in an arbitrary memory blob that may contain NULL chars.

Parameters

<i>search</i>	Pointer to the buffer to search
<i>target</i>	The C string being searched for
<i>len</i>	Length of the search buffer

Returns

Pointer to the start of the target string in the search buffer, or NULL if target not found

14.59.3.7 convertBinaryToHexAscii()

```
unsigned char * convertBinaryToHexAscii (
    unsigned char * fromBufferPtr,
    unsigned int fromByteCount,
    unsigned char * toBufferPtr,
    unsigned int toByteCount)
```

```
#include <utils.h>
```

Convert binary data to hexadecimal ASCII representation.

Converts raw binary data into a hexadecimal ASCII string where each byte is represented by two hexadecimal characters (0-9, A-F). For example, the byte value 0xFF becomes the two-character string "FF".

This function is commonly used for:

- Displaying binary data in human-readable format
- Creating hexadecimal dumps of memory or packet contents
- Encoding binary data for text-based protocols
- Debugging network packets or cryptographic operations

Parameters

<i>fromBufferPtr</i>	Pointer to the source buffer containing binary data to convert
<i>fromByteCount</i>	Number of bytes to convert from the source buffer
<i>toBufferPtr</i>	Pointer to the destination buffer for hexadecimal ASCII output
<i>toByteCount</i>	Size of the destination buffer in bytes

Returns

Pointer to the next free byte in the destination buffer after conversion. Returns NULL if the destination buffer is too small.

Note

The destination buffer must be at least $(\text{fromByteCount} * 2)$ bytes to hold the complete hexadecimal representation, plus 1 byte if null-termination is desired.

The output is NOT automatically null-terminated. Add a null terminator manually if you need a C-string: `*result = '\0';`

Uses uppercase hexadecimal characters (A-F) not lowercase (a-f)

If $\text{toByteCount} < (\text{fromByteCount} * 2)$, conversion will stop when the destination buffer is full and return NULL to indicate buffer overflow

Warning

Always ensure the destination buffer is large enough to prevent buffer overflow: $\text{toByteCount} \geq (\text{fromByteCount} * 2)$

This function does not add any separators (spaces, colons, etc.) between bytes

Expand for Example Usage**Examples****Example 1: Basic Binary to Hex Conversion**

```
unsigned char binaryData[] = {0x48, 0x65, 0x6C, 0x6C, 0x6F}; // "Hello"
unsigned char hexBuffer[20]; // Need at least 10 bytes (5 * 2)

unsigned char *nextPtr = convertBinaryToHexAscii(
    binaryData,
    sizeof(binaryData),
    hexBuffer,
    sizeof(hexBuffer)
);

if (nextPtr != NULL) {
    *nextPtr = '\0'; // Null-terminate for printing
    iprintf("Hex: %s\r\n", hexBuffer); // Output: "48656C6C6F"
}
```

Example 2: Display MAC Address in Hex

```
void DisplayMACAddress(unsigned char *macAddr) {
    unsigned char hexBuffer[13]; // 6 bytes * 2 = 12, plus null terminator

    unsigned char *result = convertBinaryToHexAscii(
        macAddr,
        6, // MAC address is 6 bytes
        hexBuffer,
        sizeof(hexBuffer) - 1 // Leave room for null terminator
    );

    if (result != NULL) {
        *result = '\0';
        // Format with colons for readability
        iprintf("MAC: %c%c:%c%c:%c%c:%c%c:%c%c\r\n",
            hexBuffer[0], hexBuffer[1], // First byte
            hexBuffer[2], hexBuffer[3], // Second byte
            hexBuffer[4], hexBuffer[5], // Third byte
            hexBuffer[6], hexBuffer[7], // Fourth byte
            hexBuffer[8], hexBuffer[9], // Fifth byte
            hexBuffer[10], hexBuffer[11]); // Sixth byte
    }
}
```

Example 3: Hex Dump of Network Packet

```

void HexDumpPacket(unsigned char *packet, unsigned int length) {
    const int bytesPerLine = 16;
    unsigned char hexBuffer[64]; // 16 bytes * 2 = 32, with extra space

    iprintf("Packet hex dump (%u bytes):\r\n", length);

    for (unsigned int offset = 0; offset < length; offset += bytesPerLine) {
        unsigned int lineBytes = (length - offset < bytesPerLine) ?
                                (length - offset) : bytesPerLine;

        // Convert this line to hex
        unsigned char *result = convertBinaryToHexAscii(
            packet + offset,
            lineBytes,
            hexBuffer,
            sizeof(hexBuffer)
        );

        if (result != NULL) {
            *result = '\0';
            iprintf("%04X: %s\r\n", offset, hexBuffer);
        }
    }
}

```

Example 4: Convert Hash to Hex String

```

#include <md5.h>

void DisplayMD5Hash(const char *data, unsigned int length) {
    unsigned char hash[16]; // MD5 produces 16 bytes
    unsigned char hexHash[33]; // 16 * 2 = 32, plus null terminator

    // Calculate MD5 hash (example function)
    MD5_CTX ctx;
    MD5Init(&ctx);
    MD5Update(&ctx, (unsigned char *)data, length);
    MD5Final(hash, &ctx);

    // Convert to hex string
    unsigned char *result = convertBinaryToHexAscii(
        hash,
        16,
        hexHash,
        sizeof(hexHash) - 1
    );

    if (result != NULL) {
        *result = '\0';
        iprintf("MD5: %s\r\n", hexHash);
    }
}

```

Example 5: Error Handling for Buffer Overflow

```

bool ConvertToHexSafely(unsigned char *binary, unsigned int binLen,
                        char *hexStr, unsigned int hexLen) {
    // Check if destination buffer is large enough
    if (hexLen < (binLen * 2 + 1)) {
        iprintf("ERROR: Hex buffer too small. Need %u bytes, have %u\r\n",
            binLen * 2 + 1, hexLen);
        return false;
    }

    unsigned char *result = convertBinaryToHexAscii(
        binary,
        binLen,
        (unsigned char *)hexStr,
        hexLen - 1 // Leave room for null terminator
    );

    if (result == NULL) {
        iprintf("ERROR: Conversion failed\r\n");
        return false;
    }

    *result = '\0';
    return true;
}

```

```

}

// Usage
unsigned char data[] = {0xDE, 0xAD, 0xBE, 0xEF};
char hexStr[20];

if (ConvertToHexSafely(data, sizeof(data), hexStr, sizeof(hexStr))) {
    iprintf("Success: %s\r\n", hexStr); // Output: "DEADBEEF"
}

```

Example 6: Encode Binary Data for HTTP/JSON

```

void SendBinaryDataAsJSON(int sock, unsigned char *data, unsigned int length) {
    unsigned char hexBuffer[512];

    // Check if data fits
    if (length * 2 >= sizeof(hexBuffer)) {
        iprintf("ERROR: Data too large for hex encoding\r\n");
        return;
    }

    unsigned char *result = convertBinaryToHexAscii(
        data,
        length,
        hexBuffer,
        sizeof(hexBuffer) - 1
    );

    if (result != NULL) {
        *result = '\0';

        // Send as JSON
        NBString json;
        json.sprintf("{\"data\":\"%s\",\"length\":%u}", hexBuffer, length);

        writestring(sock, "HTTP/1.1 200 OK\r\n");
        writestring(sock, "Content-Type: application/json\r\n\r\n");
        writestring(sock, json.c_str());
    }
}

```

Example 7: Convert Serial Number to Hex String

```

void DisplayDeviceSerialNumber() {
    unsigned char serialNum[16]; // Example: 16-byte serial number
    unsigned char hexSerial[33]; // 16 * 2 = 32, plus null

    // Get serial number from device (example function)
    GetDeviceSerialNumber(serialNum, sizeof(serialNum));

    unsigned char *result = convertBinaryToHexAscii(
        serialNum,
        sizeof(serialNum),
        hexSerial,
        sizeof(hexSerial) - 1
    );

    if (result != NULL) {
        *result = '\0';
        iprintf("Device Serial: %s\r\n", hexSerial);
    }
}

```

Example 8: Format with Spaces Between Bytes

```

void ConvertToHexWithSpaces(unsigned char *binary, unsigned int length) {
    // Need 2 chars per byte + 1 space per byte (except last)
    unsigned char hexBuffer[256];
    unsigned char *ptr = hexBuffer;

    for (unsigned int i = 0; i < length; i++) {
        // Convert one byte at a time
        unsigned char *result = convertBinaryToHexAscii(
            &binary[i],
            1, // One byte
            ptr,
            3 // Two hex chars + space
        );

        if (result == NULL) break;
    }
}

```

```

    ptr = result;

    // Add space between bytes (except after last byte)
    if (i < length - 1) {
        *ptr++ = ' ';
    }

    *ptr = '\0';
    iprintf("Hex: %s\r\n", hexBuffer);
    // Example output: "48 65 6C 6C 6F"
}

```

See also

`convertHexAsciiToBinary()` - Reverse operation: hex ASCII to binary

14.59.3.8 `convertHexAsciiToBinary()`

```

unsigned char * convertHexAsciiToBinary (
    unsigned char * fromBufferPtr,
    unsigned int fromByteCount,
    unsigned char * toBufferPtr,
    unsigned int toByteCount)

```

#include <utils.h>

Convert hexadecimal ASCII string to binary data.

Converts a hexadecimal ASCII string (where each pair of characters represents one byte) into raw binary data. This is the reverse operation of [convertBinaryToHexAscii\(\)](#). For example, the string "FF" becomes the byte value 0xFF, and "48656C6C6F" becomes the five bytes {0x48, 0x65, 0x6C, 0x6C, 0x6F} which represents "Hello".

This function is commonly used for:

- Parsing hexadecimal data from configuration files or user input
- Decoding hex-encoded network protocols
- Converting hex strings from web forms or JSON
- Processing hexadecimal MAC addresses, hashes, or serial numbers

Parameters

<i>fromBufferPtr</i>	Pointer to the source buffer containing hexadecimal ASCII string
<i>fromByteCount</i>	Number of ASCII characters to convert (must be even for complete bytes)
<i>toBufferPtr</i>	Pointer to the destination buffer for binary output
<i>toByteCount</i>	Size of the destination buffer in bytes

Returns

Pointer to the next free byte in the destination buffer after conversion. Returns NULL if conversion fails (invalid hex characters, odd length, or buffer too small).

Note

The source string should contain only valid hexadecimal characters (0-9, A-F, a-f)

`fromByteCount` should be even (two hex chars = one binary byte). If odd, the last character may be ignored or cause an error.

The destination buffer must be at least (`fromByteCount / 2`) bytes in size

Both uppercase (A-F) and lowercase (a-f) hex characters are accepted

The source string does NOT need to be null-terminated; conversion uses `fromByteCount`

Warning

If fromByteCount is odd, behavior depends on implementation - may ignore last char or return NULL. Always provide an even number of hex characters.

Invalid hex characters (G-Z, special chars, etc.) will cause conversion to fail

Always ensure the destination buffer is large enough: toByteCount >= (fromByteCount / 2)

Expand for Example Usage**Examples****Example 1: Basic Hex String to Binary Conversion**

```
const char *hexString = "48656C6C6F"; // "Hello" in hex
unsigned char binaryData[10];

unsigned char *result = convertHexAsciiToBinary(
    (unsigned char *)hexString,
    strlen(hexString), // 10 characters = 5 bytes
    binaryData,
    sizeof(binaryData)
);

if (result != NULL) {
    unsigned int bytesConverted = result - binaryData;
    iprintf("Converted %u bytes\r\n", bytesConverted);
    iprintf("Text: %.*s\r\n", bytesConverted, binaryData); // Output: "Hello"
} else {
    iprintf("Conversion failed\r\n");
}
```

Example 2: Parse MAC Address from Hex String

```
bool ParseMACAddress(const char *hexMAC, unsigned char *macBytes) {
    // Remove colons/dashes if present, or use hex string directly
    // Example input: "001122334455" (12 hex chars = 6 bytes)

    if (strlen(hexMAC) != 12) {
        iprintf("ERROR: MAC address must be 12 hex characters\r\n");
        return false;
    }

    unsigned char *result = convertHexAsciiToBinary(
        (unsigned char *)hexMAC,
        12,
        macBytes,
        6
    );

    if (result == NULL) {
        iprintf("ERROR: Invalid hex characters in MAC address\r\n");
        return false;
    }

    iprintf("MAC: %02X:%02X:%02X:%02X:%02X:%02X\r\n",
        macBytes[0], macBytes[1], macBytes[2],
        macBytes[3], macBytes[4], macBytes[5]);
    return true;
}

// Usage
unsigned char mac[6];
if (ParseMACAddress("001122AABBCC", mac)) {
    // Use MAC address
}
```

Example 3: Decode Hex Data from HTTP POST

```
void HandleHexDataPost(int sock, const char *hexData) {
    unsigned char binaryData[256];
    unsigned int hexLen = strlen(hexData);

    // Validate hex string length
    if (hexLen % 2 != 0) {
        writestring(sock, "HTTP/1.1 400 Bad Request\r\n\r\n");
        writestring(sock, "Hex string must have even length");
        return;
    }

    if (hexLen / 2 > sizeof(binaryData)) {
```

```

        writestring(sock, "HTTP/1.1 413 Payload Too Large\r\n\r\n");
        return;
    }

    // Convert hex to binary
    unsigned char *result = convertHexAsciiToBinary(
        (unsigned char *)hexData,
        hexLen,
        binaryData,
        sizeof(binaryData)
    );

    if (result == NULL) {
        writestring(sock, "HTTP/1.1 400 Bad Request\r\n\r\n");
        writestring(sock, "Invalid hex characters");
        return;
    }

    unsigned int byteCount = result - binaryData;

    // Process binary data
    ProcessBinaryData(binaryData, byteCount);

    writestring(sock, "HTTP/1.1 200 OK\r\n\r\n");
    writestring(sock, "Data processed successfully");
}

```

Example 4: Parse Configuration Value in Hex

```

bool LoadEncryptionKey(const char *hexKey, unsigned char *keyBytes,
    unsigned int expectedKeySize) {
    unsigned int hexLen = strlen(hexKey);

    // Check if hex string represents correct key size
    if (hexLen != expectedKeySize * 2) {
        fprintf("ERROR: Key must be %u bytes (%u hex chars)\r\n",
            expectedKeySize, expectedKeySize * 2);
        return false;
    }

    unsigned char *result = convertHexAsciiToBinary(
        (unsigned char *)hexKey,
        hexLen,
        keyBytes,
        expectedKeySize
    );

    if (result == NULL) {
        fprintf("ERROR: Invalid hex characters in encryption key\r\n");
        return false;
    }

    fprintf("Encryption key loaded successfully\r\n");
    return true;
}

// Usage: Load 128-bit (16 byte) AES key
unsigned char aesKey[16];
if (LoadEncryptionKey("0123456789ABCDEF0123456789ABCDEF", aesKey, 16)) {
    // Use key for encryption
}

```

Example 5: Convert JSON Hex Field to Binary

```

#include <json_lexer.h>

bool ParseHexFromJSON(const char *jsonStr, unsigned char *output,
    unsigned int maxOutputSize) {
    ParsedJsonDataSet json(jsonStr);

    // Get hex string from JSON field
    const char *hexValue = json["data"].GetStr();
    if (hexValue == NULL) {
        fprintf("ERROR: 'data' field not found in JSON\r\n");
        return false;
    }

    unsigned int hexLen = strlen(hexValue);

    if (hexLen / 2 > maxOutputSize) {
        fprintf("ERROR: Hex data too large for buffer\r\n");
        return false;
    }
}

```

```

    unsigned char *result = convertHexAsciiToBinary(
        (unsigned char *)hexValue,
        hexLen,
        output,
        maxOutputSize
    );

    return (result != NULL);
}

// Usage with JSON: {"data":"DEADBEEF"}
unsigned char binaryData[256];
if (ParseHexFromJSON(jsonString, binaryData, sizeof(binaryData))) {
    // Process binary data
}

```

Example 6: Validate and Convert Hex String

```

bool IsValidHexString(const char *str) {
    // Check for even length
    unsigned int len = strlen(str);
    if (len % 2 != 0) return false;

    // Check all characters are valid hex
    for (unsigned int i = 0; i < len; i++) {
        char c = str[i];
        if (!((c >= '0' && c <= '9') ||
            (c >= 'A' && c <= 'F') ||
            (c >= 'a' && c <= 'f')))) {
            return false;
        }
    }
    return true;
}

bool SafeHexToBinary(const char *hexStr, unsigned char *binary,
                    unsigned int binarySize) {
    // Pre-validate before conversion
    if (!IsValidHexString(hexStr)) {
        iprintf("ERROR: Invalid hex string format\r\n");
        return false;
    }

    unsigned int hexLen = strlen(hexStr);
    if (hexLen / 2 > binarySize) {
        iprintf("ERROR: Output buffer too small\r\n");
        return false;
    }

    unsigned char *result = convertHexAsciiToBinary(
        (unsigned char *)hexStr,
        hexLen,
        binary,
        binarySize
    );

    return (result != NULL);
}

```

Example 7: Round-Trip Conversion Test

```

void TestHexConversions() {
    // Original binary data
    unsigned char original[] = {0xDE, 0xAD, 0xBE, 0xEF, 0xCA, 0xFE};

    // Convert to hex
    unsigned char hexBuffer[20];
    unsigned char *hexResult = convertBinaryToHexAscii(
        original,
        sizeof(original),
        hexBuffer,
        sizeof(hexBuffer) - 1
    );

    if (hexResult == NULL) {
        iprintf("Hex conversion failed\r\n");
        return;
    }
    *hexResult = '\0';

    iprintf("Hex: %s\r\n", hexBuffer); // "DEADBEEFCAFE"
}

```

```

// Convert back to binary
unsigned char restored[10];
unsigned char *binResult = convertHexAsciiToBinary(
    hexBuffer,
    strlen((char *)hexBuffer),
    restored,
    sizeof(restored)
);

if (binResult == NULL) {
    iprintf("Binary conversion failed\r\n");
    return;
}

// Verify round-trip
if (memcmp(original, restored, sizeof(original)) == 0) {
    iprintf("Round-trip conversion successful!\r\n");
} else {
    iprintf("ERROR: Round-trip conversion mismatch\r\n");
}
}

```

Example 8: Parse Hex String with Mixed Case

```

void DemoMixedCaseHex() {
    // Both uppercase and lowercase hex chars are valid
    const char *mixedHex = "DeAdBeEf";
    unsigned char binary[4];

    unsigned char *result = convertHexAsciiToBinary(
        (unsigned char *)mixedHex,
        strlen(mixedHex),
        binary,
        sizeof(binary)
    );

    if (result != NULL) {
        iprintf("Converted: ");
        for (int i = 0; i < 4; i++) {
            iprintf("%02X ", binary[i]);
        }
        iprintf("\r\n"); // Output: "DE AD BE EF"
    }
}

```

Example 9: Parse Serial Number from User Input

```

bool SetDeviceSerialNumber(const char *hexSerial) {
    const unsigned int SERIAL_SIZE = 16; // 16 bytes = 128 bits
    unsigned char serialBytes[SERIAL_SIZE];

    // Validate input length
    if (strlen(hexSerial) != SERIAL_SIZE * 2) {
        iprintf("ERROR: Serial number must be %u hex characters\r\n",
            SERIAL_SIZE * 2);
        return false;
    }

    // Convert to binary
    unsigned char *result = convertHexAsciiToBinary(
        (unsigned char *)hexSerial,
        SERIAL_SIZE * 2,
        serialBytes,
        SERIAL_SIZE
    );

    if (result == NULL) {
        iprintf("ERROR: Invalid hex characters in serial number\r\n");
        return false;
    }

    // Store serial number (example function)
    StoreSerialNumberToFlash(serialBytes, SERIAL_SIZE);

    iprintf("Serial number set successfully\r\n");
    return true;
}

```

14.59.3.9 FdShowData()

```
void FdShowData (
    int fd,
    const uint8_t * fromptr,
    uint16_t len)
#include <utils.h>
```

Dump a block of data to file descriptor and show in ASCII and hex.

Parameters

<i>fd</i>	File descriptor to write to
<i>fromptr</i>	Pointer to data to display
<i>len</i>	Number of bytes to display

14.59.3.10 fdShowMac()

```
void fdShowMac (
    int fd,
    const MACADDR * ma)
#include <utils.h>
```

Dump a MAC address to file descriptor.

Parameters

<i>fd</i>	File descriptor to write to
<i>ma</i>	Pointer to MACADDR structure to display

14.59.3.11 FdShowRingData()

```
void FdShowRingData (
    int fd,
    const uint8_t * ringBuf,
    uint32_t bufLen,
    uint32_t start,
    uint32_t end,
    const char * indent = NULL)
#include <utils.h>
```

Dump part of a ring buffer to file descriptor.

Parameters

<i>fd</i>	File descriptor to write to
<i>ringBuf</i>	Pointer to ring buffer data
<i>bufLen</i>	Total length of ring buffer
<i>start</i>	Start offset in ring buffer
<i>end</i>	End offset in ring buffer
<i>indent</i>	Optional indentation string for formatting (can be NULL)

14.59.3.12 Get_msec()

```
unsigned long long Get_msec ()
#include <utils.h>
```

Returns the number of milliseconds as a 64-bit value.

Return values

<i>Number</i>	of milliseconds

14.59.3.13 GetPreciseTime()

```
uint32_t GetPreciseTime (
    void ) [extern]
#include <utils.h>
```

Gets the time tick since system start at a higher resolution.

Resolution depends on the platform: 0.868-us for MOD5234/70, and 1.929-us for MOD5282

Returns

High resolution time tick as uint32_t

14.59.3.14 kill()

```
int kill (
    int pid,
    int sig)
#include <utils.h>
```

Send a signal to a process.

Parameters

<i>pid</i>	Process ID
<i>sig</i>	Signal number

Returns

0 on success, -1 on error

14.59.3.15 MacToID()

```
void MacToID (
    MACADR * ma,
    char * IDBuf)
#include <utils.h>
```

Write 6 character ID string based on unique portion of MAC.

Parameters

<i>ma</i>	Pointer to MACADR structure
<i>IDBuf</i>	Buffer to write 6-character ID string to (must be at least 7 bytes for null terminator)

14.59.3.16 outbyte()

```
void outbyte (
    char c)
#include <utils.h>
```

Write out a single, unbuffered byte to stdio.

Parameters

<i>c</i>	Character to output

14.59.3.17 print()

```
void print (
    const char * str)
#include <utils.h>
Write out a zero-terminated, unbuffered string.
```

Parameters

<i>str</i>	Pointer to null-terminated string to output

14.59.3.18 putbytenum()

```
void putbytenum (
    unsigned char c)
#include <utils.h>
Write out a hexadecimal, unbuffered byte to stdio.
```

Parameters

<i>c</i>	Byte value to output in hexadecimal format

14.59.3.19 putnum()

```
void putnum (
    int i)
#include <utils.h>
Write out a hexadecimal, unbuffered number to stdio.
```

Parameters

<i>i</i>	Integer value to output in hexadecimal format

14.59.3.20 ShowData()

```
void ShowData (
    const uint8_t * fromptr,
    uint16_t len)
#include <utils.h>
Dump a block of data to stdio and show in ASCII and hex.
```

Parameters

<i>fromptr</i>	Pointer to data to display
<i>len</i>	Number of bytes to display

14.59.3.21 ShowIP4()

```
void ShowIP4 (
    const IPADDR4 ia)
#include <utils.h>
Dump an IPv4 address in ASCII IP string format to stdio.
```

Parameters

<i>ia</i>	IPv4 address to display

14.59.3.22 ShowIP6()

```
void ShowIP6 (
    const IPADDR & ia) [inline]
#include <utils.h>
Dump an IPv6 address in ASCII IP string format to stdio.
```

Parameters

<i>ia</i>	IPv6 address to display

14.59.3.23 ShowMac() [1/2]

```
void ShowMac (
    const MACADR & ma) [inline]
#include <utils.h>
Dump a MAC address to stdio (reference version)
```

Parameters

<i>ma</i>	Reference to MACADR structure to display

14.59.3.24 ShowMac() [2/2]

```
void ShowMac (
    const MACADR * ma)
#include <utils.h>
Dump a MAC address to stdio.
```

Parameters

<i>ma</i>	Pointer to MACADR structure to display

14.59.3.25 ShowRingData()

```
void ShowRingData (
    const uint8_t * ringBuf,
    uint32_t bufLen,
    uint32_t start,
    uint32_t end,
    const char * indent = NULL)
#include <utils.h>
Dump part of a ring buffer to stdio.
```

Parameters

<i>ringBuf</i>	Pointer to ring buffer data
<i>bufLen</i>	Total length of ring buffer
<i>start</i>	Start offset in ring buffer

<i>end</i>	End offset in ring buffer
<i>indent</i>	Optional indentation string for formatting (can be NULL)

14.59.3.26 snShowIP4()

```
int snShowIP4 (
    char * buf,
    size_t maxlen,
    const IPADDR4 ia)
```

#include <utils.h>

Dump an IPv4 address in ASCII IP string format to character buffer.

Parameters

<i>buf</i>	Buffer to write IP address string to
<i>maxlen</i>	Maximum length of buffer
<i>ia</i>	IPv4 address to convert

Returns

Number of characters written to buffer

14.59.3.27 snShowIP6()

```
int snShowIP6 (
    char * buf,
    size_t maxlen,
    const IPADDR & ia) [inline]
```

#include <utils.h>

Dump an IPv6 address in ASCII IP string format to character buffer.

Parameters

<i>buf</i>	Buffer to write IP address string to
<i>maxlen</i>	Maximum length of buffer
<i>ia</i>	IPv6 address to convert

Returns

Number of characters written to buffer

14.59.3.28 snShowMac() [1/2]

```
void snShowMac (
    char * buf,
    size_t maxlen,
    const MACADDR & ma) [inline]
```

#include <utils.h>

Dump a MAC address to character buffer (reference version)

Parameters

<i>buf</i>	Buffer to write MAC address string to
<i>maxlen</i>	Maximum length of buffer
<i>ma</i>	Reference to MACADDR structure to convert

14.59.3.29 snShowMac() [2/2]

```
void snShowMac (
    char * buf,
    size_t maxlen,
    const MACADR * ma)
#include <utils.h>
Dump a MAC address to character buffer.
```

Parameters

<i>buf</i>	Buffer to write MAC address string to
<i>maxlen</i>	Maximum length of buffer
<i>ma</i>	Pointer to MACADR structure to convert

14.59.3.30 sShowCounters()

```
void sShowCounters (
    char * buffer,
    int slen)
#include <utils.h>
Dump all system counters to a memory buffer.
```

Parameters

<i>buffer</i>	Pointer to buffer to store counter information
<i>slen</i>	Size of the buffer in bytes

14.59.3.31 ValidIPv4()

```
BOOL ValidIPv4 (
    const char * p)
#include <utils.h>
Validate if a string contains a valid IPv4 address.
```

Parameters

<i>p</i>	Pointer to null-terminated string to validate

Returns

TRUE if string contains valid IPv4 address, FALSE otherwise

14.60 Web Client**Topics**

- [Web Client Error Codes](#)

Classes

- class [ParsedURI](#)
Parsed Uniform Resource Identifier Class (URI)
- class [buffer_object](#)
Base class for web client response buffers.

- class [SimpleBufferObject](#)
Class for web client response buffers.
- class [StringBufferObject](#)
Class for NBString-based web client response buffers.

Functions

- void [SetHttpDiag](#) (bool b)
Enable/disable Web Client HTTP diagnostics to the console port.
- void [SetHttpDiag](#) (int level)
Enable/disable Web Client HTTP diagnostics to the console port.
- int [DoMultipartStartHttp](#) (HttpMethod method, [ParsedURI](#) &TheUri, const char *separator, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#), uint32_t contentLength=0)
Initiates a multipart HTTP request using a pre-parsed URI and returns a connection file descriptor.
- int [DoMultipartStartHttp](#) (HttpMethod method, const char *pUrl, const char *separator, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#), uint32_t contentLength=0)
Initiates a multipart HTTP request using a URL string and returns a connection file descriptor.
- int [DoMultipartStartPost](#) ([ParsedURI](#) &TheUri, const char *separator, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#), uint32_t contentLength=0)
Initiates a multipart HTTP POST request using a pre-parsed URI and returns a connection file descriptor.
- int [DoMultipartStartPost](#) (const char *pUrl, const char *separator, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#), uint32_t contentLength=0)
Initiates a multipart HTTP POST request using a URL string and returns a connection file descriptor.
- void [DoMultipartItem](#) (int tcpfd, const char *Disposition, const char *separator, const unsigned char *data, int len)
Sends a multipart data item within an active multipart HTTP request.
- void [DoMultipartBoundary](#) (int tcpfd, const char *Disposition, const char *separator)
Sends a multipart boundary section within an active multipart HTTP request.
- bool [DoMultipartFinished](#) (int tcpfd, const char *separator, [buffer_object](#) &result_buffer, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))
Completes a multipart HTTP request and retrieves the server response in a buffer object.
- bool [DoMultipartFinished](#) (int tcpfd, const char *separator, [NBString](#) &result_string, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))
Completes a multipart HTTP request and retrieves the server response in an NBString. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts. This is a convenience overload that finalizes a multipart HTTP request and stores the server response in an NBString reference. The function uses a StringBufferObject internally to handle the response data collection and forwards the call to the underlying DoMultipartFinished implementation. This provides string-based response handling for multipart operations where text-based responses are expected.
- bool [DoUrlEncodedFormHttp](#) (HttpMethod method, [ParsedURI](#) &TheUri, char *headers, char *form_data, [buffer_object](#) &result_buffer, uint16_t TIMEOUT_WAIT)
Executes an HTTP request with URL-encoded form data using a pre-parsed URI and stores the response in a buffer object.
- bool [DoUrlEncodedFormPost](#) ([ParsedURI](#) &TheUri, char *headers, char *form_data, [buffer_object](#) &result_buffer, uint16_t TIMEOUT_WAIT)
Executes an HTTP POST request with URL-encoded form data using a pre-parsed URI and stores the response in a buffer object.
- bool [DoUrlEncodedFormHttp](#) (HttpMethod method, [ParsedURI](#) &TheUri, char *headers, char *form_data, [NBString](#) &result_string, uint16_t TIMEOUT_WAIT)
Executes an HTTP request with URL-encoded form data using a pre-parsed URI and stores the response in an NBString. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts. This is a convenience overload that performs an HTTP request with the specified method using URL-encoded form data and a pre-parsed URI object. The complete response body is stored in the provided NBString reference. This function uses a StringBufferObject internally to handle the response data collection and forwards the call to the underlying DoUrlEncodedFormHttp implementation. This provides flexibility for form-based HTTP operations with pre-parsed URIs and string-based response handling.

- **bool DoUrlEncodedFormPost** (**ParsedURI** &TheUri, char *headers, char *form_data, **NBString** &result_string, uint16_t TIMEOUT_WAIT)

*Executes an HTTP POST request with URL-encoded form data using a pre-parsed URI and stores the response in an **NBString**. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.*

*This is a convenience overload that performs an HTTP POST request with URL-encoded form data using a pre-parsed URI object. The complete response body is stored in the provided **NBString** reference. This function uses a **StringBufferObject** internally to handle the response data collection and forwards the call to the underlying DoUrlEncodedFormHttp implementation. Using a pre-parsed URI can improve performance when making multiple form submissions to the same host by avoiding repeated URL parsing operations.*
- **bool DoUrlEncodedFormHttp** (HttpMethod method, const char *pUrl, char *headers, char *form_data, **buffer_object** &result_buffer, uint16_t TIMEOUT_WAIT)

Executes an HTTP request with URL-encoded form data using a URL string and stores the response in a buffer object. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is the core URL-encoded form HTTP function that performs an HTTP request with the specified method using URL-encoded form data and a URL string. The complete response body is stored in the provided buffer object. This function provides the foundation for form-based HTTP operations, supporting all standard HTTP methods while handling URL parsing and DNS resolution automatically. The form data is sent with the appropriate Content-Type header for proper server processing of web form submissions.
- **bool DoUrlEncodedFormPost** (const char *pUrl, char *headers, char *form_data, **buffer_object** &result_buffer, uint16_t TIMEOUT_WAIT)

Executes an HTTP POST request with URL-encoded form data using a URL string and stores the response in a buffer object. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request with URL-encoded form data using a URL string. The complete response body is stored in the provided buffer object. This function is a simple wrapper around the generic DoUrlEncodedFormHttp function, specifically optimized for POST operations with form data. This provides the most straightforward interface for web form submissions when you have URL-encoded form data and want to use automatic URL parsing with buffer-based response handling.
- **bool DoUrlEncodedFormPost** (const char *pUrl, char *headers, char *form_data, **NBString** &result_string, uint16_t TIMEOUT_WAIT)

*Executes an HTTP POST request with URL-encoded form data using a URL string and stores the response in an **NBString**. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.*

*This is a convenience overload that performs an HTTP POST request with URL-encoded form data using a URL string. The complete response body is stored in the provided **NBString** reference. This function uses a **StringBufferObject** internally to handle the response data collection and forwards the call to the underlying DoUrlEncodedFormHttp implementation. This provides a simple interface for form-based POST operations with string-based response handling.*
- **bool DoJsonHttp** (HttpMethod method, const char *pUrl, const char *Json_Data_To_Post, **buffer_object** &result_buffer, const char *AdditionalHeaders=NULL, uint16_t TIMEOUT_WAIT=10 ***TICKS_PER_SECOND**)

Executes an HTTP request with raw JSON data using a URL string and stores the response in a buffer object.
- **bool DoJsonPost** (const char *pUrl, const char *Json_Data_To_Post, **buffer_object** &result_buffer, const char *AdditionalHeaders=NULL, uint16_t TIMEOUT_WAIT=10 ***TICKS_PER_SECOND**)

Executes an HTTP POST request with raw JSON data using a URL string and stores the response in a buffer object.
- **bool DoJsonHttp** (HttpMethod method, const char *pUrl, const char *Json_Data_To_Post, **NBString** &result_string, const char *AdditionalHeaders=NULL, uint16_t TIMEOUT_WAIT=10 ***TICKS_PER_SECOND**)

*Executes an HTTP request with raw JSON data using a URL string and stores the response in an **NBString**. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.*

*This is a convenience overload that performs an HTTP request with the specified method using raw JSON data provided as a string and a URL string. The complete response body is stored in the provided **NBString** reference. This function uses a **StringBufferObject** internally to handle the response data collection and forwards the call to the underlying DoJsonHttp implementation. The URL string will be parsed internally and DNS resolution will be performed automatically if needed, making this ideal for simple JSON operations with pre-formatted data.*
- **bool DoJsonPost** (const char *pUrl, const char *Json_Data_To_Post, **NBString** &result_string, const char *AdditionalHeaders=NULL, uint16_t TIMEOUT_WAIT=10 ***TICKS_PER_SECOND**)

*Executes an HTTP POST request with raw JSON data using a URL string and stores the response in an **NBString**. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.*

This is a convenience overload that performs an HTTP POST request using raw JSON data provided as a string and a URL string. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoJsonHttp implementation. This provides the simplest interface for JSON POST operations when you have pre-formatted JSON data and want string-based response handling with automatic URL parsing.

- bool [DoJsonHttp](#) (HttpMethod method, [ParsedURI](#) &TheUri, const char *Json_Data_To_Post, [buffer_object](#) &result_buffer, const char *AdditionalHeaders=NULL, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request with raw JSON data using a pre-parsed URI and stores the response in a buffer object. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is the core JSON HTTP function for raw JSON string data that performs an HTTP request with the specified method using raw JSON data provided as a string and a pre-parsed URI object. The complete response body is stored in the provided buffer object. This function provides the foundation for JSON HTTP operations with pre-formatted JSON strings, offering optimal performance through pre-parsed URI components while supporting all standard HTTP methods.

- bool [DoJsonPost](#) ([ParsedURI](#) &TheUri, const char *Json_Data_To_Post, [buffer_object](#) &result_buffer, const char *AdditionalHeaders=NULL, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP POST request with raw JSON data using a pre-parsed URI and stores the response in a buffer object. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request using raw JSON data provided as a string and a pre-parsed URI object. The complete response body is stored in the provided buffer object. This function is a simple wrapper around the generic DoJsonHttp function, specifically optimized for POST operations with pre-formatted JSON strings, providing a streamlined interface when you already have JSON data in string format.

- bool [DoJsonHttp](#) (HttpMethod method, [ParsedURI](#) &TheUri, const char *Json_Data_To_Post, [NBString](#) &result_string, const char *AdditionalHeaders=NULL, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request with raw JSON data using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the specified method using raw JSON data provided as a string and a pre-parsed URI object. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoJsonHttp implementation. This provides flexibility for JSON operations with pre-formatted JSON strings and string-based response handling.

- bool [DoJsonPost](#) ([ParsedURI](#) &TheUri, const char *Json_Data_To_Post, [NBString](#) &result_string, const char *AdditionalHeaders=NULL, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP POST request with raw JSON data using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request using raw JSON data provided as a string and a pre-parsed URI object. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoJsonHttp implementation. This provides a simple interface for JSON POST operations with pre-formatted JSON strings and string-based response handling.

- bool [DoJsonHttp](#) (HttpMethod method, const char *pUrl, [ParsedJsonDataSet](#) &jsonout, [buffer_object](#) &result_buffer, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request with JSON data from a [ParsedJsonDataSet](#) using a URL string and stores the response in a buffer object. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is the core JSON HTTP function that performs an HTTP request with the specified method using JSON data from a [ParsedJsonDataSet](#) object and a URL string. The complete response body is stored in the provided buffer object. This function provides the foundation for programmatic JSON HTTP operations with string-based URLs, allowing dynamic construction and manipulation of JSON data before transmission. The URL string will be parsed internally and DNS resolution will be performed automatically if needed.

- bool [DoJsonPost](#) (const char *pUrl, [ParsedJsonDataSet](#) &jsonout, [buffer_object](#) &result_buffer, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP POST request with JSON data from a [ParsedJsonDataSet](#) using a URL string and stores the response in a buffer object. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request using JSON data from a [ParsedJsonDataSet](#) object and a URL string. The complete response body is stored in the provided buffer object. This function is a simple wrapper around the generic `DoJsonHttp` function, specifically optimized for POST operations with programmatically constructed JSON data, providing a streamlined interface for common JSON API interactions.

- `bool DoJsonHttp (HttpMethod method, const char *pUrl, ParsedJsonDataSet &jsonout, NBString &result_string, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *TICKS\_PER\_SECOND)`

Executes an HTTP request with JSON data from a [ParsedJsonDataSet](#) using a URL string and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the specified method using JSON data from a [ParsedJsonDataSet](#) object and a URL string. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying `DoJsonHttp` implementation. This provides flexibility for programmatic JSON operations with string-based response handling and simplified URL specification.

- `bool DoJsonPost (const char *pUrl, ParsedJsonDataSet &jsonout, NBString &result_string, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *TICKS\_PER\_SECOND)`

Executes an HTTP POST request with JSON data from a [ParsedJsonDataSet](#) using a URL string and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request using JSON data from a [ParsedJsonDataSet](#) object and a URL string. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying `DoJsonHttp` implementation. This provides a simple interface for JSON POST operations with programmatically constructed data and string-based response handling.

- `bool DoJsonHttp (HttpMethod method, ParsedURI &TheUri, ParsedJsonDataSet &jsonout, buffer\_object &result_buffer, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *TICKS\_PER\_SECOND)`

Executes an HTTP request with JSON data from a [ParsedJsonDataSet](#) using a pre-parsed URI and stores the response in a buffer object. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is the core JSON HTTP function that performs an HTTP request with the specified method using JSON data from a [ParsedJsonDataSet](#) object and a pre-parsed URI. The complete response body is stored in the provided buffer object. This function provides the foundation for programmatic JSON HTTP operations, allowing dynamic construction and manipulation of JSON data before transmission. The [ParsedJsonDataSet](#) will be automatically serialized to JSON format for the request body.

- `bool DoJsonPost (ParsedURI &TheUri, ParsedJsonDataSet &jsonout, buffer\_object &result_buffer, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *TICKS\_PER\_SECOND)`

Executes an HTTP POST request with JSON data from a [ParsedJsonDataSet](#) using a pre-parsed URI and stores the response in a buffer object. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request using JSON data from a [ParsedJsonDataSet](#) object and a pre-parsed URI. The complete response body is stored in the provided buffer object. This function is a simple wrapper around the generic `DoJsonHttp` function, specifically optimized for POST operations with programmatically constructed JSON data, providing a streamlined interface for common JSON API interactions.

- `bool DoJsonHttp (HttpMethod method, ParsedURI &TheUri, ParsedJsonDataSet &jsonout, NBString &result_string, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *TICKS\_PER\_SECOND)`

Executes an HTTP request with JSON data from a [ParsedJsonDataSet](#) using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the specified method using JSON data from a [ParsedJsonDataSet](#) object and a pre-parsed URI. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying `DoJsonHttp` implementation. This provides flexibility for programmatic JSON operations with string-based response handling.

- `bool DoJsonPost (ParsedURI &TheUri, ParsedJsonDataSet &jsonout, NBString &result_string, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *TICKS\_PER\_SECOND)`

Executes an HTTP POST request with JSON data from a [ParsedJsonDataSet](#) using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request using JSON data from a [ParsedJsonDataSet](#) object and a pre-parsed URI. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying

DoJsonHttp implementation. This approach allows for dynamic JSON POST requests with programmatically constructed data.

- bool [DoJsonHttpFile](#) (HttpMethod method, const char *pUrl, const char *FragmentName, [buffer_object](#) &result_buffer, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request with JSON data from a file fragment using a URL string and stores the response in a buffer object.

- bool [DoJsonPostHttpFile](#) (const char *pUrl, const char *FragmentName, [buffer_object](#) &result_buffer, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP POST request with JSON data from a file fragment using a URL string and stores the response in a buffer object.

- bool [DoJsonHttpFile](#) (HttpMethod method, const char *pUrl, const char *FragmentName, [NBString](#) &result_string, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Performs an HTTP request and stores JSON response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that wraps the result [NBString](#) in a [StringBufferObject](#) and calls the main [DoJsonHttpFile](#) function.

- bool [DoJsonPostHttpFile](#) (const char *pUrl, const char *FragmentName, [NBString](#) &result_string, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Performs an HTTP POST request and stores JSON response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience wrapper function that simplifies HTTP POST operations with JSON response handling. It internally calls [DoJsonHttpFile](#) with [HttpMethod::Post](#) and automatically manages the buffer conversion from [NBString](#) to [StringBufferObject](#). The function handles the complete HTTP transaction including connection establishment, request transmission, response reception, and JSON parsing. Only the specified JSON fragment is extracted from the response and stored in the result string, making it efficient for retrieving specific data from larger JSON responses. The function is particularly useful for REST API interactions where you need to POST data and extract a specific piece of information from the JSON response.

- bool [DoJsonHttpFile](#) (HttpMethod method, [ParsedURI](#) &TheUri, const char *FragmentName, [buffer_object](#) &result_buffer, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Sends an HTTP request and processes JSON response using a pre-parsed URI.

- bool [DoJsonPostHttpFile](#) ([ParsedURI](#) &TheUri, const char *FragmentName, [buffer_object](#) &result_buffer, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP POST request with JSON data from a file fragment using a pre-parsed URI and stores the response in a buffer object.

- bool [DoJsonHttpFile](#) (HttpMethod method, [ParsedURI](#) &TheUri, const char *FragmentName, [NBString](#) &result_string, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request with JSON data from a file fragment using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the specified method using JSON data loaded from a file fragment and a pre-parsed URI object. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying [DoJsonHttpFile](#) implementation. This approach provides maximum flexibility for JSON-based HTTP operations with pre-stored data fragments.

- bool [DoJsonPostHttpFile](#) ([ParsedURI](#) &TheUri, const char *FragmentName, [NBString](#) &result_string, const char *AdditionalHeaders, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP POST request with JSON data from a file fragment using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request using JSON data loaded from a specified file fragment and a pre-parsed URI object. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying [DoJsonHttpFile](#) implementation. This approach allows for efficient JSON POST requests with pre-defined data stored in file fragments.

- bool [DoHttp](#) (HttpMethod method, [ParsedURI](#) &TheUri, [buffer_object](#) &result_buffer, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request using a pre-parsed URI and stores the response in a buffer object.

- bool [DoGet](#) ([ParsedURI](#) &TheUri, [buffer_object](#) &result_buffer, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP GET request using a pre-parsed URI and stores the response in a buffer object.

- bool **DoHttp** (HttpMethod method, [ParsedURI](#) &TheUri, [NSString](#) &result_string, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request using a pre-parsed URI and stores the response in an [NSString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the specified method using a pre-parsed URI object and stores the complete response body in the provided [NSString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoHttp implementation that accepts a [buffer_object](#). Using a pre-parsed URI can improve performance when making multiple requests to the same host by avoiding repeated URL parsing operations.

- bool **DoGet** ([ParsedURI](#) &TheUri, [NSString](#) &result_string, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP GET request using a pre-parsed URI and stores the response in an [NSString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP GET request using a pre-parsed URI object and stores the complete response body in the provided [NSString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoHttp implementation. Using a pre-parsed URI can improve performance when making multiple requests to the same host by avoiding repeated URL parsing operations.

- bool **DoHttpEx** (HttpMethod method, [ParsedURI](#) &TheUri, const char *headers, [buffer_object](#) &result_buffer, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request with custom headers using a pre-parsed URI and stores the response in a buffer object.

- bool **DoGetEx** ([ParsedURI](#) &TheUri, const char *headers, [buffer_object](#) &result_buffer, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP GET request with custom headers using a pre-parsed URI and stores the response in a buffer object.

- bool **DoHttpEx** (HttpMethod method, [ParsedURI](#) &TheUri, const char *headers, [NSString](#) &result_string, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request with custom headers using a pre-parsed URI and stores the response in an [NSString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the specified method using a pre-parsed URI object and allows custom headers to be included in the request. The complete response body is stored in the provided [NSString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoHttpEx implementation that accepts a [buffer_object](#).

- bool **DoGetEx** ([ParsedURI](#) &TheUri, const char *headers, [NSString](#) &result_string, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP GET request with custom headers using a pre-parsed URI and stores the response in an [NSString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP GET request using a pre-parsed URI object and allows custom headers to be included in the request. The complete response body is stored in the provided [NSString](#) reference.

This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoHttpEx implementation.

- bool **DoHttp** (HttpMethod method, const char *pUrl, [buffer_object](#) &result_buffer, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP/HTTPS request using the specified method and stores the response in a buffer object.

- bool **DoGet** (const char *pUrl, [buffer_object](#) &result_buffer, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP/HTTPS GET request and stores the response in a buffer object.

- bool **DoHttp** (HttpMethod method, const char *pUrl, [NSString](#) &result_string, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Performs an HTTP request using the specified method and stores the response in an [NSString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the given method to the specified URL and stores the complete response body in the provided [NSString](#) reference. The function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoHttp implementation.

- bool **DoGet** (const char *pUrl, [NSString](#) &result_string, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Performs an HTTP GET request and stores the result in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This overload provides a convenient way to perform HTTP GET requests when you want to store the response directly in an [NBString](#) object. The function wraps the [NBString](#) in a [StringBufferObject](#) and delegates to the main [DoHttp](#) function.

- bool [DoHttpEx](#) (HttpMethod method, const char *pUrl, const char *headers, [buffer_object](#) &result_buffer, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Execute a HTTP/HTTPS request using a pointer to a URL string.

- bool [DoGetEx](#) (const char *pUrl, const char *headers, [buffer_object](#) &result_buffer, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP GET request with custom headers using a URL string and stores the response in a buffer object.

- bool [DoHttpEx](#) (HttpMethod method, const char *pUrl, const char *headers, [NBString](#) &result_string, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request with custom headers using a URL string and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the specified method and custom headers using a URL string. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying [DoHttpEx](#) implementation. This provides maximum flexibility for HTTP operations with custom headers and string-based response handling.

- bool [DoGetEx](#) (const char *pUrl, const char *headers, [NBString](#) &result_string, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP GET request with custom headers using a URL string and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP GET request with custom headers using a URL string. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying [DoHttpEx](#) implementation. This provides a simple interface for GET requests that require custom headers with string-based response handling.

- int [DoHttp](#) (HttpMethod method, [ParsedURI](#) &TheUri, unsigned char *result, int maxl, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request using a pre-parsed URI and stores the response in a raw buffer.

- int [DoHttpEx](#) (HttpMethod method, [ParsedURI](#) &TheUri, const char *headers, unsigned char *result, int maxl, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request with custom headers using a pre-parsed URI and stores the response in a raw buffer.

- int [DoHttp](#) (HttpMethod method, const char *pUrl, unsigned char *result, int maxl, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request using a URL string and stores the response in a raw buffer.

- int [DoHttpEx](#) (HttpMethod method, const char *pUrl, const char *headers, unsigned char *result, int maxl, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP request with custom headers using a URL string and stores the response in a raw buffer.

- int [DoGet](#) ([ParsedURI](#) &TheUri, unsigned char *result, int maxl, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP GET request using a pre-parsed URI and stores the response in a raw buffer.

- int [DoGetEx](#) ([ParsedURI](#) &TheUri, const char *headers, unsigned char *result, int maxl, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP GET request with custom headers using a pre-parsed URI and stores the response in a raw buffer.

- int [DoGet](#) (const char *pUrl, unsigned char *result, int maxl, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP GET request using a URL string and stores the response in a raw buffer.

- int [DoGetEx](#) (const char *pUrl, const char *headers, unsigned char *result, int maxl, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Executes an HTTP GET request with custom headers using a URL string and stores the response in a raw buffer.

- int [DoGetUpdate](#) ([ParsedURI](#) &TheUri, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Execute a firmware update from the specified URI.

- int [DoGetUpdate](#) (const char *pUrl, uint16_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))

Execute a firmware update from the specified URI.

- int [PopulateAuthHeader](#) (const char *user, const char *password, char *buffer, int maxlen)
Generates a Base64-encoded HTTP Basic Authentication header string for inclusion in HTTP requests.
- int [StartConnection](#) ([ParsedURI](#) &TheUri, uint32_t timeout=[TICKS_PER_SECOND](#) *10)
Establishes a TCP/TLS connection to a host using a pre-parsed URI with timeout specified in ticks.
- int [WriteHttpRequestHeaders](#) (int fd, [ParsedURI](#) &uri, const char *methodStr, int content_len=0, const char *content_type=0, const char *extra_header=0)
Writes HTTP request headers to an established connection file descriptor.
- int [StartTransaction](#) ([ParsedURI](#) &TheUri, const char *headers=0, const char *action="GET", uint32_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))
Initiates an HTTP transaction using a pre-parsed URI by establishing a connection and sending request headers.
- int [StartTransaction](#) (const char *pUrl, const char *headers=0, const char *action="GET", uint32_t TIMEOUT_WAIT=10 *[TICKS_PER_SECOND](#))
Initiates an HTTP transaction using a URL string by establishing a connection and sending request headers.
- bool [DoActualClientRequest](#) ([ParsedURI](#) &TheUri, uint16_t &next_time_delay)
Callback to specify for performing and handle a WebClient request.
- bool [StartWebClient](#) (int prio, const char *url1, const char *url2=NULL, bool bDoNtp=false)
Start the web client using a URL string.
- bool [StartWebClient](#) (int prio, const [NBString](#) &url1, const [NBString](#) &url2, bool bDoNtp=false)
Start the web client using a [NBString](#).
- bool [StartWebClient](#) (int prio, const [NBString](#) &url1, bool bDoNtp=false)
Start the web client using a [NBString](#).

Variables

- WebErrorReporterFunc * [pWebErrorReporter](#)
Set this variable to a callback function to specify a handler for errors.

14.60.1 Detailed Description

```
#include< http_funcs.h>
```

Functions for interacting with the web, like HTTP GET/POST requests.

An easy way to get web data (from our [GetNonJsonFromServer](#) example):

```
const char *purl = "http://www.example.com/";
int result = 0;
static unsigned char ResultBuffer[5000];

result = DoGet(purl, ResultBuffer, 5000, 60 * TICKS\_PER\_SECOND);

if (result > 0)
{
    printf("Result = %d\r\n", result);
    for (int i = 0; i < result; i++)
    {
        printf("%c", ResultBuffer[i]);
    }
    printf("]\r\n");
}
else
{
    iprintf("Failed to contact server\r\n");
}

#include< web_client.h>
```

Functions for instantiating a periodic web client

From our WebClient examples:

```
const char *url = "http://www.example.com";

void HandleErrorState(int state)
{
    if (state == WEB_CLIENT_ERROR_NO_ERROR) return;
    if ((state <= WEB_CLIENT_ERROR_LAST_STATE) && (state > 0))
        iprintf("Set Error state [%d] [%s]\r\n", state, web_error_state_text[state]);
    else
        iprintf("Error state unknown %d\r\n", state);
}

bool DoActualClientRequest(ParsedURI &TheUri, uint16_t &next_time_delay)
{
    static unsigned char ResultBuffer[5000];

    bool result = DoGet(TheUri, ResultBuffer);
    if (result)
    {
        printf("Result = %d\r\n", result);
        for (int i = 0; i < result; i++)
        {
            printf("%c", ResultBuffer[i]);
        }
        printf("]\r\n");
        next_time_delay = 10 * TICKS_PER_SECOND;
        return true;
    }

    next_time_delay = 10 * TICKS_PER_SECOND;
    return false;
}

void UserMain(void *pd)
{
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    pWebErrorReporter = HandleErrorState;
    StartWebClient(MAIN_PRIO - 2, url);

    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND * 1);
    }
}
```

14.60.2 Function Documentation

14.60.2.1 DoActualClientRequest()

```
bool DoActualClientRequest (
    ParsedURI & TheUri,
    uint16_t & next_time_delay)
#include <web_client.h>
Callback to specify for performing and handle a WebClient request.
```

Parameters

<i>TheUri</i>	Pointer to a ParsedURI object (representing the URL)
<i>next_time_delay</i>	Pointer to the number of ticks to wait before the next request

Returns

True on success, false on failure.

14.60.2.2 DoGet() [1/6]

```
bool DoGet (
    const char * pUrl,
```

```

        buffer_object & result_buffer,
        uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>

```

Executes an HTTP/HTTPS GET request and stores the response in a buffer object.

This function performs an HTTP GET request to the specified URL and stores the complete response body in the provided buffer object. The URL is parsed to extract the host information, and DNS resolution is performed automatically if a hostname is provided instead of an IP address. This is a convenience wrapper around the generic DoHttp function.

Parameters

<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the GET request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, or HTTP error)

Note

The result_buffer contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size.

14.60.2.3 DoGet() [2/6]

```

bool DoGet (
    const char * pUrl,
    NSString & result_string,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>

```

Performs an HTTP GET request and stores the result in an [NSString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This overload provides a convenient way to perform HTTP GET requests when you want to store the response directly in an [NSString](#) object. The function wraps the [NSString](#) in a [StringBufferObject](#) and delegates to the main DoHttp function.

Parameters

<i>pUrl</i>	Pointer to null-terminated string containing the URL to request
<i>result_string</i>	Reference to NSString in which to store the HTTP response
<i>TIMEOUT_WAIT</i>	Timeout value in system ticks (default: 10 seconds)

Returns

true if the HTTP request was successful, false otherwise

See also

[DoHttp\(\)](#)
[StringBufferObject](#)
[NBString](#)

14.60.2.4 DoGet() [3/6]

```
int DoGet (
    const char * pUrl,
    unsigned char * result,
    int maxl,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP GET request using a URL string and stores the response in a raw buffer.

This is a low-level HTTP GET function that performs an HTTP GET request using a URL string and stores the response body in a provided raw buffer. The function handles URL parsing and DNS resolution automatically if needed. The response is written directly to the buffer without any additional processing or wrapper objects, providing direct access to the raw HTTP response data with minimal overhead.

Parameters

<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>result</i>	Pointer to raw buffer where the HTTP response body will be stored Buffer must be pre-allocated with sufficient space for the response
<i>maxl</i>	Maximum length of the result buffer in bytes Response will be truncated if it exceeds this length
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

Number of bytes received and stored in the result buffer on success (≥ 0), or a negative error code on failure (network error, timeout, DNS resolution failure, or HTTP error response)

Note

The result buffer will contain the raw response body data. No null termination is added - treat as binary data. The response may be truncated if it exceeds the maxl parameter.

[DoGet\(const char*, buffer_object&, uint16_t\)](#) for [buffer_object](#) version

14.60.2.5 DoGet() [4/6]

```
bool DoGet (
    ParsedURI & TheUri,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP GET request using a pre-parsed URI and stores the response in a buffer object.

This function performs an HTTP GET request using a pre-parsed URI object and stores the complete response body in the provided buffer object. This is a convenience wrapper around the generic DoHttp function, providing a simple interface for GET requests while leveraging pre-parsed URI components for improved performance when making multiple requests to the same host by avoiding repeated URL parsing operations.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use <code>TICKS_PER_SECOND</code> for conversion

Returns

true if the GET request completed successfully and response was received, false on failure (network error, timeout, connection error, or HTTP error response)

Note

The *result_buffer* contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. Using pre-parsed URIs improves performance for repeated requests to the same host.

14.60.2.6 DoGet() [5/6]

```
bool DoGet (
    ParsedURI & TheUri,
    NBString & result_string,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP GET request using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP GET request using a pre-parsed URI object and stores the complete response body in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying [DoHttp](#) implementation. Using a pre-parsed URI can improve performance when making multiple requests to the same host by avoiding repeated URL parsing operations.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>result_string</i>	Reference to NBString in which to store the HTTP response body The string will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use <code>TICKS_PER_SECOND</code> for conversion

Returns

true if the GET request completed successfully and response was received, false on failure (network error, timeout, connection error, or HTTP error response)

Note

The result_string contents will be replaced with the response data. For large responses, ensure sufficient memory is available. Using pre-parsed URIs improves performance for repeated requests to the same host.

14.60.2.7 DoGet() [6/6]

```
int DoGet (
    ParsedURI & TheUri,
    unsigned char * result,
    int maxl,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP GET request using a pre-parsed URI and stores the response in a raw buffer.

This is a low-level HTTP GET function that performs an HTTP GET request using a pre-parsed URI object and stores the response body in a provided raw buffer. This function provides optimal performance by using pre-parsed URI components, eliminating URL parsing and DNS lookup overhead when making multiple GET requests to the same host. The response is written directly to the buffer without any additional processing or wrapper objects.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>result</i>	Pointer to raw buffer where the HTTP response body will be stored Buffer must be pre-allocated with sufficient space for the response
<i>maxl</i>	Maximum length of the result buffer in bytes Response will be truncated if it exceeds this length
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

Number of bytes received and stored in the result buffer on success (≥ 0), or a negative error code on failure (network error, timeout, connection error, or HTTP error response)

Note

The result buffer will contain the raw response body data. No null termination is added - treat as binary data. Using pre-parsed URIs improves performance for repeated requests to the same host. The response may be truncated if it exceeds the maxl parameter.

[DoGet\(ParsedURI&, buffer_object&, uint16_t\)](#) for [buffer_object](#) version

14.60.2.8 DoGetEx() [1/6]

```
bool DoGetEx (
    const char * pUrl,
    const char * headers,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP GET request with custom headers using a URL string and stores the response in a buffer object. This function performs an HTTP GET request with custom headers using a URL string and stores the complete response body in the provided buffer object. This is a convenience wrapper around the generic DoHttpEx function, specifically optimized for GET operations with custom header support. The URL string will be parsed internally and DNS resolution will be performed automatically if needed, making this ideal for GET requests that require additional headers such as authentication, user-agent, or content negotiation.

Parameters

<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>headers</i>	Pointer to null-terminated string containing custom HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr or empty string if no custom headers are needed
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the GET request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, or HTTP error response)

Note

The `result_buffer` contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. Custom headers must be properly formatted without trailing CRLF on the final header.

14.60.2.9 DoGetEx() [2/6]

```
bool DoGetEx (
    const char * pUrl,
    const char * headers,
    NBString & result_string,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP GET request with custom headers using a URL string and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP GET request with custom headers using a URL string. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoHttpEx implementation. This provides a simple interface for GET requests that require custom headers with string-based response handling.

Parameters

<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>headers</i>	Pointer to null-terminated string containing custom HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr or empty string if no custom headers are needed
<i>result_string</i>	Reference to NBString in which to store the HTTP response body The string will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the GET request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, or HTTP error response)

Note

The result_string contents will be replaced with the response data. For large responses, ensure sufficient memory is available. Custom headers must be properly formatted without trailing CRLF on the final header.

14.60.2.10 DoGetEx() [3/6]

```
int DoGetEx (
    const char * pUrl,
    const char * headers,
    unsigned char * result,
    int maxl,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
```

```
#include <http_funcs.h>
```

Executes an HTTP GET request with custom headers using a URL string and stores the response in a raw buffer. This is a low-level extended HTTP GET function that performs an HTTP GET request with custom headers using a URL string and stores the response body in a provided raw buffer. The function handles URL parsing and DNS resolution automatically while supporting custom headers for authentication, content negotiation, or other advanced GET operations. The response is written directly to the buffer without any additional processing.

Parameters

<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>headers</i>	Pointer to null-terminated string containing custom HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr or empty string if no custom headers are needed
<i>result</i>	Pointer to raw buffer where the HTTP response body will be stored Buffer must be pre-allocated with sufficient space for the response
<i>maxl</i>	Maximum length of the result buffer in bytes Response will be truncated if it exceeds this length

<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use <i>TICKS_PER_SECOND</i> for conversion

Returns

Number of bytes received and stored in the result buffer on success (≥ 0), or a negative error code on failure (network error, timeout, DNS resolution failure, or HTTP error response)

Note

The result buffer will contain the raw response body data. No null termination is added - treat as binary data. Custom headers must be properly formatted without trailing CRLF on the final header. The response may be truncated if it exceeds the *maxl* parameter.

14.60.2.11 DoGetEx() [4/6]

```
bool DoGetEx (
    ParsedURI & TheUri,
    const char * headers,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP GET request with custom headers using a pre-parsed URI and stores the response in a buffer object.

This function performs an HTTP GET request using a pre-parsed URI object and allows custom headers to be included in the request. The complete response body is stored in the provided buffer object. This is a convenience wrapper around the generic [DoHttpEx](#) function, providing enhanced control over the request headers while using pre-parsed URI components for improved performance when making multiple requests to the same host.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>headers</i>	Pointer to null-terminated string containing custom HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr or empty string if no custom headers are needed
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use <i>TICKS_PER_SECOND</i> for conversion

Returns

true if the GET request completed successfully and response was received, false on failure (network error, timeout, connection error, or HTTP error response)

Note

The `result_buffer` contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. Headers must be properly formatted without trailing CRLF on the final header. Using pre-parsed URIs can improve performance for repeated requests to the same host.

```
bool DoGetEx (
    ParsedURI & TheUri,
    const char * headers,
    NBString & result_string,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP GET request with custom headers using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP GET request using a pre-parsed URI object and allows custom headers to be included in the request. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying `DoHttpEx` implementation.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, etc.)
<i>headers</i>	Pointer to null-terminated string containing custom HTTP headers Headers should be formatted as "Header: Value\r\n" pairs Pass nullptr or empty string if no custom headers are needed
<i>result_string</i>	Reference to NBString in which to store the HTTP response body The string will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use <code>TICKS_PER_SECOND</code> for conversion

Returns

true if the GET request completed successfully and response was received, false on failure (network error, timeout, connection error, or HTTP error response)

Note

The `result_string` contents will be replaced with the response data. For large responses, ensure sufficient memory is available. Custom headers must be properly formatted with CRLF line endings.

```
int DoGetEx (
    ParsedURI & TheUri,
    const char * headers,
    unsigned char * result,
    int maxl,
    uint16_t TIMEOUT_WAIT = 10 * TICKS\_PER\_SECOND) [inline]
```

```
#include <http_funcs.h>
```

Executes an HTTP GET request with custom headers using a pre-parsed URI and stores the response in a raw buffer.

This is a low-level extended HTTP GET function that performs an HTTP GET request with custom headers using a pre-parsed URI object and stores the response body in a provided raw buffer. This function provides optimal performance through pre-parsed URI components while supporting custom headers for authentication, content negotiation, or other advanced GET operations. The response is written directly to the buffer without any additional processing.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>headers</i>	Pointer to null-terminated string containing custom HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr or empty string if no custom headers are needed
<i>result</i>	Pointer to raw buffer where the HTTP response body will be stored Buffer must be pre-allocated with sufficient space for the response
<i>maxl</i>	Maximum length of the result buffer in bytes Response will be truncated if it exceeds this length
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

Number of bytes received and stored in the result buffer on success (≥ 0), or a negative error code on failure (network error, timeout, connection error, or HTTP error response)

Note

The result buffer will contain the raw response body data. No null termination is added - treat as binary data. Custom headers must be properly formatted without trailing CRLF on the final header. Using pre-parsed URIs improves performance for repeated requests to the same host. The response may be truncated if it exceeds the *maxl* parameter.

14.60.2.14 DoGetUpdate() [1/2]

```
int DoGetUpdate (
    const char * pUrl,
    uint16_t TIMEOUT_WAIT = 10 * TICKS\_PER\_SECOND)
```

```
#include <http_funcs.h>
```

Execute a firmware update from the specified URI.

Parameters

<i>pUrl</i>	Pointer to a URL string. A DNS lookup will be done if necessary.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

14.60.2.15 DoGetUpdate() [2/2]

```
int DoGetUpdate (
    ParsedURI & TheUri,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)
#include <http_funcs.h>
Execute a firmware update from the specified URI.
```

Parameters

<i>TheUri</i>	Reference to the ParsedURI object.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

14.60.2.16 DoHttp() [1/6]

```
bool DoHttp (
    HttpMethod method,
    const char * pUrl,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)
#include <http_funcs.h>
```

Executes an HTTP/HTTPS request using the specified method and stores the response in a buffer object. This function performs an HTTP request with the given method to the specified URL and stores the complete response body in the provided buffer object. The URL is parsed to extract the host information, port, and path components. DNS resolution is performed automatically if a hostname is provided instead of an IP address. This is the core HTTP client function that supports all standard HTTP methods.

Parameters

<i>method</i>	HTTP method to use for the request (GET, POST, PUT, DELETE, etc.) See HttpMethod enumeration for all supported methods
<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, invalid URL, connection refused, or HTTP error response)

Note

The `result_buffer` contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. For HTTPS URLs, SSL/TLS connection will be established automatically.

#include <http_funcs.h>
```

Performs an HTTP request using the specified method and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the given method to the specified URL and stores the complete response body in the provided [NBString](#) reference. The function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying `DoHttp` implementation.

Parameters

<i>method</i>	HTTP method to use for the request (GET, POST, PUT, DELETE, etc.) See <code>HttpMethod</code> enumeration for available options
<i>pUrl</i>	Pointer to null-terminated string containing the target URL
<i>result_string</i>	Reference to NBString in which to store the HTTP response body
<i>TIMEOUT_WAIT</i>	Optional timeout in system ticks (default: 10 seconds) Use <code>TICKS_PER_SECOND</code> to convert from seconds to ticks

Returns

true if the HTTP request completed successfully, false on failure (timeout, network error, or HTTP error response)

Note

The `result_string` will be cleared and populated with the response data. For large responses, ensure sufficient memory is available.

14.60.2.19 DoHttp() [4/6]

```
bool DoHttp (
    HttpMethod method,
    ParsedURI & TheUri,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)
```

```
#include <http_funcs.h>
```

Executes an HTTP request using a pre-parsed URI and stores the response in a buffer object.

This is the core HTTP client function that performs an HTTP request with the specified method using a pre-parsed URI object and stores the complete response body in the provided buffer object. This function provides enhanced performance by using pre-parsed URI components, eliminating the overhead of repeated URL parsing when making multiple requests to the same host. It supports all standard HTTP methods and handles the complete request/response cycle.

Parameters

<i>method</i>	HTTP method to use for the request (GET, POST, PUT, DELETE, etc.) See HttpMethod enumeration for all supported methods
<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, fragment, etc.)
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, connection error, invalid method, or HTTP error response)

Note

The result_buffer contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. For HTTPS URLs, SSL/TLS connection will be established automatically. Using pre-parsed URIs improves performance for repeated requests to the same host.

```
int DoHttp (
    HttpMethod method,
    ParsedURI & TheUri,
    unsigned char * result,
    int maxl,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)
#include <http_funcs.h>
```

Executes an HTTP request using a pre-parsed URI and stores the response in a raw buffer.

This is a low-level HTTP client function that performs an HTTP request with the specified method using a pre-parsed URI object and stores the response body in a provided raw buffer. This function provides optimal performance by using pre-parsed URI components, eliminating URL parsing and DNS lookup overhead when making multiple requests to the same host. The response is written directly to the buffer without any additional processing or wrapper objects.

Parameters

<i>method</i>	HTTP method to use for the request (GET, POST, PUT, DELETE, etc.) See HttpMethod enumeration for all supported methods
<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>result</i>	Pointer to raw buffer where the HTTP response body will be stored Buffer must be pre-allocated with sufficient space for the response
<i>maxl</i>	Maximum length of the result buffer in bytes Response will be truncated if it exceeds this length
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

Number of bytes received and stored in the result buffer on success (≥ 0), or a negative error code on failure (network error, timeout, connection error, or HTTP error response)

Note

The result buffer will contain the raw response body data. No null termination is added - treat as binary data. Using pre-parsed URIs improves performance for repeated requests to the same host. The response may be truncated if it exceeds the `maxl` parameter.

    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)
```

```
#include <http_funcs.h>
```

Execute a HTTP/HTTPS request using a pointer to a URL string.

This function will parse the URL string to connect to the host.

Parameters

<i>method</i>	HTTP Method to use
<i>pUrl</i>	Pointer to a URL string. A DNS lookup will be done if necessary.
<i>headers</i>	Additional HTTP header fields. Multiple header fields should be concatenated together and separated by by <code>\r\n</code> Do not put <code>\r\n</code> for last header (no trailing <code>\r\n</code>)
<i>&result_buffer</i>	Reference to the memory buffer in which to store the result.
<i>TIMEOUT_WAIT</i>	Timeout in in system time ticks to wait for a response.

Returns

True on success, false on failure.

14.60.2.23 DoHttpEx() [2/6]

```
bool DoHttpEx (
    HttpMethod method,
    const char * pUrl,
    const char * headers,
    NBString & result_string,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]

#include <http_funcs.h>
```

Executes an HTTP request with custom headers using a URL string and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the specified method and custom headers using a URL string. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying `DoHttpEx` implementation. This provides maximum flexibility for HTTP operations with custom headers and string-based response handling.

Parameters

<i>method</i>	HTTP method to use for the request (GET, POST, PUT, DELETE, etc.) See HttpMethod enumeration for all supported methods
<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>headers</i>	Pointer to null-terminated string containing custom HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr or empty string if no custom headers are needed
<i>result_string</i>	Reference to NSString in which to store the HTTP response body The string will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, or HTTP error response)

Note

The result_string contents will be replaced with the response data. For large responses, ensure sufficient memory is available. Custom headers must be properly formatted without trailing CRLF on the final header.

[DoHttp\(HttpMethod, const char*, NSString&, uint16_t\)](#) for requests without custom headers

14.60.2.24 DoHttpEx() [3/6]

```
int DoHttpEx (
    HttpMethod method,
    const char * pUrl,
    const char * headers,
    unsigned char * result,
    int maxl,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)
```

```
#include <http_funcs.h>
```

Executes an HTTP request with custom headers using a URL string and stores the response in a raw buffer.

This is a low-level extended HTTP client function that performs an HTTP request with the specified method and custom headers using a URL string. The response body is stored in a provided raw buffer. The function handles URL parsing and DNS resolution automatically if needed while supporting custom headers for authentication, content negotiation, or other advanced HTTP operations. The response is written directly to the buffer without any additional processing.

Parameters

<i>method</i>	HTTP method to use for the request (GET, POST, PUT, DELETE, etc.) See HttpMethod enumeration for all supported methods
<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>headers</i>	Pointer to null-terminated string containing custom HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr or empty string if no custom headers are needed

Parameters

<i>result</i>	Pointer to raw buffer where the HTTP response body will be stored Buffer must be pre-allocated with sufficient space for the response
<i>maxl</i>	Maximum length of the result buffer in bytes Response will be truncated if it exceeds this length
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

Number of bytes received and stored in the result buffer on success (≥ 0), or a negative error code on failure (network error, timeout, DNS resolution failure, or HTTP error response)

Note

The result buffer will contain the raw response body data. No null termination is added - treat as binary data. Custom headers must be properly formatted without trailing CRLF on the final header. The response may be truncated if it exceeds the *maxl* parameter.

HttpMethod for available HTTP methods

[DoHttpEx\(HttpMethod, ParsedURI&, const char*, unsigned char*, int, uint16_t\)](#) for pre-parsed URI version

[DoHttpEx\(HttpMethod, const char*, const char*, buffer_object&, uint16_t\)](#) for [buffer_object](#) version

14.60.2.25 DoHttpEx() [4/6]

```
bool DoHttpEx (
    HttpMethod method,
    ParsedURI & TheUri,
    const char * headers,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)
#include <http_funcs.h>
```

Executes an HTTP request with custom headers using a pre-parsed URI and stores the response in a buffer object. This is the core extended HTTP client function that performs an HTTP request with the specified method using a pre-parsed URI object and allows custom headers to be included in the request. The complete response body is stored in the provided buffer object. This function provides maximum flexibility and control over HTTP requests, supporting all standard HTTP methods, custom headers, and pre-parsed URIs for optimal performance when making multiple requests.

Parameters

<i>method</i>	HTTP method to use for the request (GET, POST, PUT, DELETE, etc.) See HttpMethod enumeration for all supported methods
<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, fragment, etc.)
<i>headers</i>	Pointer to null-terminated string containing custom HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr or empty string if no custom headers are needed
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, connection error, invalid method, malformed headers, or HTTP error response)

Note

The `result_buffer` contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. Headers must be properly formatted without trailing CRLF on the final header. This is the most comprehensive HTTP client function providing full control. For HTTPS URLs, SSL/TLS connection will be established automatically. Using pre-parsed URIs improves performance for repeated requests to the same host.

```
bool DoJsonHttp (
    HttpMethod method,
    const char * pUrl,
    const char * Json_Data_To_Post,
    buffer_object & result_buffer,
    const char * AdditionalHeaders = NULL,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)
#include <http_funcs.h>
```

Executes an HTTP request with raw JSON data using a URL string and stores the response in a buffer object. This is the core JSON HTTP function for raw JSON string data that performs an HTTP request with the specified method using raw JSON data provided as a string and a URL string. The complete response body is stored in the provided buffer object. This function provides the foundation for JSON HTTP operations with pre-formatted JSON strings, supporting all standard HTTP methods while handling URL parsing and DNS resolution automatically. The JSON data is sent with the appropriate Content-Type header for proper server processing.

Parameters

<i>method</i>	HTTP method to use for the request (POST, PUT, PATCH recommended for JSON data) See <code>HttpMethod</code> enumeration for all supported methods
<i>pUrl</i>	Pointer to null-terminated URL string (<code>http://</code> or <code>https://</code>) DNS lookup will be performed automatically for hostnames
<i>Json_Data_To_Post</i>	Pointer to null-terminated string containing the raw JSON data to be sent in the request body. Must be valid, serialized JSON format
<i>result_buffer</i>	Reference to <code>buffer_object</code> where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>AdditionalHeaders</i>	Pointer to null-terminated string containing additional HTTP headers Multiple headers should be concatenated and separated by <code>"\r\n"</code> Do not include trailing <code>"\r\n"</code> after the last header Pass <code>nullptr</code> if no additional headers are needed (default: <code>NULL</code>)
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use <code>TICKS_PER_SECOND</code> for conversion

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, or HTTP error response)

Note

The `result_buffer` contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. Content-Type header is automatically set to "application/json" for the request. The provided JSON string must be properly formatted, serialized, and null-terminated.

    const char * AdditionalHeaders = NULL,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
```

```
#include <http_funcs.h>
```

Executes an HTTP request with raw JSON data using a URL string and stores the response in an [NSString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the specified method using raw JSON data provided as a string and a URL string. The complete response body is stored in the provided [NSString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoJsonHttp implementation. The URL string will be parsed internally and DNS resolution will be performed automatically if needed, making this ideal for simple JSON operations with pre-formatted data.

Parameters

<i>method</i>	HTTP method to use for the request (POST, PUT, PATCH recommended for JSON data) See HttpMethod enumeration for all supported methods
<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>Json_Data_To_Post</i>	Pointer to null-terminated string containing the raw JSON data to be sent in the request body. Must be valid JSON format
<i>result_string</i>	Reference to NSString in which to store the HTTP response body The string will be populated with the complete response data
<i>AdditionalHeaders</i>	Pointer to null-terminated string containing additional HTTP headers Headers should be formatted as "Header: Value\r\n" pairs Pass nullptr if no additional headers are needed (default: NULL)
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, or HTTP error response)

Note

The result_string contents will be replaced with the response data. For large responses, ensure sufficient memory is available. Content-Type header is automatically set to "application/json" for the request. The provided JSON string must be properly formatted and null-terminated.

```
bool DoJsonHttp (
    HttpMethod method,
    const char * pUrl,
    ParsedJsonDataSet & jsonout,
    buffer_object & result_buffer,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)
```

```
#include <http_funcs.h>
```

Executes an HTTP request with JSON data from a [ParsedJsonDataSet](#) using a URL string and stores the response in a buffer object. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is the core JSON HTTP function that performs an HTTP request with the specified method using JSON data from a [ParsedJsonDataSet](#) object and a URL string. The complete response body is stored in the provided buffer object. This function provides the foundation for programmatic JSON HTTP operations with string-based URLs, allowing dynamic construction and manipulation of JSON data before transmission. The URL string will be parsed internally and DNS resolution will be performed automatically if needed.

Parameters

<i>method</i>	HTTP method to use for the request (POST, PUT, PATCH recommended for JSON data) See HttpMethod enumeration for all supported methods
<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>jsonout</i>	Reference to ParsedJsonDataSet containing the JSON data to be serialized and sent in the request body
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>AdditionalHeaders</i>	Pointer to null-terminated string containing additional HTTP headers Headers should be formatted as "Header: Value\r\n" pairs Pass nullptr or empty string if no additional headers are needed
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, JSON serialization error, or HTTP error response)

Note

The result_buffer contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. The JSON data will be automatically serialized with Content-Type "application/json".

    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP request with JSON data from a [ParsedJsonDataSet](#) using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the specified method using JSON data from a [ParsedJsonDataSet](#) object and a pre-parsed URI. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoJsonHttp implementation. This provides flexibility for programmatic JSON operations with string-based response handling.

Parameters

<i>method</i>	HTTP method to use for the request (POST, PUT, PATCH recommended for JSON data) See HttpMethod enumeration for all supported methods
<i>TheUri</i>	Reference to ParsedUri object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>jsonout</i>	Reference to ParsedJsonDataSet containing the JSON data to be serialized and sent in the request body
<i>result_string</i>	Reference to NBString in which to store the HTTP response body The string will be populated with the complete response data
<i>AdditionalHeaders</i>	Pointer to null-terminated string containing additional HTTP headers Headers should be formatted as "Header: Value\r\n" pairs Pass nullptr or empty string if no additional headers are needed
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, connection error, JSON serialization error, or HTTP error response)

Note

The result_string contents will be replaced with the response data. For large responses, ensure sufficient memory is available. The JSON data will be automatically serialized with Content-Type "application/json".

14.60.2.36 DoJsonHttpFile() [1/4]

```
bool DoJsonHttpFile (
    HttpMethod method,
    const char * pUrl,
    const char * FragmentName,
    buffer_object & result_buffer,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)
#include <http_funcs.h>
```

Executes an HTTP request with JSON data from a file fragment using a URL string and stores the response in a buffer object.

This is the core JSON HTTP file function that performs an HTTP request with the specified method using JSON data loaded from a file fragment and a URL string. The complete response body is stored in the provided buffer object. This function supports JSON file templates with dynamic variable substitution, function callbacks, and other advanced features similar to the NetBurner web server system. The URL string will be parsed internally and DNS resolution will be performed automatically if needed.

Parameters

<i>method</i>	HTTP method to use for the request (POST, PUT, PATCH recommended for JSON data) See HttpMethod enumeration for all supported methods
<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>FragmentName</i>	Pointer to null-terminated string specifying the name of the file fragment containing the JSON template data with optional variable substitutions
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>AdditionalHeaders</i>	Pointer to null-terminated string containing additional HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr or empty string if no additional headers are needed
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, fragment not found, template processing error, or HTTP error response)

Note

The result_buffer contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. The JSON file fragment supports template processing with variable substitution. Content-Type header is automatically set to "application/json" for the request.

14.60.2.37 DoJsonHttpFile() [2/4]

```
bool DoJsonHttpFile (
    HttpMethod method,
    const char * pUrl,
    const char * FragmentName,
    NBString & result_string,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Performs an HTTP request and stores JSON response in an [NBString](#) This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that wraps the result [NBString](#) in a [StringBufferObject](#) and calls the main DoJsonHttpFile function.

Parameters

<i>method</i>	HTTP method to use (GET, POST, PUT, DELETE, etc.)
<i>pUrl</i>	URL to send the HTTP request to
<i>FragmentName</i>	Name of the JSON fragment to extract from response
<i>result_string</i>	Reference to NBString in which to store the result
<i>AdditionalHeaders</i>	Additional HTTP headers to include in the request (can be NULL)
<i>TIMEOUT_WAIT</i>	Timeout value in system ticks (default: 10 seconds)

Returns

true if the HTTP request was successful and JSON was parsed, false otherwise

See also

[DoJsonHttpFile\(HttpMethod, const char*, const char*, StringBufferObject&, const char*, uint16_t\)](#)

14.60.2.38 DoJsonHttpFile() [3/4]

```
bool DoJsonHttpFile (
    HttpMethod method,
    ParsedURI & TheUri,
    const char * FragmentName,
    buffer_object & result_buffer,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND)
#include <http_funcs.h>
```

Sends an HTTP request and processes JSON response using a pre-parsed URI.

This function performs HTTP operations with JSON response processing using a pre-parsed URI object, providing more control and efficiency when the same URI will be used multiple times. It supports various HTTP methods (Post, Put, Patch) commonly used in REST API operations for creating, updating, and modifying resources. The function establishes an HTTP connection to the specified URI, sends the request with any additional headers, waits for the server response within the specified timeout period, and then parses the JSON response to extract only the requested fragment. This selective extraction reduces memory usage and processing overhead when dealing

with large JSON responses. The use of a pre-parsed URI object eliminates repeated URI parsing overhead and provides better performance for repeated requests to the same endpoint. The function handles all aspects of the HTTP transaction including error conditions, timeouts, and malformed responses.

Parameters

<i>method</i>	HTTP method to use (Post, Put, or Patch)
<i>TheUri</i>	Reference to the pre-parsed URI object containing host, port, and path information
<i>FragmentName</i>	Name of the JSON fragment to extract from the response
<i>result_buffer</i>	Reference to the buffer object where the result will be stored
<i>AdditionalHeaders</i>	Additional HTTP headers to include in the request (may be NULL)
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for response (default: 10 seconds)

Returns

true on success, false on failure

14.60.2.39 DoJsonHttpFile() [4/4]

```
bool DoJsonHttpFile (
    HttpMethod method,
    ParsedURI & TheUri,
    const char * FragmentName,
    NBString & result_string,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP request with JSON data from a file fragment using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the specified method using JSON data loaded from a file fragment and a pre-parsed URI object. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoJsonHttpFile implementation. This approach provides maximum flexibility for JSON-based HTTP operations with pre-stored data fragments.

Parameters

<i>method</i>	HTTP method to use for the request (GET, POST, PUT, DELETE, etc.) See HttpMethod enumeration for all supported methods
<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>FragmentName</i>	Pointer to null-terminated string specifying the name of the file fragment containing the JSON data to be sent in the request body
<i>result_string</i>	Reference to NBString in which to store the HTTP response body The string will be populated with the complete response data
<i>AdditionalHeaders</i>	Pointer to null-terminated string containing additional HTTP headers Headers should be formatted as "Header: Value\r\n" pairs Pass nullptr or empty string if no additional headers are needed
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, connection error, fragment not found, invalid method, or HTTP error response)

Note

The `result_string` contents will be replaced with the response data. For large responses, ensure sufficient memory is available. The specified file fragment must exist and contain valid JSON data. Content-Type header is automatically set to "application/json" for the request.

14.60.2.40 DoJsonPost() [1/8]

```
bool DoJsonPost (
    const char * pUrl,
    const char * Json_Data_To_Post,
    buffer_object & result_buffer,
    const char * AdditionalHeaders = NULL,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP POST request with raw JSON data using a URL string and stores the response in a buffer object. This function performs an HTTP POST request using raw JSON data provided as a string and a URL string. The complete response body is stored in the provided buffer object. This is a convenience wrapper around the generic `DoJsonHttp` function, specifically optimized for POST operations with pre-formatted JSON strings. This provides the most straightforward interface for JSON POST operations when you have serialized JSON data and want to use automatic URL parsing with buffer-based response handling.

Parameters

<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>Json_Data_To_Post</i>	Pointer to null-terminated string containing the raw JSON data to be sent in the POST request body. Must be valid, serialized JSON format
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>AdditionalHeaders</i>	Pointer to null-terminated string containing additional HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr if no additional headers are needed (default: NULL)
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use <code>TICKS_PER_SECOND</code> for conversion

Returns

true if the POST request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, or HTTP error response)

Note

The `result_buffer` contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. Content-Type header is automatically set to "application/json" for the request. The provided JSON string must be properly formatted, serialized, and null-terminated.

#include <http_funcs.h>
```

Executes an HTTP POST request with JSON data from a [ParsedJsonDataSet](#) using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request using JSON data from a [ParsedJsonDataSet](#) object and a pre-parsed URI. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoJsonHttp implementation. This approach allows for dynamic JSON POST requests with programmatically constructed data.

Parameters

<i>TheUri</i>	Reference to ParsedUri object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>jsonout</i>	Reference to ParsedJsonDataSet containing the JSON data to be sent in the POST request body
<i>result_string</i>	Reference to NBString in which to store the HTTP response body The string will be populated with the complete response data
<i>AdditionalHeaders</i>	Pointer to null-terminated string containing additional HTTP headers Headers should be formatted as "Header: Value\r\n" pairs Pass nullptr or empty string if no additional headers are needed

<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use <i>TICKS_PER_SECOND</i> for conversion

Returns

true if the POST request completed successfully and response was received, false on failure (network error, timeout, connection error, JSON serialization error, or HTTP error response)

Note

The *result_string* contents will be replaced with the response data. For large responses, ensure sufficient memory is available. The JSON data will be automatically serialized and sent with Content-Type "application/json".

14.60.2.48 DoJsonPostHttpFile() [1/4]

```
bool DoJsonPostHttpFile (
    const char * pUrl,
    const char * FragmentName,
    buffer_object & result_buffer,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP POST request with JSON data from a file fragment using a URL string and stores the response in a buffer object.

This function performs an HTTP POST request using JSON data loaded from a specified file fragment and a URL string. The complete response body is stored in the provided buffer object. This is a convenience wrapper around the generic [DoJsonHttpFile](#) function, providing a simple interface for JSON POST operations with file-based templates that support dynamic variable substitution, function callbacks, and other advanced processing features similar to the NetBurner web server system.

Parameters

<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>FragmentName</i>	Pointer to null-terminated string specifying the name of the file fragment containing the JSON template data with optional variable substitutions
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>AdditionalHeaders</i>	Pointer to null-terminated string containing additional HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr or empty string if no additional headers are needed
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use <i>TICKS_PER_SECOND</i> for conversion

Returns

true if the POST request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, fragment not found, template processing error, or HTTP error response)

Note

The `result_buffer` contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. The JSON file fragment supports template processing with variable substitution. Content-Type header is automatically set to "application/json" for the request.

14.60.2.49 DoJsonPostHttpFile() [2/4]

```
bool DoJsonPostHttpFile (
    const char * pUrl,
    const char * FragmentName,
    NBString & result_string,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Performs an HTTP POST request and stores JSON response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience wrapper function that simplifies HTTP POST operations with JSON response handling. It internally calls `DoJsonHttpFile` with `HttpMethod::Post` and automatically manages the buffer conversion from [NBString](#) to [StringBufferObject](#). The function handles the complete HTTP transaction including connection establishment, request transmission, response reception, and JSON parsing. Only the specified JSON fragment is extracted from the response and stored in the result string, making it efficient for retrieving specific data from larger JSON responses. The function is particularly useful for REST API interactions where you need to POST data and extract a specific piece of information from the JSON response.

Parameters

<i>pUrl</i>	URL to send the HTTP POST request to
<i>FragmentName</i>	Name of the JSON fragment to extract from response
<i>result_string</i>	Reference to NBString where the result will be stored
<i>AdditionalHeaders</i>	Additional HTTP headers to include in the request (may be NULL)
<i>TIMEOUT_WAIT</i>	Timeout value in system ticks (default: 10 seconds)

Returns

true if the HTTP POST request succeeded and JSON was parsed successfully, false otherwise

See also

[DoJsonHttpFile\(HttpMethod, const char*, const char*, NBString&, const char*, uint16_t\)](#)

14.60.2.50 DoJsonPostHttpFile() [3/4]

```
bool DoJsonPostHttpFile (
    ParsedURI & TheUri,
    const char * FragmentName,
    buffer_object & result_buffer,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
```

```
#include <http_funcs.h>
```

Executes an HTTP POST request with JSON data from a file fragment using a pre-parsed URI and stores the response in a buffer object.

This function performs an HTTP POST request using JSON data loaded from a specified file fragment and a pre-parsed URI object. The complete response body is stored in the provided buffer object. This is a convenience wrapper around the generic DoJsonHttpFile function, specifically optimized for POST operations with pre-defined JSON data stored in file fragments, eliminating the need to construct JSON payloads programmatically.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>FragmentName</i>	Pointer to null-terminated string specifying the name of the file fragment containing the JSON data to be sent in the POST request body
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>AdditionalHeaders</i>	Pointer to null-terminated string containing additional HTTP headers Headers should be formatted as "Header: Value\r\n" pairs Pass nullptr or empty string if no additional headers are needed
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the POST request completed successfully and response was received, false on failure (network error, timeout, connection error, fragment not found, or HTTP error response)

Note

The result_buffer contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. The specified file fragment must exist and contain valid JSON data. Content-Type header is automatically set to "application/json" for the request.

14.60.2.51 DoJsonPostHttpFile() [4/4]

```
bool DoJsonPostHttpFile (
    ParsedURI & TheUri,
    const char * FragmentName,
    NBString & result_string,
    const char * AdditionalHeaders,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Executes an HTTP POST request with JSON data from a file fragment using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request using JSON data loaded from a specified file fragment and a pre-parsed URI object. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoJsonHttpFile implementation. This approach allows for efficient JSON POST requests with pre-defined data stored in file fragments.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>FragmentName</i>	Pointer to null-terminated string specifying the name of the file fragment containing the JSON data to be sent in the POST request body
<i>result_string</i>	Reference to NBString in which to store the HTTP response body The string will be populated with the complete response data
<i>AdditionalHeaders</i>	Pointer to null-terminated string containing additional HTTP headers Headers should be formatted as "Header: Value\r\n" pairs Pass nullptr or empty string if no additional headers are needed
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the POST request completed successfully and response was received, false on failure (network error, timeout, connection error, fragment not found, or HTTP error response)

Note

The result_string contents will be replaced with the response data. For large responses, ensure sufficient memory is available. The specified file fragment must exist and contain valid JSON data. Content-Type header is automatically set to "application/json" for the request.

14.60.2.52 DoMultipartBoundary()

```
void DoMultipartBoundary (
    int tcpfd,
    const char * Disposition,
    const char * separator)
#include <http_funcs.h>
```

Sends a multipart boundary section within an active multipart HTTP request.

This function sends a multipart boundary with content disposition headers but without any data payload as part of a multipart HTTP request. This is useful for creating empty form fields or marking section boundaries within the multipart stream according to the multipart/form-data specification. The boundary is properly formatted with the specified separator and disposition information.

Parameters

<i>tcpfd</i>	TCP file descriptor of the active HTTP connection Must be a valid descriptor returned from DoMultipartStartPost()
<i>Disposition</i>	Content-Disposition header value for this multipart section Should follow RFC format (e.g., "form-data; name=\"fieldname\"") Used to identify this section even though no data follows
<i>separator</i>	Multipart boundary separator string used to delimit sections Must be the same separator used throughout the entire multipart request

Note

This function must be called between [DoMultipartStartPost\(\)](#) and [DoMultipartFinished\(\)](#). The TCP connection must remain active throughout the entire multipart sequence. The separator string must be consistent across all multipart operations in the same request. This creates a boundary marker without associated data content.

See also

[DoMultipartStartPost\(\)](#) to initiate a multipart request
[DoMultipartItem\(\)](#) to send boundary sections with data
[DoMultipartFinished\(\)](#) to complete the request and receive the response

14.60.2.53 DoMultipartFinished() [1/2]

```
bool DoMultipartFinished (
    int tcpfd,
    const char * separator,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)

#include <http_funcs.h>
```

Completes a multipart HTTP request and retrieves the server response in a buffer object.

This function finalizes a multipart HTTP request by sending the closing boundary, waiting for the server response, and parsing the complete response into the provided buffer object. This must be called after all multipart items and boundaries have been sent using [DoMultipartItem\(\)](#) and [DoMultipartBoundary\(\)](#) functions. The function handles the proper termination of the multipart stream and manages the HTTP response parsing.

Parameters

<i>tcpfd</i>	TCP file descriptor of the active HTTP connection Must be a valid descriptor returned from DoMultipartStartPost()
<i>separator</i>	Multipart boundary separator string used throughout the request Must match the separator used in all previous multipart operations
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete server response
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the server response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the request completed successfully with a 200 OK response containing a body, false on failure (network error, timeout, non-200 response, or parsing error)

Note

This function closes the multipart request and invalidates the TCP file descriptor. The *result_buffer* contents will be replaced with the server response data. Ensure the buffer object has sufficient capacity for the expected response size. A successful return indicates both proper multipart transmission and a valid HTTP response.

See also

14.60.2.54 DoMultipartFinished() [2/2]

```
bool DoMultipartFinished (
    int tcpfd,
    const char * separator,
    NBString & result_string,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND) [inline]
#include <http_funcs.h>
```

Completes a multipart HTTP request and retrieves the server response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts. This is a convenience overload that finalizes a multipart HTTP request and stores the server response in an [NBString](#) reference. The function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoMultipartFinished implementation. This provides string-based response handling for multipart operations where text-based responses are expected.

Parameters

<i>tcpfd</i>	TCP file descriptor of the active HTTP connection Must be a valid descriptor returned from DoMultipartStartPost()
<i>separator</i>	Multipart boundary separator string used throughout the request Must match the separator used in all previous multipart operations
<i>result_string</i>	Reference to NBString in which to store the HTTP response body The string will be populated with the complete server response
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the server response (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

true if the request completed successfully with a 200 OK response containing a body, false on failure (network error, timeout, non-200 response, or parsing error)

Note

This function closes the multipart request and invalidates the TCP file descriptor. The result_string contents will be replaced with the server response data. For large responses, ensure sufficient memory is available. A successful return indicates both proper multipart transmission and a valid HTTP response.

14.60.2.55 DoMultipartItem()

```
void DoMultipartItem (
    int tcpfd,
    const char * Disposition,
    const char * separator,
```

```

        const unsigned char * data,
        int len)
#include <http_funcs.h>

```

Sends a multipart data item within an active multipart HTTP request.

This function sends a single data item as part of a multipart HTTP request that was previously initiated with [DoMultipartStartPost\(\)](#). The function handles the proper formatting of the multipart boundary, content disposition headers, and the actual data payload according to the multipart/form-data specification. This allows for sending binary data, files, or form fields as individual parts of a larger multipart submission.

Parameters

<i>tcpfd</i>	TCP file descriptor of the active HTTP connection Must be a valid descriptor returned from DoMultipartStartPost()
<i>Disposition</i>	Content-Disposition header value for this multipart section Should follow RFC format (e.g., "form-data; name=\"fieldname\"" or "form-data; name=\"file\"; filename=\"example.txt\"")
<i>separator</i>	Multipart boundary separator string used to delimit sections Must be the same separator used throughout the entire multipart request
<i>data</i>	Pointer to the binary data to be sent in this multipart section Can contain any type of data including binary files or text
<i>len</i>	Length of the data in bytes Must accurately represent the size of the data buffer

Note

This function must be called between [DoMultipartStartPost\(\)](#) and [DoMultipartFinished\(\)](#). The TCP connection must remain active throughout the entire multipart sequence. The separator string must be consistent across all multipart operations in the same request. Content-Type headers for individual parts can be included in the Disposition parameter.

- [DoMultipartFinished\(\)](#) to complete the request and receive the response

14.60.2.56 DoMultipartStartHttp() [1/2]

```

int DoMultipartStartHttp (
    HttpMethod method,
    const char * pUrl,
    const char * separator,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND,
    uint32_t contentLength = 0)
#include <http_funcs.h>

```

Initiates a multipart HTTP request using a URL string and returns a connection file descriptor.

This is the core multipart HTTP function that establishes an HTTP connection and begins a multipart request with the specified method using a URL string. The function performs URL parsing, DNS resolution if needed, establishes the TCP/TLS connection, and sends the initial HTTP headers including the multipart/form-data content type with the specified boundary separator. The returned file descriptor is used for subsequent multipart operations.

Parameters

<i>method</i>	HTTP method to use for the multipart request (POST, PUT, PATCH recommended) See HttpMethod enumeration for all supported methods
<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames For HTTPS URLs, SSL/TLS connection will be established automatically

Parameters

<i>separator</i>	Multipart boundary separator string used to delimit sections Must be unique and not appear in the actual data being transmitted Commonly generated as a random string or UUID
<i>TIMEOUT_WAIT</i>	Timeout in system ticks for connection establishment and initial request (default: 10 seconds). Use TICKS_PER_SECOND for conversion
<i>contentLength</i>	Total content length for the entire multipart request in bytes If 0, chunked transfer encoding will be used (default: 0) If specified, must accurately represent the total payload size

Returns

TCP/TLS file descriptor (> 0) if connection was successfully established and headers sent, or a negative tcpSocketStatus error code on failure (connection error, DNS resolution failure, timeout, or HTTP protocol error)

Note

The returned file descriptor must be used with [DoMultipartItem\(\)](#), [DoMultipartBoundary\(\)](#), and [DoMultipartFinished\(\)](#) to complete the multipart request sequence. The connection remains active until [DoMultipartFinished\(\)](#) is called. If contentLength is specified, the total data sent must match exactly. The separator string must be consistent throughout all subsequent multipart operations.

14.60.2.57 DoMultipartStartHttp() [2/2]

```
int DoMultipartStartHttp (
    HttpMethod method,
    ParsedURI & TheUri,
    const char * separator,
    uint16_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND,
    uint32_t contentLength = 0)
#include <http_funcs.h>
```

Initiates a multipart HTTP request using a pre-parsed URI and returns a connection file descriptor.

This is the core multipart HTTP function that establishes an HTTP connection and begins a multipart request with the specified method using a pre-parsed URI object. The function uses the pre-parsed URI components to establish the TCP/TLS connection directly, eliminating URL parsing overhead and providing optimal performance for repeated multipart requests to the same host. The function sends the initial HTTP headers including the multipart/form-data content type with the specified boundary separator.

Parameters

<i>method</i>	HTTP method to use for the multipart request (POST, PUT, PATCH recommended) See HttpMethod enumeration for all supported methods
<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.) For HTTPS schemes, SSL/TLS connection will be established automatically
<i>separator</i>	Multipart boundary separator string used to delimit sections Must be unique and not appear in the actual data being transmitted Commonly generated as a random string or UUID

Parameters

<i>TIMEOUT_WAIT</i>	Timeout in system ticks for connection establishment and initial request (default: 10 seconds). Use TICKS_PER_SECOND for conversion
<i>contentLength</i>	Total content length for the entire multipart request in bytes. If 0, chunked transfer encoding will be used (default: 0). If specified, must accurately represent the total payload size

Returns

TCP/TLS file descriptor (> 0) if connection was successfully established and headers sent, or a negative tcpSocketStatus error code on failure (connection error, timeout, or HTTP protocol error)

Note

The returned file descriptor must be used with [DoMultipartItem\(\)](#), [DoMultipartBoundary\(\)](#), and [DoMultipartFinished\(\)](#) to complete the multipart request sequence. Using pre-parsed URLs improves performance for repeated requests to the same host. The connection remains active until [DoMultipartFinished\(\)](#) is called. If contentLength is specified, the total data sent must match exactly. The separator string must be consistent throughout all subsequent multipart operations.

14.60.2.58 DoMultipartStartPost() [1/2]

```
int DoMultipartStartPost (
    const char * pUrl,
    const char * separator,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND,
    uint32_t contentLength = 0) [inline]
#include <http_funcs.h>
```

Initiates a multipart HTTP POST request using a URL string and returns a connection file descriptor.

This is a convenience function that establishes an HTTP POST connection and begins a multipart request using a URL string. This function provides the simplest interface for starting multipart POST operations, handling URL parsing, DNS resolution, connection establishment, and sending the initial HTTP headers with multipart/form-data content type. This is ideal for straightforward multipart file uploads or form submissions.

Parameters

<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames. For HTTPS URLs, SSL/TLS connection will be established automatically.
<i>separator</i>	Multipart boundary separator string used to delimit sections. Must be unique and not appear in the actual data being transmitted. Commonly generated as a random string or UUID.
<i>TIMEOUT_WAIT</i>	Timeout in system ticks for connection establishment and initial request (default: 10 seconds). Use TICKS_PER_SECOND for conversion.
<i>contentLength</i>	Total content length for the entire multipart request in bytes. If 0, chunked transfer encoding will be used (default: 0). If specified, must accurately represent the total payload size.

Returns

TCP/TLS file descriptor (> 0) if connection was successfully established and headers sent, or a negative `tcpSocketStatus` error code on failure (connection error, DNS resolution failure, timeout, or HTTP protocol error)

Note

The returned file descriptor must be used with [DoMultipartItem\(\)](#), [DoMultipartBoundary\(\)](#), and [DoMultipartFinished\(\)](#) to complete the multipart request sequence. If `contentLength` is specified, the total data sent must match exactly. The separator string must be consistent throughout all subsequent multipart operations.

14.60.2.59 DoMultipartStartPost() [2/2]

```
int DoMultipartStartPost (
    ParsedURI & TheUri,
    const char * separator,
    uint16_t TIMEOUT_WAIT = 10 * TICKS_PER_SECOND,
    uint32_t contentLength = 0) [inline]
```

```
#include <http_funcs.h>
```

Initiates a multipart HTTP POST request using a pre-parsed URI and returns a connection file descriptor.

This is a convenience function that establishes an HTTP POST connection and begins a multipart request using a pre-parsed URI object. This function provides enhanced performance by using pre-parsed URI components, eliminating URL parsing overhead when making multiple multipart requests to the same host. The function establishes the connection and sends the initial HTTP headers with multipart/form-data content type.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>separator</i>	Multipart boundary separator string used to delimit sections. Must be unique and not appear in the actual data being transmitted. Commonly generated as a random string or UUID.
<i>TIMEOUT_WAIT</i>	Timeout in system ticks for connection establishment and initial request (default: 10 seconds). Use <code>TICKS_PER_SECOND</code> for conversion.
<i>contentLength</i>	Total content length for the entire multipart request in bytes. If 0, chunked transfer encoding will be used (default: 0). If specified, must accurately represent the total payload size.

Returns

TCP/TLS file descriptor (> 0) if connection was successfully established and headers sent, or a negative `tcpSocketStatus` error code on failure (connection error, timeout, or HTTP protocol error)

Note

The returned file descriptor must be used with [DoMultipartItem\(\)](#), [DoMultipartBoundary\(\)](#), and [DoMultipartFinished\(\)](#) to complete the multipart request sequence. Using pre-parsed URIs improves performance for repeated requests to the same host. If `contentLength` is specified, the total data sent must match exactly. The separator string must be consistent throughout all subsequent multipart operations.

14.60.2.60 DoUrlEncodedFormHttp() [1/3]

```

bool DoUrlEncodedFormHttp (
    HttpMethod method,
    const char * pUrl,
    char * headers,
    char * form_data,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT)
  
```

```
#include <http_funcs.h>
```

Executes an HTTP request with URL-encoded form data using a URL string and stores the response in a buffer object. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is the core URL-encoded form HTTP function that performs an HTTP request with the specified method using URL-encoded form data and a URL string. The complete response body is stored in the provided buffer object. This function provides the foundation for form-based HTTP operations, supporting all standard HTTP methods while handling URL parsing and DNS resolution automatically. The form data is sent with the appropriate Content-Type header for proper server processing of web form submissions.

Parameters

<i>method</i>	HTTP method to use for the request (POST recommended for form data) See HttpMethod enumeration for all supported methods
<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>headers</i>	Pointer to null-terminated string containing HTTP headers Headers should be formatted as "Header: Value\r\n" pairs Pass nullptr if no custom headers are needed
<i>form_data</i>	Pointer to null-terminated string containing URL-encoded form data Data should be in "key1=value1&key2=value2" format with proper URL encoding
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response Use TICKS_PER_SECOND for conversion from seconds to ticks

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, or HTTP error response)

Note

The result_buffer contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. Content-Type header is automatically set to "application/x-www-form-urlencoded". Form data must be properly URL-encoded before passing to this function.

14.60.2.61 DoUrlEncodedFormHttp() [2/3]

```
bool DoUrlEncodedFormHttp (
    HttpMethod method,
    ParsedURI & TheUri,
    char * headers,
    char * form_data,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT)
```

```
#include <http_funcs.h>
```

Executes an HTTP request with URL-encoded form data using a pre-parsed URI and stores the response in a buffer object.

This is the core URL-encoded form HTTP function that performs an HTTP request with the specified method using URL-encoded form data and a pre-parsed URI object. The complete response body is stored in the provided buffer object. This function provides the foundation for form-based HTTP operations with optimal performance through pre-parsed URI components, supporting all standard HTTP methods while eliminating the overhead of repeated URL parsing when making multiple form submissions to the same host.

Parameters

<i>method</i>	HTTP method to use for the request (POST, PUT, PATCH recommended for form data) See HttpMethod enumeration for all supported methods
<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>headers</i>	Pointer to null-terminated string containing additional HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr if no additional headers are needed
<i>form_data</i>	Pointer to null-terminated string containing URL-encoded form data Data should be in "key1=value1&key2=value2" format with proper URL encoding
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response Use TICKS_PER_SECOND for conversion from seconds to ticks

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, connection error, or HTTP error response)

Note

The result_buffer contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. Content-Type header is automatically set to "application/x-www-form-urlencoded". Form data must be properly URL-encoded before passing to this function. Using pre-parsed URIs improves performance for repeated requests to the same host.

[DoUrlEncodedFormHttp\(HttpMethod, const char*, char*, char*, buffer_object&, uint16_t\)](#) for string URL version

14.60.2.62 DoUrlEncodedFormHttp() [3/3]

```
bool DoUrlEncodedFormHttp (
    HttpMethod method,
    ParsedURI & TheUri,
    char * headers,
    char * form_data,
    NBString & result_string,
    uint16_t TIMEOUT_WAIT) [inline]
```

```
#include <http_funcs.h>
```

Executes an HTTP request with URL-encoded form data using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP request with the specified method using URL-encoded form data and a pre-parsed URI object. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying DoUrlEncodedFormHttp implementation. This provides flexibility for form-based HTTP operations with pre-parsed URIs and string-based response handling.

Parameters

<i>method</i>	HTTP method to use for the request (POST, PUT, PATCH recommended for form data) See HttpMethod enumeration for all supported methods
<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>headers</i>	Pointer to null-terminated string containing additional HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr if no additional headers are needed
<i>form_data</i>	Pointer to null-terminated string containing URL-encoded form data Data should be in "key1=value1&key2=value2" format with proper URL encoding
<i>result_string</i>	Reference to NBString in which to store the HTTP response body The string will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response Use TICKS_PER_SECOND for conversion from seconds to ticks

Returns

true if the HTTP request completed successfully and response was received, false on failure (network error, timeout, connection error, or HTTP error response)

Note

The result_string contents will be replaced with the response data. For large responses, ensure sufficient memory is available. Content-Type header is automatically set to "application/x-www-form-urlencoded". Form data must be properly URL-encoded before passing to this function. Using pre-parsed URIs improves performance for repeated requests to the same host.

14.60.2.63 DoUrlEncodedFormPost() [1/4]

```
bool DoUrlEncodedFormPost (
    const char * pUrl,
    char * headers,
    char * form_data,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT) [inline]
```

```
#include <http_funcs.h>
```

Executes an HTTP POST request with URL-encoded form data using a URL string and stores the response in a buffer object. This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request with URL-encoded form data using a URL string. The complete response body is stored in the provided buffer object. This function is a simple wrapper around the generic [DoUrlEncodedFormHttp](#) function, specifically optimized for POST operations with form data. This provides the most straightforward interface for web form submissions when you have URL-encoded form data and want to use automatic URL parsing with buffer-based response handling.

Parameters

<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>headers</i>	Pointer to null-terminated string containing HTTP headers Headers should be formatted as "Header: Value\r\n" pairs Pass nullptr if no custom headers are needed
<i>form_data</i>	Pointer to null-terminated string containing URL-encoded form data Data should be in "key1=value1&key2=value2" format with proper URL encoding
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response Use TICKS_PER_SECOND for conversion from seconds to ticks

Returns

true if the POST request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, or HTTP error response)

Note

The *result_buffer* contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. Content-Type header is automatically set to "application/x-www-form-urlencoded". Form data must be properly URL-encoded before passing to this function.

14.60.2.64 DoUrlEncodedFormPost() [2/4]

```
bool DoUrlEncodedFormPost (
    const char * pUrl,
    char * headers,
    char * form_data,
    NSString & result_string,
    uint16_t TIMEOUT_WAIT) [inline]
```

```
#include <http_funcs.h>
```

Executes an HTTP POST request with URL-encoded form data using a URL string and stores the response in an [NSString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request with URL-encoded form data using a URL string. The complete response body is stored in the provided [NSString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying [DoUrlEncodedFormHttp](#) implementation. This provides a simple interface for form-based POST operations with string-based response handling.

Parameters

<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>headers</i>	Pointer to null-terminated string containing HTTP headers Headers should be formatted as "Header: Value\r\n" pairs Pass nullptr if no custom headers are needed
<i>form_data</i>	Pointer to null-terminated string containing URL-encoded form data Data should be in "key1=value1&key2=value2" format
<i>result_string</i>	Reference to NSString in which to store the HTTP response body The string will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response Use TICKS_PER_SECOND for conversion from seconds to ticks

Returns

true if the POST request completed successfully and response was received, false on failure (network error, timeout, DNS resolution failure, or HTTP error response)

Note

The *result_string* contents will be replaced with the response data. For large responses, ensure sufficient memory is available. Content-Type header is automatically set to "application/x-www-form-urlencoded". Form data must be properly URL-encoded before passing to this function.

14.60.2.65 DoUrlEncodedFormPost() [3/4]

```
bool DoUrlEncodedFormPost (
    ParsedURI & TheUri,
    char * headers,
    char * form_data,
    buffer_object & result_buffer,
    uint16_t TIMEOUT_WAIT) [inline]
#include <http_funcs.h>
```

Executes an HTTP POST request with URL-encoded form data using a pre-parsed URI and stores the response in a buffer object.

This function performs an HTTP POST request with URL-encoded form data using a pre-parsed URI object. The complete response body is stored in the provided buffer object. This is a convenience wrapper around the generic `DoUrlEncodedFormHttp` function, specifically optimized for POST operations with form data. This provides enhanced performance for web form submissions by using pre-parsed URI components, eliminating URL parsing overhead for repeated submissions to the same endpoint.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>headers</i>	Pointer to null-terminated string containing additional HTTP headers Multiple headers should be concatenated and separated by "\r\n" Do not include trailing "\r\n" after the last header Pass nullptr if no additional headers are needed
<i>form_data</i>	Pointer to null-terminated string containing URL-encoded form data Data should be in "key1=value1&key2=value2" format with proper URL encoding
<i>result_buffer</i>	Reference to buffer_object where the HTTP response body will be stored The buffer will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response Use TICKS_PER_SECOND for conversion from seconds to ticks

Returns

true if the POST request completed successfully and response was received, false on failure (network error, timeout, connection error, or HTTP error response)

Note

The `result_buffer` contents will be replaced with the response data. Ensure the buffer object has sufficient capacity for the expected response size. Content-Type header is automatically set to "application/x-www-form-urlencoded". Form data must be properly URL-encoded before passing to this function. Using pre-parsed URIs improves performance for repeated requests to the same host.

14.60.2.66 DoUrlEncodedFormPost() [4/4]

```
bool DoUrlEncodedFormPost (
    ParsedURI & TheUri,
    char * headers,
    char * form_data,
    NBString & result_string,
    uint16_t TIMEOUT_WAIT) [inline]
```

```
#include <http_funcs.h>
```

Executes an HTTP POST request with URL-encoded form data using a pre-parsed URI and stores the response in an [NBString](#). This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This is a convenience overload that performs an HTTP POST request with URL-encoded form data using a pre-parsed URI object. The complete response body is stored in the provided [NBString](#) reference. This function uses a [StringBufferObject](#) internally to handle the response data collection and forwards the call to the underlying `DoUrlEncodedFormHttp` implementation. Using a pre-parsed URI can improve performance when making multiple form submissions to the same host by avoiding repeated URL parsing operations.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the pre-parsed URL components (host, port, path, scheme, query parameters, etc.)
<i>headers</i>	Pointer to null-terminated string containing HTTP headers Headers should be formatted as "Header: Value\r\n" pairs Pass nullptr if no custom headers are needed
<i>form_data</i>	Pointer to null-terminated string containing URL-encoded form data Data should be in "key1=value1&key2=value2" format
<i>result_string</i>	Reference to NBString in which to store the HTTP response body The string will be populated with the complete response data
<i>TIMEOUT_WAIT</i>	Timeout in system ticks to wait for the complete response Use TICKS_PER_SECOND for conversion from seconds to ticks

Returns

true if the POST request completed successfully and response was received, false on failure (network error, timeout, connection error, or HTTP error response)

Note

The *result_string* contents will be replaced with the response data. For large responses, ensure sufficient memory is available. Content-Type header is automatically set to "application/x-www-form-urlencoded". Form data must be properly URL-encoded before passing to this function. Using pre-parsed URIs improves performance for repeated requests to the same host.

14.60.2.67 PopulateAuthHeader()

```
int PopulateAuthHeader (
    const char * user,
    const char * password,
    char * buffer,
    int maxlen)
```

```
#include <http_funcs.h>
```

Generates a Base64-encoded HTTP Basic Authentication header string for inclusion in HTTP requests.

This function creates a properly formatted HTTP Basic Authentication header by combining the provided username and password, encoding them using Base64, and formatting the result as an "Authorization: Basic" header string. The generated header can be used directly in HTTP requests that require Basic Authentication. The function handles the complete authentication header construction according to RFC 7617 specifications.

Parameters

<i>user</i>	Pointer to null-terminated string containing the username Must not contain colon characters as they are used as delimiters
<i>password</i>	Pointer to null-terminated string containing the password Can be empty string for username-only authentication scenarios
<i>buffer</i>	Pointer to destination buffer where the formatted authentication header will be written Buffer will contain "Authorization: Basic <base64-credentials>" format
<i>maxlen</i>	Maximum number of characters that can be written to the buffer including null terminator Must be sufficient to hold the complete formatted header string

Returns

Number of characters written to the buffer (excluding null terminator) on success, or a negative value if the buffer was insufficient to hold the complete header string

Note

The generated header string is null-terminated and ready for direct use in HTTP requests. The buffer must be large enough to accommodate the Base64-encoded credentials plus header formatting. Base64 encoding increases the size of the credentials by approximately 33%. The function does not validate credential format - ensure username does not contain colons. This implements HTTP Basic Authentication which transmits credentials in encoded but not encrypted form.

14.60.2.68 SetHttpDiag() [1/2]

```
void SetHttpDiag (
    bool b)
#include <http_funcs.h>
Enable/disable Web Client HTTP diagnostics to the console port.
```

Parameters

<i>b</i>	Set true to enable, false to disable.

14.60.2.69 SetHttpDiag() [2/2]

```
void SetHttpDiag (
    int level)
#include <http_funcs.h>
Enable/disable Web Client HTTP diagnostics to the console port.
```

Parameters

<i>level</i>	Set 1 to enable, 0 to disable, or 2 for extra verbosity.

14.60.2.70 StartConnection()

```
int StartConnection (
    ParsedURI & TheUri,
    uint32_t timeout = TICKS_PER_SECOND*10) [inline]
#include <http_funcs.h>
```

Establishes a TCP/TLS connection to a host using a pre-parsed URI with timeout specified in ticks.

This is a convenience overload that establishes a connection to the host specified in the pre-parsed URI object using a timeout value expressed in system ticks. The function creates a TickTimeout object internally and forwards the call to the underlying StartConnection implementation. This provides a simple interface for connection establishment when you need to specify timeout in system ticks rather than using a TickTimeout object directly.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the connection details (host, port, scheme for HTTP/HTTPS selection)
<i>timeout</i>	Connection timeout in system ticks (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

TCP/TLS file descriptor (> 0) if connection was successfully established, or a negative error code on failure (connection refused, timeout, DNS resolution failure, or network error)

Note

For HTTPS URLs, SSL/TLS connection will be established automatically. The returned file descriptor must be properly closed when no longer needed. Connection timeout includes both DNS resolution and TCP connection establishment time.

14.60.2.71 StartTransaction() [1/2]

```
int StartTransaction (
    const char * pUrl,
    const char * headers = 0,
    const char * action = "GET",
    uint32_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)
#include <http_funcs.h>
```

Initiates an HTTP transaction using a URL string by establishing a connection and sending request headers. This function performs the initial phase of an HTTP request by parsing the provided URL, establishing a connection to the specified host, and sending the HTTP request headers including the request line, Host header, and any additional custom headers. The function returns a file descriptor for the established connection that can be used to send request body data (if needed) and receive the server response. This provides a simple interface for starting HTTP transactions with automatic URL parsing and DNS resolution.

Parameters

<i>pUrl</i>	Pointer to null-terminated URL string (http:// or https://) DNS lookup will be performed automatically for hostnames
<i>headers</i>	Pointer to null-terminated string containing additional HTTP headers Headers should be formatted without leading or trailing "\r\n" Each header should be on a separate line with "\r\n" between headers Pass nullptr if no additional headers are needed (default: nullptr)
<i>action</i>	Pointer to null-terminated string containing the HTTP method (default: "GET"). Common values: "GET", "POST", "PUT", "DELETE"
<i>TIMEOUT_WAIT</i>	Timeout in system ticks for URL parsing, connection establishment, and header transmission (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

TCP/TLS file descriptor (> 0) if connection was established and headers sent successfully, or a negative error code on failure (URL parsing error, DNS resolution failure, connection error, timeout, or header transmission failure)

Note

The returned file descriptor can be used to send request body data and receive responses. The Host header is automatically included based on the parsed URL information. For HTTPS URLs, SSL/TLS connection will be established automatically. The connection remains active until explicitly closed. Custom headers must be properly formatted without leading/trailing CRLF.

See also

[StartTransaction\(ParsedURI&, const char*, const char*, uint32_t\)](#) for pre-parsed URI version

14.60.2.72 StartTransaction() [2/2]

```
int StartTransaction (
    ParsedURI & TheUri,
    const char * headers = 0,
    const char * action = "GET",
    uint32_t TIMEOUT_WAIT = 10 *TICKS_PER_SECOND)
#include <http_funcs.h>
```

Initiates an HTTP transaction using a pre-parsed URI by establishing a connection and sending request headers. This function performs the initial phase of an HTTP request by establishing a connection to the specified host and sending the HTTP request headers including the request line, Host header, and any additional custom headers. The function returns a file descriptor for the established connection that can be used to send request body data (if needed) and receive the server response. This provides low-level control over the HTTP transaction lifecycle with optimal performance through pre-parsed URI components.

Parameters

<i>TheUri</i>	Reference to ParsedURI object containing the connection and request details (host, port, path, scheme, query parameters)
<i>headers</i>	Pointer to null-terminated string containing additional HTTP headers Headers should be formatted without leading or trailing "\r\n" Each header should be on a separate line with "\r\n" between headers Pass nullptr if no additional headers are needed (default: nullptr)
<i>action</i>	Pointer to null-terminated string containing the HTTP method (default: "GET"). Common values: "GET", "POST", "PUT", "DELETE"
<i>TIMEOUT_WAIT</i>	Timeout in system ticks for connection establishment and header transmission (default: 10 seconds). Use TICKS_PER_SECOND for conversion

Returns

TCP/TLS file descriptor (> 0) if connection was established and headers sent successfully, or a negative error code on failure (connection error, timeout, or header transmission failure)

Note

The returned file descriptor can be used to send request body data and receive responses. The Host header is automatically included based on the URI information. For HTTPS URLs, SSL/TLS connection will be established automatically. The connection remains active until explicitly closed. Custom headers must be properly formatted without leading/trailing CRLF.

14.60.2.73 StartWebClient() [1/3]

```
bool StartWebClient (
    int prio,
    const char * url1,
    const char * url2 = NULL,
    bool bDoNtp = false)
#include <web_client.h>
```

Start the web client using a URL string.

Parameters

<i>prio</i>	Priority

<i>url1</i>	Pointer to a string representing the URL.
<i>url2</i>	Pointer to a second URL. Optional parameter, default is NULL.
<i>bDoNtp</i>	Enable the Network Time Protocol (NTP). Optional parameter, default is false.

Returns

True on success, false on failure.

14.60.2.74 StartWebClient() [2/3]

```
bool StartWebClient (  
    int prio,  
    const NSString & url1,  
    bool bDoNtp = false)  
#include <web_client.h>  
Start the web client using a NSString.
```

Parameters

<i>prio</i>	Priority
<i>url1</i>	Reference to a NSString representing the URL.
<i>bDoNtp</i>	Enable the Network Time Protocol (NTP). Optional parameter, default is false.

Returns

True on success, false on failure.

14.60.2.75 StartWebClient() [3/3]

```
bool StartWebClient (  
    int prio,  
    const NSString & url1,  
    const NSString & url2,  
    bool bDoNtp = false)  
#include <web_client.h>  
Start the web client using a NSString.
```

Parameters

<i>prio</i>	Priority
<i>url1</i>	Reference to a string representing the URL.
<i>url2</i>	Reference to a second URL. Optional parameter, default is NULL.
<i>bDoNtp</i>	Enable the Network Time Protocol (NTP). Optional parameter, default is false.

Returns

True on success, false on failure.

14.60.2.76 WriteHttpRequestHeaders()

```
int WriteHttpRequestHeaders (
    int fd,
    ParsedURI & uri,
    const char * methodStr,
    int content_len = 0,
    const char * content_type = 0,
    const char * extra_header = 0)
#include <http_funcs.h>
```

Writes HTTP request headers to an established connection file descriptor.

This function writes properly formatted HTTP request headers to an established TCP/TLS connection using information from a parsed URI object. The function constructs and sends the HTTP request line, Host header, and any additional headers as specified. This is typically used after establishing a connection but before sending any request body data. The headers are formatted according to HTTP/1.1 specification requirements.

Parameters

<i>fd</i>	TCP/TLS file descriptor of an established connection Must be a valid descriptor returned from connection establishment functions
<i>uri</i>	Reference to ParsedURI object containing the request details (host, port, path, query parameters for request construction)
<i>methodStr</i>	Pointer to null-terminated string containing the HTTP method (e.g., "GET", "POST", "PUT", "DELETE")
<i>content_len</i>	Content length for the request body in bytes If 0, no Content-Length header is added (default: 0) If > 0, Content-Length header is automatically included
<i>content_type</i>	Pointer to null-terminated string containing the Content-Type header value If nullptr, no Content-Type header is added (default: nullptr) Common values include "application/json", "application/x-www-form-urlencoded"
<i>extra_header</i>	Pointer to null-terminated string containing additional custom headers Multiple headers should be separated by "\r\n" If nullptr, no extra headers are added (default: nullptr)

Returns

Number of bytes written to the connection on success (> 0), or a negative error code on failure (write error, connection closed, or formatting error)

Note

The function automatically adds required HTTP/1.1 headers including Host header. Headers are properly terminated with "\r\n\r\n" to indicate end of header section. The connection must be established before calling this function. This function only writes headers - request body must be sent separately if needed. Custom headers in *extra_header* parameter must be properly formatted.

14.60.3 Web Client Error Codes

Macros

- `#define WEB_CLIENT_ERROR_NO_ETHERNET (1)`
No Ethernet connection.
- `#define WEB_CLIENT_ERROR_NO_ADDRESS (2)`
Interface has no IP address.

- `#define WEB_CLIENT_ERROR_NO_GATEWAY (3)`
Interface has no gateway IP address.
- `#define WEB_CLIENT_ERROR_GATEWAY_WRONG (4)`
Interface has incorrect gateway IP address.
- `#define WEB_CLIENT_ERROR_NO_DNS_ADDR (5)`
Interface has a DNS error.
- `#define WEB_CLIENT_ERROR_NO_DNS_RESOLVE (6)`
DNS was not able to resolve the URL name.
- `#define WEB_CLIENT_ERROR_NO_NTP (7)`
NTP failed.
- `#define WEB_CLIENT_ERROR_NO_SERVER_RESPONSE (8)`
No response from server.
- `#define WEB_CLIENT_ERROR_NO_SERVER_CONNECT (9)`
Unable to connect to server.
- `#define WEB_CLIENT_ERROR_NO_ERROR (10)`
No error.
- `#define WEB_CLIENT_ERROR_INVALID_REQ (11)`
Invalid request.

14.60.3.1 Detailed Description

```
#include< web_client.h>
```

Web Client error codes

14.61 Web Sockets

Web Socket functions and definitions.

Topics

- [Web Socket Definitions](#)
WebSocket Protocol Implementation for Real-Time Bidirectional Communication `#include< websockets.h>`

Classes

- class [NB::WebSocket](#)
WebSocket connection management class.

Functions

- int [WSPing](#) (int fd, uint32_t len, uint32_t *sentTick)
Send a WebSocket ping frame to test connection liveness and measure round-trip time.
- int [WSGetPingReplyTick](#) (int fd, uint32_t *replyTick)
Retrieve the timestamp of the most recent pong reply received on a WebSocket connection.
- int [WSWaitForPingReply](#) (int fd, uint32_t timeout)
Wait for a pong reply to a previously sent ping with a specified timeout.
- int [WSUpgrade](#) ([HTTP_Request](#) *req, int sock)
Upgrade an HTTP connection to a WebSocket connection.

14.61.1 Detailed Description

Web Socket functions and definitions.

14.61.2 Function Documentation

14.61.2.1 WSGetPingReplyTick()

```
int WSGetPingReplyTick (
    int fd,
    uint32_t * replyTick)
```

```
#include <websockets.h>
```

Retrieve the timestamp of the most recent pong reply received on a WebSocket connection.

Gets the system tick count when the last pong frame was received in response to a ping. This function is used in conjunction with [WSPing\(\)](#) to measure round-trip time and verify connection responsiveness. The reply tick is automatically recorded by the WebSocket implementation when a pong frame arrives.

This is useful for:

- Calculating network latency after sending a ping
- Verifying that a connection is still responsive
- Implementing timeout detection for unresponsive connections
- Gathering connection quality metrics

Parameters

<i>fd</i>	The file descriptor of the WebSocket connection
<i>replyTick</i>	Pointer to store the tick count when the last pong was received. If no pong has been received yet, the value is undefined.

Returns

Returns a status code indicating success or failure:

- 0 or positive: Success, replyTick contains the timestamp of the last pong
- Negative value: Error occurred (invalid fd, no pong received, connection closed, etc.)

Note

This function returns the timestamp of the most recently received pong frame

Call this after sending a ping with [WSPing\(\)](#) to measure round-trip time

The returned tick value is in system ticks (use TICKS_PER_SECOND to convert)

If no pong has been received since the connection opened, behavior is undefined

Compare with the sentTick from [WSPing\(\)](#) to calculate latency

The pong reply is automatically processed by the WebSocket stack

Multiple pings can be in flight, but this function only returns the most recent pong timestamp.

Expand for Example Usage

Examples

Example 1: Basic Round-Trip Time Measurement

```
int wsFd = ...; // WebSocket connection
uint32_t pingSent, pongReceived;

// Send ping
if (WSPing(wsFd, 0, &pingSent) >= 0) {
    printf("Ping sent at tick %lu\r\n", pingSent);

    // Wait a moment for the pong
    OSTimeDly(TICKS_PER_SECOND / 10); // 100ms

    // Get pong reply time
    if (WSGetPingReplyTick(wsFd, &pongReceived) >= 0) {
        uint32_t rtt = pongReceived - pingSent;
        uint32_t rttMs = rtt / (TICKS_PER_SECOND / 1000);
        printf("Round-trip time: %lu ms\r\n", rttMs);
    } else {
        printf("No pong received yet\r\n");
    }
}
```

Example 2: Polling for Pong Response

```
#define PONG_TIMEOUT_MS 3000

bool WaitForPong(int wsFd, uint32_t pingSentTick, uint32_t *latencyMs) {
    uint32_t startWait = TimeTick;
    uint32_t pongTick;

    while (1) {
        // Check if pong received
        if (WSGetPingReplyTick(wsFd, &pongTick) >= 0) {
            // Verify this pong is for our ping
            if (pongTick > pingSentTick) {
                uint32_t rtt = pongTick - pingSentTick;
                *latencyMs = rtt / (TICKS_PER_SECOND / 1000);
                return true;
            }
        }

        // Check timeout
        uint32_t elapsed = TimeTick - startWait;
        if (elapsed / (TICKS_PER_SECOND / 1000) > PONG_TIMEOUT_MS) {
            printf("Pong timeout\r\n");
            return false;
        }

        OSTimeDly(TICKS_PER_SECOND / 100); // 10ms poll interval
    }
}

// Usage
uint32_t pingSent, latency;
WSPing(wsFd, 0, &pingSent);
if (WaitForPong(wsFd, pingSent, &latency)) {
    printf("Connection latency: %lu ms\r\n", latency);
}
```

Example 3: Connection Quality Monitoring

```
struct ConnectionStats {
    uint32_t minLatency;
    uint32_t maxLatency;
    uint32_t avgLatency;
    uint32_t sampleCount;
};

void UpdateConnectionStats(int wsFd, uint32_t pingSent, ConnectionStats *stats) {
    uint32_t pongReceived;

    if (WSGetPingReplyTick(wsFd, &pongReceived) >= 0) {
        if (pongReceived > pingSent) {
            uint32_t latency = (pongReceived - pingSent) / (TICKS_PER_SECOND / 1000);

            // Update statistics
            if (stats->sampleCount == 0 || latency < stats->minLatency) {
                stats->minLatency = latency;
            }
            if (latency > stats->maxLatency) {
                stats->maxLatency = latency;
            }

            // Calculate running average
            stats->avgLatency = ((stats->avgLatency * stats->sampleCount) + latency)
                               / (stats->sampleCount + 1);
            stats->sampleCount++;

            printf("Latency: %lu ms (min: %lu, max: %lu, avg: %lu)\r\n",
                   latency, stats->minLatency, stats->maxLatency, stats->avgLatency);
        }
    }
}
```

Example 4: Timeout Detection

```
#define PING_INTERVAL_SEC 30
#define PONG_TIMEOUT_SEC 5

void ConnectionHealthCheck(int wsFd) {
    static uint32_t lastPingSent = 0;
    static bool waitingForPong = false;
    uint32_t pongReceived;
```

```

if (!waitingForPong) {
    // Time to send a new ping
    if (WSPing(wsFd, 0, &lastPingSent) >= 0) {
        waitingForPong = true;
        printf("Ping sent\r\n");
    }
} else {
    // Check for pong response
    if (WSGetPingReplyTick(wsFd, &pongReceived) >= 0) {
        if (pongReceived > lastPingSent) {
            uint32_t rtt = pongReceived - lastPingSent;
            printf("Pong received, RTT: %lu ms\r\n",
                rtt / (TICKS_PER_SECOND / 1000));
            waitingForPong = false;
        }
    }

    // Check for timeout
    uint32_t elapsed = TimeTick - lastPingSent;
    if (elapsed / TICKS_PER_SECOND > PONG_TIMEOUT_SEC) {
        printf("ERROR: Pong timeout - connection may be dead\r\n");
        close(wsFd);
        return;
    }
}
}
}

```

Example 5: Detailed Latency Analysis

```

void AnalyzeConnectionLatency(int wsFd) {
    const int NUM_PINGS = 10;
    uint32_t latencies[NUM_PINGS];
    int successCount = 0;

    printf("Starting latency analysis (%d pings)...\r\n", NUM_PINGS);

    for (int i = 0; i < NUM_PINGS; i++) {
        uint32_t pingSent, pongReceived;

        // Send ping
        if (WSPing(wsFd, 0, &pingSent) < 0) {
            printf("Ping %d failed\r\n", i + 1);
            continue;
        }

        // Wait for pong (with timeout)
        uint32_t waitStart = TimeTick;
        bool gotPong = false;

        while ((TimeTick - waitStart) < TICKS_PER_SECOND) {
            if (WSGetPingReplyTick(wsFd, &pongReceived) >= 0) {
                if (pongReceived > pingSent) {
                    latencies[successCount++] =
                        (pongReceived - pingSent) / (TICKS_PER_SECOND / 1000);
                    gotPong = true;
                    break;
                }
            }
            OSTimeDly(TICKS_PER_SECOND / 100); // 10ms
        }

        if (!gotPong) {
            printf("Ping %d timeout\r\n", i + 1);
        }

        // Small delay between pings
        OSTimeDly(TICKS_PER_SECOND / 2);
    }

    // Calculate statistics
    if (successCount > 0) {
        uint32_t sum = 0, min = latencies[0], max = latencies[0];
        for (int i = 0; i < successCount; i++) {
            sum += latencies[i];
            if (latencies[i] < min) min = latencies[i];
            if (latencies[i] > max) max = latencies[i];
        }

        printf("\nLatency Analysis Results:\r\n");
        printf("  Successful pings: %d/%d\r\n", successCount, NUM_PINGS);
        printf("  Min: %lu ms\r\n", min);
        printf("  Max: %lu ms\r\n", max);
        printf("  Avg: %lu ms\r\n", sum / successCount);
    }
}

14.61.2.2 WSPing()

```
int WSPing (  
    int fd,  
    uint32_t len,  
    uint32_t * sentTick)  
#include <websockets.h>
```

Send a WebSocket ping frame to test connection liveness and measure round-trip time.

14.61.3 WSPing

14.61.3.1 Description

Sends a WebSocket ping control frame with optional payload data. The server or client should respond with a pong frame containing the same payload. This function records the tick count when the ping is sent, allowing calculation of round-trip time when the corresponding pong is received.

Ping frames are used to:

- Verify that the connection is still alive
- Measure network latency
- Keep the connection active (prevent timeouts)
- Detect unresponsive peers

14.61.3.2 Parameters

Parameters

<i>fd</i>	The file descriptor of the WebSocket connection
<i>len</i>	Length of the ping payload data in bytes (typically 0-125 bytes)
<i>sentTick</i>	Pointer to store the system tick count when the ping was sent. Can be NULL if timestamp recording is not needed. Use this value with the pong response timestamp to calculate round-trip time.

14.61.3.3 Return Value

Returns the number of bytes sent on success, or a negative value on error:

- Positive value: Number of bytes successfully sent (ping frame)
- Negative value: Error occurred (connection closed, invalid parameters, etc.)

14.61.3.4 Usage Notes

- Ping payloads should be small (WebSocket spec recommends 125 bytes or less)
- The peer must respond with a pong frame containing the same payload
- Store the sentTick value to calculate latency when the pong arrives

- Convert ticks to milliseconds using: $(\text{receivedTick} - \text{sentTick}) / (\text{TICKS\_PER\_SECOND} / 1000)$
- Frequent pings can be used as a keep-alive mechanism
- If no pong is received within a reasonable timeout, the connection may be dead

Expand for Example Usage

Examples

Example 1: Basic Ping without Payload

```
int wsFd = ...; // WebSocket connection
uint32_t pingTime;

// Send ping with no payload
int result = WSPing(wsFd, 0, &pingTime);
if (result >= 0) {
    printf("Ping sent at tick %lu\r\n", pingTime);
} else {
    printf("Failed to send ping\r\n");
}
```

Example 2: Measuring Round-Trip Time

```
uint32_t pingSentTick;
uint32_t pongReceivedTick;

// Send ping
if (WSPing(wsFd, 0, &pingSentTick) >= 0) {
    // Wait for pong response (in your pong handler)
    // ... receive pong ...
    pongReceivedTick = TimeTick;

    // Calculate latency
    uint32_t latencyTicks = pongReceivedTick - pingSentTick;
    uint32_t latencyMs = latencyTicks / (TICKS_PER_SECOND / 1000);
    printf("Round-trip time: %lu ms\r\n", latencyMs);
}
```

Example 3: Periodic Keep-Alive Pings

```
void KeepAliveTask(void *pd) {
    int wsFd = (int)(intptr_t)pd;
    uint32_t lastPingTime;

    while (1) {
        // Send ping every 30 seconds
        OSTimeDly(TICKS_PER_SECOND * 30);

        int result = WSPing(wsFd, 0, &lastPingTime);
        if (result < 0) {
            printf("Keep-alive ping failed, connection may be closed\r\n");
            break;
        }
    }
}
```

Example 4: Ping with Payload for Identification

```
// Send ping with small payload to identify the ping
uint32_t pingId = 12345;
uint32_t sentTime;

// In practice, you'd write the payload first using WSWrite or similar
// This example shows the WSPing call
int result = WSPing(wsFd, sizeof(pingId), &sentTime);
if (result >= 0) {
    printf("Sent ping #%lu at tick %lu\r\n", pingId, sentTime);
}
```

Example 5: Connection Health Monitoring

```

#define PING_TIMEOUT_MS 5000
#define MAX_MISSED_PONGS 3

struct WSConnection {
    int fd;
    uint32_t lastPingSent;
    uint32_t lastPongReceived;
    int missedPongs;
};

void MonitorConnection(WSConnection *conn) {
    // Send ping
    if (WSPing(conn->fd, 0, &conn->lastPingSent) < 0) {
        printf("Connection lost\r\n");
        return;
    }

    // Check if previous pong was received
    uint32_t elapsed = TimeTick - conn->lastPingSent;
    uint32_t elapsedMs = elapsed / (TICKS_PER_SECOND / 1000);

    if (elapsedMs > PING_TIMEOUT_MS) {
        conn->missedPongs++;
        if (conn->missedPongs >= MAX_MISSED_PONGS) {
            printf("Connection appears dead, closing\r\n");
            close(conn->fd);
        }
    }
}

```

14.61.3.5 See Also

- WSPong() - Send a pong response frame
- WSRead() - Read WebSocket frames (including pong responses)
- WSWrite() - Send WebSocket data frames
- WSClose() - Close a WebSocket connection

Note

The WebSocket protocol requires that a pong frame echo back the exact payload received in the ping frame.

14.61.3.6 WSUpgrade()

```

int WSUpgrade (
    HTTP_Request * req,
    int sock)

```

```
#include <websockets.h>
```

Upgrade an HTTP connection to a WebSocket connection.

Performs the WebSocket handshake by upgrading an existing HTTP request to the WebSocket protocol. This function validates the upgrade request, sends the appropriate handshake response, and transitions the socket into WebSocket mode. After a successful upgrade, the socket can be used with WebSocket functions like WSRead() and WSWrite().

This function handles:

- Validation of WebSocket upgrade headers (Upgrade, Connection, Sec-WebSocket-Key)
- Generation of the Sec-WebSocket-Accept response header
- Protocol version negotiation
- Switching the connection from HTTP to WebSocket mode

Parameters

<i>req</i>	Pointer to the HTTP_Request structure containing the upgrade request. The request must contain valid WebSocket upgrade headers including: • Upgrade: websocket • Connection: Upgrade • Sec-WebSocket-Key: <client key> • Sec-WebSocket-Version: 13
<i>sock</i>	The socket file descriptor of the HTTP connection to upgrade. This socket will be transitioned to WebSocket mode on success.

Returns

Returns a status code indicating the result:

- 0 or positive: Success, connection upgraded to WebSocket
- Negative value: Error occurred (invalid request, missing headers, handshake failed)

Note

This function must be called from within an HTTP request handler

After successful upgrade, do not send HTTP responses on this socket

The socket remains open and must be managed using WebSocket functions

Subprotocol negotiation (Sec-WebSocket-Protocol) may be handled automatically

Extensions (Sec-WebSocket-Extensions) may be negotiated based on implementation

After upgrade, use WSRead() and WSWrite() for all communication on this socket

The HTTP request handler should return without sending additional HTTP data

Always check the return value to ensure the upgrade was successful

Expand for Example Usage

Examples

Example 1: Basic WebSocket Upgrade Handler

```
// HTTP handler for WebSocket endpoint
int HandleWebSocketUpgrade(HTTP_Request *req, int sock) {
    // Attempt to upgrade to WebSocket
    if (WSUpgrade(req, sock) >= 0) {
        printf("WebSocket connection established on socket %d\r\n", sock);

        // Connection is now in WebSocket mode
        // Handle WebSocket communication here or in a separate task
        return 0; // Don't send HTTP response
    } else {
        printf("WebSocket upgrade failed\r\n");

        // Send error response
        writestring(sock, "HTTP/1.1 400 Bad Request\r\n");
        writestring(sock, "Content-Type: text/plain\r\n\r\n");
        writestring(sock, "WebSocket upgrade failed");
        return -1;
    }
}

// Register the handler
void UserMain(void *pd) {
    init();
    StartHttp();

    // Register WebSocket endpoint
    SetNewWSHandler("/ws", HandleWebSocketUpgrade);

    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

Example 2: WebSocket Upgrade with Echo Server

```
// Simple echo server after upgrade
void WebSocketEchoTask(void *pd) {
    int sock = (int)(intptr_t)pd;
    char buffer[256];

    printf("WebSocket echo task started on socket %d\r\n", sock);

    while (1) {
        // Read WebSocket frame
        int len = WSRead(sock, buffer, sizeof(buffer) - 1, TICKS_PER_SECOND * 30);

        if (len > 0) {
            buffer[len] = '\0';
            printf("Received: %s\r\n", buffer);

            // Echo back
            if (WSWrite(sock, buffer, len) < 0) {
                printf("Failed to echo message\r\n");
                break;
            }
        } else if (len < 0) {
            printf("WebSocket connection closed or error\r\n");
            break;
        }
    }

    close(sock);
    printf("WebSocket echo task ended\r\n");
}

int HandleWebSocketUpgrade(HTTP_Request *req, int sock) {
    if (WSUpgrade(req, sock) >= 0) {
        // Spawn task to handle WebSocket communication
        OSSimpleTaskCreateWithName(WebSocketEchoTask,
                                   MAIN_PRIO - 1,
                                   (void *) (intptr_t) sock,
                                   "WSEcho");
        return 0;
    }

    return -1;
}
```

Example 3: Multiple WebSocket Endpoints

```
// Chat endpoint handler
int HandleChatWebSocket(HTTP_Request *req, int sock) {
    if (WSUpgrade(req, sock) >= 0) {
        printf("Chat WebSocket connected\r\n");
        // Start chat handler task
        OSSimpleTaskCreateWithName(ChatTask, MAIN_PRIO - 1,
                                   (void *) (intptr_t) sock, "WSChat");
        return 0;
    }
    return -1;
}

// Data stream endpoint handler
int HandleDataWebSocket(HTTP_Request *req, int sock) {
    if (WSUpgrade(req, sock) >= 0) {
        printf("Data WebSocket connected\r\n");
        // Start data streaming task
        OSSimpleTaskCreateWithName(DataStreamTask, MAIN_PRIO - 1,
                                   (void *) (intptr_t) sock, "WSData");
        return 0;
    }
    return -1;
}

void UserMain(void *pd) {
    init();
    StartHttp();

    // Register multiple WebSocket endpoints
    SetNewWSHandler("/chat", HandleChatWebSocket);
    SetNewWSHandler("/data", HandleDataWebSocket);

    printf("WebSocket server running with multiple endpoints\r\n");

    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

```
}
```

Example 4: WebSocket Upgrade with Authentication

```
// Check authentication token from query string or headers
bool ValidateWebSocketAuth(HTTP_Request *req) {
    // Example: Check for auth token in query string
    const char *token = GetRequestParam(req, "token");
    if (token == NULL) {
        return false;
    }

    // Validate token (simplified example)
    return (strcmp(token, "secret123") == 0);
}

int HandleSecureWebSocket(HTTP_Request *req, int sock) {
    // Authenticate before upgrading
    if (!ValidateWebSocketAuth(req)) {
        printf("WebSocket authentication failed\r\n");

        writestring(sock, "HTTP/1.1 401 Unauthorized\r\n");
        writestring(sock, "Content-Type: text/plain\r\n\r\n");
        writestring(sock, "Authentication required");
        return -1;
    }

    // Upgrade to WebSocket
    if (WSUpgrade(req, sock) >= 0) {
        printf("Authenticated WebSocket connection established\r\n");
        OSSimpleTaskCreateWithName(SecureWSTask, MAIN_PRIO - 1,
                                   (void *) (intptr_t) sock, "WSSecure");
        return 0;
    }

    return -1;
}
```

Example 5: WebSocket Upgrade with Connection Tracking

```
#define MAX_WS_CONNECTIONS 10

struct WSConnectionInfo {
    int sock;
    bool active;
    uint32_t connectedTime;
    char clientIP[16];
};

WSConnectionInfo wsConnections[MAX_WS_CONNECTIONS];
OS_CRIT wsCrit;

// Add connection to tracking array
bool AddWSConnection(int sock, const char *clientIP) {
    OSCritEnter(&wsCrit, TICKS_PER_SECOND);

    for (int i = 0; i < MAX_WS_CONNECTIONS; i++) {
        if (!wsConnections[i].active) {
            wsConnections[i].sock = sock;
            wsConnections[i].active = true;
            wsConnections[i].connectedTime = Secs;
            strncpy(wsConnections[i].clientIP, clientIP,
                    sizeof(wsConnections[i].clientIP) - 1);
            OSCritLeave(&wsCrit);
            return true;
        }
    }

    OSCritLeave(&wsCrit);
    return false; // No slots available
}

int HandleTrackedWebSocket(HTTP_Request *req, int sock) {
    // Get client IP
    IPADDR clientAddr = req->client_addr;
    char ipStr[16];
    sprintf(ipStr, "%d.%d.%d.%d",
            (int)clientAddr.GetByte(0), (int)clientAddr.GetByte(1),
            (int)clientAddr.GetByte(2), (int)clientAddr.GetByte(3));

    // Check connection limit
    if (!AddWSConnection(sock, ipStr)) {
        printf("Maximum WebSocket connections reached\r\n");
    }
}
```

```

        writestring(sock, "HTTP/1.1 503 Service Unavailable\r\n");
        writestring(sock, "Content-Type: text/plain\r\n\r\n");
        writestring(sock, "Too many connections");
        return -1;
    }

    // Upgrade to WebSocket
    if (WSUpgrade(req, sock) >= 0) {
        printf("WebSocket connected from %s (socket %d)\r\n", ipStr, sock);
        OSSimpleTaskCreateName(TrackedWSTask, MAIN_PRIO - 1,
                               (void *) (intptr_t) sock, "WSTracked");

        return 0;
    } else {
        // Remove from tracking on upgrade failure
        OSCritEnter(&wsCrit, TICKS_PER_SECOND);
        for (int i = 0; i < MAX_WS_CONNECTIONS; i++) {
            if (wsConnections[i].sock == sock) {
                wsConnections[i].active = false;
                break;
            }
        }
        OSCritLeave(&wsCrit);
    }

    return -1;
}

// Display active connections
void ShowWSConnections() {
    OSCritEnter(&wsCrit, TICKS_PER_SECOND);

    printf("\nActive WebSocket Connections:\r\n");
    for (int i = 0; i < MAX_WS_CONNECTIONS; i++) {
        if (wsConnections[i].active) {
            uint32_t uptime = Secs - wsConnections[i].connectedTime;
            printf("  [%d] %s (socket %d) - uptime: %lu sec\r\n",
                   i, wsConnections[i].clientIP,
                   wsConnections[i].sock, uptime);
        }
    }

    OSCritLeave(&wsCrit);
}

```

Example 6: WebSocket Upgrade with Subprotocol Negotiation

```

// Check if client requested a specific subprotocol
const char* NegotiateSubprotocol(HTTP_Request *req) {
    // Example: Client sends "Sec-WebSocket-Protocol: chat, superchat"
    const char *requested = GetRequestHeader(req, "Sec-WebSocket-Protocol");

    if (requested == NULL) {
        return NULL; // No subprotocol requested
    }

    // Check if we support the requested protocol
    if (strstr(requested, "chat") != NULL) {
        return "chat";
    }

    return NULL; // Unsupported subprotocol
}

int HandleSubprotocolWebSocket(HTTP_Request *req, int sock) {
    const char *subprotocol = NegotiateSubprotocol(req);

    if (subprotocol) {
        printf("Negotiated subprotocol: %s\r\n", subprotocol);
        // Note: WSUpgrade may handle this automatically
        // or you may need to add the header before calling WSUpgrade
    }

    if (WSUpgrade(req, sock) >= 0) {
        printf("WebSocket upgraded with subprotocol: %s\r\n",
               subprotocol ? subprotocol : "none");
        return 0;
    }

    return -1;
}

```

14.61.3.7 WSWaitForPingReply()

```
int WSWaitForPingReply (
    int fd,
    uint32_t timeout)
#include <websockets.h>
```

Wait for a pong reply to a previously sent ping with a specified timeout.

Blocks execution until a pong frame is received in response to a ping, or until the specified timeout expires. This is a convenience function that combines waiting and timeout detection, simplifying the common pattern of sending a ping and waiting for the corresponding pong response.

This function is useful for:

- Synchronous ping/pong operations with automatic timeout handling
- Verifying connection responsiveness in a blocking manner
- Simplifying connection health checks without manual polling
- Testing connection latency with built-in timeout protection

Parameters

<i>fd</i>	The file descriptor of the WebSocket connection
<i>timeout</i>	Maximum time to wait for a pong reply, in system ticks. Use TICKS_PER_SECOND to specify timeout in seconds (e.g., TICKS_PER_SECOND * 5 for a 5-second timeout). A timeout of 0 returns immediately.

Returns

Returns a status code indicating the result:

- 0 or positive: Success, pong received within timeout period
- Negative value: Error occurred (timeout expired, connection closed, invalid parameters)

Note

This function blocks the calling task until a pong is received or timeout expires

A ping should be sent using [WSPing\(\)](#) before calling this function

The timeout parameter is in system ticks, not milliseconds

Use TICKS_PER_SECOND to convert seconds to ticks: `timeout = TICKS_PER_SECOND * seconds`

This function does not return the latency; use [WSGetPingReplyTick\(\)](#) if you need timing info

If multiple pongs arrive, this returns on the first pong received during the wait period

For non-blocking operations, use [WSGetPingReplyTick\(\)](#) with manual polling instead

Expand for Example Usage**Examples**

Example 1: Basic Ping/Pong with Timeout

```

int wsFd = ...; // WebSocket connection
uint32_t pingSent;

// Send ping
if (WSPing(wsFd, 0, &pingSent) >= 0) {
    printf("Ping sent, waiting for reply...\r\n");

    // Wait up to 3 seconds for pong
    int result = WSWaitForPingReply(wsFd, TICKS_PER_SECOND * 3);
    if (result >= 0) {
        printf("Pong received!\r\n");
    } else {
        printf("Timeout or error waiting for pong\r\n");
    }
}

```

Example 2: Connection Health Check with Blocking Wait

```

bool CheckConnectionHealth(int wsFd) {
    uint32_t pingSent;

    // Send ping and wait for reply
    if (WSPing(wsFd, 0, &pingSent) < 0) {
        printf("Failed to send ping\r\n");
        return false;
    }

    // Wait up to 5 seconds for pong
    if (WSWaitForPingReply(wsFd, TICKS_PER_SECOND * 5) >= 0) {
        printf("Connection is healthy\r\n");
        return true;
    } else {
        printf("Connection appears unhealthy or slow\r\n");
        return false;
    }
}

```

Example 3: Periodic Keep-Alive with Timeout Detection

```

void KeepAliveTask(void *pd) {
    int wsFd = (int)(intptr_t)pd;
    uint32_t pingSent;
    int consecutiveFailures = 0;
    const int MAX_FAILURES = 3;

    while (1) {
        // Wait 30 seconds between pings
        OSTimeDly(TICKS_PER_SECOND * 30);

        // Send ping
        if (WSPing(wsFd, 0, &pingSent) < 0) {
            printf("Failed to send ping\r\n");
            consecutiveFailures++;
        } else {
            // Wait for pong with 10 second timeout
            if (WSWaitForPingReply(wsFd, TICKS_PER_SECOND * 10) >= 0) {
                printf("Keep-alive successful\r\n");
                consecutiveFailures = 0;
            } else {
                printf("Keep-alive timeout\r\n");
                consecutiveFailures++;
            }
        }

        // Check if connection is dead
        if (consecutiveFailures >= MAX_FAILURES) {
            printf("Connection lost after %d failures\r\n", MAX_FAILURES);
            close(wsFd);
            break;
        }
    }
}

```

Example 4: Connection Latency Measurement

```

bool MeasureLatency(int wsFd, uint32_t *latencyMs) {
    uint32_t pingSent, pongReceived;

```

```

    // Send ping
    if (WSPing(wsFd, 0, &pingSent) < 0) {
        return false;
    }

    // Wait for pong with 2 second timeout
    if (WSWaitForPingReply(wsFd, TICKS_PER_SECOND * 2) < 0) {
        printf("Ping timeout\r\n");
        return false;
    }

    // Get the pong timestamp to calculate latency
    if (WSGetPingReplyTick(wsFd, &pongReceived) >= 0) {
        uint32_t rtt = pongReceived - pingSent;
        *latencyMs = rtt / (TICKS_PER_SECOND / 1000);
        return true;
    }

    return false;
}

// Usage
uint32_t latency;
if (MeasureLatency(wsFd, &latency)) {
    printf("Connection latency: %lu ms\r\n", latency);
}

```

Example 5: Progressive Timeout Strategy

```

typedef enum {
    CONN_EXCELLENT, // < 100ms
    CONN_GOOD,      // < 500ms
    CONN_FAIR,      // < 2000ms
    CONN_POOR       // >= 2000ms or timeout
} ConnectionQuality;

ConnectionQuality AssessConnectionQuality(int wsFd) {
    uint32_t pingSent, pongReceived;

    // Send ping
    if (WSPing(wsFd, 0, &pingSent) < 0) {
        return CONN_POOR;
    }

    // Try quick response first (100ms)
    if (WSWaitForPingReply(wsFd, TICKS_PER_SECOND / 10) >= 0) {
        return CONN_EXCELLENT;
    }

    // Try good response (additional 400ms)
    if (WSWaitForPingReply(wsFd, (TICKS_PER_SECOND * 4) / 10) >= 0) {
        return CONN_GOOD;
    }

    // Try fair response (additional 1500ms)
    if (WSWaitForPingReply(wsFd, (TICKS_PER_SECOND * 15) / 10) >= 0) {
        return CONN_FAIR;
    }

    return CONN_POOR;
}

// Usage
ConnectionQuality quality = AssessConnectionQuality(wsFd);
const char* qualityStr[] = {"Excellent", "Good", "Fair", "Poor"};
printf("Connection quality: %s\r\n", qualityStr[quality]);

```

Example 6: Batch Connection Testing

```

struct WSConnection {
    int fd;
    char name[32];
    bool isAlive;
};

void TestMultipleConnections(WSConnection *connections, int count) {
    printf("Testing %d WebSocket connections...\r\n", count);

    for (int i = 0; i < count; i++) {
        uint32_t pingSent;

        printf("Testing %s... ", connections[i].name);
    }
}

```

```

// Send ping
if (WSPing(connections[i].fd, 0, &pingSent) < 0) {
    printf("FAILED (ping)\r\n");
    connections[i].isAlive = false;
    continue;
}

// Wait for pong with 3 second timeout
if (WSWaitForPingReply(connections[i].fd, TICKS_PER_SECOND * 3) >= 0) {
    printf("OK\r\n");
    connections[i].isAlive = true;
} else {
    printf("FAILED (timeout)\r\n");
    connections[i].isAlive = false;
}
}

// Summary
int aliveCount = 0;
for (int i = 0; i < count; i++) {
    if (connections[i].isAlive) aliveCount++;
}
printf("\nResults: %d/%d connections alive\r\n", aliveCount, count);
}

```

14.61.4 Web Socket Definitions

WebSocket Protocol Implementation for Real-Time Bidirectional Communication `#include< websockets.h>`

Macros

- **#define WS_BUFFER_SEGMENTS 4**
Number of buffer segments per WebSocket connection (RX, TX, Control buffers)
- **#define WS_MAX_SOCKETS 4**
Maximum number of simultaneous WebSocket connections supported.
- **#define WS_BUFFER_MIN 10**
Minimum buffer space threshold (bytes) before triggering flush/block.
- **#define WS_ACCUM_DLY ((TICKS_PER_SECOND / 4) + 1)**
Accumulation delay (ticks) for batching small writes (~250ms)
- **#define WS_FLUSH_TIMEOUT 0**
Flush operation timeout in ticks (0 = non-blocking)
- **#define WS_FIN_BIT 0x80**
Frame FIN bit (0x80) indicating final fragment of message.
- **#define WS_OP_CONT 0x0**
WebSocket continuation frame opcode for message fragments.
- **#define WS_OP_TEXT 0x1**
WebSocket text frame opcode for UTF-8 encoded text data.
- **#define WS_OP_BIN 0x2**
WebSocket binary frame opcode for raw binary data.
- **#define WS_OP_CLOSE 0x8**
WebSocket close frame opcode for graceful connection termination.
- **#define WS_OP_PING 0x9**
WebSocket ping frame opcode for connection liveness check.

- `#define WS_OP_PONG 0xA`
WebSocket pong frame opcode for ping response.
- `#define WS_SO_TEXT 0x8`
Socket option flag to enable text frame mode (vs binary mode)

14.61.4.1 Detailed Description

WebSocket Protocol Implementation for Real-Time Bidirectional Communication `#include <websockets.h>`

14.61.4.2 Overview

The NetBurner WebSocket implementation provides full-duplex communication channels over a single TCP connection, enabling real-time data exchange between clients and servers. WebSockets upgrade from HTTP connections and maintain persistent connections for efficient, low-latency bidirectional messaging.

Key features include:

- RFC 6455 compliant WebSocket protocol implementation
- Automatic connection upgrade from HTTP to WebSocket
- Support for text and binary data frames
- Built-in ping/pong for connection health monitoring
- Efficient buffering and flow control
- Support for both client and server roles
- Graceful connection closure with status codes
- Frame fragmentation for large messages

Functions

- `nbWifiScanResult * WifilnitScan_SPI` (int irqNum=-1, int moduleNum=-1, int csNum=-1, int connectorNum=-1, int gpioPinNum=-1, int resetPinNum=-1)
Initializes the WiFi hardware, initializes the driver over the SPI bus, and performs an AP scan.
- `int WifilnitScanAndShow_SPI` (int irqNum=-1, int moduleNum=-1, int csNum=-1, int connectorNum=-1, int gpioPinNum=-1, int resetPinNum=-1)
Initializes the WiFi hardware, initializes the driver using the SPI bus, performs an AP scan, and prints the scan results via serial output.
- `int InitWifi_SPI` (const char *SSID="", const char *password="", int irqNum=-1, int moduleNum=-1, int csNum=-1, int connectorNum=-1, int gpioPinNum=-1, int resetPinNum=-1)
Initializes the WiFi hardware, initializes the driver using the SPI bus, and attempts to establish the specified connection.
- `int InitAP_SPI` (const char *SSID="", const char *password="", uint8_t channel=NBWIFI_DEFAULT_WIFICHANNEL, int irqNum=-1, int moduleNum=-1, int csNum=-1, int connectorNum=-1, int gpioPinNum=-1, int resetPinNum=-1)
Initializes the WiFi hardware, initializes the driver using the SPI bus, and attempts to establish the specified access point.
- `nbWifiScanResult * WifilnitScan_Serial` (int portNum=-1, int resetPinNum=-1, int connectorNum=-1)
Initializes the WiFi hardware, initializes the driver using the UART interface, performs an AP scan, and prints the scan results via serial output.
- `int WifilnitScanAndShow_Serial` (int portNum=-1, int resetPinNum=-1, int connectorNum=-1)
Initializes the WiFi hardware, initializes the driver using the UART interface, performs an AP scan, and prints the scan results via serial output.
- `int InitWifi_Serial` (const char *SSID="", const char *password="", int portNum=-1, int resetPinNum=-1, int connectorNum=-1)
Initializes the WiFi hardware, initializes the driver using the UART interface, and attempts to establish the specified access point.
- `void SetWifiSPISpeed` (int busSpeed)
Set SPI bus speed.
- `void ScanAndShowNetworks` ()
Scan for surrounding access points and print the results via iprintf.
- `nbWifiScanResult * ScanForNetworks` ()
Scan for surrounding access points.

14.62.1 Detailed Description

NetBurner WiFi API.

```
#include< nbWifiConstants.h>
```

Initialize and use a NetBurner WiFi module via SPI or Serial in either Client or AP mode.

```
#include< wifi.h>
```

See also

[WiFi Examples](#)

14.62.2 Function Documentation

14.62.2.1 InitAP_SPI()

```
int InitAP_SPI (
    const char * SSID = "",
    const char * password = "",
    uint8_t channel = NBWIFI_DEFAULT_WIFICHANNEL,
    int irqNum = -1,
    int moduleNum = -1,
```

```

int csNum = -1,
int connectorNum = -1,
int gpioPinNum = -1,
int resetPinNum = -1)

```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver using the SPI bus, and attempts to establish the specified access point.

Parameters

in	<i>SSID</i>	Service Set Identity (SSID), nullptr uses SSID stored in the configuration record.
in	<i>password</i>	key shared with access point/peer; nullptr uses the key stored in the configuration record.
in	<i>channel</i>	802.11 channel to establish an access point on.
in	<i>irqNum</i>	IRQ signal used to communicate with the WiFi module.
in	<i>moduleNum</i>	SPI module number used to communicate with the WiFi module.
in	<i>csNum</i>	Chip Select signal used for SPI communication.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.
in	<i>gpioPinNum</i>	GPIO pin number to use for the SPI chip select if not using the SPI module's native chip select signal.
in	<i>resetPinNum</i>	pin number to use as an reset signal output to the wifi module.

Returns

returns the Wifi interface number, if successful. Otherwise, returns [NB::Error::GeneralErrors](#) or [NB::Error::Init::InitializationErrors](#)

14.62.2.2 InitWifi_Serial()

```

int InitWifi_Serial (
    const char * SSID = "",
    const char * password = "",
    int portNum = -1,
    int resetPinNum = -1,
    int connectorNum = -1)

```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver using the UART interface, and attempts to establish the specified access point.

NOTE: Serial functions pertaining to WiFi are only available for the NBWIFIIN.

Parameters

in	<i>SSID</i>	Service Set Identity (SSID), nullptr uses SSID stored in the configuration record.
in	<i>password</i>	key shared with access point/peer; nullptr uses the key stored in the configuration record.
in	<i>portNum</i>	UART number
in	<i>resetPinNum</i>	pin number to use as an reset signal output to the wifi module.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.

Returns

returns zero if successful, otherwise returns [NB::Error::GeneralErrors](#) or [NB::Error::Init::InitializationErrors](#)

14.62.2.3 InitWifi_SPI()

```
int InitWifi_SPI (
    const char * SSID = "",
    const char * password = "",
    int irqNum = -1,
    int moduleNum = -1,
    int csNum = -1,
    int connectorNum = -1,
    int gpioPinNum = -1,
    int resetPinNum = -1)
```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver using the SPI bus, and attempts to establish the specified connection.

Parameters

in	<i>SSID</i>	Service Set Identity (SSID), nullptr uses SSID stored in the configuration record.
in	<i>password</i>	key shared with access point/peer; nullptr uses the key stored in the configuration record.
in	<i>irqNum</i>	IRQ signal used to communicate with the WiFi module.
in	<i>moduleNum</i>	SPI module number used to communicate with the WiFi module.
in	<i>csNum</i>	Chip Select signal used for SPI communication.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.
in	<i>gpioPinNum</i>	GPIO pin number to use for the SPI chip select, if not using the SPI's native chip select signal.
in	<i>resetPinNum</i>	pin number to use as an reset signal output to the wifi module.

Returns

returns the Wifi interface number, if successful. Otherwise, returns [NB::Error::GeneralErrors](#) or [NB::Error::Init::InitializationErrors](#)

14.62.2.4 ScanAndShowNetworks()

```
void ScanAndShowNetworks ()
#include <wifi.h>
```

Scan for surrounding access points and print the results via iprintf.
This function is bus interface agnostic.

14.62.2.5 ScanForNetworks()

```
nbWifiScanResult * ScanForNetworks ()
#include <wifi.h>
```

Scan for surrounding access points.

Returns

nbWifiScanResult Head of linked list containing the AP scan results. nullptr if scan failed or no access points were found

This function is bus interface agnostic.

14.62.2.6 SetWifiSPISpeed()

```
void SetWifiSPISpeed (
    int busSpeed)
#include <wifi.h>
```

Set SPI bus speed.

Parameters

in	<i>busSpeed</i>	Bus speed in Hz.

14.62.2.7 WifilnitScan_Serial()

```
nbWifiScanResult * WifiInitScan_Serial (
    int portNum = -1,
    int resetPinNum = -1,
    int connectorNum = -1)
```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver using the UART interface, performs an AP scan, and prints the scan results via serial output.

NOTE: Serial functions pertaining to WiFi are only available for the NBWIFIIN.

Parameters

in	<i>portNum</i>	UART number
in	<i>resetPinNum</i>	pin number to use as an reset signal output to the wifi module.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.

Returns

nbWifiScanResult Head of linked list containing the AP scan results. nullptr if scan failed or no access points were found

14.62.2.8 WifilnitScan_SPI()

```
nbWifiScanResult * WifiInitScan_SPI (
    int irqNum = -1,
    int moduleNum = -1,
    int csNum = -1,
    int connectorNum = -1,
    int gpioPinNum = -1,
    int resetPinNum = -1)
```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver over the SPI bus, and performs an AP scan.

Parameters

in	<i>irqNum</i>	IRQ signal used to communicate with the WiFi module.
in	<i>moduleNum</i>	SPI module number used to communicate with the WiFi module.
in	<i>csNum</i>	Chip Select signal used for SPI communication.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.
in	<i>gpioPinNum</i>	GPIO pin number to use for the SPI chip select if not using the SPI's native chip select signal.
in	<i>resetPinNum</i>	pin number to use as an reset signal output to the wifi module.

Returns

nbWifiScanResult Head of linked list containing the AP scan results. nullptr if scan failed or no access points were found

Initializes the WiFi Driver to communicate with the WiFi module over the SPI bus and performs a scan for surrounding access points (AP). The result of the scan is returned as the head of a linked list that contains the scan results. If the WiFi driver has already been initialized by a previous call to one of the Wifilnit function variations, then only a scan will be performed.

14.62.2.9 WifilnitScanAndShow_Serial()

```
int WifiInitScanAndShow_Serial (
    int portNum = -1,
    int resetPinNum = -1,
    int connectorNum = -1)
```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver using the UART interface, performs an AP scan, and prints the scan results via serial output.

NOTE: Serial functions pertaining to WiFi are only available for the NBWIFIIN.

Parameters

in	<i>portNum</i>	UART number
in	<i>resetPinNum</i>	pin number to use as an reset signal output to the wifi module.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.

Returns

the Wifi interface number if successful. Otherwise, returns [NB::Error::GeneralErrors](#) or [NB::Error::Init::InitializationErrors](#)

14.62.2.10 WifilnitScanAndShow_SPI()

```
int WifiInitScanAndShow_SPI (
    int irqNum = -1,
    int moduleNum = -1,
    int csNum = -1,
    int connectorNum = -1,
    int gpioPinNum = -1,
    int resetPinNum = -1)
```

```
#include <wifi.h>
```

Initializes the WiFi hardware, initializes the driver using the SPI bus, performs an AP scan, and prints the scan results via serial output.

Parameters

in	<i>irqNum</i>	IRQ signal used to communicate with the WiFi module.
in	<i>moduleNum</i>	SPI module number used to communicate with the WiFi module.
in	<i>csNum</i>	Chip Select signal used for SPI communication.
in	<i>connectorNum</i>	physical header number of the NetBurner module used.
in	<i>gpioPinNum</i>	GPIO pin number to use for the SPI chip select if not using the SPI's native chip select signal.
in	<i>resetPinNum</i>	pin number to use as an reset signal output to the wifi module.

Returns

returns the Wifi interface number, if successful. Otherwise, returns [NB::Error::GeneralErrors](#) or [NB::Error::Init::InitializationErrors](#)

14.62.3 BSS Options

Option list BSS type values.

Macros

- #define **BSSTYPE_VALUE_INFR** (0x00)

Infrastructure.

- #define **BSSTYPE_VALUE_ADHOC** (0x01)

ADHOC.

- #define **BSSTYPE_VALUE_ANY** (0x02)

Any.

- #define **BSSTYPE_VALUE_UNKNOWN** (0xFF)

Unknown.

14.62.3.1 Detailed Description

Option list BSS type values.

14.62.4 Cipher Options

Macros

- #define **CIPH_VALUE_NONE** (0x00)

Option list cipher value: No cipher.

- #define **CIPH_VALUE_TKIP** (0x01)

Option list cipher value: TKIP.

- #define **CIPH_VALUE_AES** (0x02)

Option list cipher value: AES.

- #define **CIPH_VALUE_MIXED** (0x03)

Option list cipher value: Mixed TKIP/AES.

- #define **CIPH_VALUE_UNKNOWN** (0xFF)

Option list cipher value: Unknown cipher.

14.62.4.1 Detailed Description

14.62.5 Configuration Errors

Macros

- #define **CONFIG_ERR_SUCCESS** 0

Success.

- #define **CONFIG_ERR_MSG_LENGTH** -1

Message length.

- #define **CONFIG_ERR_SSID_LEN_SHORT** -2

SSID length too short.

- #define **CONFIG_ERR_SSID_LEN_LONG** -3

SSID length too long.

- #define **CONFIG_ERR_PASSWD_LEN_LONG** -4

Password length too long.

- #define **CONFIG_ERR_INVALID_TABLE** -5

Invalid table.

- #define **CONFIG_ERR_INVALID_OPTION** -6

Invalid option.

- #define **CONFIG_ERR_BSSID_OVERRUN** -7

BSSID overrun.

- #define **CONFIG_ERR_BSSID_UNDERRUN** -8

BSSID underrun.

- #define **CONFIG_ERR_MULTI_CHANNEL** -9

Multi-channel.

- #define **CONFIG_ERR_CONNECTED** -10

Already connected.

- #define **CONFIG_ERR_UNKNOWN** 1

Unknown.

14.62.5.1 Detailed Description

14.62.6 Connect Request Errors

Macros

- #define **CONNECT_ERR_SUCCESS** 0
Successfull connect request.
- #define **CONNECT_ERR_NOT_CONFIG** -1
Paramaters not configured.
- #define **CONNECT_ERR_INVALID_CONFIG_NUM** -2
Invalid config number.
- #define **CONNECT_ERR_CONNECTED** -3
Already connected.
- #define **CONNECT_ERR_SSID_NOT_FOUND** -4
SSID not found.
- #define **CONNECT_ERR_BSSID_NOT_FOUND** -5
BSSID not found.
- #define **CONNECT_ERR_SEC_MISMATCH** -6
Security mismatch.
- #define **CONNECT_ERR_CIPH_MISMATCH** -7
Cipher mismatch.
- #define **CONNECT_ERR_INVALID_KEY** -8
Invalid password.
- #define **CONNECT_ERR_UNKNOWN** 1
Unknown error.

14.62.6.1 Detailed Description

14.62.7 Save Config Record Errors

Macros

- #define **SAVE_CONF_ERR_SUCCESS** 0
Success.
- #define **SAVE_CONF_ERR_INVALID_CONFIG_NUM** -1
Invalid configuration number.
- #define **SAVE_CONF_ERR_NOT_CONFIGURED** -2
Not configured.
- #define **SAVE_CONF_ERR_UNKNOWN** 1
Unknown error.

14.62.7.1 Detailed Description

14.62.8 Scan Request Errors

Macros

- #define **SCAN_ERR_SUCCESS** 0
Success.
- #define **SCAN_ERR_MSG_LENGTH** -1
Invalid message length.

- #define **SCAN_ERR_IN_PROGRESS** -2
Scan in progress.
- #define **SCAN_ERR_SSID_LEN_LONG** -3
SSID length too long.
- #define **SCAN_ERR_INVALID_TABLE** -4
Invalid table.
- #define **SCAN_ERR_INVALID_OPTION** -5
Invalid option.
- #define **SCAN_ERR_TOO_MANY_CHANNELS** -6
Too many channels.
- #define **SCAN_ERR_UNKNOWN** 1
Unknown error.

14.62.8.1 Detailed Description

14.62.9 Security Options

Macros

- #define **SEC_VALUE_OPEN** (0x00)
Option list security value: Open network.
- #define **SEC_VALUE_WEP** (0x01)
Option list security value: WEP.
- #define **SEC_VALUE_WPA** (0x02)
Option list security value: WPA.
- #define **SEC_VALUE_WPA2** (0x03)
Option list security value: WPA2.
- #define **SEC_VALUE_WPS** (0x04)
Option list security value: WPS.
- #define **SEC_VALUE_ANY** (0xFE)
Option list security value: Any, used to connect as a client regardless of how security is configured for AP.
- #define **SEC_VALUE_UNKNOWN** (0xFF)
Option list security value: Unknown security.

14.62.9.1 Detailed Description

Chapter 15

Namespace Documentation

15.1 canMCF5441x Namespace Reference

[canMCF5441x](#) namespace

Classes

- class [CanRxMessage](#)
Class to hold received CAN messages.

15.1.1 Detailed Description

[canMCF5441x](#) namespace

15.2 DHCP Namespace Reference

[DHCP](#) Namespace.

Classes

- class [BlockAllocator](#)
Basic allocator that handles multiple leases in a contiguous IP block.
- struct [DhcpInfo](#)
DHCP Info.
- struct [DhcpLeaseData](#)
Lease Data.
- struct [DhcpLeaseRequest](#)
Lease Request.
- class [LeaseAllocator](#)
Base class/interface for lease allocators for the [DHCP](#) server.
- class [MacPrefixAllocator](#)
Derived from [BlockAllocator](#) Has the ability to whitelist/blacklist certain mac address ranges based on a mask. Useful for allocating addresses based on device manufacturer.
- class [Server](#)
DHCP Server class Requires a lease allocator to be added in order to function.
- class [SingleAllocator](#)
Stripped down allocator Fails to conform to many standard behaviors, but shows the basics of what needs to be implemented.

Typedefs

- typedef enum [DHCP::LeaseState](#) **LeaseState_t**
Lease State.

Enumerations

- enum [LeaseState](#) {
[LEASE_OPEN](#) = 0x0 , [LEASE_OFFERED](#) = 0x1 , [LEASE_TAKEN](#) = 0x2 , [LEASE_STATIC](#) = 0x3 ,
[ARP_CONFLICT](#) = 0x4 }
Lease State.

15.2.1 Detailed Description

[DHCP](#) Namespace.

15.2.2 Enumeration Type Documentation

15.2.2.1 LeaseState

enum [DHCP::LeaseState](#)
Lease State.

Enumerator

LEASE_OPEN	
LEASE_OFFERED	
LEASE_TAKEN	
LEASE_STATIC	
ARP_CONFLICT	

15.3 mcanMODM7AE70 Namespace Reference

[mcanMODM7AE70](#) namespace

Classes

- class [CanRxMessage](#)
Class to hold received CAN messages.
- class [mcan_config](#)
MCAN configuration structure.
- class [mcan_module](#)
MCAN Module Class.

Variables

MCAN Constants

- const uint32_t **CONF_MCAN_RX_FIFO_0_NUM** = 32
Range: 1..64.
- const uint32_t **CONF_MCAN_RX_FIFO_1_NUM** = 1
Range: 1..64.
- const uint32_t **CONF_MCAN_RX_BUFFER_NUM** = 1
Range: 1..64.
- const uint32_t **CONF_MCAN_TX_BUFFER_NUM** = 8
Range: 1..16.

- const uint32_t **CONF_MCAN_TX_FIFO_QUEUE_NUM** = 1
Range: 1..16.
- const uint32_t **CONF_MCAN_TX_EVENT_FIFO** = 8
Range: 1..32.
- const uint32_t **CONF_MCAN_RX_STANDARD_ID_FILTER_NUM** = 32
Range: 1..128.
- const uint32_t **CONF_MCAN_RX_EXTENDED_ID_FILTER_NUM** = 32
Range: 1..64.

15.3.1 Detailed Description

[mcanMODM7AE70](#) namespace

15.4 MQTT Namespace Reference

[MQTT](#) Namespace.

Namespaces

- namespace [PacketInfo](#)
[MQTT PacketInfo](#) Namespace.

Classes

- class [Client](#)
Advanced low-level [MQTT Client](#) for interacting with Mqtt Brokers. The client handles all network communications with the Broker and handles local message queueing and dispatching to topic handlers.
- class [ConfigExposer](#)
Easy MqttObj class for automatically publishing and subscribing NetBurner Config system objects to/from an [MQTT](#) topic. Use like a normal ConfigObj.
- class [ConfiguredClient](#)
Easy [MQTT Client](#) wrapper for interacting with [MQTT](#) brokers. The client handles all network communications with the Broker and handles local message queueing and dispatching to topic handlers. Adds ConfigObj for automatically configuring all [Client](#) settings via the Config System.
- struct [ConnectRequest](#)
Structure used to specify details for a Publish call.
- class [mqtt_bool](#)
Easy MqttObj class for automatically publishing and subscribing boolean values to/from an [MQTT](#) topic. Use like a normal bool.
- class [mqtt_float](#)
Easy MqttObj class for automatically publishing and subscribing floating point values to/from an [MQTT](#) topic. Use like a normal double.
- class [mqtt_int](#)
Easy MqttObj class for automatically publishing and subscribing unsigned integer values to/from an [MQTT](#) topic. Use like a normal int32_t.
- class [mqtt_IO](#)
Easy MqttObj class for automatically publishing and subscribing hardware GPIO pins to/from an [MQTT](#) topic. Use like a normal [PinIO](#).
- class [mqtt_IO_Input](#)
MqttObj connecting hardware GPIO pins to an Mqtt Broker. This class defaults the pin to an Input state.
- class [mqtt_IO_Output](#)
MqttObj connecting hardware GPIO pins to an Mqtt Broker. This class defaults the pin to an Output state.
- class [mqtt_leaf](#)
Base class for all Mqtt Objects (MqttObj). Mqtt Objects provide a seamless bridge/synchronization to communicate information through an [MQTT](#) Broker via a [Client](#) object.

- class [mqtt_obj](#)
Base class for easy [MQTT](#) Objects (MqttObj). [mqtt_obj](#) are comprised of higher order parent objects that contain registered child objects.
- class [mqtt_string](#)
Easy MqttObj class for automatically publishing and subscribing string values to/from an [MQTT](#) topic. Use like a normal [NBString](#).
- class [mqtt_uint](#)
Easy MqttObj class for automatically publishing and subscribing unsigned integer values to/from an [MQTT](#) topic. Use like a normal [uint32_t](#).
- struct [PublishRequest](#)
Structure used to specify details for a Publish call.
- class [SubHandler](#)
Easy class for registering a callback function that receives messages on an [MQTT](#) topic and handles them appropriately. Behaves similarly to [HttpResponseHandler](#).
- struct [SubscribeFilter](#)
Structure used to specify a topic filter for subscriptions.
- struct [SubscribeFilter_NbStr](#)
Structure used to specify a topic filter for subscriptions.
- struct [SubscribeRequest](#)
Structure used to specify details for a Subscribe call.
- struct [TopicHandler](#)
[TopicHandler](#) context definition.

Typedefs

- typedef int(* [MsgCallback_t](#)) ([MQTT::Client](#) *mConn, int mqttFd, [MQTT::PacketInfo::Msg](#) *msg, void *ctx)
Function signature for a user-implemented callback function to receive messages from a subscription.

Enumerations

- enum [eResult_t](#) {
[eResult_Success](#) = 0 , [eResult_Mqtt_Unspecified](#) = -Pkt::eReason_Error_Unspecified , [eResult_Mqtt_MalformedPkt](#) = -Pkt::eReason_Error_MalformedPkt , [eResult_Mqtt_Protocol](#) = -Pkt::eReason_Error_Protocol ,

eResult_Cont_Auth = -258 , eResult_Error_InvalidURI = -259 , eResult_Error_NoneAvail = -260 ,
eResult_Error_Malformed = -261 ,
eResult_Error_Timeout = -262 , eResult_Error_BadProp = -263 , eResult_Error_NoSuchConn = -264 ,
eResult_Error_BadArg = -265 }
```

MQTT library return codes.

- enum {
 eObj_Flag_PubOnWrite = 0x0001 , eObj_Flag_PubQoS_AtLeastOnce = 0x0002 , eObj_Flag_PubQoS_ExactlyOnce = 0x0004 , eObj_Flag_PubRetain = 0x0008 ,
 eObj_Flag_Subscribe = 0x0010 , eObj_Flag_Sub_HandlerOnly = 0x0020 , eObj_Flag_Sub_IncludeLocal = 0x0040 , eObj_Flag_Sub_QoS_AtLeastOnce = 0x0080 ,
 eObj_Flag_Sub_QoS_ExactlyOnce = 0x0100 , eObj_Flag_Sub_NoLocal = 0x0200 , eObj_Flag_Sub_Retained_IfNew = 0x0400 , eObj_Flag_Sub_Retained_Never = 0x0800 ,
 eObj_Flag_WaitForPub = 0x1000 , eObj_Flag_DynTopicName = 0x2000 }

MqttObj Control Flags.

- enum eObj_Serialize_t {
 eObj_Serialize_Disabled = 0x00 , eObj_Serialize_String = 0x01 , eObj_Serialize_JSON = 0x02 ,
 eObj_Serialize_JSON_ValOnly = 0x04 ,
 eObj_Serialize_MqttString = 0x08 , eObj_Serialize_BigEndian = 0x10 , eObj_Serialize_LittleEndian = 0x20 ,
 eObj_Serialize_NativeEndian = 0x40 ,
 eObj_Serialize_CURRENT_FORM = 0x80 }

MqttObj Serialization Formats.

Functions

- const char * [GetPacketTypeString](#) (Pkt::eType_t pkt)

Get the name of a specific eType_t protocol packet type.
- const char * [GetReturnCodeString](#) (MQTT::eResult_t result)

Get the name of a specific API eResult_t return code.
- const char * [GetConnectionStatusString](#) (int status)

Get the name of a specific GetConnectionStatus return code.

15.4.1 Detailed Description

MQTT Namespace.

```
#include <mqtt/mqtt.h>
```

[Client](#) or [ConfiguredClient](#) are the base classes to use MQTT.

[SubHandler](#) and [TopicHandler](#) are event callbacks for the [Client](#).

[ConfigExposer](#) and the mqtt_* classes are "magic" classes that automatically handle pub/sub of the associated object to/from the specified MQTT topic.

Topic Names are also handled as an [NBInterpolatedString](#) and so can be dynamically assigned to NetBurner Config System values using specially formatting strings.

See the [MQTT](#) examples folder for more details.

15.4.2 Typedef Documentation

15.4.2.1 MsgCallback_t

```
typedef int(* MQTT::MsgCallback_t) (MQTT::Client *mConn, int mqttFd, MQTT::PacketInfo::Msg *msg, void *ctx)
```

Function signature for a user-implemented callback function to receive messages from a subscription.

Parameters

<i>*mConn</i>	Pointer to the Mqtt Client that received the message
<i>mqttFd</i>	The file descriptor for the socket the message was received on
<i>*msg</i>	Pointer to the message struct
<i>*ctx</i>	A void pointer passed into the register function. Can be used to reference objects or other data

See also

[TopicHandler](#), [RegisterTopicHandler](#)

15.4.3 Enumeration Type Documentation

15.4.3.1 anonymous enum

`anonymous enum`

MqttObj Control Flags.

Describes how the object should behave in relation to the [Client](#) and normal code.

Enumerator

<code>eObj_Flag_PubOnWrite</code>	Publish object whenever it is written to.
<code>eObj_Flag_PubQoS_AtLeastOnce</code>	Publish using QoS == At Least Once.
<code>eObj_Flag_PubQoS_ExactlyOnce</code>	Publish using QoS == At Most Once.
<code>eObj_Flag_PubRetain</code>	Publish with Retain set.
<code>eObj_Flag_Subscribe</code>	Automatically subscribe to the objects Topic.
<code>eObj_Flag_Sub_HandlerOnly</code>	<++>
<code>eObj_Flag_Sub_IncludeLocal</code>	Receive Publish messages sent by the object's client (aka, receive an Echo)
<code>eObj_Flag_Sub_QoS_AtLeastOnce</code>	Receive Publish messages at QoS == At Least Once.
<code>eObj_Flag_Sub_QoS_ExactlyOnce</code>	Receive Publish messages at QoS == At Most Once.
<code>eObj_Flag_Sub_NoLocal</code>	Do not Receive Local Publish Messages.
<code>eObj_Flag_Sub_Retained_IfNew</code>	When subscribing/connecting, only receive the Retained Publish, if it is new since last subscribed/connected.
<code>eObj_Flag_Sub_Retained_Never</code>	Never receive Retained messages, unless connected and subscribed when they are sent.
<code>eObj_Flag_WaitForPub</code>	Assigning to the object blocks until new value has been published.
<code>eObj_Flag_DynTopicName</code>	<++>

15.4.3.2 eObj_Serialize_t

`enum MQTT::eObj_Serialize_t`

MqttObj Serialization Formats.

Enumerator

<code>eObj_Serialize_Disabled</code>	Do not serialize, used to disable serialization of branches in complex structures.
<code>eObj_Serialize_String</code>	Serialize as a null terminated string.
<code>eObj_Serialize_JSON</code>	Serialize as a JSON name:value pair.
<code>eObj_Serialize_JSON_ValOnly</code>	Serialize as a JSON value.
<code>eObj_Serialize_MqttString</code>	Serialize as a MQTT Protocol level string.
<code>eObj_Serialize_BigEndian</code>	Serialize as binary, Big Endian ordering.

Enumerator

eObj_Serialize_LittleEndian	Serialize as binary, Little Endian ordering.
eObj_Serialize_NativeEndian	Serialize as binary, host native ordering.
eObj_Serialize_CURRENT_FORM	Serialize as the object's current defined form (only valid if the object has a currently assigned format)

15.4.3.3 eResult_t

enum MQTT::eResult_t
MQTT library return codes.

Enumerator

eResult_Success	No error, completed successfully.
eResult_Mqtt_Unspecified	Unknown/Unspecified error.
eResult_Mqtt_MalformedPkt	Malformed Mqtt msg was sent/received.
eResult_Mqtt_Protocol	Unsupported or unknown protocol.
eResult_Mqtt_Implementation	Feature/option not implemented.
eResult_Mqtt_UnsupportedProtoVer	Unsupported MQTT protocol version.
eResult_Mqtt_ClientIdInvalid	Broker refusing current Client ID.
eResult_Mqtt_UserPassword	Invalid Username/password.
eResult_Mqtt_NotAuthorized	Client not authorized.
eResult_Mqtt_ServerUnavail	Broker unavailable.
eResult_Mqtt_ServerBusy	Broker is unable to process message at this time.
eResult_Mqtt_Banned	Client is banned by the broker.
eResult_Mqtt_ServerShutdown	Broker is shutting down.
eResult_Mqtt_BadAuthMethod	Broker does not support the requested authentication method.
eResult_Mqtt_KATimeout	Keep Alive Timeout exceeded.
eResult_Mqtt_SessTakeover	Session has been taken over by another connection.
eResult_Mqtt_FilterInvalid	A submitted request filter is invalid.
eResult_Mqtt_NameInvalid	Submitted Topic Name is invalid.
eResult_Mqtt_PktId_InUse	Broker has an outstanding Reliable QOS Packet with the same ID (sending Subscribe when a Publish with the same ID is in progress, etc.)
eResult_Mqtt_PktId_NotFound	Broker has no outstanding packet with the requested ID.
eResult_Mqtt_RcvMax_Exceeded	< ++ >
eResult_Mqtt_TopicAlias_Invalid	Requested Topic Alias is invalid/unknown.
eResult_Mqtt_TooLarge	Message Size too large.
eResult_Mqtt_MsgRate	Exceeded client rate limit.
eResult_Mqtt_Quota	Exceeded client message quota.
eResult_Mqtt_Admin	General Administrative error.
eResult_Mqtt_PayFmt_Invalid	Payload Format error (malformed message)
eResult_Mqtt_NotSupported_Retain	Retain not supported for prior Publish Message.
eResult_Mqtt_NotSupported_QoS	Requested QoS level not supported for prior Publish Message.
eResult_Mqtt_UseOther	Client should connect to specified Other Broker (equivalent to HTTP 3xx redirect)
eResult_Mqtt_ServerMoved	Broker Permanently Moved to new address.
eResult_Mqtt_NotSupported_SharedSubs	Broker does not support Shared Subscriptions.
eResult_Mqtt_ConnRate	Exceeded Connection Rate Limit.

Enumerator

eResult_Mqtt_MaxConnTime	Exceeded Maximum Connection Time limit.
eResult_Mqtt_NotSupported_SubIds	Broker does not support Subscription IDs.
eResult_Mqtt_NotSupported_WildSubs	Broker does not support Wildcard Subscriptions.
eResult_Mqtt_Transport_Error	Transport layer error.
eResult_Error_NetErr	General network layer error.
eResult_Socket_TryAgain	Client Network Socket error, try again.
eResult_Socket_NeedDNS	Broker address failed to resolve DNS.
eResult_Cont_Auth	<++>
eResult_Error_InvalidURI	Provided Broker address URI is invalid.
eResult_Error_NoneAvail	Required resource exhausted, none available.
eResult_Error_Malformed	Malformed argument.
eResult_Error_Timeout	Operation timed out.
eResult_Error_BadProp	Argument contains malformed Message Property.
eResult_Error_NoSuchConn	No such connection.
eResult_Error_BadArg	General Bad Argument.

15.4.4 Function Documentation

15.4.4.1 GetConnectionStatusString()

```
const char * MQTT::GetConnectionStatusString (
    int status)
```

Get the name of a specific GetConnectionStatus return code.

Parameters

<i>status</i>	The integer output from GetConnectionStatus()

Returns

A pointer to the string containing the return code name.

See also

[Client::Connect](#), [Client::Disconnect](#), [Client::GetConnectionStatus](#)

15.4.4.2 GetPacketTypeString()

```
const char * MQTT::GetPacketTypeString (
    Pkt::eType_t pkt)
```

Get the name of a specific eType_t protocol packet type.

Parameters

<i>pkt</i>	The protocol packet type to get the name of.

Returns

A pointer to the string containing the packet type name.

See also

[GetReturnCodeString](#)

15.4.4.3 GetReturnCodeString()

```
const char * MQTT::GetReturnCodeString (
    MQTT::eResult_t result)
```

Get the name of a specific API eResult_t return code.

Parameters

<i>result</i>	The return code to get the name of.

Returns

A pointer to the string containing the return code name.

See also

[GetReturnCodeString](#)

15.5 MQTT::PacketInfo Namespace Reference

[MQTT PacketInfo](#) Namespace.

Classes

- struct [Msg](#)
PacketInfo::Msg message data structure.

15.5.1 Detailed Description

[MQTT PacketInfo](#) Namespace.

15.6 NB::Error Namespace Reference

Namespaces

- namespace [Connect](#)
- namespace [Init](#)
- namespace [Scan](#)

Enumerations

- enum [GeneralErrors](#) {
[NoError](#) = 0 , [Timeout](#) = -256 , [BusTimeout](#) = -257 , [InvalidArgument](#) = -258 ,
[TooManyPendingCommands](#) = -259 , [InvalidRequest](#) = -512 }

15.6.1 Detailed Description

[NB::Error](#) namespace that describes WiFi request errors. See also [InitWifi_SPI\(\)](#), [InitAP_SPI\(\)](#), [InitWifi_Serial\(\)](#), [NB::Master::ConnectToAP\(\)](#), [NB::Master::StartAP\(\)](#), [WifiInitScanAndShow_SPI\(\)](#), [WifiInitScanAndShow_Serial\(\)](#)

15.6.2 Enumeration Type Documentation

15.6.2.1 GeneralErrors

```
enum NB::Error::GeneralErrors
```

15.6.3 GeneralErrors

8 bit values reserved for command specific errors

Enumerator

NoError	Successful execution.
Timeout	Request timed out.
BusTimeout	Request timed out on the bus.
InvalidArgument	Parameter/argument not defined or is invalid.
TooManyPendingCommands	Too many pending commands.
InvalidRequest	Invalid request.

15.7 NB::Error::Connect Namespace Reference

Enumerations

- enum [ConnectErrors](#) {
[Success](#) = 0 , [NotInitialized](#) = -1 , [AlreadyConnected](#) = -2 , [Option](#) = -3 ,
[CouldNotConfig](#) = -4 , [SSID_NotFound](#) = -5 , [BSSID_NotFound](#) = -6 , [Sec_NotFound](#) = -7 ,
[Cipher_NotFound](#) = -8 , [ConnectFailed](#) = -9 }

15.7.1 Detailed Description

[NB::Error::Connect](#) namespace that describes WiFi connect request errors. See also [InitWifi_SPI\(\)](#), [InitAP_SPI\(\)](#), [InitWifi_Serial\(\)](#), [NB::Master::ConnectToAP\(\)](#), [NB::Master::StartAP\(\)](#)

15.7.2 Enumeration Type Documentation

15.7.2.1 ConnectErrors

```
enum NB::Error::Connect::ConnectErrors
```

15.7.3 ConnectErrors

Enumerator

Success	Success.
NotInitialized	Not Initialized.
AlreadyConnected	Already Connected.
Option	Option.
CouldNotConfig	Could Not Configure.
SSID_NotFound	SSID Not Found.
BSSID_NotFound	BSSID Not Found.
Sec_NotFound	Sec Not Found.
Cipher_NotFound	Cipher Not Found.
ConnectFailed	Connect Failed.

15.8 NB::Error::Init Namespace Reference

Enumerations

- enum [InitializationErrors](#) {
[Success](#) = 0 , [AlreadyInit](#) = -1 , [NoDevice](#) = -2 , [InvalidInfo](#) = -3 ,
[DevFirmVer](#) = -4 , [DevHwVer](#) = -5 , [OptionTables](#) = -6 }

15.8.1 Detailed Description

[NB::Error::Init](#) namespace that describes WiFi initialization request errors. See also [WifiInitScanAndShow_SPI\(\)](#), [WifiInitScanAndShow_Serial\(\)](#), [InitWifi_SPI\(\)](#), [InitAP_SPI\(\)](#), [InitWifi_Serial\(\)](#)

15.8.2 Enumeration Type Documentation

15.8.2.1 InitializationErrors

enum [NB::Error::Init::InitializationErrors](#)

15.8.3 InitializationErrors

Enumerator

Success	Success.
AlreadyInit	Already Initialized.
NoDevice	No Device detected or attempting to use WiFi functions on an un-initialized device.
InvalidInfo	Invalid Info.
DevFirmVer	Device Firmware Version.
DevHwVer	Device Hardware Version.
OptionTables	Option Tables.

15.9 NB::Error::Scan Namespace Reference

Enumerations

- enum [ScanErrors](#) { [Success](#) = 0 , [NotInitialized](#) = -1 , [InProgress](#) = -2 , [Option](#) = -3 }

15.9.1 Detailed Description

[NB::Error::Scan](#) namespace that describes WiFi access point scan request errors. See also [WifiInitScanAndShow_SPI\(\)](#), [WifiInitScanAndShow_Serial\(\)](#)

15.9.2 Enumeration Type Documentation

15.9.2.1 ScanErrors

enum [NB::Error::Scan::ScanErrors](#)

15.9.3 ScanErrors

Enumerator

Success	Success.
NotInitialized	Not Initialized.
InProgress	In Progress.
Option	Option.

15.10 ReceiveUDP Namespace Reference

Functions

- [signal_handler](#) (sig, frame)
- [send_test_packet](#) (host, port, message)

15.10.1 Detailed Description

UDP Packet Receiver and Display Tool

This application listens for UDP packets on a specified port and displays their contents in real-time with timestamps and sender information.

15.10.2 Function Documentation

15.10.2.1 `send_test_packet()`

```
ReceiveUDP.send_test_packet (  
    host,  
    port,  
    message)
```

Send a test UDP packet (for testing purposes)

15.10.2.2 `signal_handler()`

```
ReceiveUDP.signal_handler (  
    sig,  
    frame)
```

Handle Ctrl+C gracefully

Chapter 16

Class Documentation

16.1 `_edma_channel_Preemption_config` Struct Reference

eDMA channel priority configuration

```
#include <fsl_edma.h>
```

Public Attributes

- bool [enableChannelPreemption](#)
- bool [enablePreemptAbility](#)
- uint8_t [channelPriority](#)

16.1.1 Detailed Description

eDMA channel priority configuration

16.1.2 Member Data Documentation

16.1.2.1 `channelPriority`

```
uint8_t _edma_channel_Preemption_config::channelPriority
```

Channel priority

16.1.2.2 `enableChannelPreemption`

```
bool _edma_channel_Preemption_config::enableChannelPreemption
```

If true: a channel can be suspended by other channel with higher priority

16.1.2.3 `enablePreemptAbility`

```
bool _edma_channel_Preemption_config::enablePreemptAbility
```

If true: a channel can suspend other channel with low priority

The documentation for this struct was generated from the following file:

- `fsl_edma.h`

16.2 `_edma_config` Struct Reference

eDMA global configuration structure.

```
#include <fsl_edma.h>
```

Public Attributes

- bool [enableContinuousLinkMode](#)
- bool [enableHaltOnError](#)

- bool [enableRoundRobinArbitration](#)
- bool [enableDebugMode](#)

16.2.1 Detailed Description

eDMA global configuration structure.

16.2.2 Member Data Documentation

16.2.2.1 enableContinuousLinkMode

```
bool _edma_config::enableContinuousLinkMode
```

Enable (true) continuous link mode. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself.

16.2.2.2 enableDebugMode

```
bool _edma_config::enableDebugMode
```

Enable(true) eDMA debug mode. When in debug mode, the eDMA stalls the start of a new channel. Executing channels are allowed to complete.

16.2.2.3 enableHaltOnError

```
bool _edma_config::enableHaltOnError
```

Enable (true) transfer halt on error. Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.

16.2.2.4 enableRoundRobinArbitration

```
bool _edma_config::enableRoundRobinArbitration
```

Enable (true) round robin channel arbitration method or fixed priority arbitration is used for channel selection

The documentation for this struct was generated from the following file:

- [fsl_edma.h](#)

16.3 _edma_handle Struct Reference

eDMA transfer handle structure

```
#include <fsl_edma.h>
```

Public Attributes

- edma_callback [callback](#)
- void * [userData](#)
- DMA_Type * [base](#)
- [edma_tcd_t](#) * [tcdPool](#)
- uint8_t [channel](#)
- volatile int8_t [header](#)
- volatile int8_t [tail](#)
- volatile int8_t [tcdUsed](#)
- volatile int8_t [tcdSize](#)
- uint8_t [flags](#)

16.3.1 Detailed Description

eDMA transfer handle structure

16.3.2 Member Data Documentation

16.3.2.1 base

DMA_Type* _edma_handle::base
eDMA peripheral base address.

16.3.2.2 callback

edma_callback _edma_handle::callback
Callback function for major count exhausted.

16.3.2.3 channel

uint8_t _edma_handle::channel
eDMA channel number.

16.3.2.4 flags

uint8_t _edma_handle::flags
The status of the current channel.

16.3.2.5 header

volatile int8_t _edma_handle::header
The first TCD index. Should point to the next TCD to be loaded into the eDMA engine.

16.3.2.6 tail

volatile int8_t _edma_handle::tail
The last TCD index. Should point to the next TCD to be stored into the memory pool.

16.3.2.7 tcdPool

edma_tcd_t* _edma_handle::tcdPool
Pointer to memory stored TCDs.

16.3.2.8 tcdSize

volatile int8_t _edma_handle::tcdSize
The total number of TCD slots in the queue.

16.3.2.9 tcdUsed

volatile int8_t _edma_handle::tcdUsed
The number of used TCD slots. Should reflect the number of TCDs can be used/loaded in the memory.

16.3.2.10 userData

void* _edma_handle::userData
Callback function parameter.
The documentation for this struct was generated from the following file:

- fsl_edma.h

16.4 _edma_minor_offset_config Struct Reference

eDMA minor offset configuration
#include <fsl_edma.h>

Public Attributes

- bool [enableSrcMinorOffset](#)
- bool [enableDestMinorOffset](#)
- uint32_t [minorOffset](#)

16.4.1 Detailed Description

eDMA minor offset configuration

16.4.2 Member Data Documentation**16.4.2.1 enableDestMinorOffset**

bool `_edma_minor_offset_config::enableDestMinorOffset`

Enable(true) or Disable(false) destination minor loop offset.

16.4.2.2 enableSrcMinorOffset

bool `_edma_minor_offset_config::enableSrcMinorOffset`

Enable(true) or Disable(false) source minor loop offset.

16.4.2.3 minorOffset

uint32_t `_edma_minor_offset_config::minorOffset`

Offset for a minor loop mapping.

The documentation for this struct was generated from the following file:

- `fsl_edma.h`

16.5 _edma_tcd Struct Reference

eDMA TCD.

```
#include <fsl_edma.h>
```

Public Attributes

- __IO uint32_t [SADDR](#)
- __IO uint16_t [SOFF](#)
- __IO uint16_t [ATTR](#)
- __IO uint32_t [NBYTES](#)
- __IO uint32_t [SLAST](#)
- __IO uint32_t [DADDR](#)
- __IO uint16_t [DOFF](#)
- __IO uint16_t [CITER](#)
- __IO uint32_t [DLAST_SGA](#)
- __IO uint16_t [CSR](#)
- __IO uint16_t [BITER](#)

16.5.1 Detailed Description

eDMA TCD.

This structure is same as TCD register which is described in reference manual, and is used to configure the scatter/gather feature as a next hardware TCD.

16.5.2 Member Data Documentation

16.5.2.1 ATTR

`__IO uint16_t _edma_tcd::ATTR`

ATTR register, source/destination transfer size and modulo

16.5.2.2 BITER

`__IO uint16_t _edma_tcd::BITER`

BITER register, begin minor loop count.

16.5.2.3 CITER

`__IO uint16_t _edma_tcd::CITER`

CITER register, current minor loop numbers, for unfinished minor loop.

16.5.2.4 CSR

`__IO uint16_t _edma_tcd::CSR`

CSR register, for TCD control status

16.5.2.5 DADDR

`__IO uint32_t _edma_tcd::DADDR`

DADDR register, used for destination address

16.5.2.6 DLAST_SGA

`__IO uint32_t _edma_tcd::DLAST_SGA`

DLASTSGA register, next tcd address used in scatter-gather mode

16.5.2.7 DOFF

`__IO uint16_t _edma_tcd::DOFF`

DOFF register, used for destination offset

16.5.2.8 NBYTES

`__IO uint32_t _edma_tcd::NBYTES`

Nbytes register, minor loop length in bytes

16.5.2.9 SADDR

`__IO uint32_t _edma_tcd::SADDR`

SADDR register, used to save source address

16.5.2.10 SLAST

`__IO uint32_t _edma_tcd::SLAST`

SLAST register

16.5.2.11 SOFF

`__IO uint16_t _edma_tcd::SOFF`

SOFF register, save offset bytes every transfer

The documentation for this struct was generated from the following file:

- fsl_edma.h

16.6 `_edma_transfer_config` Struct Reference

eDMA transfer configuration

```
#include <fsl_edma.h>
```

Public Attributes

- `uint32_t` [srcAddr](#)
- `uint32_t` [destAddr](#)
- `edma_transfer_size_t` [srcTransferSize](#)
- `edma_transfer_size_t` [destTransferSize](#)
- `int16_t` [srcOffset](#)
- `int16_t` [destOffset](#)
- `uint32_t` [minorLoopBytes](#)
- `uint32_t` [majorLoopCounts](#)

16.6.1 Detailed Description

eDMA transfer configuration

This structure configures the source/destination transfer attribute.

16.6.2 Member Data Documentation

16.6.2.1 `destAddr`

```
uint32_t _edma_transfer_config::destAddr
```

Destination data address.

16.6.2.2 `destOffset`

```
int16_t _edma_transfer_config::destOffset
```

Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed.

16.6.2.3 `destTransferSize`

```
edma_transfer_size_t _edma_transfer_config::destTransferSize
```

Destination data transfer size.

16.6.2.4 `majorLoopCounts`

```
uint32_t _edma_transfer_config::majorLoopCounts
```

Major loop iteration count.

16.6.2.5 `minorLoopBytes`

```
uint32_t _edma_transfer_config::minorLoopBytes
```

Bytes to transfer in a minor loop

16.6.2.6 `srcAddr`

```
uint32_t _edma_transfer_config::srcAddr
```

Source data address.

16.6.2.7 `srcOffset`

```
int16_t _edma_transfer_config::srcOffset
```

Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

16.6.2.8 srcTransferSize

edma_transfer_size_t _edma_transfer_config::srcTransferSize

Source data transfer size.

The documentation for this struct was generated from the following file:

- fsl_edma.h

16.7 _EthernetFrameHeader Struct Reference

Ethernet Type II Frame Header.

```
#include <ethernet.h>
```

Public Attributes

- MACADDRESS_48 **destinationMacAddress**
Destination MAC address.
- MACADDRESS_48 **sourceMacAddress**
Source MAC address.
- beuint16_t **etherType**
Protocol.

16.7.1 Detailed Description

Ethernet Type II Frame Header.

The documentation for this struct was generated from the following file:

- ethernet.h

16.8 _flexcan_config Struct Reference

FlexCAN module configuration structure.

```
#include <fsl_flexcan.h>
```

Public Attributes

- flexcan_clock_source_t clkSrc
- flexcan_wake_up_source_t wakeupSrc
- uint8_t maxMbNum
- bool enableLoopBack
- bool enableTimerSync
- bool enableSelfWakeup
- bool enableIndividMask
- bool disableSelfReception
- bool enableListenOnlyMode
- bool enableSupervisorMode

16.8.1 Detailed Description

FlexCAN module configuration structure.

Deprecated Do not use the baudRate. It has been superceded bitRate

Do not use the baudRateFD. It has been superceded bitRateFD

16.8.2 Member Data Documentation

16.8.2.1 baudRate

`uint32_t _flexcan_config::baudRate`

FlexCAN bit rate in bps, for classical CAN or CANFD nominal phase.

16.8.2.2 bitRate

`uint32_t _flexcan_config::bitRate`

FlexCAN bit rate in bps, for classical CAN or CANFD nominal phase.

16.8.2.3 clkSrc

`flexcan_clock_source_t _flexcan_config::clkSrc`

Clock source for FlexCAN Protocol Engine.

16.8.2.4 disableSelfReception

`bool _flexcan_config::disableSelfReception`

Enable or Disable Self Reflection.

16.8.2.5 enableIndividMask

`bool _flexcan_config::enableIndividMask`

Enable or Disable Rx Individual Mask and Queue feature.

16.8.2.6 enableListenOnlyMode

`bool _flexcan_config::enableListenOnlyMode`

Enable or Disable Listen Only Mode.

16.8.2.7 enableLoopBack

`bool _flexcan_config::enableLoopBack`

Enable or Disable Loop Back Self Test Mode.

16.8.2.8 enableSelfWakeup

`bool _flexcan_config::enableSelfWakeup`

Enable or Disable Self Wakeup Mode.

16.8.2.9 enableSupervisorMode

`bool _flexcan_config::enableSupervisorMode`

Enable or Disable Supervisor Mode, enable this mode will make registers allow only Supervisor access.

16.8.2.10 enableTimerSync

`bool _flexcan_config::enableTimerSync`

Enable or Disable Timer Synchronization.

16.8.2.11 maxMbNum

`uint8_t _flexcan_config::maxMbNum`

The maximum number of Message Buffers used by user.

16.8.2.12 wakeupSrc

`flexcan_wake_up_source_t _flexcan_config::wakeupSrc`

Wake up source selection.

The documentation for this struct was generated from the following file:

- FlexcanLoopback/src/fsl_flexcan.h

16.9 _flexcan_fifo_transfer Struct Reference

FlexCAN Rx FIFO transfer.

```
#include <fsl_flexcan.h>
```

Public Attributes

- `flexcan_frame_t* frame`
- `size_t frameNum`

16.9.1 Detailed Description

FlexCAN Rx FIFO transfer.

16.9.2 Member Data Documentation

16.9.2.1 frame

`flexcan_frame_t* _flexcan_fifo_transfer::frame`

The buffer of CAN Message to be received from Legacy Rx FIFO.

16.9.2.2 frameNum

`size_t _flexcan_fifo_transfer::frameNum`

Number of CAN Message need to be received from Legacy or Enhanced Rx FIFO.

The documentation for this struct was generated from the following file:

- FlexcanLoopback/src/fsl_flexcan.h

16.10 _flexcan_frame Struct Reference

FlexCAN message frame structure.

```
#include <fsl_flexcan.h>
```

16.10.1 Detailed Description

FlexCAN message frame structure.

16.10.2 Member Data Documentation

16.10.2.1 __pad0__

`uint32_t _flexcan_frame::__pad0__`

Reserved.

16.10.2.2 dataByte0

`uint8_t _flexcan_frame::dataByte0`

CAN Frame payload byte0.

16.10.2.3 dataByte1

`uint8_t _flexcan_frame::dataByte1`
CAN Frame payload byte1.

16.10.2.4 dataByte2

`uint8_t _flexcan_frame::dataByte2`
CAN Frame payload byte2.

16.10.2.5 dataByte3

`uint8_t _flexcan_frame::dataByte3`
CAN Frame payload byte3.

16.10.2.6 dataByte4

`uint8_t _flexcan_frame::dataByte4`
CAN Frame payload byte4.

16.10.2.7 dataByte5

`uint8_t _flexcan_frame::dataByte5`
CAN Frame payload byte5.

16.10.2.8 dataByte6

`uint8_t _flexcan_frame::dataByte6`
CAN Frame payload byte6.

16.10.2.9 dataByte7

`uint8_t _flexcan_frame::dataByte7`
CAN Frame payload byte7.

16.10.2.10 dataWord0

`uint32_t _flexcan_frame::dataWord0`
CAN Frame payload word0.

16.10.2.11 dataWord1

`uint32_t _flexcan_frame::dataWord1`
CAN Frame payload word1.

16.10.2.12 format

`uint32_t _flexcan_frame::format`
CAN Frame Identifier(STD or EXT format).

16.10.2.13 id

`uint32_t _flexcan_frame::id`
CAN Frame Identifier, should be set using [FLEXCAN_ID_EXT\(\)](#) or [FLEXCAN_ID_STD\(\)](#) macro.

16.10.2.14 idhit

`uint32_t _flexcan_frame::idhit`
CAN Rx FIFO filter hit [id](#)(This value is only used in Rx FIFO receive mode).

16.10.2.15 length

```
uint32_t _flexcan_frame::length
```

CAN frame data length in bytes (Range: 0~8).

16.10.2.16 timestamp

```
uint32_t _flexcan_frame::timestamp
```

FlexCAN internal Free-Running Counter Time Stamp.

16.10.2.17 type

```
uint32_t _flexcan_frame::type
```

CAN Frame Type(DATA or REMOTE).

The documentation for this struct was generated from the following file:

- FlexcanLoopback/src/fsl_flexcan.h

16.11 _flexcan_handle Struct Reference

FlexCAN handle structure.

```
#include <fsl_flexcan.h>
```

Public Attributes

- flexcan_transfer_callback_t [callback](#)
- void * [userData](#)
- [flexcan_frame_t](#) *volatile [mbFrameBuf](#) [CAN_WORD1_COUNT]
- [flexcan_frame_t](#) *volatile [rxFifoFrameBuf](#)
- size_t [rxFifoFrameNum](#)
- size_t [rxFifoTransferTotalNum](#)
- volatile uint8_t [mbState](#) [CAN_WORD1_COUNT]
- volatile uint8_t [rxFifoState](#)
- volatile uint32_t [timestamp](#) [CAN_WORD1_COUNT]

16.11.1 Detailed Description

FlexCAN handle structure.

16.11.2 Member Data Documentation**16.11.2.1 callback**

```
flexcan_transfer_callback_t _flexcan_handle::callback
```

Callback function.

16.11.2.2 mbFrameBuf

```
flexcan\_frame\_t* volatile _flexcan_handle::mbFrameBuf [CAN_WORD1_COUNT]
```

The buffer for received CAN data from Message Buffers.

16.11.2.3 mbState

```
volatile uint8_t _flexcan_handle::mbState [CAN_WORD1_COUNT]
```

Message Buffer transfer state.

16.11.2.4 rxFifoFrameBuf

```
flexcan\_frame\_t* volatile _flexcan_handle::rxFifoFrameBuf
```

The buffer for received CAN data from Legacy Rx FIFO.

16.11.2.5 rxFifoFrameNum

size_t _flexcan_handle::rxFifoFrameNum

The number of CAN messages remaining to be received from Legacy or Enhanced Rx FIFO.

16.11.2.6 rxFifoState

volatile uint8_t _flexcan_handle::rxFifoState

Rx FIFO transfer state.

16.11.2.7 rxFifoTransferTotalNum

size_t _flexcan_handle::rxFifoTransferTotalNum

Total CAN Message number need to be received from Legacy or Enhanced Rx FIFO.

16.11.2.8 timestamp

volatile uint32_t _flexcan_handle::timestamp[CAN_WORD1_COUNT]

Mailbox transfer timestamp.

16.11.2.9 userData

void* _flexcan_handle::userData

FlexCAN callback function parameter.

The documentation for this struct was generated from the following file:

- FlexcanLoopback/src/fsl_flexcan.h

16.12 _flexcan_mb_transfer Struct Reference

FlexCAN Message Buffer transfer.

```
#include <fsl_flexcan.h>
```

Public Attributes

- [flexcan_frame_t](#) * frame
- uint8_t mbIdx

16.12.1 Detailed Description

FlexCAN Message Buffer transfer.

16.12.2 Member Data Documentation

16.12.2.1 frame

[flexcan_frame_t](#)* _flexcan_mb_transfer::frame

The buffer of CAN Message to be transfer.

16.12.2.2 mbIdx

uint8_t _flexcan_mb_transfer::mbIdx

The index of Message buffer used to transfer Message.

The documentation for this struct was generated from the following file:

- FlexcanLoopback/src/fsl_flexcan.h

16.13 _flexcan_rx_fifo_config Struct Reference

FlexCAN Legacy Rx FIFO configuration structure.

```
#include <fsl_flexcan.h>
```

Public Attributes

- [uint32_t * idFilterTable](#)
- [uint8_t idFilterNum](#)
- [flexcan_rx_fifo_filter_type_t idFilterType](#)
- [flexcan_rx_fifo_priority_t priority](#)

16.13.1 Detailed Description

FlexCAN Legacy Rx FIFO configuration structure.

16.13.2 Member Data Documentation

16.13.2.1 idFilterNum

```
uint8_t _flexcan_rx_fifo_config::idFilterNum
```

The FlexCAN Legacy Rx FIFO Filter elements quantity.

16.13.2.2 idFilterTable

```
uint32_t* _flexcan_rx_fifo_config::idFilterTable
```

Pointer to the FlexCAN Legacy Rx FIFO identifier filter table.

16.13.2.3 idFilterType

```
flexcan_rx_fifo_filter_type_t _flexcan_rx_fifo_config::idFilterType
```

The FlexCAN Legacy Rx FIFO Filter type.

16.13.2.4 priority

```
flexcan_rx_fifo_priority_t _flexcan_rx_fifo_config::priority
```

The FlexCAN Legacy Rx FIFO receive priority.

The documentation for this struct was generated from the following file:

- FlexcanLoopback/src/fsl_flexcan.h

16.14 _flexcan_rx_mb_config Struct Reference

FlexCAN Receive Message Buffer configuration structure.

```
#include <fsl_flexcan.h>
```

Public Attributes

- [uint32_t id](#)
- [flexcan_frame_format_t format](#)
- [flexcan_frame_type_t type](#)

16.14.1 Detailed Description

FlexCAN Receive Message Buffer configuration structure.

This structure is used as the parameter of [FLEXCAN_SetRxMbConfig\(\)](#) function. The [FLEXCAN_SetRxMbConfig\(\)](#) function is used to configure FlexCAN Receive Message Buffer. The function abort previous receiving process, clean the Message Buffer and activate the Rx Message Buffer using given Message Buffer setting.

16.14.2 Member Data Documentation

16.14.2.1 format

`flexcan_frame_format_t _flexcan_rx_mb_config::format`
CAN Frame Identifier [format\(Standard of Extend\)](#).

16.14.2.2 id

`uint32_t _flexcan_rx_mb_config::id`
CAN Message Buffer Frame Identifier, should be set using [FLEXCAN_ID_EXT\(\)](#) or [FLEXCAN_ID_STD\(\)](#) macro.

16.14.2.3 type

`flexcan_frame_type_t _flexcan_rx_mb_config::type`
CAN Frame Type(Data or Remote).
The documentation for this struct was generated from the following file:

- FlexcanLoopback/src/fsl_flexcan.h

16.15 _flexcan_timing_config Struct Reference

FlexCAN protocol timing characteristic configuration structure.
`#include <fsl_flexcan.h>`

Public Attributes

- `uint16_t preDivider`
- `uint8_t rJumpwidth`
- `uint8_t phaseSeg1`
- `uint8_t phaseSeg2`
- `uint8_t propSeg`

16.15.1 Detailed Description

FlexCAN protocol timing characteristic configuration structure.

16.15.2 Member Data Documentation

16.15.2.1 phaseSeg1

`uint8_t _flexcan_timing_config::phaseSeg1`
Classic CAN or CAN FD nominal phase Segment 1.

16.15.2.2 phaseSeg2

`uint8_t _flexcan_timing_config::phaseSeg2`
Classic CAN or CAN FD nominal phase Segment 2.

16.15.2.3 preDivider

`uint16_t _flexcan_timing_config::preDivider`
Classic CAN or CAN FD nominal phase bit rate prescaler.

16.15.2.4 propSeg

`uint8_t _flexcan_timing_config::propSeg`
Classic CAN or CAN FD nominal phase Propagation Segment.

16.15.2.5 rJumpwidth

uint8_t _flexcan_timing_config::rJumpwidth

Classic CAN or CAN FD nominal phase Re-sync Jump Width.

The documentation for this struct was generated from the following file:

- FlexcanLoopback/src/fsl_flexcan.h

16.16 _FlexSPIConfig Struct Reference

FlexSPI Memory Configuration Block.

```
#include <evkmimxrt1060_flexspi_nor_config.h>

16.17 _IpHeaderIPv4 Struct Reference

IP Header Structure (IPv4)

```
#include <ip.h>
```

Public Attributes

- **uint8_t versionNLength**
Version (4 bits) and header length (4 bits). Version=4 for IPv4, length in 32-bit words [IPPKT::bVerHdrLen](#).
- **uint8_t diffServNEcn**
Differentiated Services Code Point (6 bits) and Explicit Congestion Notification (2 bits) - used for QoS [IPPKT::bTos](#).
- **beuint16_t totalLength**
Total datagram size in bytes including IP header and data payload [IPPKT::wLength](#).
- **beuint16_t identification**
Fragment identification field - same for all fragments of a datagram [IPPKT::wpktId](#).
- **beuint16_t flagsNFragmentOffset**
Flags (3 bits) and fragment offset (13 bits) - offset in 8-byte units [IPPKT::wFlags_Frag](#).
- **uint8_t timeToLive**
Time To Live - typically used as hop count, decremented by each router [IPPKT::bTTL](#).
- **uint8_t protocol**
IANA protocol number identifying next-level protocol (TCP=6, UDP=17, ICMP=1) [IPPKT::proto](#).
- **beuint16_t headerChecksum**
Header checksum - 16-bit one's complement checksum of IP header only (not data) [IPPKT::hCSum](#).
- **beuint32_t sourceAddress**
Source IP address as 4 octets in network byte order [IPPKT::ipSrc](#).
- **beuint32_t destinationAddress**
Destination IP address as 4 octets in network byte order [IPPKT::ipDst](#).

16.17.1 Detailed Description

IP Header Structure (IPv4)

Standard IPv4 packet header as defined in IETF RFC 791 (September 1981) and MIL-STD-1777. This structure represents the 20-byte minimum IP header. IP options, if present, follow this structure and are indicated by a header length value greater than 5.

All multi-byte fields are in network byte order (big-endian) and use the beuint types for automatic endianness handling.

Note

The structure is packed to ensure proper alignment with network packet data.

Standard header is 20 bytes when no options are present (header length = 5).

Maximum header size is 60 bytes (header length = 15) when options are included.

See also

[IPPKT](#) for the internal representation used within NetBurner stack

The documentation for this struct was generated from the following file:

- ip.h

16.18 _lpspi_master_config Struct Reference

LPSPi master configuration structure.

```
#include <fsl_lpspi.h>
```

Public Attributes

- uint32_t [baudRate](#)
- uint32_t [bitsPerFrame](#)
- lpspi_clock_polarity_t [cpol](#)
- lpspi_clock_phase_t [cpha](#)
- lpspi_shift_direction_t [direction](#)
- uint32_t [pcsToSckDelayInNanoSec](#)
- uint32_t [lastSckToPcsDelayInNanoSec](#)
- uint32_t [betweenTransferDelayInNanoSec](#)
- lpspi_which_pcs_t [whichPcs](#)
- lpspi_pcs_polarity_config_t [pcsActiveHighOrLow](#)

16.18.1 Detailed Description

LPSPi master configuration structure.

16.18.2 Member Data Documentation

16.18.2.1 baudRate

```
uint32_t _lpspi_master_config::baudRate
```

Baud Rate for LPSPi.

16.18.2.2 betweenTransferDelayInNanoSec

```
uint32_t _lpspi_master_config::betweenTransferDelayInNanoSec
```

After the SCK delay time with nanoseconds, setting to 0 sets the minimum delay. It sets the boundary value if out of range.

16.18.2.3 bitsPerFrame

```
uint32_t _lpspi_master_config::bitsPerFrame
```

Bits per frame, minimum 8, maximum 4096.

16.18.2.4 cpha

```
lpspi_clock_phase_t _lpspi_master_config::cpha
```

Clock phase.

16.18.2.5 cpol

```
lpspi_clock_polarity_t _lpspi_master_config::cpol
```

Clock polarity.

16.18.2.6 dataOutConfig

```
lpspi_data_out_config_t _lpspi_master_config::dataOutConfig
```

Configures if the output data is tristated between accesses (LPSPi_PCS is negated).

16.18.2.7 direction

`lpspi_shift_direction_t _lpspi_master_config::direction`
 MSB or LSB data shift direction.

16.18.2.8 enableInputDelay

`bool _lpspi_master_config::enableInputDelay`
 Enable master to sample the input data on a delayed SCK. This can help improve slave setup time. Refer to device data sheet for specific time length.

16.18.2.9 lastSckToPcsDelayInNanoSec

`uint32_t _lpspi_master_config::lastSckToPcsDelayInNanoSec`
 Last SCK to PCS delay time in nanoseconds, setting to 0 sets the minimum delay. It sets the boundary value if out of range.

16.18.2.10 pcsActiveHighOrLow

`lpspi_pcs_polarity_config_t _lpspi_master_config::pcsActiveHighOrLow`
 Desired PCS active high or low

16.18.2.11 pcsToSckDelayInNanoSec

`uint32_t _lpspi_master_config::pcsToSckDelayInNanoSec`
 PCS to SCK delay time in nanoseconds, setting to 0 sets the minimum delay. It sets the boundary value if out of range.

16.18.2.12 pinCfg

`lpspi_pin_config_t _lpspi_master_config::pinCfg`
 Configures which pins are used for input and output data during single bit transfers.

16.18.2.13 whichPcs

`lpspi_which_pcs_t _lpspi_master_config::whichPcs`
 Desired Peripheral Chip Select (PCS).
 The documentation for this struct was generated from the following file:

- `fsl_lpspi.h`

16.19 _lpspi_master_edma_handle Struct Reference

LPSPi master eDMA transfer handle structure used for transactional API.
`#include <fsl_lpspi_edma.h>`

Public Attributes

16.19.1 Detailed Description

LPSPi master eDMA transfer handle structure used for transactional API.

16.19.2 Member Data Documentation

16.19.2.1 bytesEachRead

volatile uint8_t _lpspi_master_edma_handle::bytesEachRead
Bytes for each read RDR.

16.19.2.2 bytesEachWrite

volatile uint8_t _lpspi_master_edma_handle::bytesEachWrite
Bytes for each write TDR.

16.19.2.3 bytesLastRead

volatile uint8_t _lpspi_master_edma_handle::bytesLastRead
Bytes for last read RDR.

16.19.2.4 callback

lpspi_master_edma_transfer_callback_t _lpspi_master_edma_handle::callback
Completion callback.

16.19.2.5 edmaRxRegToRxDataHandle

edma_handle_t* _lpspi_master_edma_handle::edmaRxRegToRxDataHandle
edma_handle_t handle point used for RxReg to RxData buff

16.19.2.6 edmaTxDataToTxRegHandle

edma_handle_t* _lpspi_master_edma_handle::edmaTxDataToTxRegHandle
edma_handle_t handle point used for TxData to TxReg buff

16.19.2.7 fifoSize

volatile uint8_t _lpspi_master_edma_handle::fifoSize
FIFO dataSize.

16.19.2.8 isByteSwap

volatile bool _lpspi_master_edma_handle::isByteSwap
A flag that whether should byte swap.

16.19.2.9 isPcsContinuous

`volatile bool _lpspi_master_edma_handle::isPcsContinuous`
Is PCS continuous in transfer.

16.19.2.10 isThereExtraRxBytes

`volatile bool _lpspi_master_edma_handle::isThereExtraRxBytes`
Is there extra RX byte.

16.19.2.11 lpspiSoftwareTCD

`edma_tcd_t _lpspi_master_edma_handle::lpspiSoftwareTCD[3]`
SoftwareTCD, internal used

16.19.2.12 nbytes

`uint8_t _lpspi_master_edma_handle::nbytes`
eDMA minor byte transfer count initially configured.

16.19.2.13 readRegRemainingTimes

`volatile uint32_t _lpspi_master_edma_handle::readRegRemainingTimes`
Read RDR register remaining times.

16.19.2.14 rxBuffIfNull

`uint32_t _lpspi_master_edma_handle::rxBuffIfNull`
Used if there is not rxData for DMA purpose.

16.19.2.15 rxData

`uint8_t* volatile _lpspi_master_edma_handle::rxData`
Receive buffer.

16.19.2.16 rxRemainingByteCount

`volatile size_t _lpspi_master_edma_handle::rxRemainingByteCount`
Number of bytes remaining to receive.

16.19.2.17 rxWatermark

`volatile uint8_t _lpspi_master_edma_handle::rxWatermark`
Rx watermark.

16.19.2.18 state

`volatile uint8_t _lpspi_master_edma_handle::state`
LPSPi transfer state , `_lpspi_transfer_state`.

16.19.2.19 totalByteCount

`uint32_t _lpspi_master_edma_handle::totalByteCount`
Number of transfer bytes

16.19.2.20 transmitCommand

`uint32_t _lpspi_master_edma_handle::transmitCommand`
Used to write TCR for DMA purpose.

16.19.2.21 txBuffIfNull

```
uint32_t _lpspi_master_edma_handle::txBuffIfNull
```

Used if there is not txData for DMA purpose.

16.19.2.22 txData

```
uint8_t* volatile _lpspi_master_edma_handle::txData
```

Send buffer.

16.19.2.23 txRemainingByteCount

```
volatile size_t _lpspi_master_edma_handle::txRemainingByteCount
```

Number of bytes remaining to send.

16.19.2.24 userData

```
void* _lpspi_master_edma_handle::userData
```

Callback user data.

16.19.2.25 writeRegRemainingTimes

```
volatile uint32_t _lpspi_master_edma_handle::writeRegRemainingTimes
```

Write TDR register remaining times.

The documentation for this struct was generated from the following file:

- fsl_lpspi_edma.h

16.20 _lpspi_master_edma_private_handle Struct Reference

Structure definition for `dsapi_master_edma_private_handle_t`. The structure is private.

```
#include <dsapi.h>
```

Public Attributes

- `LPSPI_Type * base`
- `lpspi_master_edma_handle_t * handle`

16.20.1 Detailed Description

Structure definition for `dsapi_master_edma_private_handle_t`. The structure is private.

16.20.2 Member Data Documentation**16.20.2.1 base**

```
LPSPI_Type* _lpspi_master_edma_private_handle::base
```

LPSPI peripheral base address.

16.20.2.2 handle

```
lpspi_master_edma_handle_t* _lpspi_master_edma_private_handle::handle
```

`lpspi_master_edma_handle_t` handle

The documentation for this struct was generated from the following file:

- cortex-m7/cpu/MIMXRT10xx/include/dsapi.h

16.21 `_lpspi_master_handle` Struct Reference

LPSPi master transfer handle structure used for transactional API.

```
#include <fsl_lpspi.h>
```

Public Attributes

16.21.1 Detailed Description

LPSPi master transfer handle structure used for transactional API.

16.21.2 Member Data Documentation

16.21.2.1 `bytesEachRead`

```
volatile uint8_t _lpspi_master_handle::bytesEachRead
```

Bytes for each read RDR.

16.21.2.2 `bytesEachWrite`

```
volatile uint8_t _lpspi_master_handle::bytesEachWrite
```

Bytes for each write TDR.

16.21.2.3 `bytesPerFrame`

```
volatile uint16_t _lpspi_master_handle::bytesPerFrame
```

Number of bytes in each frame

16.21.2.4 `callback`

```
lpspi_master_transfer_callback_t _lpspi_master_handle::callback
```

Completion callback.

16.21.2.5 `fifoSize`

```
volatile uint8_t _lpspi_master_handle::fifoSize
```

FIFO dataSize.

16.21.2.6 isByteSwap

```
volatile bool _lpspi_master_handle::isByteSwap
```

A flag that whether should byte swap.

16.21.2.7 isPcsContinuous

```
volatile bool _lpspi_master_handle::isPcsContinuous
```

Is PCS continuous in transfer.

16.21.2.8 isTxMask

```
volatile bool _lpspi_master_handle::isTxMask
```

A flag that whether TCR[TXMSK] is set.

16.21.2.9 readRegRemainingTimes

```
volatile uint32_t _lpspi_master_handle::readRegRemainingTimes
```

Read RDR register remaining times.

16.21.2.10 rxData

```
uint8_t* volatile _lpspi_master_handle::rxData
```

Receive buffer.

16.21.2.11 rxRemainingByteCount

```
volatile size_t _lpspi_master_handle::rxRemainingByteCount
```

Number of bytes remaining to receive.

16.21.2.12 rxWatermark

```
volatile uint8_t _lpspi_master_handle::rxWatermark
```

Rx watermark.

16.21.2.13 state

```
volatile uint8_t _lpspi_master_handle::state
```

LPSPi transfer state , _lpspi_transfer_state.

16.21.2.14 totalByteCount

```
uint32_t _lpspi_master_handle::totalByteCount
```

Number of transfer bytes

16.21.2.15 txBuffIfNull

```
uint32_t _lpspi_master_handle::txBuffIfNull
```

Used if the txData is NULL.

16.21.2.16 txData

```
uint8_t* volatile _lpspi_master_handle::txData
```

Send buffer.

16.21.2.17 txRemainingByteCount

```
volatile size_t _lpspi_master_handle::txRemainingByteCount
```

Number of bytes remaining to send.

16.21.2.18 userData

`void* _lpspi_master_handle::userData`
Callback user data.

16.21.2.19 writeRegRemainingTimes

`volatile uint32_t _lpspi_master_handle::writeRegRemainingTimes`
Write TDR register remaining times.

16.21.2.20 writeTcrInIsr

`volatile bool _lpspi_master_handle::writeTcrInIsr`
A flag that whether should write TCR in ISR.
The documentation for this struct was generated from the following file:

- `fsl_lpspi.h`

16.22 _lpspi_slave_config Struct Reference

LPSPi slave configuration structure.
`#include <fsl_lpspi.h>`

Public Attributes

- `uint32_t bitsPerFrame`
- `lpspi_clock_polarity_t cpol`
- `lpspi_clock_phase_t cpha`
- `lpspi_shift_direction_t direction`
- `lpspi_which_pcs_t whichPcs`
- `lpspi_pcs_polarity_config_t pcsActiveHighOrLow`
- `lpspi_pin_config_t pinCfg`
- `lpspi_data_out_config_t dataOutConfig`

16.22.1 Detailed Description

LPSPi slave configuration structure.

16.22.2 Member Data Documentation

16.22.2.1 bitsPerFrame

`uint32_t _lpspi_slave_config::bitsPerFrame`
Bits per frame, minimum 8, maximum 4096.

16.22.2.2 cpha

`lpspi_clock_phase_t _lpspi_slave_config::cpha`
Clock phase.

16.22.2.3 cpol

`lpspi_clock_polarity_t _lpspi_slave_config::cpol`
Clock polarity.

16.22.2.4 dataOutConfig

`lpspi_data_out_config_t _lpspi_slave_config::dataOutConfig`
Configures if the output data is tristated between accesses (LPSPi_PCS is negated).

16.22.2.5 direction

`lpspi_shift_direction_t _lpspi_slave_config::direction`
MSB or LSB data shift direction.

16.22.2.6 pcsActiveHighOrLow

`lpspi_pcs_polarity_config_t _lpspi_slave_config::pcsActiveHighOrLow`
Desired PCS active high or low

16.22.2.7 pinCfg

`lpspi_pin_config_t _lpspi_slave_config::pinCfg`
Configures which pins are used for input and output data during single bit transfers.

16.22.2.8 whichPcs

`lpspi_which_pcs_t _lpspi_slave_config::whichPcs`
Desired Peripheral Chip Select (pcs)
The documentation for this struct was generated from the following file:

- `fsl_lpspi.h`

16.23 _lpspi_slave_edma_handle Struct Reference

LPSPi slave eDMA transfer handle structure used for transactional API.

16.23.1 Detailed Description

LPSPi slave eDMA transfer handle structure used for transactional API.

16.23.2 Member Data Documentation

16.23.2.1 bytesEachRead

`volatile uint8_t _lpspi_slave_edma_handle::bytesEachRead`
Bytes for each read RDR.

16.23.2.2 bytesEachWrite

`volatile uint8_t _lpspi_slave_edma_handle::bytesEachWrite`
Bytes for each write TDR.

16.23.2.3 bytesLastRead

`volatile uint8_t _lpspi_slave_edma_handle::bytesLastRead`
Bytes for last read RDR.

16.23.2.4 callback

`lpspi_slave_edma_transfer_callback_t _lpspi_slave_edma_handle::callback`
Completion callback.

16.23.2.5 edmaRxRegToRxDataHandle

`edma_handle_t* _lpspi_slave_edma_handle::edmaRxRegToRxDataHandle`
`edma_handle_t` handle point used for RxReg to RxData buff

16.23.2.6 edmaTxDataToTxRegHandle

`edma_handle_t* _lpspi_slave_edma_handle::edmaTxDataToTxRegHandle`
`edma_handle_t` handle point used for TxData to TxReg

16.23.2.7 errorCount

`uint32_t _lpspi_slave_edma_handle::errorCount`
Error count for slave transfer.

16.23.2.8 fifoSize

`volatile uint8_t _lpspi_slave_edma_handle::fifoSize`
FIFO dataSize.

16.23.2.9 isByteSwap

`volatile bool _lpspi_slave_edma_handle::isByteSwap`
A flag that whether should byte swap.

16.23.2.10 isThereExtraRxBytes

`volatile bool _lpspi_slave_edma_handle::isThereExtraRxBytes`
Is there extra RX byte.

16.23.2.11 lpspiSoftwareTCD

`edma_tcd_t _lpspi_slave_edma_handle::lpspiSoftwareTCD[2]`
SoftwareTCD, internal used

16.23.2.12 nbytes

`uint8_t _lpspi_slave_edma_handle::nbytes`
eDMA minor byte transfer count initially configured.

16.23.2.13 readRegRemainingTimes

`volatile uint32_t _lpspi_slave_edma_handle::readRegRemainingTimes`
Read RDR register remaining times.

16.23.2.14 rxBuffIfNull

`uint32_t _lpspi_slave_edma_handle::rxBuffIfNull`
Used if there is not rxData for DMA purpose.

16.23.2.15 rxData

`uint8_t* volatile _lpspi_slave_edma_handle::rxData`
Receive buffer.

16.23.2.16 rxRemainingByteCount

`volatile size_t _lpspi_slave_edma_handle::rxRemainingByteCount`
Number of bytes remaining to receive.

16.23.2.17 rxWatermark

`volatile uint8_t _lpspi_slave_edma_handle::rxWatermark`
Rx watermark.

16.23.2.18 state

`volatile uint8_t _lpspi_slave_edma_handle::state`
LPSPi transfer state.

16.23.2.19 totalByteCount

`uint32_t _lpspi_slave_edma_handle::totalByteCount`
Number of transfer bytes

16.23.2.20 txBuffIfNull

`uint32_t _lpspi_slave_edma_handle::txBuffIfNull`
Used if there is not txData for DMA purpose.

16.23.2.21 txData

`uint8_t* volatile _lpspi_slave_edma_handle::txData`
Send buffer.

16.23.2.22 txRemainingByteCount

`volatile size_t _lpspi_slave_edma_handle::txRemainingByteCount`
Number of bytes remaining to send.

16.23.2.23 userData

`void* _lpspi_slave_edma_handle::userData`
Callback user data.

16.23.2.24 writeRegRemainingTimes

`volatile uint32_t _lpspi_slave_edma_handle::writeRegRemainingTimes`
Write TDR register remaining times.

The documentation for this struct was generated from the following file:

- `fsl_lpspi_edma.h`

16.24 _lpspi_slave_handle Struct Reference

LPSPi slave transfer handle structure used for transactional API.

```
#include <fsl_lpspi.h>
```

Public Attributes

16.24.1 Detailed Description

LPSPi slave transfer handle structure used for transactional API.

16.24.2 Member Data Documentation

16.24.2.1 bytesEachRead

```
volatile uint8_t _lpspi_slave_handle::bytesEachRead
```

Bytes for each read RDR.

16.24.2.2 bytesEachWrite

```
volatile uint8_t _lpspi_slave_handle::bytesEachWrite
```

Bytes for each write TDR.

16.24.2.3 callback

```
lpspi_slave_transfer_callback_t _lpspi_slave_handle::callback
```

Completion callback.

16.24.2.4 errorCount

```
volatile uint32_t _lpspi_slave_handle::errorCount
```

Error count for slave transfer.

16.24.2.5 fifoSize

```
volatile uint8_t _lpspi_slave_handle::fifoSize
```

FIFO dataSize.

16.24.2.6 isByteSwap

```
volatile bool _lpspi_slave_handle::isByteSwap
```

A flag that whether should byte swap.

16.24.2.7 readRegRemainingTimes

`volatile uint32_t _lpspi_slave_handle::readRegRemainingTimes`
Read RDR register remaining times.

16.24.2.8 rxData

`uint8_t* volatile _lpspi_slave_handle::rxData`
Receive buffer.

16.24.2.9 rxRemainingByteCount

`volatile size_t _lpspi_slave_handle::rxRemainingByteCount`
Number of bytes remaining to receive.

16.24.2.10 rxWatermark

`volatile uint8_t _lpspi_slave_handle::rxWatermark`
Rx watermark.

16.24.2.11 state

`volatile uint8_t _lpspi_slave_handle::state`
LPSPI transfer state , `_lpspi_transfer_state`.

16.24.2.12 totalByteCount

`uint32_t _lpspi_slave_handle::totalByteCount`
Number of transfer bytes

16.24.2.13 txData

`uint8_t* volatile _lpspi_slave_handle::txData`
Send buffer.

16.24.2.14 txRemainingByteCount

`volatile size_t _lpspi_slave_handle::txRemainingByteCount`
Number of bytes remaining to send.

16.24.2.15 userData

`void* _lpspi_slave_handle::userData`
Callback user data.

16.24.2.16 writeRegRemainingTimes

`volatile uint32_t _lpspi_slave_handle::writeRegRemainingTimes`
Write TDR register remaining times.
The documentation for this struct was generated from the following file:

- `fsl_lpspi.h`

16.25 _lpspi_transfer Struct Reference

LPSPI master/slave transfer structure.
`#include <fsl_lpspi.h>`

Public Attributes

- uint8_t * [txData](#)
- uint8_t * [rxData](#)
- volatile size_t [dataSize](#)
- uint32_t [configFlags](#)

16.25.1 Detailed Description

LPSPi master/slave transfer structure.

16.25.2 Member Data Documentation

16.25.2.1 configFlags

uint32_t _lpspi_transfer::configFlags

Transfer transfer configuration flags. Set from _lpspi_transfer_config_flag_for_master if the transfer is used for master or _lpspi_transfer_config_flag_for_slave enumeration if the transfer is used for slave.

16.25.2.2 dataSize

volatile size_t _lpspi_transfer::dataSize

Transfer bytes.

16.25.2.3 rxData

uint8_t* _lpspi_transfer::rxData

Receive buffer.

16.25.2.4 txData

uint8_t* _lpspi_transfer::txData

Send buffer.

The documentation for this struct was generated from the following file:

- fsl_lpspi.h

16.26 _lut_sequence Struct Reference

FlexSPI LUT Sequence structure.

```
#include <evkmimxrt1060_flexspi_nor_config.h>
```

Public Attributes

- uint8_t **seqNum**
Sequence Number, valid number: 1-16.
- uint8_t **seqId**
Sequence Index, valid number: 0-15.

16.26.1 Detailed Description

FlexSPI LUT Sequence structure.

The documentation for this struct was generated from the following file:

- evkmimxrt1060_flexspi_nor_config.h

16.27 _PinVector Class Reference

GPIO Pin Vector Base Class.

#include <cpu_pins.h>

Inherited by [PinVector< 4 >](#), [PinVector< 4 >](#), [PinVector< n >](#), and [PinVector< n >](#).

Public Member Functions

- `uint32_t operator= (uint32_t val)`
Assign a value to the [_PinVector](#) Bus.
- `PinIO operator[] (int idx)`
Access the [PinIO](#) for a specific bit position in the [_PinVector](#).
- `void config (uint32_t idx, PinIO cfg)`
Set the [PinIO](#) that will be used for a given bit position in the [_PinVector](#).
- `void config (PinIO *pinCfgs, uint32_t count)`
Configure the [_PinVector](#) based on an array of PinIOs. The index of the [PinIO](#) in the configuration array will determine the bit position within the [_PinVector](#) that that [PinIO](#) represents.
- `operator uint32_t () const`
Read the line state of the [_PinVector](#) bus.

16.27.1 Detailed Description

GPIO Pin Vector Base Class.

This class is for building semi-parallel buses using GPIO pins. It facilitates driving a numeric value across a parallel bus of GPIO pins. It should not be confused with a true parallel bus, as each individual pin in the bus is modified sequentially/independently during a bus assignment.

Parameters

<code>_Pin::len</code>	Number of pins managed by the _PinVector .

16.27.2 Member Function Documentation

16.27.2.1 config() [1/2]

```
void _PinVector::config (
    PinIO * pinCfgs,
    uint32_t count)
```

Configure the [_PinVector](#) based on an array of PinIOs. The index of the [PinIO](#) in the configuration array will determine the bit position within the [_PinVector](#) that that [PinIO](#) represents.

Parameters

<code>pinCfgs</code>	The configuration to be used.
<code>count</code>	The number of PinIOs in the configuration array to be used.

16.27.2.2 config() [2/2]

```
void _PinVector::config (
    uint32_t idx,
    PinIO cfg)
```

Set the [PinIO](#) that will be used for a given bit position in the [_PinVector](#).

Parameters

<i>idx</i>	The bit position to be configured.
<i>cfg</i>	The PinIO that bit position will represent.

16.27.2.3 operator uint32_t()

`_PinVector::operator uint32_t () const`
 Read the line state of the [_PinVector](#) bus.

Returns

The current bus value as read from the line state.

16.27.2.4 operator=()

`uint32_t _PinVector::operator= (`
 `uint32_t val)`
 Assign a value to the [_PinVector](#) Bus.

Parameters

<i>val</i>	The value to assign to the bus.

Returns

The value driven on the bus.

16.27.2.5 operator[]()

`PinIO _PinVector::operator[] (`
 `int idx)`
 Access the [PinIO](#) for a specific bit position in the [_PinVector](#).

Parameters

<i>idx</i>	The bit index to access in the _PinVector .

Returns

The [PinIO](#) for the given bit position.

The documentation for this class was generated from the following files:

- cortex-m7/cpu/SAME70/include/cpu_pins.h
- cortex-m7/cpu/MIMXRT10xx/include/cpu_pins.h

16.28 _pit_config Struct Reference

PIT configuration structure.
`#include <fsl_pit.h>`

Public Attributes

- bool [enableRunInDebug](#)

16.28.1 Detailed Description

PIT configuration structure.

This structure holds the configuration settings for the PIT peripheral. To initialize this structure to reasonable defaults, call the `PIT_GetDefaultConfig()` function and pass a pointer to your config structure instance.

The configuration structure can be made constant so it resides in flash.

16.28.2 Member Data Documentation

16.28.2.1 enableRunInDebug

```
bool _pit_config::enableRunInDebug
```

true: Timers run in debug mode; false: Timers stop in debug mode

The documentation for this struct was generated from the following file:

- `fsl_pit.h`

16.29 _qtmr_config Struct Reference

Quad Timer config structure.

```
#include <fsl_qtmr.h>
```

Public Attributes

- [qtmr_primary_count_source_t](#) primarySource
- [qtmr_input_source_t](#) secondarySource
- bool [enableMasterMode](#)
- bool [enableExternalForce](#)
- [uint8_t](#) [faultFilterCount](#)
- [uint8_t](#) [faultFilterPeriod](#)
- [qtmr_debug_action_t](#) debugMode

16.29.1 Detailed Description

Quad Timer config structure.

This structure holds the configuration settings for the Quad Timer peripheral. To initialize this structure to reasonable defaults, call the [QTMR_GetDefaultConfig\(\)](#) function and pass a pointer to your config structure instance.

The config struct can be made const so it resides in flash

16.29.2 Member Data Documentation

16.29.2.1 debugMode

```
qtmr_debug_action_t _qtmr_config::debugMode
```

Operation in Debug mode

16.29.2.2 enableExternalForce

```
bool _qtmr_config::enableExternalForce
```

true: Compare from another counter force state of OFLAG signal false: OFLAG controlled by local counter

16.29.2.3 enableMasterMode

```
bool _qtmr_config::enableMasterMode
```

true: Broadcast compare function output to other counters; false no broadcast

16.29.2.4 faultFilterCount

```
uint8_t _qtmr_config::faultFilterCount
```

Fault filter count

16.29.2.5 faultFilterPeriod

`uint8_t _qtmr_config::faultFilterPeriod`
Fault filter period;value of 0 will bypass the filter

16.29.2.6 primarySource

`qtmr_primary_count_source_t _qtmr_config::primarySource`
Specify the primary count source

16.29.2.7 secondarySource

`qtmr_input_source_t _qtmr_config::secondarySource`
Specify the secondary count source
The documentation for this struct was generated from the following file:

- [fsl_qtmr.h](#)

16.30 _tempmon_config Struct Reference

TEMPMON temperature structure.
`#include <fsl_tempmon.h>`

Public Attributes

- `uint16_t` [frequency](#)
- `int8_t` [highAlarmTemp](#)
- `int8_t` [panicAlarmTemp](#)
- `int8_t` [lowAlarmTemp](#)

16.30.1 Detailed Description

TEMPMON temperature structure.

16.30.2 Member Data Documentation

16.30.2.1 frequency

`uint16_t _tempmon_config::frequency`
The temperature measure frequency.

16.30.2.2 highAlarmTemp

`int8_t _tempmon_config::highAlarmTemp`
The high alarm temperature.

16.30.2.3 lowAlarmTemp

`int8_t _tempmon_config::lowAlarmTemp`
The low alarm temperature.

16.30.2.4 panicAlarmTemp

`int8_t _tempmon_config::panicAlarmTemp`
The panic alarm temperature.
The documentation for this struct was generated from the following file:

- [fsl_tempmon.h](#)

16.31 AcmeServletObject Class Reference

Main ACME Client Class.

#include <acmeRFC8555Servlet.h>

Inherits [DiagItemClass](#), and [WebClientServlet](#).

Inherited by [BuyPassAcmeServletObject](#), and [LetsEncryptAcmeServletObject](#).

Public Member Functions

- void [Delete_Everything_Restart](#) ()
Re-request the ACME certificate.
- void [SetDiag](#) (bool v)
Turn on diganostic printf messages to the console.
- [NBString](#) [GetGlobalStateString](#) ()
Returns the detailed state of the ACME process.
- [NBString](#) [GetStateString](#) ()
Returns the specific state condition of the acmeservlet.
- const char * [GetStateCC](#) ()
Returns the specific state condition of the acmeservlet.
- [AcmeServletObject](#) (const char *pUrlDir)
ACME Client Constructor.

Friends

- [CertGenData](#) * [GetDataForCertGen](#) ()
A function to be overridden to pass certificate details to the certificate generator.

16.31.1 Detailed Description

Main ACME Client Class.

16.31.2 Constructor & Destructor Documentation

16.31.2.1 AcmeServletObject()

```
AcmeServletObject::AcmeServletObject (
    const char * pUrlDir) [inline]
```

ACME Client Constructor.

Parameters

<i>pUrlDir</i>	URL for the ACME API directory endpoint (required, i.e. https://acme.example.com/dir)

16.31.3 Member Function Documentation

16.31.3.1 Delete_Everything_Restart()

```
void AcmeServletObject::Delete_Everything_Restart ()
```

Re-request the ACME certificate.

Once the system has loaded valid keys and certificate It sleeps and does not do much. If you want to change the names, or want to re-run the ACME protocol for debugging/diagnostic purposes, this function erases all keys, the certificate, and restarts the certificate issuing process.

16.31.3.2 GetStateCC()

```
const char * AcmeServletObject::GetStateCC ()
```

Returns the specific state condition of the acmeservlet.

16.31.4 Friends And Related Symbol Documentation

16.31.4.1 GetDataForCertGen

```
CertGenData * GetDataForCertGen () [friend]
```

A function to be overridden to pass certificate details to the certificate generator.

The library provides this function as a weak reference. The values returned by this weak reference are likely wrong for any real application and the user should provide their own function. Applicable for both self signed and ACME certificates generated onboard.

Returns

pointer to a [CertGenData](#) struct

The documentation for this class was generated from the following file:

- acmeRFC8555Servlet.h

16.32 aes_context Struct Reference

AES context structure.

```
#include <aes.h>
```

Public Attributes

- unsigned long [erk](#) [64]
- unsigned long [drk](#) [64]
- int [nr](#)

16.32.1 Detailed Description

AES context structure.

16.32.2 Member Data Documentation

16.32.2.1 drk

```
unsigned long aes_context::drk[64]
```

decryption round keys

16.32.2.2 erk

```
unsigned long aes_context::erk[64]
```

encryption round keys

16.32.2.3 nr

```
int aes_context::nr
```

number of rounds

The documentation for this struct was generated from the following file:

- aes.h

16.33 ARM_MPU_Region_t Struct Reference

```
#include <mpu_armv7.h>
```

Public Attributes

- uint32_t **RBAR**
The region base address register value (RBAR)
- uint32_t **RASR**
The region attribute and size register value (RASR)

16.33.1 Detailed Description

Struct for a single MPU Region

The documentation for this struct was generated from the following file:

- mpu_armv7.h

16.34 ARP Struct Reference

Address Resolution Protocol packet structure.

```
#include <arp.h>
```

Public Attributes

- beuint16_t [hard_Type](#)
Hardware type (1 for Ethernet)
- beuint16_t [prot_Type](#)
Protocol type (0x0800 for IPv4)
- uint8_t [hard_size](#)
Hardware address length (6 for MAC)
- uint8_t [prot_size](#)
Protocol address length (4 for IPv4)
- beuint16_t [op_code](#)
Operation: 1=Request, 2=Reply.
- [MACADR sender_phy](#)
Sender MAC address.
- [IPADDR4 sender_ip](#)
Sender IP address.
- [MACADR target_phy](#)
Target MAC address.
- [IPADDR4 target_ip](#)
Target IP address.

16.34.1 Detailed Description

Address Resolution Protocol packet structure.

Defines the structure of an [ARP](#) packet as transmitted on Ethernet networks. This structure matches the [ARP](#) packet format defined in RFC 826.

[ARP](#) packets are used to resolve IP addresses to MAC addresses on local networks. The packet contains both the sender's and target's IP and MAC addresses, along with operation type.

The documentation for this struct was generated from the following file:

- arp.h

16.35 BBI2C Class Reference

[I2C](#) Peripheral Class.

```
#include <bb_i2c.h>
```

Public Types

- enum [Result_t](#) {
[I2C_RES_ACK](#) , [I2C_RES_NACK](#) , [I2C_RES_ARB_LST](#) , [I2C_RES_BUSY](#) ,
[I2C_RES_ARG](#) , [I2C_RES_IN_PROGRESS](#) , [I2C_RES_ERR](#) }

Public Member Functions

- [BBI2C](#) ([PinIO](#) scl, [PinIO](#) sda)
Constructor for the [I2C](#) peripheral module.
- void [setup](#) (uint32_t maxBusSpeed)
Setup the [I2C](#) peripheral interface.
- void [resetBus](#) ()
Reset the [I2C](#) bus.
- void [setNumAddressBytes](#) (uint8_t numAddressBytes=1)
Specify the register address size for a read or write transaction. A number of bytes, from 0 to 3, can be sent to specify an address up to 24-bit (3 bytes): 0 = none, 1 = 8-bits, 2 = 16-bits, 3 = 24-bits.
- virtual [Result_t](#) [writeReg8](#) (uint8_t devAddr, uint32_t reg, uint8_t data)
Write an 8-bit value to a [I2C](#) slave device register.
- virtual [Result_t](#) [readReg8](#) (uint8_t devAddr, uint32_t reg, uint8_t &data)
Read an 8-bit value form an [I2C](#) slave device register.
- virtual [Result_t](#) [writeRegN](#) (uint8_t devAddr, uint32_t reg, uint8_t *buf, uint32_t blen)
Write a number of 8-bit values to an [I2C](#) slave to the specified register address.
- virtual [Result_t](#) [readRegN](#) (uint8_t devAddr, uint32_t reg, uint8_t *buf, uint32_t blen)
Read a number of 8-bit values from an [I2C](#) slave at the specified register address.
- void [SetMaxBusDelay](#) (uint16_t milliseconds)
Set the maximum duration that the bus is allowed to be in use without being clocked before being forcibly reset.

Friends

- class [WireIntf](#)

16.35.1 Detailed Description

[I2C](#) Peripheral Class.

For [I2C](#) communication, you can choose the [WireIntf](#) class, or the [I2C](#) class. The [WireIntf](#) class is simpler to use, while the [I2C](#) class provides more low level control.

Note that the system automatically instantiates [I2C](#) and [WireIntf](#) objects for each of the [I2C](#) peripheral modules. The [WireIntf](#) objects can be accessed with: Wire, Wire1 and Wire2. The [I2C](#) objects can be accessed with [I2C](#)[0], [I2C](#)[1] and [I2C](#)[2].

16.35.2 Member Enumeration Documentation

16.35.2.1 Result_t

enum [BBI2C::Result_t](#)

Enumerator

I2C_RES_ACK	Acknowledged.
I2C_RES_NACK	Not acknowledged.
I2C_RES_ARB_LST	Arbitration listening.
I2C_RES_BUSY	Bus is busy.
I2C_RES_ARG	Bad argument.
I2C_RES_IN_PROGRESS	Another transaction is currently in progress.
I2C_RES_ERR	Unknown Error.

16.35.3 Constructor & Destructor Documentation

16.35.3.1 BBI2C()

```
BBI2C::BBI2C (
    PinIO scl,
    PinIO sda)
```

Constructor for the [I2C](#) peripheral module.

Parameters

<i>scl</i>	
<i>sda</i>	

16.35.4 Member Function Documentation

16.35.4.1 readReg8()

```
virtual Result_t BBI2C::readReg8 (
    uint8_t devAddr,
    uint32_t reg,
    uint8_t & data) [virtual]
```

Read an 8-bit value form an [I2C](#) slave device register.

Parameters

<i>devAddr</i>	Address of I2C device
<i>reg</i>	Register address to read
<i>data</i>	Reference to variable in which to store the register data

Returns

[Result_t](#)

16.35.4.2 readRegN()

```
virtual Result_t BBI2C::readRegN (
    uint8_t devAddr,
    uint32_t reg,
    uint8_t * buf,
    uint32_t blen) [virtual]
```

Read a number of 8-bit values from an [I2C](#) slave at the specified register address.

Parameters

<i>devAddr</i>	Address of I2C device
<i>reg</i>	Register address to read
<i>*buf</i>	Pointer to buffer to store received data
<i>blen</i>	Number of bytes to read

Returns

[Result_t](#)

16.35.4.3 SetMaxBusDelay()

```
void BBI2C::SetMaxBusDelay (
    uint16_t milliseconds)
```

Set the maximum duration that the bus is allowed to be in use without being clocked before being forcibly reset.

Parameters

<i>milliseconds</i>	Maximum number of milliseconds before triggering a bus reset

16.35.4.4 setNumAddressBytes()

```
void BBI2C::setNumAddressBytes (
    uint8_t numAddressBytes = 1) [inline]
```

Specify the register address size for a read or write transaction. A number of bytes, from 0 to 3, can be sent to specify an address up to 24-bit (3 bytes): 0 = none, 1 = 8-bits, 2 = 16-bits, 3 = 24-bits.

If you are using a single [I2C](#) device, or all devices use the same address size, this function only needs to be called once. If you have multiple [I2C](#) devices with different address/register bit sizes, then this function should be called before each read/write operation for each different device.

Parameters

<i>numAddressBytes</i>	The number of address bytes to send: 0 - 3. The default value is 1 byte.

16.35.4.5 setup()

```
void BBI2C::setup (
    uint32_t maxBusSpeed)
```

Setup the [I2C](#) peripheral interface.

Parameters

<i>maxBusSpeed</i>	Target bus speed. If the specified speed cannot be achieved, a lower bus speed may be enabled.

16.35.4.6 writeReg8()

```
virtual Result_t BBI2C::writeReg8 (
    uint8_t devAddr,
    uint32_t reg,
    uint8_t data) [virtual]
```

Write an 8-bit value to a [I2C](#) slave device register.

Parameters

<i>devAddr</i>	Address of I2C device
<i>reg</i>	Register address to write
<i>data</i>	Data to write to register

Returns

[Result_t](#)

16.35.4.7 writeRegN()

```
virtual Result_t BBI2C::writeRegN (
    uint8_t devAddr,
    uint32_t reg,
    uint8_t * buf,
    uint32_t blen) [virtual]
```

Write a number of 8-bit values to an [I2C](#) slave to the specified register address.

Executing this function will send the following: a start bit, the slave device address and read/write bit, the 8-bit data bytes, and finally a stop bit. Note that the address is not incremented with each 8-bit data value.

Parameters

<i>devAddr</i>	Address of I2C device
<i>reg</i>	Register address to write
<i>*buf</i>	Pointer to buffer containing data to write
<i>blen</i>	Number of bytes to write

Returns

[Result_t](#)

The documentation for this class was generated from the following file:

16.36 DHCP::BlockAllocator Class Reference

Basic allocator that handles multiple leases in a contiguous IP block.

```
#include <dhcpd.h>
```

Inherits [DHCP::LeaseAllocator](#).

Inherited by [DHCP::MacPrefixAllocator](#), and [MyModAlloc](#).

16.36.1 Detailed Description

Basic allocator that handles multiple leases in a contiguous IP block.

The documentation for this class was generated from the following file:

- [dhcpd.h](#)

16.37 buffer_list Class Reference

Doubly-linked list management for buffers.

```
#include <buffers.h>
```

Public Member Functions

- void [InsertHead](#) ([PoolPtr](#) buffer)
Insert buffer at the head of the list.
- void [InsertTail](#) ([PoolPtr](#) buffer)
Insert buffer at the tail of the list.
- void [InsertBefore](#) ([PoolPtr](#) buf2insert, [PoolPtr](#) b4buffer)
Insert buffer before specified buffer in list.
- void [InsertAfter](#) ([PoolPtr](#) buf2insert, [PoolPtr](#) after_buffer)
Insert buffer after specified buffer in list.
- void [Remove](#) ([PoolPtr](#) buffer)
Remove specified buffer from the list.
- [PoolPtr](#) [RemoveHead](#) ()
Remove and return the head buffer.
- [PoolPtr](#) [RemoveTail](#) ()
Remove and return the tail buffer.
- [uint16_t](#) [GetCount](#) ()
Get current number of buffers in the list.

Public Attributes

- [PoolPtr](#) **m_Head**
First buffer in the list.
- [PoolPtr](#) **m_Tail**
Last buffer in the list.
- `uint16_t` **m_wElements**
Current number of elements in list.

16.37.1 Detailed Description

Doubly-linked list management for buffers.

Provides efficient insertion, removal, and traversal operations for managing lists of [pool_buffer](#) structures. Used internally by the buffer system and FIFO storage classes.

16.37.2 Member Function Documentation**16.37.2.1 GetCount()**

```
uint16_t buffer_list::GetCount () [inline]
```

Get current number of buffers in the list.

Returns

Number of buffers

16.37.2.2 InsertAfter()

```
void buffer_list::InsertAfter (
    PoolPtr buf2insert,
    PoolPtr after_buffer)
```

Insert buffer after specified buffer in list.

Parameters

<i>buf2insert</i>	Buffer to insert
<i>after_buffer</i>	Buffer to insert after

16.37.2.3 InsertBefore()

```
void buffer_list::InsertBefore (
    PoolPtr buf2insert,
    PoolPtr b4buffer)
```

Insert buffer before specified buffer in list.

Parameters

<i>buf2insert</i>	Buffer to insert
<i>b4buffer</i>	Buffer to insert before

16.37.2.4 InsertHead()

```
void buffer_list::InsertHead (
    PoolPtr buffer)
```

Insert buffer at the head of the list.

Parameters

<i>buffer</i>	Buffer to insert

16.37.2.5 InsertTail()

```
void buffer_list::InsertTail (  
    PoolPtr buffer)
```

Insert buffer at the tail of the list.

Parameters

<i>buffer</i>	Buffer to insert

16.37.2.6 Remove()

```
void buffer_list::Remove (  
    PoolPtr buffer)
```

Remove specified buffer from the list.

Parameters

<i>buffer</i>	Buffer to remove

16.37.2.7 RemoveHead()

```
PoolPtr buffer_list::RemoveHead ()
```

Remove and return the head buffer.

Returns

Head buffer, or NULL if list is empty

16.37.2.8 RemoveTail()

```
PoolPtr buffer_list::RemoveTail ()
```

Remove and return the tail buffer.

Returns

Tail buffer, or NULL if list is empty

16.39 BuyPassAcmeServletObject Class Reference

ACME Client for BuyPass.

#include <acmeRFC8555Servlet.h>

Inherits [AcmeServletObject](#).

Public Member Functions

- **BuyPassAcmeServletObject** ()
Enable the BuyPass ACME client.

Public Member Functions inherited from [AcmeServletObject](#)

- void [Delete_Everything_Restart](#) ()
Re-request the ACME certificate.
- void **SetDiag** (bool v)
Turn on diagnostic printf messages to the console.
- [NBString](#) **GetGlobalStateString** ()
Returns the detailed state of the ACME process.
- [NBString](#) **GetStateString** ()
Returns the specific state condition of the acmeservlet.
- const char * [GetStateCC](#) ()
Returns the specific state condition of the acmeservlet.
- [AcmeServletObject](#) (const char *pUrlDir)
ACME Client Constructor.

16.39.1 Detailed Description

ACME Client for BuyPass.

The documentation for this class was generated from the following file:

- acmeRFC8555Servlet.h

16.40 CallbackFunctionPageHandler Class Reference

Implements the [HtmlPageHandler](#) class as a function pointer callback for GET requests.

#include <http.h>

Inherits [HtmlPageHandler](#).

Public Member Functions

- virtual int [ProcessRaw](#) (int sock, [HTTP_Request](#) &pdt)
Pure virtual method that must be implemented to process HTTP requests.
- [CallbackFunctionPageHandler](#) (const char *pUrl, [http_gethandlerfunc](#) *pFunction, [HTTP_RequestTypes](#) reqType=[tGet](#), int accessGroup=0, bool beforeFiles=false)
Constructor for HTTP GET callback function.
- [CallbackFunctionPageHandler](#) (const char *pUrl, [http_gethandlerfunc](#) *pFunction, [http_matchhandlerfunc](#) *pMatchFunction, [HTTP_RequestTypes](#) reqType=[tGet](#), int accessGroup=0, bool beforeFiles=false)
Constructor for HTTP GET callback function, includes option for function to match the requested name.
- virtual bool **Match** ([HTTP_Request](#) &req)
Determines if this handler matches the incoming request.

Public Member Functions inherited from [HtmlPageHandler](#)

- [HtmlPageHandler](#) (const char *url, [HTTP_RequestTypes](#) rt=tGet, int accessGroup=0, bool BeforeFiles=false)
Constructs and registers an HTTP request handler for a specific URL pattern and method.
- [~HtmlPageHandler](#) ()
Destructor that automatically unregisters the handler from the global chain.
- void [MoveHandlerToLast](#) ()
Moves this handler to the end of the handler chain, making it function as a 404 handler.
- int [GetGroup](#) ()
Returns the access control group identifier for this handler.

Additional Inherited Members

Static Public Member Functions inherited from [HtmlPageHandler](#)

- static [HtmlPageHandler](#) * [FindHandler](#) ([HTTP_Request](#) &req, bool bBeforeFiles)
Locates the appropriate handler for an incoming HTTP request.

Protected Member Functions inherited from [HtmlPageHandler](#)

- void [InsertSort](#) ([HtmlPageHandler](#) *&ph)
Inserts handler into sorted linked list based on priority.
- int [SortValue](#) ([HtmlPageHandler](#) *pv)
Compares handler priorities for sorting (-1, 0, 1)
- void [Remove](#) ()
Removes handler from the linked list.

Protected Attributes inherited from [HtmlPageHandler](#)

- [HtmlPageHandler](#) * [m_pNextHandler](#)
Pointer to next handler in the linked list for efficient traversal.
- const char * [m_pUrlName](#)
URL pattern to match. Empty string or NULL matches all requests.
- int [m_access_group](#)
Access control group identifier for authorization checks.
- [HTTP_RequestTypes](#) [m_requestTypes](#)
HTTP method types this handler responds to (GET, POST, etc.)

16.40.1 Detailed Description

Implements the [HtmlPageHandler](#) class as a function pointer callback for GET requests.

16.40.2 Constructor & Destructor Documentation

16.40.2.1 [CallBackFunctionPageHandler\(\)](#) [1/2]

```
CallBackFunctionPageHandler::CallBackFunctionPageHandler (
    const char * pUrl,
    http_gethandlerfunc * pFunction,
    HTTP_RequestTypes reqType = tGet,
    int accessGroup = 0,
    bool beforeFiles = false) [inline]
```

Constructor for HTTP GET callback function.

Parameters

<i>pUrl</i>	Pointer to the URL to intercept from normal system processing
<i>pFunction</i>	Pointer to the function to call for the requested URL
<i>reqType</i>	Optional type of request to intercept, HTTP_RequestTypes . Default is tGet
<i>accessGroup</i>	Optional password group access level. Default is 0 = no password, maximum is 255.
<i>beforeFiles</i>	Optional parameter to specify a check for just a name, or the name of an actual file in the system. true = intercept before checking for a file of the same name false = check for any files of the requested name before intercepting

16.40.2.2 CallbackFunctionPageHandler() [2/2]

```

CallbackFunctionPageHandler::CallbackFunctionPageHandler (
    const char * pUrl,
    http_gethandlerfunc * pFunction,
    http_matchhandlerfunc * pMatchFunction,
    HTTP_RequestTypes reqType = tGet,
    int accessGroup = 0,
    bool beforeFiles = false) [inline]

```

Constructor for HTTP GET callback function, includes option for function to match the requested name.

Parameters

<i>pUrl</i>	Pointer to the URL to intercept from normal system processing
<i>pFunction</i>	Pointer to the function to call for the requested URL
<i>pMatchFunction</i>	Pointer to function to perform the match check
<i>reqType</i>	Optional type of request to intercept, HTTP_RequestTypes . Default is tGet
<i>accessGroup</i>	Optional parameter to set a password group access level. Default is 0 = no password.
<i>beforeFiles</i>	Optional parameter to process a file name before checking for a compiled-in file of the same name. Default is false = check for any files of the requested name before intercepting

16.40.3 Member Function Documentation

16.40.3.1 ProcessRaw()

```

virtual int CallbackFunctionPageHandler::ProcessRaw (
    int sock,
    HTTP_Request & pd) [inline], [virtual]

```

Pure virtual method that must be implemented to process HTTP requests.

This method is called when a matching request is received and must contain the actual request processing logic. Implementations should read request data, perform necessary processing, and send appropriate HTTP responses.

Parameters

<i>sock</i>	Socket file descriptor for the client connection
<i>pd</i>	HTTP request object containing parsed request details (headers, URL, method, body data, etc.)

Returns

Non-zero if the request was successfully processed and a response was sent, or 0 if the request was not processed (allows fallback to other handlers)

Implements [HtmlPageHandler](#).

The documentation for this class was generated from the following file:

- [http.h](#)

16.41 CallbackFunctionPostHandler Class Reference

Implements the HtmlPostHandler class as a function pointer callback for POST requests.

```
#include <httppost.h>
```

Inherits HtmlPostHandler.

Public Member Functions

- virtual int [ProcessRaw](#) (int sock, [HTTP_Request](#) &pdt)
Pure virtual method that must be implemented to process HTTP requests.

16.41.1 Detailed Description

Implements the HtmlPostHandler class as a function pointer callback for POST requests.

16.41.2 Member Function Documentation

16.41.2.1 ProcessRaw()

```
virtual int CallbackFunctionPostHandler::ProcessRaw (
    int sock,
    HTTP\_Request & pd) [inline], [virtual]
```

Pure virtual method that must be implemented to process HTTP requests.

This method is called when a matching request is received and must contain the actual request processing logic. Implementations should read request data, perform necessary processing, and send appropriate HTTP responses.

Parameters

<i>sock</i>	Socket file descriptor for the client connection
<i>pd</i>	HTTP request object containing parsed request details (headers, URL, method, body data, etc.)

Returns

Non-zero if the request was successfully processed and a response was sent, or 0 if the request was not processed (allows fallback to other handlers)

Implements [HtmlPageHandler](#).

The documentation for this class was generated from the following file:

- httppost.h

16.42 canMCF5441x::CanRxMessage Class Reference

Class to hold received CAN messages.

```
#include <multican.h>
```

Public Member Functions

- uint8_t [GetLength](#) ()
Returns the amount of data stored in the message.
- uint8_t [GetData](#) (uint8_t *buffer, uint8_t max_len)
Copy the data in the message up to max_len.
- uint32_t [GetId](#) ()
Returns the ID of the message.
- uint16_t [GetTimeStamp](#) ()
Returns the time stamp of the message.
- BOOL [IsValid](#) ()

Check to verify the [CanRxMessage](#) is a valid message.

- [CanRxMessage](#) (OS_FIFO *pFifo, uint16_t timeout)

Build a [CanRxMessage](#) from a FIFO.

- [CanRxMessage](#) (int moduleNum, uint32_t id, uint16_t timeout)

Constructor that sends out a RTR request to ID and waits for a response.

- [~CanRxMessage](#) ()

Destructor.

- BOOL [GetNewMessage](#) (OS_FIFO *pFifo, uint16_t timeout)

Get a new message from the FIFO. If no message is available, wait up to the timeout for one to be received.

16.42.1 Detailed Description

Class to hold received CAN messages.

16.42.2 Constructor & Destructor Documentation

16.42.2.1 CanRxMessage() [1/2]

```
canMCF5441x::CanRxMessage::CanRxMessage (
    OS_FIFO * pFifo,
    uint16_t timeout)
```

Build a [CanRxMessage](#) from a FIFO.

The FIFO must be registered to listen for incoming messages. If no messages are received in the timeout interval, the returned [CanRxMessage](#) will be marked as not valid. A Timeout value of 0 will wait forever.

Parameters

<i>pFifo</i>	Pointer to an OS_FIFO to store the message
<i>timeout</i>	Message timeout in TICKS_PER_SECOND

16.42.2.2 CanRxMessage() [2/2]

```
canMCF5441x::CanRxMessage::CanRxMessage (
    int moduleNum,
    uint32_t id,
    uint16_t timeout)
```

Constructor that sends out a RTR request to ID and waits for a response.

The CAN system uses any unused channel to send and receive the buffer. The constructor can return an invalid message for two reasons:

1. The timeout interval has expired
2. There were no free CAN channels available to send the request

Parameters

<i>moduleNum</i>	CAN module number
<i>id</i>	CAN ID number
<i>timeout</i>	Message timeout in TICKS_PER_SECOND. A value of 0 will wait forever.

16.42.3 Member Function Documentation

16.42.3.1 GetData()

```
uint8_t canMCF5441x::CanRxMessage::GetData (  
    uint8_t * buffer,  
    uint8_t max_len)
```

Copy the data in the message up to *max_len*.

Parameters

<i>buffer</i>	Pointer to destination storage buffer
<i>max_len</i>	Maximum number of bytes to copy

Returns

The number of bytes copied

16.42.3.2 GetNewMessage()

```

BOOL canMCF5441x::CanRxMessage::GetNewMessage (
    OS_FIFO * pFifo,
    uint16_t timeout)

```

Get a new message from the FIFO. If no message is available, wait up to the timeout for one to be received.

Parameters

<i>pFifo</i>	Pointer to the OS_FIFO.
<i>timeout</i>	Timeout to wait if no messages are currently available. Value is in TICKS_PER_SECOND, a value of 0 will wait forever.

16.42.3.3 IsValid()

```

BOOL canMCF5441x::CanRxMessage::IsValid ()

```

Check to verify the [CanRxMessage](#) is a valid message.

Please refer to the CanRxMessage() constructor for further information on valid messages.

The documentation for this class was generated from the following file:

- multican.h

16.43 mcanMODM7AE70::CanRxMessage Class Reference

Class to hold received CAN messages.

```
#include <mcan.h>
```

Public Member Functions

- uint8_t [GetLength](#) ()
Returns the amount of data stored in the message.
- uint8_t [CopyData](#) (uint8_t *buffer, uint8_t max_len)
Copy the data in the message up to max_len.
- const uint8_t * [GetData](#) ()
Returns a pointer to the message data.
- uint32_t [GetId](#) ()
Returns the ID of the message.
- uint16_t [GetTimeStamp](#) ()
Returns the time stamp of the message.
- BOOL [IsValid](#) ()
Check to verify the [CanRxMessage](#) is a valid message.
- [CanRxMessage](#) (OS_FIFO *pFifo, uint32_t timeout=WAIT_FOREVER)
Build a [CanRxMessage](#) from a FIFO.
- [~CanRxMessage](#) ()
Destructor.
- BOOL [GetNewMessage](#) (OS_FIFO *pFifo, uint32_t timeout=WAIT_FOREVER)
Get a new message from the FIFO. If no message is available, wait up to the timeout for one to be received.

16.43.1 Detailed Description

Class to hold received CAN messages.

16.43.2 Constructor & Destructor Documentation

16.43.2.1 CanRxMessage()

```
mcanMODM7AE70::CanRxMessage::CanRxMessage (
    OS_FIFO * pFifo,
    uint32_t timeout = WAIT_FOREVER)
```

Build a [CanRxMessage](#) from a FIFO.

The FIFO must be registered to listen for incoming messages. If no messages are received in the timeout interval, the returned [CanRxMessage](#) will be marked as not valid. A Timeout value of 0 will wait forever.

Parameters

<i>pFifo</i>	Pointer to an OS_FIFO to store the message
<i>timeout</i>	Optional message timeout in TICKS_PER_SECOND

16.43.3 Member Function Documentation

16.43.3.1 CopyData()

```
uint8_t mcanMODM7AE70::CanRxMessage::CopyData (
    uint8_t * buffer,
    uint8_t max_len)
```

Copy the data in the message up to *max_len*.

Parameters

<i>buffer</i>	Pointer to destination storage buffer
<i>max_len</i>	Maximum number of bytes to copy

Returns

The number of bytes copied

16.43.3.2 GetData()

```
const uint8_t * mcanMODM7AE70::CanRxMessage::GetData ()
```

Returns a pointer to the message data.

Warning

Invalid after destructor is called

16.43.3.3 GetId()

```
uint32_t mcanMODM7AE70::CanRxMessage::GetId ()
```

Returns the ID of the message.

Returns

The message ID

16.43.3.4 GetLength()

```
uint8_t mcanMODM7AE70::CanRxMessage::GetLength ()
```

Returns the amount of data stored in the message.

Returns

Length of data stored

16.43.3.5 GetNewMessage()

```
BOOL mcanMODM7AE70::CanRxMessage::GetNewMessage (
    OS_FIFO * pFifo,
    uint32_t timeout = WAIT_FOREVER)
```

Get a new message from the FIFO. If no message is available, wait up to the timeout for one to be received.

Parameters

<i>pFifo</i>	Pointer to the OS_FIFO
<i>timeout</i>	Optional parameter to wait if no messages are currently available. Value is in TICKS_PER_SECOND, a value of 0 will wait forever.

Returns

True on success, otherwise false

16.43.3.6 GetTimeStamp()

```
uint16_t mcanMODM7AE70::CanRxMessage::GetTimeStamp ()
```

Returns the time stamp of the message.

For timestamp generation the MCAN supplies a 16-bit wrap-around counter. A prescaler TSCC.TCP can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable via MCAN_TSCV.TSC. A write access to the Timestamp Counter Value register (MCAN_TSCV) resets the counter to zero. When the timestamp counter wraps around, interrupt flag MCAN_IR.TSW is set. On start of frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer / Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

The internal/external Timestamp Counter value is captured on start of frame (both Receive and Transmit). When MCAN_TSCC.TSS = 1, the Timestamp Counter is incremented in multiples of CAN bit times [1-16] depending on the configuration of MCAN_TSCC.TCP. A wrap around sets interrupt flag MCAN_IR.TSW. Write access resets the counter to zero.

Returns

Time stamp of the message

16.43.3.7 IsValid()

```
BOOL mcanMODM7AE70::CanRxMessage::IsValid ()
```

Check to verify the [CanRxMessage](#) is a valid message.

Please refer to the CanRxMessage() constructor for further information on valid messages.

Returns

True if valid, otherwise false

The documentation for this class was generated from the following file:

- mcan.h

16.44 CertData Class Reference

```
#include <certgen.h>
```

Inherits [config_obj](#).

Additional Inherited Members

Public Member Functions inherited from [config_obj](#)

- [config_obj](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_obj](#) (const char *name, const char *desc)
Object constructor.
- virtual void [GetTextValue](#) ([NBString](#) &s) override
Get the object value as a text string to the specified [NBString](#) object.
- virtual void [GetTypeValue](#) ([NBString](#) &s) override
Assigns the object type value to the specified [NBString](#) object.

16.44.1 Detailed Description

The documentation for this class was generated from the following file:

- certgen.h

16.45 CertGenData Struct Reference

Used to store the information that is passed in when enabling onboard generated certificates, as well as the information needed to determine when they need to be regenerated.

```
#include <certgen.h>
```

Public Attributes

- const char * **m_commonName**
Common Name.
- int **m_yrsValid**
Number of years.
- [NBString](#) **m_altNamesString**
Alternate names string.
- time_t **m_certExpTime**
Certificate expiration time.

16.45.1 Detailed Description

Used to store the information that is passed in when enabling onboard generated certificates, as well as the information needed to determine when they need to be regenerated.

The documentation for this struct was generated from the following file:

- certgen.h

16.46 MQTT::Client Class Reference

Advanced low-level [MQTT Client](#) for interacting with Mqtt Brokers. The client handles all network communications with the Broker and handles local message queueing and dispatching to topic handlers.

```
#include <mqtt.h>
```

Inherits [TimeOutManager](#).

Inherited by [MQTT::ConfiguredClient](#).

Public Types

- enum [eSessionLimit](#) {
[eLimit_Size_Tx](#) , [eLimit_Size_Rx](#) , [eLimit_InFlight_Tx](#) , [eLimit_InFlight_Rx](#) ,
[eLimit_Subscriptions](#) , [eLimit_SubAliases](#) , [eLimit_PublishAliases](#) , [eLimit_QoS](#) ,
[eLimit_SessionExpiry](#) }
Limit types for the [Client](#) interactions with the Broker.
- enum [eRateLimitType](#) { [eRateLimit_Publish](#) , [eRateLimit_Subscribe](#) }
Rate limit types for [Client](#) messaging.
- enum [eRateLimitAdjustMethod](#) { [eRateLimitAdj_None](#) , [eRateLimitAdj_Set](#) , [eRateLimitAdj_Add](#) ,
[eRateLimitAdj_Subtract](#) }
How to adjust rate limit buckets when modifying the current rate limit.
- enum [eConnectionStatus](#) {
[eConnStat_Error](#) , [eConnStat_No_Broker_Configured](#) , [eConnStat_Resolving](#) , [eConnStat_InProgress](#) ,
[eConnStat_Established](#) , [eConnStat_Refused](#) , [eConnStat_Disconnected](#) }
Connection state values.

Public Member Functions

- [Client](#) (const char *brokerURI, const char *pClientId, uint16_t maxKeepAlive=[MQTT_DEFAULT_KEEP_ALIVE](#), bool bCleanStart=true, [PublishRequest](#) *lwtMsg=NULL, const char *pConnMsg=NULL, const char *pDisconnMsg=NULL, const char *pUsername=NULL, const char *pPassword=NULL, RequestProperty *addProps=NULL, bool ConnectOnStartup=true)
Constructor. This version takes a raw string for the broker URI.
- [Client](#) (const [ParsedURI](#) *brokerURI, const char *pClientId, uint16_t maxKeepAlive=[MQTT_DEFAULT_KEEP_ALIVE](#), bool bCleanStart=true, [PublishRequest](#) *lwtMsg=NULL, const char *pConnMsg=NULL, const char *pDisconnMsg=NULL, const char *pUsername=NULL, const char *pPassword=NULL, RequestProperty *addProps=NULL, bool ConnectOnStartup=true)
Constructor. This version takes a [ParsedURI](#) object for the broker URI.
- int [Connect](#) (bool bWaitForConnection, const char *pNewBrokerURI, ConnAckCb_t notifyCb=NULL, void *notifyCtx=NULL)
Begin the process of Connecting the client to the Broker.
- int [Connect](#) (bool bWaitForConnection=true, const [ParsedURI](#) *pNewBrokerURI=NULL, ConnAckCb_t notifyCb=NULL, void *notifyCtx=NULL)
Begin the process of Connecting the client to the Broker.
- int [Disconnect](#) ()
Disconnect the [Client](#) from the Broker.
- void [SetConnectNotify](#) (ConnAckCb_t notifyCb, void *notifyCtx)
Set the connection notification callback and it's context information.
- int [SetRateLimit](#) ([eRateLimitType](#) type, uint8_t bucketMax, uint8_t fillCount, uint8_t fillTicks, [eRateLimitAdjustMethod](#) adjMethod, uint8_t adjCount)
Set the value for a given rate limit.
- int [SetRateLimit_Publish](#) (int reqPerSecond)
Set the Publish rate limit. This method automatically determines the fillCount and fillTicks to use for refilling the credit bucket.
- int [SetRateLimit_Subscribe](#) (int reqPerSecond)
Set the Subscribe rate limit. This method automatically determines the fillCount and fillTicks to use for refilling the credit bucket.
- [eConnectionStatus](#) [GetConnectionStatus](#) ()
Get the current state of the [Client](#)'s connection to the Broker.
- void [SetClientCert](#) (uint8_t *cert, uint32_t len, uint8_t *privkey, uint32_t privlen)
Set the [Client](#) Certificate and Private Key to use when connecting to a Broker via TLS.
- void [GetClientCert](#) (uint8_t **cert, uint32_t *len, uint8_t **privkey, uint32_t *privlen)
Set the [Client](#) Certificate and Private Key to use when connecting to a Broker via TLS.

- int [QueuePublish](#) ([mqtt_leaf](#) &leaf)
Queue an MqttObj to be published.
- int [QueueSubscribe](#) ([mqtt_leaf](#) &leaf)
Queue an MqttObj to subscribe.
- int [QueueUnsubscribe](#) ([mqtt_leaf](#) &leaf)
Queue an MqttObj to unsubscribe.
- int [QueueAllSubscriptions](#) ()
Queue all [Client](#)'s registered MqttObjs to be subscribed and published according to the object's operation flags.
- int [Publish](#) (const char *topic, uint8_t *pData, uint32_t len, int prio, TickTimeout &t, uint8_t qos=0)
Publish a binary payload message.
- int [Publish](#) (const char *topic, const char *pStr, int prio, TickTimeout &t, uint8_t qos=0)
Publish a message.
- int [Publish](#) ([PublishRequest](#) *req, int prio, TickTimeout &t)
Publish a fully defined request.
- int [QueuePublish](#) ([PublishRequest](#) *req, int *prio)
Queue a publish message from a fully defined request.
- int [Subscribe](#) ([TopicHandler](#) &handler, int *handlerIdx, TickTimeout &t, uint8_t subOpts=Pkt::eSubOpt_No↔ Local)
Register a [TopicHandler](#) and subscribe its Topic on the Broker.
- int [Subscribe](#) ([SubscribeRequest](#) *req, int *handlerIdx, TickTimeout &t)
Register a [TopicHandler](#) (via fully specified [SubscribeRequest](#)) and subscribe its Topic on the Broker.
- int [QueueSubscribe](#) (SubUnsubQueueMsg *qmsg)
Register a [TopicHandler](#) and subscribe its Topic on the Broker.
- int [Unsubscribe](#) (int handlerIdx, TickTimeout &t, const char *topicFilter=NULL)
Unsubscribe and deregister a [TopicHandler](#).
- int [Unsubscribe](#) (const char *topicFilter, TickTimeout &t)
Unsubscribe and deregister a [TopicHandler](#).
- int [QueueUnsubscribe](#) (SubUnsubQueueMsg *qmsg)
Queue unsubscribing and deregistering a [TopicHandler](#).
- int [RegisterTopicHandler](#) ([TopicHandler](#) *newHandler, int *handlerIdx)
Register a [TopicHandler](#) with the [Client](#).
- int [RemoveTopicHandler](#) ([TopicHandler](#) *handler)
Remove/deregister a [TopicHandler](#) from the [Client](#) by reference.
- int [RemoveTopicHandler](#) (int handlerIdx)
Remove/deregister a [TopicHandler](#) from the [Client](#) by index.
- void [RegisterMqttObj](#) ([mqtt_leaf](#) &leaf, uint32_t interval=0)
Register an MqttObj with the [Client](#).
- void [RemoveObj](#) ([mqtt_leaf](#) &leaf)
Deregister/remove an MqttObj from the [Client](#).
- int [SendNextPubReq](#) ()
Send the next queued Publish Request.
- int [SendNextSubReq](#) ()
Send the next queued SubUnSub Request.

Static Public Member Functions

- static void [StartTask](#) (uint8_t taskPrio=MQTT_TASK_PRIO)
Start the [Client](#) Task.
- static [Client](#) * [GetFirstClient](#) ()
Start the [Client](#) Task.

16.46.1 Detailed Description

Advanced low-level [MQTT Client](#) for interacting with Mqtt Brokers. The client handles all network communications with the Broker and handles local message queueing and dispatching to topic handlers.

Basic users should use the [ConfiguredClient](#) for easier implementation.

16.46.2 Member Enumeration Documentation

16.46.2.1 eConnectionStatus

enum [MQTT::Client::eConnectionStatus](#)

Connection state values.

Enumerator

eConnStat_Error	General error with client connection.
eConnStat_No_Broker_Configured	Error, no broker configured to be used.
eConnStat_Resolving	Currently resolving broker address.
eConnStat_InProgress	Connection to broker in progress.
eConnStat_Established	Connection with broker established.
eConnStat_Refused	Connection refused by broker.

16.46.2.2 eRateLimitAdjustMethod

enum [MQTT::Client::eRateLimitAdjustMethod](#)

How to adjust rate limit buckets when modifying the current rate limit.

Enumerator

eRateLimitAdj_None	Do not modify the current limit token count.
eRateLimitAdj_Set	Set the current limit token count to the adjustment value.
eRateLimitAdj_Add	Add the adjustment value to the current token count.
eRateLimitAdj_Subtract	Subtract the adjustment value from the current token count.

16.46.2.3 eRateLimitType

enum [MQTT::Client::eRateLimitType](#)

Rate limit types for [Client](#) messaging.

Enumerator

eRateLimit_Publish	Limit for Publish requests per second.
eRateLimit_Subscribe	Limit for Subscribe requests per second.

16.46.2.4 eSessionLimit

enum [MQTT::Client::eSessionLimit](#)

Limit types for the [Client](#) interactions with the Broker.

Enumerator

eLimit_Size_Tx	Maximum receive message size accepted.
eLimit_Size_Rx	Maximum transmit message size allowed.
eLimit_InFlight_Tx	Maximum number of outstanding tx messages with QoS > 0.

Enumerator

eLimit_InFlight_Rx	Maximum number of outstanding rx messages with QoS > 0.
eLimit_Subscriptions	Maximum number of topic subscriptions.
eLimit_SubAliases	Maximum number of subscription aliases.
eLimit_PublishAliases	Maximum number of Publish topic name aliases.
eLimit_QoS	Maximum QoS for messages.
eLimit_SessionExpiry	Maximum time for Session before expiring.

16.46.3 Constructor & Destructor Documentation

16.46.3.1 Client() [1/2]

```
MQTT::Client::Client (
    const char * brokerURI,
    const char * pClientId,
    uint16_t maxKeepAlive = MQTT_DEFAULT_KEEP_ALIVE,
    bool bCleanStart = true,
    PublishRequest * lwtMsg = NULL,
    const char * pConnMsg = NULL,
    const char * pDisconnMsg = NULL,
    const char * pUsername = NULL,
    const char * pPassword = NULL,
    RequestProperty * addProps = NULL,
    bool ConnectOnStartup = true)
```

Constructor. This version takes a raw string for the broker URI.

Parameters

<i>*brokerURI</i>	The URI for the broker to use. (Must be a URI with protocol, like <code>mqtt://1.2.3.4</code>)
<i>*pClientId</i>	A string containing the Client ID to use with the broker
<i>maxKeepAlive</i>	The number of seconds when, after multiple failed MQTT keepalive messages, the connection will be automatically restarted (Note: the server may impose a different maximum keepalive)
<i>bCleanStart</i>	Whether the broker start a fresh session and remove any previous subscriptions.
<i>*lwtMsg</i>	Pointer to a PublishRequest containing the Last Will and Testament to use for this client's connections
<i>*pConnMsg</i>	Message payload to send to the LWT topic after connecting to the broker.
<i>*pDisconnMsg</i>	Message payload to send to the LWT topic just prior to intentionally disconnecting from the broker.
<i>*pUsername</i>	Username to use when connecting to the broker.
<i>*pPassword</i>	Password to use when connecting to the broker.
<i>*addProps</i>	Additional message Properties to send with Connection Requests
<i>ConnectOnStartup</i>	Whether the client should automatically connect after startup.

16.46.3.2 Client() [2/2]

```
MQTT::Client::Client (
    const ParsedURI * brokerURI,
    const char * pClientId,
    uint16_t maxKeepAlive = MQTT_DEFAULT_KEEP_ALIVE,
    bool bCleanStart = true,
    PublishRequest * lwtMsg = NULL,
```

```

const char * pConnMsg = NULL,
const char * pDisconnMsg = NULL,
const char * pUsername = NULL,
const char * pPassword = NULL,
RequestProperty * addProps = NULL,
bool ConnectOnStartup = true)

```

Constructor. This version takes a [ParsedURI](#) object for the broker URI.

Parameters

<i>*brokerURI</i>	The URI for the broker to use. (Must be a URI with protocol, like <code>mqtt://1.2.3.4</code>)
<i>*pClientId</i>	A string containing the Client ID to use with the broker
<i>maxKeepAlive</i>	The number of seconds when, after multiple failed MQTT keepalive messages, the connection will be automatically restarted (Note: the server may impose a different maximum keepalive)
<i>bCleanStart</i>	Whether the broker start a fresh session and remove any previous subscriptions.
<i>*lwtMsg</i>	Pointer to a PublishRequest containing the Last Will and Testament to use for this client's connections
<i>*pConnMsg</i>	Message payload to send to the LWT topic after connecting to the broker.
<i>*pDisconnMsg</i>	Message payload to send to the LWT topic just prior to intentionally disconnecting from the broker.
<i>*pUsername</i>	Username to use when connecting to the broker.
<i>*pPassword</i>	Password to use when connecting to the broker.
<i>*addProps</i>	Additional message Properties to send with Connection Requests
<i>ConnectOnStartup</i>	Whether the client should automatically connect after startup.

16.46.4 Member Function Documentation

16.46.4.1 Connect() [1/2]

```

int MQTT::Client::Connect (
    bool bWaitForConnection,
    const char * pNewBrokerURI,
    ConnAckCb_t notifyCb = NULL,
    void * notifyCtx = NULL)

```

Begin the process of Connecting the client to the Broker.

Parameters

<i>bWaitForConnection</i>	Wait for the client to finish connecting to the broker before returning.
<i>pNewBrokerURI</i>	If non-null, a pointer to the new Broker URI to use
<i>notifyCb</i>	Pointer to a notification callback for connection state events.
<i>notifyCtx</i>	Context to pass to the notification callback as additional data.

Returns

`eResult_t` indicating result

16.46.4.2 Connect() [2/2]

```

int MQTT::Client::Connect (
    bool bWaitForConnection = true,
    const ParsedURI * pNewBrokerURI = NULL,
    ConnAckCb_t notifyCb = NULL,
    void * notifyCtx = NULL)

```

Begin the process of Connecting the client to the Broker.

Parameters

<i>bWaitForConnection</i>	Wait for the client to finish connecting to the broker before returning.
<i>pNewBrokerURI</i>	If non-null, a pointer to the new Broker ParsedURI to use
<i>notifyCb</i>	Pointer to a notification callback for connection state events.
<i>notifyCtx</i>	Context to pass to the notification callback as additional data.

Returns

`eResult_t` indicating result

16.46.4.3 Disconnect()

```
int MQTT::Client::Disconnect ()
```

Disconnect the [Client](#) from the Broker.

Returns

`eResult_t` indicating result

16.46.4.4 GetClientCert()

```
void MQTT::Client::GetClientCert (
    uint8_t ** cert,
    uint32_t * len,
    uint8_t ** privkey,
    uint32_t * privlen) [inline]
```

Set the [Client](#) Certificate and Private Key to use when connecting to a Broker via TLS.

Parameters

<i>**cert</i>	Pointer to return pointer for the certificate buffer address
<i>*len</i>	Pointer to return value for the length of the certificate
<i>**privkey</i>	Pointer to return pointer for the the private key buffer address
<i>*privlen</i>	Pointer to return value for the length of the private key

See also

[Client::GetClientCert](#)

16.46.4.5 GetConnectionStatus()

```
eConnectionStatus MQTT::Client::GetConnectionStatus ()
```

Get the current state of the [Client](#)'s connection to the Broker.

Returns

`eConnectionStatus` The current status of the client's connection to the Broker

See also

[Client::Connect](#), [Client::Disconnect](#), [Client::GetConnectionStatusString](#)

16.46.4.6 GetFirstClient()

```
static Client * MQTT::Client::GetFirstClient () [inline], [static]
```

Start the [Client](#) Task.

Returns

Pointer to the first registered [Client](#)

16.46.4.7 Publish() [1/3]

```
int MQTT::Client::Publish (
    const char * topic,
    const char * pStr,
    int prio,
    TickTimeout & t,
    uint8_t qos = 0)
```

Publish a message.

Parameters

<i>*topic</i>	Topic to publish message to
<i>*pStr</i>	String containing data to be published
<i>prio</i>	Priority level of the message to be published (see MQTT_OBJ_PRIORITY_MAX and MQTT_OBJ_PRIORITY_MIN)
<i>&t</i>	Timeout indicating how long to block before returning timeout error
<i>qos</i>	Quality of Service level to use for the resulting Publish message

Returns

eResult_t return code

See also

[Client::QueuePublish](#)

16.46.4.8 Publish() [2/3]

```
int MQTT::Client::Publish (
    const char * topic,
    uint8_t * pData,
    uint32_t len,
    int prio,
    TickTimeout & t,
    uint8_t qos = 0)
```

Publish a binary payload message.

Parameters

<i>*topic</i>	Topic to publish message to
<i>*pData</i>	Data to be published
<i>len</i>	Length of data to be published
<i>prio</i>	Priority level of the message to be published (see MQTT_OBJ_PRIORITY_MAX and MQTT_OBJ_PRIORITY_MIN)
<i>&t</i>	Timeout indicating how long to block before returning timeout error
<i>qos</i>	Quality of Service level to use for the resulting Publish message

Returns

eResult_t return code

See also

[Client::QueuePublish](#)

16.46.4.9 Publish() [3/3]

```
int MQTT::Client::Publish (  
    PublishRequest * req,  
    int prio,  
    TickTimeout & t)
```

Publish a fully defined request.

Parameters

<i>*req</i>	Publish Request describing the message to be sent
<i>prio</i>	Priority level of the message to be published (see MQTT_OBJ_PRIORITY_MAX and MQTT_OBJ_PRIORITY_MIN)
<i>&t</i>	Timeout indicating how long to block before returning timeout error

Returns

eResult_t return code

See also

[Client::QueuePublish](#)

16.46.4.10 QueueAllSubscriptions()

```
int MQTT::Client::QueueAllSubscriptions ()
```

Queue all [Client](#)'s registered MqttObjs to be subscribed and published according to the object's operation flags.

Returns

eResult_t return code

See also

[Client::QueuePublish](#), [Client::QueueSubscribe](#)

16.46.4.11 QueuePublish() [1/2]

```
int MQTT::Client::QueuePublish (  
    mqtt_leaf & leaf)
```

Queue an MqttObj to be published.

Parameters

<i>&leaf</i>	Reference to the object to publish.

Returns

eResult_t return code

See also

[Client::QueueSubscribe](#), [Client::QueueUnsubscribe](#)

16.46.4.12 QueuePublish() [2/2]

```
int MQTT::Client::QueuePublish (  
    PublishRequest * req,  
    int * prio)
```

Queue a publish message from a fully defined request.

Parameters

<i>*req</i>	Publish Request describing the message to be sent
<i>prio</i>	Priority level of the message to be published (see MQTT_OBJ_PRIORITY_MAX and MQTT_OBJ_PRIORITY_MIN)

Returns

eResult_t return code

See also

[Client::Publish](#)

16.46.4.13 QueueSubscribe() [1/2]

```
int MQTT::Client::QueueSubscribe (
    mqtt_leaf & leaf)
```

Queue an MqttObj to subscribe.

Parameters

<i>&leaf</i>	Reference to the object to subscribe.

Returns

eResult_t return code

See also

[Client::QueuePublish](#), [Client::QueueUnsubscribe](#)

16.46.4.14 QueueSubscribe() [2/2]

```
int MQTT::Client::QueueSubscribe (
    SubUnsubQueueMsg * qmsg)
```

Register a [TopicHandler](#) and subscribe its Topic on the Broker.

Parameters

<i>*qmsg</i>	Pointer to asynchronous Subscription Request structure

Returns

eResult_t return code

See also

[Client::Subscribe](#)

16.46.4.15 QueueUnsubscribe() [1/2]

```
int MQTT::Client::QueueUnsubscribe (
    mqtt_leaf & leaf)
```

Queue an MqttObj to unsubscribe.

Parameters

<i>&leaf</i>	Reference to the object to unsubscribe.

Returns

eResult_t return code

See also

[Client::QueuePublish](#), [Client::QueueSubscribe](#)

16.46.4.16 QueueUnsubscribe() [2/2]

```
int MQTT::Client::QueueUnsubscribe (
    SubUnsubQueueMsg * qmsg)
```

Queue unsubscribing and deregistering a [TopicHandler](#).

Parameters

<i>*qmsg</i>	Pointer to fully defined unsubscription request

Returns

eResult_t return code

See also

[Client::Unsubscribe](#)

16.46.4.17 RegisterMqttObj()

```
void MQTT::Client::RegisterMqttObj (
    mqtt_leaf & leaf,
    uint32_t interval = 0)
```

Register an MqttObj with the [Client](#).

Parameters

<i>&leaf</i>	Reference to the MqttObj to be registered with the Client
<i>interval</i>	Publication interval (in TimeTicks) for the registered object

See also

[Client::RemoveObj](#)

16.46.4.18 RegisterTopicHandler()

```
int MQTT::Client::RegisterTopicHandler (
    TopicHandler * newHandler,
    int * handlerIdx)
```

Register a [TopicHandler](#) with the [Client](#).

Parameters

<i>*newHandler</i>	Pointer to the TopicHanler to Register
<i>*handlerIdx</i>	Pointer to return value of the index the handler is registered at

Returns

eResult_t return code

See also

[Client::Subscribe](#)

16.46.4.19 RemoveObj()

```
void MQTT::Client::RemoveObj (
    mqtt_leaf & leaf)
```

Deregister/remove an MqttObj from the [Client](#).

Parameters

<i>&leaf</i>	Reference to the MqttObj to be removed from the Client

See also

[Client::RemoveObj](#)

16.46.4.20 RemoveTopicHandler() [1/2]

```
int MQTT::Client::RemoveTopicHandler (
    int handlerIdx)
```

Remove/deregister a [TopicHandler](#) from the [Client](#) by index.

Parameters

<i>handlerIdx</i>	Registration index of the topic handler to be removed

Returns

eResult_t return code

See also

[Client::Unsubscribe](#)

16.46.4.21 RemoveTopicHandler() [2/2]

```
int MQTT::Client::RemoveTopicHandler (
    TopicHandler * handler)
```

Remove/deregister a [TopicHandler](#) from the [Client](#) by reference.

Parameters

<i>*handler</i>	Pointer to the TopicHandler to be removed

Returns

eResult_t return code

See also

[Client::Unsubscribe](#)

16.46.4.22 SendNextPubReq()

```
int MQTT::Client::SendNextPubReq ()
```

Send the next queued Publish Request.

Returns

eResult_t return code

See also

[Client::SendNextSubReq](#)

16.46.4.23 SendNextSubReq()

```
int MQTT::Client::SendNextSubReq ()
```

Send the next queued SubUnSub Request.

Returns

eResult_t return code

See also

[Client::SendNextPubReq](#)

16.46.4.24 SetClientCert()

```
void MQTT::Client::SetClientCert (
    uint8_t * cert,
    uint32_t len,
    uint8_t * privkey,
    uint32_t privlen) [inline]
```

Set the [Client](#) Certificate and Private Key to use when connecting to a Broker via TLS.

Parameters

<i>*cert</i>	Pointer to the certificate buffer to use
<i>len</i>	Length of the certificate
<i>*privkey</i>	Pointer to the private key buffer
<i>privlen</i>	Length of the private key

See also

[Client::GetClientCert](#)

16.46.4.25 SetConnectNotify()

```
void MQTT::Client::SetConnectNotify (
    ConnAckCb_t notifyCb,
    void * notifyCtx)
```

Set the connection notification callback and it's context information.

Parameters

<i>notifyCb</i>	Notification callback for connection state events.
<i>notifyCtx</i>	Context to pass to the notification callback as additional data.

16.46.4.26 SetRateLimit()

```
int MQTT::Client::SetRateLimit (
    eRateLimitType type,
    uint8_t bucketMax,
    uint8_t fillCount,
    uint8_t fillTicks,
    eRateLimitAdjustMethod adjMethod,
    uint8_t adjCount)
```

Set the value for a given rate limit.

Parameters

<i>type</i>	The rate limit to set the value of.
<i>bucketMax</i>	The maximum count for the limit bucket (i.e. burst maximum)
<i>fillCount</i>	The count to add to the bucket each time interval
<i>fillTicks</i>	The interval, in TimeTicks, between each filling of the bucket.
<i>adjMethod</i>	The adjustment type to perform to the current bucket count when setting the new rate limit.
<i>adjCount</i>	The count to use when adjusting the current bucket count.

Returns

eResult_t Return code

See also

[Client::SetRateLimit_Publish](#), [Client::SetRateLimit_Subscribe](#)

16.46.4.27 SetRateLimit_Publish()

```
int MQTT::Client::SetRateLimit_Publish (
    int reqPerSecond)
```

Set the Publish rate limit. This method automatically determines the fillCount and fillTicks to use for refilling the credit bucket.

Parameters

<i>reqPerSecond</i>	The maximum number of allowed Publish messages per second.

Returns

eResult_t Return code

See also

[Client::SetRateLimit](#), [Client::SetRateLimit_Subscribe](#)

16.46.4.28 SetRateLimit_Subscribe()

```
int MQTT::Client::SetRateLimit_Subscribe (
    int reqPerSecond)
```

Set the Subscribe rate limit. This method automatically determines the fillCount and fillTicks to use for refilling the credit bucket.

Parameters

<i>reqPerSecond</i>	The maximum number of allowed Publish messages per second.

Returns

eResult_t Return code

See also

[Client::SetRateLimit](#), [Client::SetRateLimit_Publish](#)

16.46.4.29 StartTask()

```
static void MQTT::Client::StartTask (
    uint8_t taskPrio = MQTT_TASK_PRIO) [static]
```

Start the [Client](#) Task.

Parameters

<i>taskPrio</i>	The OS Task Priority to assign to the Client Task

16.46.4.30 Subscribe() [1/2]

```
int MQTT::Client::Subscribe (
    SubscribeRequest * req,
    int * handlerIdx,
    TickTimeout & t)
```

Register a [TopicHandler](#) (via fully specified [SubscribeRequest](#)) and subscribe its Topic on the Broker.

Parameters

<i>*req</i>	Fully described subscription request to be sent to the Broker
<i>*handlerIdx</i>	Pointer to int to return the registration index of the TopicHandler
<i>&t</i>	Timeout indicating how long to block before returning timeout error

Returns

eResult_t return code

See also

[Client::QueueSubscribe](#)

16.46.4.31 Subscribe() [2/2]

```
int MQTT::Client::Subscribe (
    TopicHandler & handler,
    int * handlerIdx,
    TickTimeout & t,
    uint8_t subOpts = Pkt::eSubOpt_NoLocal)
```

Register a [TopicHandler](#) and subscribe its Topic on the Broker.

Parameters

<i>&handler</i>	TopicHandler to be registered and subscribed
<i>*handlerIdx</i>	Pointer to int to return the registration index of the TopicHandler
<i>&t</i>	Timeout indicating how long to block before returning timeout error
<i>subOpts</i>	Flags describing Subscription options to request when Subscribing on the Broker

Returns

eResult_t return code

See also

[Client::QueueSubscribe](#)

16.46.4.32 Unsubscribe() [1/2]

```
int MQTT::Client::Unsubscribe (  
    const char * topicFilter,  
    TickTimeout & t)
```

Unsubscribe and deregister a [TopicHandler](#).

Parameters

<i>*topicFilter</i>	The Topic Filter of the registered TopicHandler and on the broker to be Unsubscribed from
<i>&t</i>	Timeout indicating how long to block before returning timeout error

Returns

eResult_t return code

See also

[Client::QueueUnsubscribe](#)

16.46.4.33 Unsubscribe() [2/2]

```
int MQTT::Client::Unsubscribe (  
    int handlerIdx,  
    TickTimeout & t,  
    const char * topicFilter = NULL)
```

Unsubscribe and deregister a [TopicHandler](#).

Parameters

<i>handlerIdx</i>	The registration index of the TopicHandler to unsubscribe and deregister
<i>&t</i>	Timeout indicating how long to block before returning timeout error
<i>*topicFilter</i>	The Topic Filter on the broker to be Unsubscribed from

Returns

eResult_t return code

See also

[Client::QueueUnsubscribe](#)

16.47 config_bool Class Reference

Boolean Configuration Variable.

#include <config_obj.h>

Inherits [config_value](#).

Inherited by reboot_obj.

Public Member Functions

- virtual void [GetTextValue](#) (NBString &s) override
Copy the object value as a text string to the specified NBString object.
- [config_bool](#) (config_obj &owner, bool def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_bool](#) (bool def_val, const char *name, const char *desc=NULL)
Object constructor.
- [operator bool](#) () const
Return the object value.
- [config_bool](#) & [operator=](#) (const bool v)
Assign the config_bool object value to the specified bool value.
- [config_bool](#) & [operator=](#) (const [config_bool](#) &cb)
Copy one config_bool object to another.
- [config_bool](#) & [operator=](#) (const int i)
Assign a config_bool object value to the specified integer value.
- virtual void [GetTypeValue](#) (NBString &s) override
Copy the object type value to the specified NBString object.

Additional Inherited Members

Protected Member Functions inherited from [config_value](#)

- [config_value](#) (config_obj &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.47.1 Detailed Description

Boolean Configuration Variable.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.47.2 Constructor & Destructor Documentation

16.47.2.1 config_bool() [1/2]

```
config_bool::config_bool (
    config_obj & owner,
    bool def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Parameters

<i>owner</i>	Reference to parent leaf
<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.47.2.2 config_bool() [2/2]

```
config_bool::config_bool (
    bool def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor.

Parameters

<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description, used for info/tool tips

16.47.3 Member Function Documentation

16.47.3.1 GetTextValue()

```
virtual void config_bool::GetTextValue (
    NBString & s) [inline], [override], [virtual]
```

Copy the object value as a text string to the specified [NBString](#) object.

Writes either "true" or "false". This is a virtual function that can be overridden in a derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result

Implements [config_value](#).

16.47.3.2 GetTypeValue()

```
virtual void config_bool::GetTypeValue (
    NBString & s) [inline], [override], [virtual]
```

Copy the object type value to the specified [NBString](#) object.

Parameters

<i>s</i>	NBString object to hold the type value string

16.47.3.3 operator bool()

```
config_bool::operator bool () const [inline]
```

Return the object value.

Returns

The object value as a bool

Example: for a variable named `configInt` of type [config_double](#):

```
bool boolValue = bool(NV_Settings.m_nvBool);
iprintf("boolValue: %d\r\n", boolValue);
```

16.47.3.4 operator=() [1/3]

```
config_bool & config_bool::operator= (
    const bool v) [inline]
```

Assign the [config_bool](#) object value to the specified bool value.

Parameters

<i>v</i>	Value of type bool

16.47.3.5 operator=() [2/3]

```
config_bool & config_bool::operator= (
    const config_bool & cb) [inline]
```

Copy one [config_bool](#) object to another.

Parameters

<i>cb</i>	Reference to a config_bool object

16.47.3.6 operator=() [3/3]

```
config_bool & config_bool::operator= (
    const int i) [inline]
```

Assign a [config_bool](#) object value to the specified integer value.

Parameters

<i>i</i>	Integer value, either 0 (false) or 1 (true)

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.48 config_chooser Class Reference

Chooser Configuration Variable - Select From a List of Items.

```
#include <config_obj.h>
```

Inherits [config_obj](#).

Public Member Functions

- [config_chooser](#) ([config_obj](#) &owner, const char *name, const char *in_value, const char *in_choices, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_chooser](#) (const char *name, const char *in_value, const char *in_choices, const char *desc=NULL)
Object constructor.
- bool [IsSelected](#) (const char *choice)
Check if a particular choice option is selected.
- bool [IsSelected](#) (const [NBString](#) &s)
Check if a particular choice option is selected.
- bool [IsInChoices](#) (const char *str, size_t strLen)
Check if a string is in the list of possible choices. A comparison will continue until a null character is found, or the length of the longer of the two strings being compared is reached (strLen is used to determine if str is longer than the current element being compared.)
- bool [IsInChoices](#) (const [NBString](#) &str, size_t strLen)
Check if a string is in the list of possible choices. A comparison will continue until a null character is found, or the length of the longer of the two strings being compared is reached (strLen is used to determine if str is longer than the current element being compared.)
- const [config_string](#) & [GetChoices](#) ()

- *Get the list of choices.*
const [config_string](#) & [SetChoices](#) (const char *in_choices)
- *Set the list of choices.*
operator [NBString](#) () const
Returns the object value.
- [config_chooser](#) & operator= (const char *p)
Assign the selected list item from a const char value.*
- [config_chooser](#) & operator= (const [NBString](#) &s)
Assign the [config_string](#) object value from a [NBString](#) object.
- [config_chooser](#) & operator= (const [config_chooser](#) &ci)
Copy one [config_chooser](#) object to another.
- virtual void [GetTypeValue](#) ([NBString](#) &s) override
Assigns the object type value to the specified [NBString](#) object.

Public Member Functions inherited from [config_obj](#)

- [config_obj](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_obj](#) (const char *name, const char *desc)
Object constructor.
- virtual void [GetTextValue](#) ([NBString](#) &s) override
Get the object value as a text string to the specified [NBString](#) object.

16.48.1 Detailed Description

Chooser Configuration Variable - Select From a List of Items.

The [config_chooser](#) class provides a list of options with the ability to select one. If used on a web page it would appear as a drop down box. For example, the choices could be "one", "two", or "three", and "two" could be the item selected. Since the items are JSON, the selected item is identified by the option name, not a list index.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.48.2 Constructor & Destructor Documentation

16.48.2.1 [config_chooser](#)() [1/2]

```
config_chooser::config_chooser (
    config\_obj & owner,
    const char * name,
    const char * in_value,
    const char * in_choices,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>name</i>	Field name assigned to the value
<i>in_value</i>	The option value selected
<i>in_choices</i>	The list of option choices
<i>desc</i>	Description used for info/tool tip

16.48.2.2 config_chooser() [2/2]

```
config_chooser::config_chooser (
    const char * name,
    const char * in_value,
    const char * in_choices,
    const char * desc = NULL) [inline]
```

Object constructor.

Parameters

<i>name</i>	Field name assigned to the value
<i>in_value</i>	The option value selected
<i>in_choices</i>	The list of option choices
<i>desc</i>	Description used for info/tool tip

16.48.3 Member Function Documentation**16.48.3.1 GetChoices()**

```
const config\_string & config_chooser::GetChoices () [inline]
```

Get the list of choices.

Returns

A [config_string](#) object containing the list of choices

16.48.3.2 GetTypeValue()

```
virtual void config_chooser::GetTypeValue (
    NBString & s) [inline], [override], [virtual]
```

Assigns the object type value to the specified [NBString](#) object.
The type value "object" is written to the [NBString](#) object.

Parameters

<i>s</i>	NBString object to hold the type value string

Reimplemented from [config_obj](#).

16.48.3.3 IsInChoices() [1/2]

```
bool config_chooser::IsInChoices (
    const char * str,
    size_t strLen) [inline]
```

Check if a string is in the list of possible choices. A comparison will continue until a null character is found, or the length of the longer of the two strings being compared is reached (strLen is used to determine if str is longer than the current element being compared.)

Parameters

<i>str</i>	NBString to attempt to find inside the list of choices
<i>strLen</i>	Length of str. This value is used to determine the amount of characters to compare for each element in the list of choices.

Return values

<i>true</i>	if str is found as an option in list of choices
<i>false</i>	if str is not found in the list of choices

16.48.3.4 IsInChoices() [2/2]

```
bool config_chooser::IsInChoices (
    const NBString & str,
    size_t strLen) [inline]
```

Check if a string is in the list of possible choices. A comparison will continue until a null character is found, or the length of the longer of the two strings being compared is reached (strLen is used to determine if str is longer than the current element being compared.)

Parameters

<i>str</i>	NBString to attempt to find inside the list of choices
<i>strLen</i>	Length of str. This value is used to determine the amount of characters to compare for each element in the list of choices.

Return values

<i>true</i>	if str is found as an option in list of choices
<i>false</i>	if str is not found in the list of choices

16.48.3.5 IsSelected() [1/2]

```
bool config_chooser::IsSelected (
    const char * choice) [inline]
```

Check if a particular choice option is selected.

Parameters

<i>choice</i>	Choice to test as a string type

Return values

<i>true</i>	Selected
<i>false</i>	Not Selected

16.48.3.6 IsSelected() [2/2]

```
bool config_chooser::IsSelected (
    const NBString & s) [inline]
```

Check if a particular choice option is selected.

Parameters

<i>s</i>	Choice to test as a NBString type

Return values

<i>true</i>	Selected
<i>false</i>	Not Selected

16.48.3.7 operator NSString()

```
config_chooser::operator NSString () const [inline]
```

Returns the object value.

Returns

The currently selected list option as a [NSString](#)

16.48.3.8 operator=() [1/3]

```
config_chooser & config_chooser::operator= (  
    const char * p) [inline]
```

Assign the selected list item from a const char* value.

Parameters

<i>p</i>	Selected list item to assign

16.48.3.9 operator=() [2/3]

```
config_chooser & config_chooser::operator= (  
    const config_chooser & ci) [inline]
```

Copy one [config_chooser](#) object to another.

Parameters

<i>ci</i>	Reference to a config_chooser object

16.48.3.10 operator=() [3/3]

```
config_chooser & config_chooser::operator= (  
    const NSString & s) [inline]
```

Assign the [config_string](#) object value from a [NSString](#) object.

Parameters

<i>s</i>	Reference to a NSString object

16.48.3.11 SetChoices()

```
const config_string & config_chooser::SetChoices (  
    const char * in_choices) [inline]
```

Set the list of choices.

Parameters

<i>in_choices</i>	The list of option choices

Returns

A [config_string](#) object containing the list of choices

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.49 [config_double](#) Class Reference

Double Float Configuration Variable.

`#include <config_obj.h>`

Inherits [config_value](#).

Inherited by [config_double_limit](#).

Public Member Functions

- virtual void [GetTextValue](#) ([NBString](#) &s) override
Copy the object value as a text string to the specified [NBString](#) object.
- [config_double](#) ([config_obj](#) &owner, double def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_double](#) (double def_val, const char *name, const char *desc=NULL)
Object constructor.
- [operator int](#) () const
Return the object value as an int.
- [operator float](#) () const
Return the object value as a float.
- [operator double](#) () const
Returns the object value as a double float.
- [config_double](#) & [operator=](#) (const double d)
Assign the [config_double](#) object value from a double value.
- [config_double](#) & [operator=](#) (const [config_double](#) &ci)
Copy one [config_double](#) object to another.
- virtual void [GetTypeValue](#) ([NBString](#) &s) override
Copy the object type value in the specified [NBString](#) object.

Additional Inherited Members**Protected Member Functions inherited from [config_value](#)**

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.49.1 Detailed Description

Double Float Configuration Variable.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.49.2 Constructor & Destructor Documentation

16.49.2.1 config_double() [1/2]

```
config_double::config_double (
    config_obj & owner,
    double def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Parameters

<i>owner</i>	Reference to parent leaf
<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.49.2.2 config_double() [2/2]

```
config_double::config_double (
    double def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor.

Parameters

<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.49.3 Member Function Documentation

16.49.3.1 GetTextValue()

```
virtual void config_double::GetTextValue (
    NBString & s) [inline], [override], [virtual]
```

Copy the object value as a text string to the specified [NBString](#) object.

This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result

Implements [config_value](#).

16.49.3.2 GetTypeValue()

```
virtual void config_double::GetTypeValue (
    NBString & s) [inline], [override], [virtual]
```

Copy the object type value in the specified [NBString](#) object.

The type value "string" is written to the [NBString](#) object, since browsers don't handle decimal numbers well with a "number" type unless the "step" attribute is also specified

Parameters

<code>s</code>	Reference to a NBString object

Reimplemented in [config_double_limit](#).

16.49.3.3 operator double()

```
config_double::operator double () const [inline]
```

Returns the object value as a double float.

Returns

The double float value of the object

Example: for a variable named `configInt` of type [config_double](#):

```
double value = double(configInt);
iprintf("int = %f\r\n", value);
```

16.49.3.4 operator float()

```
config_double::operator float () const [inline]
```

Return the object value as a float.

Returns

The float value of the object

Example: for a variable named `configFloat` of type [config_double](#):

```
float value = float(configFloat);
iprintf("int = %f\r\n", value);
```

16.49.3.5 operator int()

```
config_double::operator int () const [inline]
```

Return the object value as an int.

Returns

The integer value of the object

Example: for a variable named `configInt` of type [config_double](#):

```
int value = int(configInt);
iprintf("int = %d\r\n", value);
```

16.49.3.6 operator=() [1/2]

```
config_double & config_double::operator= (
    const config_double & ci) [inline]
```

Copy one [config_double](#) object to another.

Parameters

<code>ci</code>	Reference to a config_double object

16.49.3.7 operator=() [2/2]

```
config_double & config_double::operator= (
    const double d) [inline]
```

Assign the [config_double](#) object value from a double value.

Parameters

<i>d</i>	Value of type double

The documentation for this class was generated from the following file:

- config_obj.h

16.50 config_double_limit Class Reference

A [config_double](#) with minimum and/or maximum values Attempting to set a value lower than the minimum or greater than the maximum will fail with an error both programmatically and in the Config Web UI.

```
#include <config_obj.h>
```

Inherits [config_double](#).

Public Member Functions

- [config_double_limit](#) ([config_obj](#) &owner, double def_val, double minv=-DBL_MAX, double maxv=DBL_MAX, double stepv=0.01, const char *name=NULL, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter and limits.
- [config_double_limit](#) (double def_val, double minv=-DBL_MAX, double maxv=DBL_MAX, double stepv=0.01, const char *name=NULL, const char *desc=NULL)
Object constructor with limits.
- [config_double_limit](#) & [operator=](#) (const [config_double](#) &ci)
Copy a [config_double](#) object into the [config_double_limit](#).
- [config_double_limit](#) & [operator=](#) (const [config_double_limit](#) &cil)
Copy one [config_double_limit](#) object to another.
- virtual void [GetTypeValue](#) ([NBString](#) &s) override
Copy the object type value in the specified [NBString](#) object.

Public Member Functions inherited from [config_double](#)

- virtual void [GetTextValue](#) ([NBString](#) &s) override
Copy the object value as a text string to the specified [NBString](#) object.
- [config_double](#) ([config_obj](#) &owner, double def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_double](#) (double def_val, const char *name, const char *desc=NULL)
Object constructor.
- [operator int](#) () const
Return the object value as an int.
- [operator float](#) () const
Return the object value as a float.
- [operator double](#) () const
Returns the object value as a double float.
- [config_double](#) & [operator=](#) (const double d)
Assign the [config_double](#) object value from a double value.
- [config_double](#) & [operator=](#) (const [config_double](#) &ci)
Copy one [config_double](#) object to another.

Additional Inherited Members

Protected Member Functions inherited from [config_value](#)

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.50.1 Detailed Description

A [config_double](#) with minimum and/or maximum values Attempting to set a value lower than the minimum or greater than the maximum will fail with an error both programmatically and in the Config Web UI.

16.50.2 Constructor & Destructor Documentation

16.50.2.1 [config_double_limit\(\)](#) [1/2]

```
config_double_limit::config_double_limit (
    config\_obj & owner,
    double def_val,
    double minv = -DBL_MAX,
    double maxv = DBL_MAX,
    double stepv = 0.01,
    const char * name = NULL,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter and limits.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value
<i>minv</i>	Minimum value
<i>maxv</i>	Maximum value
<i>stepv</i>	Step value (for HTML-side validation, not strictly enforced)
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.50.2.2 [config_double_limit\(\)](#) [2/2]

```
config_double_limit::config_double_limit (
    double def_val,
    double minv = -DBL_MAX,
    double maxv = DBL_MAX,
    double stepv = 0.01,
    const char * name = NULL,
    const char * desc = NULL) [inline]
```

Object constructor with limits.

Parameters

<i>def_val</i>	Default value
<i>minv</i>	Minimum value
<i>maxv</i>	Maximum value
<i>stepv</i>	Step value (for HTML-side validation, not strictly enforced)
<i>name</i>	Field name assigned to the value

<i>desc</i>	Description used for info/tool tip

16.50.3 Member Function Documentation

16.50.3.1 GetTypeValue()

```
virtual void config_double_limit::GetTypeValue (
    NBString & s) [inline], [override], [virtual]
```

Copy the object type value in the specified [NBString](#) object.
The type value "number" is written to the [NBString](#) object.

Parameters

<i>s</i>	Reference to a NBString object

Reimplemented from [config_double](#).

16.50.3.2 operator=() [1/2]

```
config_double_limit & config_double_limit::operator= (
    const config_double & ci) [inline]
```

Copy a [config_double](#) object into the [config_double_limit](#).

Parameters

<i>ci</i>	Reference to a config_double object

16.50.3.3 operator=() [2/2]

```
config_double_limit & config_double_limit::operator= (
    const config_double_limit & cil) [inline]
```

Copy one [config_double_limit](#) object to another.

Parameters

<i>cil</i>	Reference to a config_double_limit object

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.51 config_int Class Reference

Signed 32-bit Integer Configuration Variable.

#include <config_obj.h>

Inherits [config_value](#).

Inherited by [config_int_limit](#), and [version_obj](#).

Public Member Functions

- virtual void [GetTextValue](#) ([NBString](#) &s) override
Copy the object value to the specified [NBString](#) object.
- [config_int](#) ([config_obj](#) &owner, int def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.

- [config_int](#) (int def_val, const char *name, const char *desc=NULL)
Object constructor.
- [operator int](#) () const
Return the object value as an int.
- [config_int](#) & [operator=](#) (const int i)
Assign the [config_int](#) object value to the specified int value.
- [config_int](#) & [operator=](#) (const [config_int](#) &ci)
Copy one [config_int](#) object to another.
- virtual void [GetTypeValue](#) (NBString &s) override
Copy the object type value in the specified [NBString](#) object.

Additional Inherited Members

Protected Member Functions inherited from [config_value](#)

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.51.1 Detailed Description

Signed 32-bit Integer Configuration Variable.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.51.2 Constructor & Destructor Documentation

16.51.2.1 [config_int](#)() [1/2]

```
config_int::config_int (
    config\_obj & owner,
    int def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.51.2.2 [config_int](#)() [2/2]

```
config_int::config_int (
    int def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor.

Parameters

<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.51.3 Member Function Documentation**16.51.3.1 GetTextValue()**

```
virtual void config_int::GetTextValue (
    NBString & s) [inline], [override], [virtual]
```

Copy the object value to the specified [NBString](#) object.

This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result

Implements [config_value](#).

16.51.3.2 GetTypeValue()

```
virtual void config_int::GetTypeValue (
    NBString & s) [inline], [override], [virtual]
```

Copy the object type value in the specified [NBString](#) object.

The type value "integer" is written to the [NBString](#) object.

Parameters

<i>s</i>	Reference to a NBString object

16.51.3.3 operator int()

```
config_int::operator int () const [inline]
```

Return the object value as an int.

Returns

The integer value of the object

Example: for a variable named configInt of type [config_int](#):

```
int value = int(configInt);
iprintf("int = %d\r\n", value);
```

16.51.3.4 operator=() [1/2]

```
config_int & config_int::operator= (
    const config_int & ci) [inline]
```

Copy one [config_int](#) object to another.

Parameters

<i>ci</i>	Reference to a config_int object

16.51.3.5 operator=() [2/2]

```
config_int & config_int::operator= (  
    const int i) [inline]
```

Assign the [config_int](#) object value to the specified int value.

Parameters

<i>i</i>	Integer value

The documentation for this class was generated from the following file:

- config_obj.h

16.52 config_int_limit Class Reference

A [config_int](#) with minimum and/or maximum values Attempting to set a value lower than the minimum or greater than the maximum will fail with an error both programmatically and in the Config Web UI.

```
#include <config_obj.h>
```

Inherits [config_int](#).

Public Member Functions

- [config_int_limit](#) ([config_obj](#) &owner, int def_val, int minv=INT_MIN, int maxv=INT_MAX, const char *name=NULL, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter and limits.
- [config_int_limit](#) (int def_val, int minv=INT_MIN, int maxv=INT_MAX, const char *name=NULL, const char *desc=NULL)
Object constructor with limits.
- [config_int_limit](#) & [operator=](#) (const [config_int](#) &ci)
Copy a [config_int](#) object into the [config_int_limit](#).
- [config_int_limit](#) & [operator=](#) (const [config_int_limit](#) &cil)
Copy one [config_int_limit](#) object to another.

Public Member Functions inherited from [config_int](#)

- virtual void [GetTextValue](#) (NSString &s) override
Copy the object value to the specified [NSString](#) object.
- [config_int](#) ([config_obj](#) &owner, int def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_int](#) (int def_val, const char *name, const char *desc=NULL)
Object constructor.
- [operator int](#) () const
Return the object value as an int.
- [config_int](#) & [operator=](#) (const int i)
Assign the [config_int](#) object value to the specified int value.
- [config_int](#) & [operator=](#) (const [config_int](#) &ci)
Copy one [config_int](#) object to another.
- virtual void [GetTypeValue](#) (NSString &s) override
Copy the object type value in the specified [NSString](#) object.

Additional Inherited Members

Protected Member Functions inherited from [config_value](#)

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.52.1 Detailed Description

A [config_int](#) with minimum and/or maximum values Attempting to set a value lower than the minimum or greater than the maximum will fail with an error both programmatically and in the Config Web UI.

16.52.2 Constructor & Destructor Documentation

16.52.2.1 [config_int_limit\(\)](#) [1/2]

```
config_int_limit::config_int_limit (
    config\_obj & owner,
    int def_val,
    int minv = INT_MIN,
    int maxv = INT_MAX,
    const char * name = NULL,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter and limits.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value
<i>minv</i>	Minimum value
<i>maxv</i>	Maximum value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.52.2.2 [config_int_limit\(\)](#) [2/2]

```
config_int_limit::config_int_limit (
    int def_val,
    int minv = INT_MIN,
    int maxv = INT_MAX,
    const char * name = NULL,
    const char * desc = NULL) [inline]
```

Object constructor with limits.

Parameters

<i>def_val</i>	Default value
<i>minv</i>	Minimum value
<i>maxv</i>	Maximum value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.52.3 Member Function Documentation

16.52.3.1 [operator=\(\)](#) [1/2]

```
config\_int\_limit & config\_int\_limit::operator= (
    const config\_int & ci) [inline]
```

Copy a [config_int](#) object into the [config_int_limit](#).

Parameters

<i>ci</i>	Reference to a config_int object

16.52.3.2 operator=() [2/2]

```
config_int_limit & config_int_limit::operator= (
    const config_int_limit & cil) [inline]
```

Copy one [config_int_limit](#) object to another.

Parameters

<i>cil</i>	Reference to a config_int_limit object

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.53 config_IPADDR Class Reference

Configuration Variable for IPADDR (IPv6) object type.

```
#include <config_obj.h>
```

Inherits [config_value](#).

Public Member Functions

- virtual void [GetTextValue](#) ([NBString](#) &s) override
Get the object value as a text string with quotations to the specified [NBString](#) object.
- [config_IPADDR](#) ([config_obj](#) &owner, [IPADDR](#) def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_IPADDR](#) ([IPADDR](#) def_val, const char *name, const char *desc=NULL)
Object constructor.
- [config_IPADDR](#) ([config_obj](#) &owner, const char *def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_IPADDR](#) (const char *def_val, const char *name, const char *desc=NULL)
Object constructor.
- [operator IPADDR](#) () const
Returns the object value.
- bool [IsNull](#) () const
Check if the IP address is null.
- bool [NotNull](#) () const
Check if the IP address is not null.
- void [SetNull](#) ()
Set the IP address value of an [config_IPADDR](#) object to null.
- [config_IPADDR](#) & [operator=](#) (const [IPADDR](#) &i6)
Copy an IPADDR object value to a [config_IPADDR](#) object.
- [config_IPADDR](#) & [operator=](#) (const [config_IPADDR](#) &ci)
Copy one [config_IPADDR](#) object to another.
- virtual void [GetTypeValue](#) ([NBString](#) &s) override
Copy the object type value to the specified [NBString](#) object.

Additional Inherited Members

Protected Member Functions inherited from [config_value](#)

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.53.1 Detailed Description

Configuration Variable for IPADDR (IPv6) object type.

See also

[config_IPADDR4](#)

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.53.2 Constructor & Destructor Documentation

16.53.2.1 config_IPADDR() [1/4]

```
config_IPADDR::config_IPADDR (
    config_obj & owner,
    IPADDR def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.
Default value assigned with an IPADDR object

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type IPADDR
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.53.2.2 config_IPADDR() [2/4]

```
config_IPADDR::config_IPADDR (
    IPADDR def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor.
Default value assigned with an IPADDR object

Parameters

<i>def_val</i>	Default value of type NBString
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.53.2.3 config_IPADDR() [3/4]

```
config_IPADDR::config_IPADDR (
    config_obj & owner,
    const char * def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.
Default value assigned with an const char * string. IP address is converted using the SetFromAscii() IPADDR member function.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type char * in IPv6 format
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.53.2.4 config_IPADDR() [4/4]

```
config_IPADDR::config_IPADDR (
    const char * def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor.

Default value assigned with an const char * string. IP address is converted using the SetFromAscii() IPADDR member function.

Parameters

<i>def_val</i>	Default value of type char * in IPv6 format
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.53.3 Member Function Documentation**16.53.3.1 GetTextValue()**

```
virtual void config_IPADDR::GetTextValue (
    NBString & s) [inline], [override], [virtual]
```

Get the object value as a text string with quotations to the specified [NBString](#) object.

This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result

Implements [config_value](#).

16.53.3.2 GetTypeValue()

```
virtual void config_IPADDR::GetTypeValue (
    NBString & s) [inline], [override], [virtual]
```

Copy the object type value to the specified [NBString](#) object.

The type value "string" is written to the [NBString](#) object.

Parameters

<i>s</i>	NBString object to hold the type value string

16.53.3.3 IsNull()

```
bool config_IPADDR::IsNull () const [inline]
```

Check if the IP address is null.

Return values

<i>true</i>	if the IP address value is null

See also

[NotNull\(\)](#)**16.53.3.4 NotNull()**

```
bool config_IPADDR::NotNull () const [inline]
```

Check if the IP address is not null.

Return values

<i>true</i>	if the IP address value is not null

See also

[IsNull\(\)](#)**16.53.3.5 operator IPADDR()**

```
config_IPADDR::operator IPADDR () const [inline]
```

Returns the object value.

Returns

The value of the object as an IPADDR object

16.53.3.6 operator=() [1/2]

```
config_IPADDR & config_IPADDR::operator= (  
    const config_IPADDR & ci) [inline]
```

Copy one [config_IPADDR](#) object to another.

Parameters

<i>ci</i>	Reference to a config_IPADDR object

16.53.3.7 operator=() [2/2]

```
config_IPADDR & config_IPADDR::operator= (  
    const IPADDR & i6) [inline]
```

Copy an IPADDR object value to a [config_IPADDR](#) object.

Parameters

<i>i6</i>	Reference to an IPADDR object

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.54 config_IPADDR4 Class Reference

Configuration Variable for [IPADDR4](#) (IPv4) object types.

#include <config_obj.h>

Inherits [config_value](#).

Public Member Functions

- virtual void [GetTextValue](#) (NBString &s) override
Get the object value as a text string with quotations to the specified NBString object.
- [config_IPADDR4](#) (config_obj &owner, IPADDR4 def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_IPADDR4](#) (IPADDR4 def_val, const char *name, const char *desc=NULL)
Object constructor.
- [config_IPADDR4](#) (config_obj &owner, const char *def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_IPADDR4](#) (const char *def_val, const char *name, const char *desc=NULL)
Object constructor.
- [operator IPADDR4](#) () const
Returns the object value.
- bool [IsNull](#) () const
Check if the IP address is null.
- bool [NotNull](#) () const
Check if the IP address is not null.
- void [SetNull](#) ()
Set the IP address to null.
- [config_IPADDR4](#) & [operator=](#) (const IPADDR4 &i4)
Copy an IPADDR4 object value to a config_IPADDR4 object.
- [config_IPADDR4](#) & [operator=](#) (const config_IPADDR4 &ci)
Copy one config_IPADDR4 object to another.
- virtual void [GetTypeValue](#) (NBString &s) override
Copy the object type value to the specified NBString object.

Additional Inherited Members

Protected Member Functions inherited from [config_value](#)

- [config_value](#) (config_obj &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.54.1 Detailed Description

Configuration Variable for [IPADDR4](#) (IPv4) object types.

See also

[config_IPADDR](#)

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.54.2 Constructor & Destructor Documentation

16.54.2.1 config_IPADDR4() [1/4]

```
config_IPADDR4::config_IPADDR4 (  
    config_obj & owner,  
    IPADDR4 def_val,  
    const char * name,  
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value assigned with an [IPADDR4](#) object

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type IPADDR4
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.54.2.2 config_IPADDR4() [2/4]

```
config_IPADDR4::config_IPADDR4 (  
    IPADDR4 def_val,  
    const char * name,  
    const char * desc = NULL) [inline]
```

Object constructor.

Default value assigned with an [IPADDR4](#) object

Parameters

<i>def_val</i>	Default value of type NBString
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.54.2.3 config_IPADDR4() [3/4]

```
config_IPADDR4::config_IPADDR4 (  
    config_obj & owner,  
    const char * def_val,  
    const char * name,  
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value assigned with an const char * string. IP address is converted using the [IPADDR4](#) SetFromAscii() member function.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type char *. Format is: "xxx.xxx.xxx.xxx". For example, "10.1.1.100"
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.54.2.4 config_IPADDR4() [4/4]

```
config_IPADDR4::config_IPADDR4 (
    const char * def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor.

Default value assigned with an const char * string. IP address is converted using the [IPADDR4](#) SetFromAscii() member function.

Parameters

<i>def_val</i>	Default value of type char *. Format is: "xxx.xxx.xxx.xxx". For example, "10.1.1.100"
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.54.3 Member Function Documentation**16.54.3.1 GetTextValue()**

```
virtual void config_IPADDR4::GetTextValue (
    NBString & s) [inline], [override], [virtual]
```

Get the object value as a text string with quotations to the specified [NBString](#) object.

The format of the string is: "xxx.xxx.xxx.xxx". This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result

Implements [config_value](#).

16.54.3.2 GetTypeValue()

```
virtual void config_IPADDR4::GetTypeValue (
    NBString & s) [inline], [override], [virtual]
```

Copy the object type value to the specified [NBString](#) object.

The type value "string" is written to the [NBString](#) object.

Parameters

<i>s</i>	NBString object to hold the type value string

16.54.3.3 IsNull()

```
bool config_IPADDR4::IsNull () const [inline]
```

Check if the IP address is null.

Return values

<i>true</i>	if the IP address value is null

See also

[NotNull\(\)](#), [SetNull\(\)](#)

16.54.3.4 NotNull()

```
bool config_IPADDR4::NotNull () const [inline]
```

Check if the IP address is not null.

Return values

<code>true</code>	if the IP address value is not null

See also

[IsNull\(\)](#), [SetNull\(\)](#)

16.54.3.5 operator IPADDR4()

```
config_IPADDR4::operator IPADDR4 () const [inline]
```

Returns the object value.

Returns

The value of the object as an [IPADDR4](#)

16.54.3.6 operator=() [1/2]

```
config_IPADDR4 & config_IPADDR4::operator= (
    const config_IPADDR4 & ci) [inline]
```

Copy one [config_IPADDR4](#) object to another.

Parameters

<code>ci</code>	Reference to a config_IPADDR4 object

16.54.3.7 operator=() [2/2]

```
config_IPADDR4 & config_IPADDR4::operator= (
    const IPADDR4 & i4) [inline]
```

Copy an [IPADDR4](#) object value to a [config_IPADDR4](#) object.

Parameters

<code>i4</code>	Reference to an IPADDR4 object

16.54.3.8 SetNull()

```
void config_IPADDR4::SetNull () [inline]
```

Set the IP address to null.

See also

[IsNull\(\)](#), [NotNull\(\)](#)

Object constructor.

16.55.1 Detailed Description

Configure device network name.

16.55.2 Constructor & Destructor Documentation

16.55.2.1 config_localname() [1/4]

```
config_localname::config_localname (  
    config\_obj & owner,  
    NBString def_val,  
    const char * name,  
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.
Default value is assigned with a [NBString](#)

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type NBString
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.55.2.2 config_localname() [2/4]

```
config_localname::config_localname (  
    NBString def_val,  
    const char * name,  
    const char * desc = NULL) [inline]
```

Object constructor.
Default value is assigned with a [NBString](#)

Parameters

<i>def_val</i>	Default value of type NBString
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.55.2.3 config_localname() [3/4]

```
config_localname::config_localname (  
    config\_obj & owner,  
    const char * def_val,  
    const char * name,  
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.
Default value is assigned with a character string

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type char *
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.55.2.4 config_localname() [4/4]

```
config_localname::config_localname (  
    const char * def_val,  
    const char * name,  
    const char * desc = NULL) [inline]
```

Object constructor.

Default value is assigned with a character string

Parameters

<i>def_val</i>	Default value of type char *
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.55.3 Member Function Documentation**16.55.3.1 operator NBString()**

```
config_localname::operator NBString () const [inline]
```

Returns the object value.

Returns

The value of the object as a [NBString](#)

16.55.3.2 operator=() [1/4]

```
config_localname & config_localname::operator= (  
    const char * p) [inline]
```

Assign the [config_localname](#) object value from a const char* value.

Parameters

<i>p</i>	String to assign

16.55.3.3 operator=() [2/4]

```
config_localname & config_localname::operator= (  
    const config_localname & ci) [inline]
```

Copy one [config_localname](#) object to another.

Parameters

<i>ci</i>	Reference to a config_localname object

16.55.3.4 operator=() [3/4]

```
config_localname & config_localname::operator= (
    const config_string & ci) [inline]
```

Copy a [config_string](#) object to a [config_localname](#) object.

Parameters

<i>ci</i>	Reference to a config_string object

16.55.3.5 operator=() [4/4]

```
config_localname & config_localname::operator= (
    const NBString & s) [inline]
```

Assign the [config_localname](#) object value from a [NBString](#) object.

Parameters

<i>s</i>	Reference to a NBString object

The documentation for this class was generated from the following file:

- [config_netobj.h](#)

16.56 config_MACADR Class Reference

Configuration Variable for [MACADR](#) object type.

Object constructor.

16.56.1 Detailed Description

Configuration Variable for [MACADR](#) object type.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.56.2 Constructor & Destructor Documentation

16.56.2.1 [config_MACADR\(\)](#) [1/4]

```
config_MACADR::config_MACADR (
    config\_obj & owner,
    MACADR def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value assigned with an [MACADR](#) object

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type MACADR
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.56.2.2 [config_MACADR\(\)](#) [2/4]

```
config_MACADR::config_MACADR (
    MACADR def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor.

Default value assigned with an [MACADR](#) object

Parameters

<i>def_val</i>	Default value of type MACADR
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.56.2.3 config_MACADR() [3/4]

```
config_MACADR::config_MACADR (
    config_obj & owner,
    const char * def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value is assigned with a const char * string. The [AsciiToMac\(\)](#) function is used to convert the string to a [MACADR](#).

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default MAC Address value of type char *. The hexidical format must be 6 octets, with or without ':' separators. For example, "0123456789AB", or "01:23:45:67:89:AB"
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.56.2.4 config_MACADR() [4/4]

```
config_MACADR::config_MACADR (
    const char * def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor.

Default value is assigned with a const char * string. The [AsciiToMac\(\)](#) function is used to convert the string to a [MACADR](#).

Parameters

<i>def_val</i>	Default MAC Address value of type char *. The hexidical format must be 6 octets, with or without ':' separators. For example, "0123456789AB", or "01:23:45:67:89:AB"
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.56.3 Member Function Documentation**16.56.3.1 GetTextValue()**

```
virtual void config_MACADR::GetTextValue (
    NBString & s) [inline], [override], [virtual]
```

Get the object value as a text string with quotations to the specified [NBString](#) object.

The format is the hexadecimal address: "xx:xx:xx:xx:xx:xx" This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result

Implements [config_value](#).

16.56.3.2 GetTypeValue()

```
virtual void config_MACADR::GetTypeValue (
    NBString & s) [inline], [override], [virtual]
```

Copy the object type value to the specified [NSString](#) object.
The type value "string" is written to the [NSString](#) object.

Parameters

s	NBString object to hold the type value string

16.56.3.3 operator MACADR()

```
config_MACADR::operator MACADR () const [inline]
```

Returns the object value.

Returns

The value of the object as a [MACADR](#)

16.56.3.4 operator=() [1/2]

```
config_MACADR & config_MACADR::operator= (
    const config_MACADR & ci) [inline]
```

Copy one [config_MACADR](#) object to another.

Parameters

ci	Reference to a config_IPADDR object

16.56.3.5 operator=() [2/2]

```
config_MACADR & config_MACADR::operator= (
    const MACADR & ci) [inline]
```

Copy a [MACADR](#) object value to a [MACADR](#) object.

Parameters

ci	Reference to an MACADR object

The documentation for this class was generated from the following file:

Object constructor.
- virtual void [GetTextValue](#) ([NBString](#) &s) override
Get the object value as a text string to the specified [NBString](#) object.
- virtual void [GetTypeValue](#) ([NBString](#) &s) override
Assigns the object type value to the specified [NBString](#) object.

16.57.1 Detailed Description

Base class used to create configuration objects.

Base that can be used to create your own custom configuration objects in a JSON compatible format. The object can hold any number of JSON compatible types: integer, boolean, null, string, object or array.

A [config_obj](#) can hold multiple values in a JSON object. A [config_value](#) holds only a single JSON value.

See also

[config_value](#)

The example below demonstrates how to create a thermostat object with a temperature range derived from a [config_obj](#):

Note

Please check the Configuration Class example in the `\nburn\examples` folder for the latest code updates.

The use of config objects should be done at a global scope. They can contain any number of members, which should be given a [default](#) value and a name used as an identifier. The name value [for each](#) member variable should be unique, otherwise it can lead to issues inside the config tree.

```
class TempRange : public config_obj
{
public:
    // Class variables
    config_int m_maxTemp{100, "MaxTemp"};
    config_int m_setTemp{30, "SetTemp"};
    config_int m_minTemp{10, "MinTemp"};
    ConfigEndMarker; // No new data members below this line

    // Class constructors
    TempRange(const char *name, const char *desc = nullptr) : config_obj(name, desc){};
    TempRange(config_obj &owner, const char *name, const char *desc = nullptr) : config_obj(owner, name,
        desc){};
};

class Thermostat : public TempRange
{
public:
    config_int m_tempRec1{101, "TempRecord_1"};
    config_int m_tempRec2{102, "TempRecord_2"};
    config_bool m_active{true, "Active"};
    config_string m_location{"Warehouse 1", "Thermostat Location"};
    config_chooser m_tempScale{"Temperature Scale", "Fahrenheit", "Fahrenheit", "Celsius", "Kelvin"};
    ConfigEndMarker; // No new data members below this line

    Thermostat(const char *name, const char *desc = nullptr) : TempRange(name, desc){};
    Thermostat(config_obj &owner, const char *name, const char *desc = nullptr) : TempRange(owner, name,
        desc){};
};

static Thermostat thermo(appdata, "Thermostat", "The primary thermostat");
```

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.57.2 Constructor & Destructor Documentation

16.57.2.1 config_obj() [1/2]

```
config_obj::config_obj (
    config_obj & owner,
    const char * name,
    const char * desc) [inline]
```

Object constructor with the parent/owner leaf parameter.

For example,

```
myObject(config_obj &owner, const char *name, const char *desc = nullptr) : config_obj(owner, name, desc){};
```

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>name</i>	Field name

<i>desc</i>	Description used for info/tool tip

16.57.2.2 config_obj() [2/2]

```
config_obj::config_obj (
    const char * name,
    const char * desc) [inline]
```

Object constructor.

This constructor should be called as part of the derived class constructor. For example,
`myObject(const char *name, const char *desc = nullptr) : config_obj(name, desc){}`

Parameters

<i>name</i>	Field name
<i>desc</i>	Description used for info/tool tip

16.57.3 Member Function Documentation

16.57.3.1 GetTextValue()

```
virtual void config_obj::GetTextValue (
    NBString & s) [override], [virtual]
```

Get the object value as a text string to the specified [NBString](#) object.
 This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result

16.57.3.2 GetTypeValue()

```
virtual void config_obj::GetTypeValue (
    NBString & s) [inline], [override], [virtual]
```

Assigns the object type value to the specified [NBString](#) object.
 The type value "object" is written to the [NBString](#) object.

Parameters

<i>s</i>	NBString object to hold the type value string

Reimplemented in [config_chooser](#).

The documentation for this class was generated from the following file:

- `config_obj.h`

16.58 config_pass Class Reference

Password string Configuration Variable.

`#include <config_obj.h>`

Inherits [config_string](#).

Inherited by [config_pass_limit](#).

Public Member Functions

- [config_pass](#) ([config_obj](#) &owner, [NBString](#) def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_pass](#) ([NBString](#) def_val, const char *name, const char *desc=NULL)
Object constructor.
- [config_pass](#) ([config_obj](#) &owner, const char *def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_pass](#) (const char *def_val, const char *name, const char *desc=NULL)
Object constructor.
- virtual void [GetTextValue](#) ([NBString](#) &s) override
Get the [config_pass](#) object value as a text string.
- virtual void [GetRawValue](#) ([NBString](#) &s) override
Copy the raw [config_string](#) object value to the [NBString](#) object.
- [operator NBString](#) () const
Returns the object value.
- [config_pass](#) & [operator=](#) (const char *p)
Assign the [config_pass](#) object value from a const char value.*
- [config_pass](#) & [operator=](#) (const [NBString](#) &s)
Assign the [config_pass](#) object value from a [NBString](#) object.
- [config_pass](#) & [operator=](#) (const [config_string](#) &ci)
Copy a [config_string](#) object to a [config_pass](#) object.
- [config_pass](#) & [operator=](#) (const [config_pass](#) &ci)
Copy one [config_pass](#) object to another.

Public Member Functions inherited from [config_string](#)

- [config_string](#) ([config_obj](#) &owner, [NBString](#) def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_string](#) ([NBString](#) def_val, const char *name, const char *desc=NULL)
Object constructor.
- [config_string](#) ([config_obj](#) &owner, const char *def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_string](#) (const char *def_val, const char *name, const char *desc=NULL)
Object constructor.
- void [SetEnumList](#) ([NBString](#) s)
Renders the data used to explain the schema/descriptions for the list of choices.
- [operator NBString](#) () const
Return the object value.
- [config_string](#) & [operator=](#) (const char *p)
Assign the [config_string](#) object value from a const char string.*
- [config_string](#) & [operator=](#) (const [NBString](#) &s)
Assign the [config_string](#) object value from a [NBString](#) object.
- [config_string](#) & [operator=](#) (const [config_string](#) &ci)
Copy one [config_string](#) object to another.
- const char * [c_str](#) () const
Returns the object value as a string.
- size_t [length](#) () const
Returns the string length in bytes.
- const char & [operator\[\]](#) (size_t pos) const
Return the value of a character in the string.
- virtual void [GetTypeValue](#) ([NBString](#) &s) override
Copy the object type value to the specified [NBString](#) object.

Additional Inherited Members

Protected Member Functions inherited from [config_value](#)

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.58.1 Detailed Description

Password string Configuration Variable.

A [config_pass](#) is like a [config_string](#), but the data is hidden by '*' characters.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.58.2 Constructor & Destructor Documentation

16.58.2.1 config_pass() [1/4]

```
config_pass::config_pass (
    config\_obj & owner,
    NBString def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value is assigned with a [NBString](#)

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type NBString
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.58.2.2 config_pass() [2/4]

```
config_pass::config_pass (
    NBString def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor.

Default value is assigned with a [NBString](#)

Parameters

<i>def_val</i>	Default value of type NBString
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.58.2.3 config_pass() [3/4]

```
config_pass::config_pass (
    config_obj & owner,
    const char * def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value is assigned with a character string

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type char *
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.58.2.4 config_pass() [4/4]

```
config_pass::config_pass (
    const char * def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor.

Default value is assigned with a character string

Parameters

<i>def_val</i>	Default value of type char *
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.58.3 Member Function Documentation

16.58.3.1 GetRawValue()

```
virtual void config_pass::GetRawValue (
    NBString & s) [override], [virtual]
```

Copy the raw [config_string](#) object value to the [NBString](#) object.

Parameters

<i>s</i>	Reference to a NBString object

This is a virtual function that can be overridden in any derived class.

16.58.3.2 GetTextValue()

```
virtual void config_pass::GetTextValue (
    NBString & s) [override], [virtual]
```

Get the [config_pass](#) object value as a text string.

This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result

Reimplemented from [config_string](#).

16.58.3.3 operator NSString()

```
config_pass::operator NSString () const [inline]
```

Returns the object value.

Returns

The value of the object as a [NSString](#)

16.58.3.4 operator=() [1/4]

```
config_pass & config_pass::operator= (  
    const char * p) [inline]
```

Assign the [config_pass](#) object value from a const char* value.

Parameters

<i>p</i>	String to assign

16.58.3.5 operator=() [2/4]

```
config_pass & config_pass::operator= (  
    const config_pass & ci) [inline]
```

Copy one [config_pass](#) object to another.

Parameters

<i>ci</i>	Reference to a config_pass object

16.58.3.6 operator=() [3/4]

```
config_pass & config_pass::operator= (  
    const config_string & ci) [inline]
```

Copy a [config_string](#) object to a [config_pass](#) object.

Parameters

<i>ci</i>	Reference to a config_string object

16.58.3.7 operator=() [4/4]

```
config_pass & config_pass::operator= (  
    const NSString & s) [inline]
```

Assign the [config_pass](#) object value from a [NSString](#) object.

Parameters

<i>s</i>	Reference to a NSString object

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.59 config_pass_limit Class Reference

A [config_pass](#) with minimum and/or maximum lengths Attempting to set a value shorter than the minimum or longer than the maximum will fail with an error both programmatically and in the Config Web UI.

```
#include <config_obj.h>
```

Inherits [config_pass](#).

Public Member Functions

- [config_pass_limit](#) ([config_obj](#) &owner, [NBString](#) def_val, size_t minl=0, size_t maxl=0, const char *name=NULL, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter and limits.
- [config_pass_limit](#) ([NBString](#) def_val, size_t minl=0, size_t maxl=0, const char *name=NULL, const char *desc=NULL)
Object constructor with limits.
- [config_pass_limit](#) & operator= (const [config_pass](#) &ci)
Copy a [config_pass](#) object into the [config_pass_limit](#).
- [config_pass_limit](#) & operator= (const [config_pass_limit](#) &cil)
Copy one [config_pass_limit](#) object to another.

Public Member Functions inherited from [config_pass](#)

- [config_pass](#) ([config_obj](#) &owner, [NBString](#) def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_pass](#) ([NBString](#) def_val, const char *name, const char *desc=NULL)
Object constructor.
- [config_pass](#) ([config_obj](#) &owner, const char *def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_pass](#) (const char *def_val, const char *name, const char *desc=NULL)
Object constructor.
- virtual void [GetTextValue](#) ([NBString](#) &s) override
Get the [config_pass](#) object value as a text string.
- virtual void [GetRawValue](#) ([NBString](#) &s) override
Copy the raw [config_string](#) object value to the [NBString](#) object.
- operator [NBString](#) () const
Returns the object value.
- [config_pass](#) & operator= (const char *p)
Assign the [config_pass](#) object value from a const char value.*
- [config_pass](#) & operator= (const [NBString](#) &s)
Assign the [config_pass](#) object value from a [NBString](#) object.
- [config_pass](#) & operator= (const [config_string](#) &ci)
Copy a [config_string](#) object to a [config_pass](#) object.
- [config_pass](#) & operator= (const [config_pass](#) &ci)
Copy one [config_pass](#) object to another.

Public Member Functions inherited from [config_string](#)

- [config_string](#) ([config_obj](#) &owner, [NBString](#) def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_string](#) ([NBString](#) def_val, const char *name, const char *desc=NULL)
Object constructor.
- [config_string](#) ([config_obj](#) &owner, const char *def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.

- [config_string](#) (const char *def_val, const char *name, const char *desc=NULL)
Object constructor.
- void [SetEnumList](#) (NBString s)
Renders the data used to explain the schema/descriptions for the list of choices.
- [operator NBString](#) () const
Return the object value.
- [config_string](#) & [operator=](#) (const char *p)
Assign the [config_string](#) object value from a const char string.*
- [config_string](#) & [operator=](#) (const NBString &s)
Assign the [config_string](#) object value from a NBString object.
- [config_string](#) & [operator=](#) (const [config_string](#) &ci)
Copy one [config_string](#) object to another.
- const char * [c_str](#) () const
Returns the object value as a string.
- size_t [length](#) () const
Returns the string length in bytes.
- const char & [operator\[\]](#) (size_t pos) const
Return the value of a character in the string.
- virtual void [GetTypeValue](#) (NBString &s) override
Copy the object type value to the specified NBString object.

Additional Inherited Members

Protected Member Functions inherited from [config_value](#)

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.59.1 Detailed Description

A [config_pass](#) with minimum and/or maximum lengths Attempting to set a value shorter than the minimum or longer than the maximum will fail with an error both programmatically and in the Config Web UI.

16.59.2 Constructor & Destructor Documentation

16.59.2.1 config_pass_limit() [1/2]

```
config_pass_limit::config_pass_limit (
    config\_obj & owner,
    NBString def_val,
    size_t minl = 0,
    size_t maxl = 0,
    const char * name = NULL,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter and limits.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value
<i>minl</i>	Minimum length
<i>maxl</i>	Maximum length
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.59.2.2 config_pass_limit() [2/2]

```
config_pass_limit::config_pass_limit (
    NBString def_val,
    size_t minl = 0,
    size_t maxl = 0,
    const char * name = NULL,
    const char * desc = NULL) [inline]
```

Object constructor with limits.

Parameters

<i>def_val</i>	Default value
<i>minl</i>	Minimum length
<i>maxl</i>	Maximum length
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.59.3 Member Function Documentation

16.59.3.1 operator=() [1/2]

```
config_pass_limit & config_pass_limit::operator= (
    const config_pass & ci) [inline]
```

Copy a [config_pass](#) object into the [config_pass_limit](#).

Parameters

<i>ci</i>	Reference to a config_pass object

16.59.3.2 operator=() [2/2]

```
config_pass_limit & config_pass_limit::operator= (
    const config_pass_limit & cil) [inline]
```

Copy one [config_pass_limit](#) object to another.

Parameters

<i>cil</i>	Reference to a config_pass_limit object

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.60 config_string Class Reference

String Configuration Variable.

```
#include <config_obj.h>
```

Inherits [config_value](#).

Inherited by [config_color_brightlimit](#), [config_fs_bulkstore](#), [config_localname](#), [config_pass](#), [config_string_limit](#), and [config_time_t](#).

Public Member Functions

- virtual void [GetTextValue](#) (NBString &s) override
Get the object value (as a text string with quotations) to the specified NBString object.
- [config_string](#) (config_obj &owner, NBString def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_string](#) (NBString def_val, const char *name, const char *desc=NULL)
Object constructor.
- [config_string](#) (config_obj &owner, const char *def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_string](#) (const char *def_val, const char *name, const char *desc=NULL)
Object constructor.
- void [SetEnumList](#) (NBString s)
Renders the data used to explain the schema/descriptions for the list of choices.
- [operator NBString](#) () const
Return the object value.
- [config_string](#) & [operator=](#) (const char *p)
Assign the config_string object value from a const char string.*
- [config_string](#) & [operator=](#) (const NBString &s)
Assign the config_string object value from a NBString object.
- [config_string](#) & [operator=](#) (const config_string &ci)
Copy one config_string object to another.
- const char * [c_str](#) () const
Returns the object value as a string.
- size_t [length](#) () const
Returns the string length in bytes.
- const char & [operator\[\]](#) (size_t pos) const
Return the value of a character in the string.
- virtual void [GetTypeValue](#) (NBString &s) override
Copy the object type value to the specified NBString object.

Friends

Object constructor.

16.60.1 Detailed Description

String Configuration Variable.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.60.2 Constructor & Destructor Documentation

16.60.2.1 config_string() [1/4]

```
config_string::config_string (  
    config_obj & owner,  
    NBString def_val,  
    const char * name,  
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value assigned with a [NBString](#)

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type NBString
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.60.2.2 config_string() [2/4]

```
config_string::config_string (  
    NBString def_val,  
    const char * name,  
    const char * desc = NULL) [inline]
```

Object constructor.

Default value assigned with a [NBString](#)

Parameters

<i>def_val</i>	Default value of type NBString
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.60.2.3 config_string() [3/4]

```
config_string::config_string (  
    config_obj & owner,  
    const char * def_val,  
    const char * name,  
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Default value assigned with a character string

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type char *
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.60.2.4 config_string() [4/4]

```
config_string::config_string (  
    const char * def_val,  
    const char * name,  
    const char * desc = NULL) [inline]
```

Object constructor.

Default value assigned with a character string

Parameters

<i>def_val</i>	Default value of type char *
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.60.3 Member Function Documentation

16.60.3.1 c_str()

```
const char * config_string::c_str () const [inline]
```

Returns the object value as a string.

Returns

String value of object

16.60.3.2 GetTextValue()

```
virtual void config_string::GetTextValue (  
    NBString & s) [override], [virtual]
```

Get the object value (as a text string with quotations) to the specified [NBString](#) object.

This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result

Implements [config_value](#).

Reimplemented in [config_pass](#).

16.60.3.3 GetTypeValue()

```
virtual void config_string::GetTypeValue (  
    NBString & s) [inline], [override], [virtual]
```

Copy the object type value to the specified [NBString](#) object.

The type value "string" is written to the [NBString](#) object.

Parameters

<i>s</i>	NBString object to hold the type value string

Reimplemented in [config_time_t](#).

16.60.3.4 length()

```
size_t config_string::length () const [inline]
```

Returns the string length in bytes.

Returns

String length

16.60.3.5 operator NBString()

```
config_string::operator NBString () const [inline]
```

Return the object value.

Returns

The value of the object as a [NBString](#)

16.60.3.6 operator=() [1/3]

```
config_string & config_string::operator= (  
    const char * p) [inline]
```

Assign the [config_string](#) object value from a const char* string.

Parameters

<i>p</i>	String to assign

16.60.3.7 operator=() [2/3]

```
config_string & config_string::operator= (  
    const config_string & ci) [inline]
```

Copy one [config_string](#) object to another.

Parameters

<i>ci</i>	Reference to a config_string object

16.60.3.8 operator=() [3/3]

```
config_string & config_string::operator= (  
    const NBString & s) [inline]
```

Assign the [config_string](#) object value from a [NBString](#) object.

Parameters

<i>s</i>	Reference to a NBString object

16.60.3.9 operator[]()

```
const char & config_string::operator[] (  
    size_t pos) const [inline]
```

Return the value of a character in the string.

Parameters

<i>pos</i>	Character index/position in the string

Returns

Character value at the specified index

16.60.3.10 SetEnumList()

```
void config_string::SetEnumList (
    NBString s) [inline]
```

Renders the data used to explain the schema/descriptions for the list of choices.

Parameters

s	Enumerated list that is a string with choices separated by commas (',') with no spaces. For example, "one,two,three"

The documentation for this class was generated from the following file:

- config_obj.h

16.61 config_string_limit Class Reference

A [config_string](#) with minimum and/or maximum lengths Attempting to set a value shorter than the minimum or longer than the maximum will fail with an error both programmatically and in the Config Web UI.

```
#include <config_obj.h>
```

Inherits [config_string](#).

Public Member Functions

- [config_string_limit](#) ([config_obj](#) &owner, [NBString](#) def_val, [size_t](#) minl=0, [size_t](#) maxl=0, const char *name=NULL, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter and limits.
- [config_string_limit](#) ([NBString](#) def_val, [size_t](#) minl=0, [size_t](#) maxl=0, const char *name=NULL, const char *desc=NULL)
Object constructor with limits.
- [config_string_limit](#) & operator= (const [config_string](#) &ci)
Copy a [config_string](#) object into the [config_string_limit](#).
- [config_string_limit](#) & operator= (const [config_string_limit](#) &cil)
Copy one [config_string_limit](#) object to another.

Public Member Functions inherited from [config_string](#)

- virtual void [GetTextValue](#) ([NBString](#) &s) override
Get the object value (as a text string with quotations) to the specified [NBString](#) object.
- [config_string](#) ([config_obj](#) &owner, [NBString](#) def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_string](#) ([NBString](#) def_val, const char *name, const char *desc=NULL)
Object constructor.
- [config_string](#) ([config_obj](#) &owner, const char *def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_string](#) (const char *def_val, const char *name, const char *desc=NULL)
Object constructor.
- void [SetEnumList](#) ([NBString](#) s)
Renders the data used to explain the schema/descriptions for the list of choices.
- [operator NBString](#) () const
Return the object value.
- [config_string](#) & operator= (const char *p)
Assign the [config_string](#) object value from a const char string.*
- [config_string](#) & operator= (const [NBString](#) &s)

- Assign the `config_string` object value from a `NBString` object.
- `config_string & operator= (const config_string &ci)`
Copy one `config_string` object to another.
- `const char * c_str () const`
Returns the object value as a string.
- `size_t length () const`
Returns the string length in bytes.
- `const char & operator[] (size_t pos) const`
Return the value of a character in the string.
- virtual void `GetTypeValue (NBString &s)` override
Copy the object type value to the specified `NBString` object.

Additional Inherited Members

Protected Member Functions inherited from `config_value`

- `config_value (config_obj &owner, const char *name, const char *desc)`
Object constructor with the parent/owner leaf parameter.
- `config_value (const char *name, const char *desc)`
Object constructor.

16.61.1 Detailed Description

A `config_string` with minimum and/or maximum lengths Attempting to set a value shorter than the minimum or longer than the maximum will fail with an error both programmatically and in the Config Web UI.

16.61.2 Constructor & Destructor Documentation

16.61.2.1 `config_string_limit()` [1/2]

```
config_string_limit::config_string_limit (
    config_obj & owner,
    NBString def_val,
    size_t minl = 0,
    size_t maxl = 0,
    const char * name = NULL,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter and limits.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value
<i>minl</i>	Minimum length
<i>maxl</i>	Maximum length
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.61.2.2 `config_string_limit()` [2/2]

```
config_string_limit::config_string_limit (
    NBString def_val,
    size_t minl = 0,
    size_t maxl = 0,
```

```
const char * name = NULL,  
const char * desc = NULL) [inline]
```

Object constructor with limits.

Parameters

<i>def_val</i>	Default value
<i>minl</i>	Minimum length
<i>maxl</i>	Maximum length
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.61.3 Member Function Documentation

16.61.3.1 operator=() [1/2]

```
config_string_limit & config_string_limit::operator= (
    const config_string & ci) [inline]
```

Copy a [config_string](#) object into the [config_string_limit](#).

Parameters

<i>ci</i>	Reference to a config_string object

16.61.3.2 operator=() [2/2]

```
config_string_limit & config_string_limit::operator= (
    const config_string_limit & cil) [inline]
```

Copy one [config_string_limit](#) object to another.

Parameters

<i>cil</i>	Reference to a config_string_limit object

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.62 config_time_t Class Reference

Class to hold time configuration.

```
#include <config_time.h>
```

Inherits [config_string](#).

Public Member Functions

- [config_time_t](#) ([config_obj](#) &owner, time_t def_val, const char *name, const char *desc=NULL, bool bUserSeesGmt=false)
Object constructor with the parent/owner leaf parameter.
- [config_time_t](#) ([config_obj](#) &owner, const char *def_val, const char *name, const char *desc=NULL, bool bUserSeesGmt=false)
Object constructor with the parent/owner leaf parameter.
- [config_time_t](#) (const char *def_val, const char *name, const char *desc=NULL, bool bUserSeesGmt=false)
Object constructor.
- [config_time_t](#) (time_t def_val, const char *name, const char *desc=NULL)
Object constructor.
- virtual void **GetTypeValue** ([NBString](#) &s)

- `operator time_t () const`
- `config_time_t & operator= (time_t t)`
Assign the `config_time_t` object value from a another `NBString` object.
- `config_time_t & operator= (const config_time_t &ci)`
Copy one `config_string` object to another.
- `NBString GetAsGmtString ()`
- `NBString GetAsLocalString ()`
- virtual int **Missing_ConfigEndMarker** (void *&startp)
This is named so error messages make sense to user, old name was `GetExtent`.
- void **RenderValue** (int fd, int len, const char *extra)
- void **RenderInput** (int fd, int len, const char *extra)
- bool **ProcessValue** (const char *pValue)

Public Member Functions inherited from `config_string`

- virtual void `GetTextValue` (`NBString` &s) override
Get the object value (as a text string with quotations) to the specified `NBString` object.
- `config_string` (`config_obj` &owner, `NBString` def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- `config_string` (`NBString` def_val, const char *name, const char *desc=NULL)
Object constructor.
- `config_string` (`config_obj` &owner, const char *def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- `config_string` (const char *def_val, const char *name, const char *desc=NULL)
Object constructor.
- void `SetEnumList` (`NBString` s)
Renders the data used to explain the schema/descriptions for the list of choices.
- `operator NBString () const`
Return the object value.
- `config_string & operator= (const char *p)`
Assign the `config_string` object value from a const char string.*
- `config_string & operator= (const NBString &s)`
Assign the `config_string` object value from a `NBString` object.
- `config_string & operator= (const config_string &ci)`
Copy one `config_string` object to another.
- const char * `c_str` () const
Returns the object value as a string.
- size_t `length` () const
Returns the string length in bytes.
- const char & `operator[]` (size_t pos) const
Return the value of a character in the string.

Static Public Member Functions

- static [NBString](#) **TimetoNBString** (time_t tv, bool bUtc=true)
- static time_t **ParseTime** (const char *cp, bool bUtc=true)
- static time_t **ParseTime** ([NBString](#) &ns, bool bUtc=true)

Additional Inherited Members

Protected Member Functions inherited from [config_value](#)

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.62.1 Detailed Description

Class to hold time configuration.

16.62.2 Constructor & Destructor Documentation

16.62.2.1 config_time_t() [1/4]

```
config_time_t::config_time_t (
    config\_obj & owner,
    time_t def_val,
    const char * name,
    const char * desc = NULL,
    bool bUserSeesGmt = false) [inline]
```

Object constructor with the parent/owner leaf parameter.
Default value assigned with a time_t

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value of type time_t
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip
<i>bUserSeesGmt</i>	If true, the user sees GMT time when displaying/reading time values. If false, localtime is used.

16.62.2.2 config_time_t() [2/4]

```
config_time_t::config_time_t (
    config\_obj & owner,
    const char * def_val,
    const char * name,
    const char * desc = NULL,
    bool bUserSeesGmt = false) [inline]
```

Object constructor with the parent/owner leaf parameter.
Default value assigned with a time_t

Parameters

<i>owner</i>	Reference to owner/parent leaf

Parameters

<i>def_val</i>	Default value of type time_t
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip
<i>bUserSeesGmt</i>	If true, the user sees GMT time when displaying/reading time values. If false, localtime is used.

16.62.2.3 config_time_t() [3/4]

```
config_time_t::config_time_t (
    const char * def_val,
    const char * name,
    const char * desc = NULL,
    bool bUserSeesGmt = false) [inline]
```

Object constructor.

Default value assigned with a time_t

Parameters

<i>def_val</i>	Default value of type time_t
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip
<i>bUserSeesGmt</i>	If true, the user sees GMT time when displaying/reading time values. If false, localtime is used.

16.62.2.4 config_time_t() [4/4]

```
config_time_t::config_time_t (
    time_t def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor.

Parameters

<i>def_val</i>	Default value of type time_t
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.62.3 Member Function Documentation**16.62.3.1 operator time_t()**

```
config_time_t::operator time_t () const [inline]
```

Return the object value

Returns

The value of the object as a time_t

16.62.3.2 operator=() [1/2]

```
config_time_t & config_time_t::operator= (
    const config_time_t & ci) [inline]
```

Copy one [config_string](#) object to another.

Parameters

<i>ci</i>	Reference to a config_string object

16.62.3.3 operator=() [2/2]

```
config_time_t & config_time_t::operator= (
    time_t t) [inline]
```

Assign the [config_time_t](#) object value from a anotherNBString object.

Parameters

<i>t</i>	time_t ↔
	<i>_t</i>

The documentation for this class was generated from the following file:

- [config_time.h](#)

16.63 config_uint Class Reference

Unsigned 32-bit Integer Configuration Variable.

```
#include <config_obj.h>
```

Inherits [config_value](#).

Inherited by [config_hex_uint](#), and [config_uint_limit](#).

Public Member Functions

- virtual void [GetTextValue](#) (NBString &s) override
Copy the object value to the specified NBString object.
- [config_uint](#) (config_obj &owner, uint32_t def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_uint](#) (uint32_t def_val, const char *name, const char *desc=NULL)
Object constructor.
- [operator uint32_t](#) () const
Return the object value.
- [config_uint](#) & [operator=](#) (const uint32_t i)
Assign the config_uint object value from a uint32_t value.
- [config_uint](#) & [operator=](#) (const [config_uint](#) &ci)
Copy one config_uint object to another.
- virtual void [GetTypeValue](#) (NBString &s) override
Copy the object type value to the specified NBString object.

Additional Inherited Members**Protected Member Functions inherited from [config_value](#)**

- [config_value](#) (config_obj &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.63.1 Detailed Description

Unsigned 32-bit Integer Configuration Variable.

Note

All modifications to configuration objects are marked as pending. A call to [SaveConfigToStorage](#) is required to save changes to flash memory.

16.63.2 Constructor & Destructor Documentation

16.63.2.1 config_uint() [1/2]

```
config_uint::config_uint (
    config_obj & owner,
    uint32_t def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.63.2.2 config_uint() [2/2]

```
config_uint::config_uint (
    uint32_t def_val,
    const char * name,
    const char * desc = NULL) [inline]
```

Object constructor.

Parameters

<i>def_val</i>	Default value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.63.3 Member Function Documentation

16.63.3.1 GetTextValue()

```
virtual void config_uint::GetTextValue (
    NBString & s) [inline], [override], [virtual]
```

Copy the object value to the specified [NBString](#) object.

This is a virtual function that can be overridden in any derived class.

Parameters

<i>s</i>	Reference to a NBString object to store the result

Implements [config_value](#).

16.63.3.2 GetTypeValue()

```
virtual void config_uint::GetTypeValue (
    NBString & s) [inline], [override], [virtual]
```

Copy the object type value to the specified [NBString](#) object.
The type value "integer" is written to the [NBString](#) object.

Parameters

<code>s</code>	NBString object to hold the type value string

16.63.3.3 operator uint32_t()

```
config_uint::operator uint32_t () const [inline]
```

Return the object value.

Returns

The value of the object as a `uint32_t`

Example: for a variable named `configuint` of type [config_uint](#):

```
uint32_t value = uint32_t(configuint);
iprintf("int = %ld\r\n", value);
```

16.63.3.4 operator=() [1/2]

```
config_uint & config_uint::operator= (
    const config_uint & ci) [inline]
```

Copy one [config_uint](#) object to another.

Parameters

<code>ci</code>	Reference to a config_uint object

16.63.3.5 operator=() [2/2]

```
config_uint & config_uint::operator= (
    const uint32_t i) [inline]
```

Assign the [config_uint](#) object value from a `uint32_t` value.

Parameters

<code>i</code>	<code>uint32_t</code> value

The documentation for this class was generated from the following file:

- `config_obj.h`

16.64 config_uint_limit Class Reference

A [config_uint](#) with minimum and/or maximum values Attempting to set a value lower than the minimum or greater than the maximum will fail with an error both programmatically and in the Config Web UI.

```
#include <config_obj.h>
```

Inherits [config_uint](#).

Public Member Functions

- [config_uint_limit](#) ([config_obj](#) &owner, uint32_t def_val, uint32_t minv=0, uint32_t maxv=UINT_MAX, const char *name=NULL, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter and limits.
- [config_uint_limit](#) (uint32_t def_val, uint32_t minv=0, uint32_t maxv=UINT_MAX, const char *name=NULL, const char *desc=NULL)
Object constructor with limits.
- [config_uint_limit](#) & [operator=](#) (const [config_uint](#) &ci)
Copy a [config_uint](#) object into the [config_uint_limit](#).
- [config_uint_limit](#) & [operator=](#) (const [config_uint_limit](#) &cil)
Copy one [config_uint_limit](#) object to another.

Public Member Functions inherited from [config_uint](#)

- virtual void [GetTextValue](#) ([NBString](#) &s) override
Copy the object value to the specified [NBString](#) object.
- [config_uint](#) ([config_obj](#) &owner, uint32_t def_val, const char *name, const char *desc=NULL)
Object constructor with the parent/owner leaf parameter.
- [config_uint](#) (uint32_t def_val, const char *name, const char *desc=NULL)
Object constructor.
- [operator uint32_t](#) () const
Return the object value.
- [config_uint](#) & [operator=](#) (const uint32_t i)
Assign the [config_uint](#) object value from a uint32_t value.
- [config_uint](#) & [operator=](#) (const [config_uint](#) &ci)
Copy one [config_uint](#) object to another.
- virtual void [GetTypeValue](#) ([NBString](#) &s) override
Copy the object type value to the specified [NBString](#) object.

Additional Inherited Members**Protected Member Functions inherited from [config_value](#)**

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.64.1 Detailed Description

A [config_uint](#) with minimum and/or maximum values Attempting to set a value lower than the minimum or greater than the maximum will fail with an error both programmatically and in the Config Web UI.

16.64.2 Constructor & Destructor Documentation**16.64.2.1 [config_uint_limit](#)() [1/2]**

```
config_uint_limit::config_uint_limit (
    config\_obj & owner,
    uint32_t def_val,
    uint32_t minv = 0,
    uint32_t maxv = UINT_MAX,
    const char * name = NULL,
    const char * desc = NULL) [inline]
```

Object constructor with the parent/owner leaf parameter and limits.

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>def_val</i>	Default value
<i>minv</i>	Minimum value
<i>maxv</i>	Maximum value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.64.2.2 config_uint_limit() [2/2]

```
config_uint_limit::config_uint_limit (
    uint32_t def_val,
    uint32_t minv = 0,
    uint32_t maxv = UINT_MAX,
    const char * name = NULL,
    const char * desc = NULL) [inline]
```

Object constructor with limits.

Parameters

<i>def_val</i>	Default value
<i>minv</i>	Minimum value
<i>maxv</i>	Maximum value
<i>name</i>	Field name assigned to the value
<i>desc</i>	Description used for info/tool tip

16.64.3 Member Function Documentation**16.64.3.1 operator=() [1/2]**

```
config_uint_limit & config_uint_limit::operator= (
    const config_uint & ci) [inline]
```

Copy a [config_uint](#) object into the [config_uint_limit](#).

Parameters

<i>ci</i>	Reference to a config_uint object

16.64.3.2 operator=() [2/2]

```
config_uint_limit & config_uint_limit::operator= (
    const config_uint_limit & cil) [inline]
```

Copy one [config_uint_limit](#) object to another.

Parameters

<i>cil</i>	Reference to a config_uint_limit object

The documentation for this class was generated from the following file:

- [config_obj.h](#)

16.65 config_value Class Reference

Base class used to create a configuration value.

```
#include <config_obj.h>
```

Inherits config_leaf.

Inherited by [CUR_IPADDR4](#), [Dynamic_IPADDR](#), [config_IPADDR](#), [config_IPADDR4](#), [config_MACADR](#), [config_bool](#), [config_double](#), [config_int](#), [config_report](#), [config_string](#), and [config_uint](#).

Protected Member Functions

- [config_value](#) ([config_obj](#) &owner, const char *name, const char *desc)
Object constructor with the parent/owner leaf parameter.
- [config_value](#) (const char *name, const char *desc)
Object constructor.

16.65.1 Detailed Description

Base class used to create a configuration value.

Base class that can be used to create custom configuration values in a JSON compatible format. The JSON compatible types are: integer, boolean, null, string, object or array.

The system already provides the common JSON value types, including: [config_int](#), [config_uint](#), [config_bool](#), [config_chooser](#), [config_string](#), [config_pass](#), [config_IPADDR4](#), [config_IPADDR](#), [config_MACADR](#),

A [config_obj](#) can hold multiple values in a JSON object. A [config_value](#) holds only a single JSON value.

See also

[config_obj](#)

16.65.2 Constructor & Destructor Documentation

16.65.2.1 config_value() [1/2]

```
config_value::config_value (
    config_obj & owner,
    const char * name,
    const char * desc) [inline], [protected]
```

Object constructor with the parent/owner leaf parameter.

For example,

```
myValue(config_obj &owner, const char *name, const char *desc = nullptr) : config_value(owner, name,
desc){};
```

Parameters

<i>owner</i>	Reference to owner/parent leaf
<i>name</i>	Field name
<i>desc</i>	Description used for info/tool tip

16.65.2.2 config_value() [2/2]

```
config_value::config_value (
    const char * name,
    const char * desc) [inline], [protected]
```

Object constructor.

This constructor should be called as part of the derived class constructor. For example,

```
myValue(const char *name, const char *desc = nullptr) : config_value(name, desc){}
```

Parameters

<i>name</i>	Field name

<i>desc</i>	Description used for info/tool tip

The documentation for this class was generated from the following file:

- config_obj.h

16.66 MQTT::ConfigExposer Class Reference

Easy MqttObj class for automatically publishing and subscribing NetBurner Config system objects to/from an [MQTT](#) topic. Use like a normal ConfigObj.

```
#include <mqtt.h>
```

Inherits [MQTT::mqtt_leaf](#).

Public Types

- enum [eRenderFlag_t](#) { [eRender_Hidden](#) , [eRender_ModifiedOnly](#) , [eRender_Pretty](#) }
Rendering options for [MQTT](#) output of Config objects.

Public Types inherited from [MQTT::mqtt_leaf](#)

- enum [eObj_State_t](#)
Mqtt Object Publication/Subscription States.

Public Member Functions

- [ConfigExposer](#) (config_leaf &leaf, const char *topicRoot, [Client](#) *mClient=NULL, uint16_t initFlags=0, uint32_t renderFlags=0)
Constructor for a standalone [ConfigExposer](#) object.
- [ConfigExposer](#) (mqtt_leaf &parent, config_leaf &leaf, const char *topicRoot, [Client](#) *mClient=NULL, uint16_t initFlags=0, uint32_t renderFlags=0)
Constructor for a [ConfigExposer](#) object that has a parent.
- virtual int [GetPubTopicName](#) (NBString &s) override
Get the Topic Name this object Publishes to.
- virtual int [GetSubTopicFilter](#) (NBString &s) override
Get the Subscription Topic Filter this object Subscribes to.
- virtual ValueTestResult [TestOrSetValue](#) (ParsedJsonDataSet &pjs, bool setVal) override
whether the current index of a JSON dataset is valid for this object, or assign the value at the current index of the dataset to this object.
- virtual int [SubscribeEvent](#) (int mqttFd, [PacketInfo::Msg](#) *msg) override
Handle a message sent by the Broker triggered by this object's Subscription.
- virtual int [GetRenderLength](#) ([eObj_Serialize_t](#) form=[eObj_Serialize_CURRENT_FORM](#)) override
the number of bytes used to serialize this object in a particular format.
- virtual int [RenderToBuffer](#) ([eObj_Serialize_t](#) form, uint8_t *buf, int buflen) override
Render this object to an output buffer.
- virtual int [RenderToFd](#) ([eObj_Serialize_t](#) form, int fd) override
Render this object to an output socket.

Public Member Functions inherited from MQTT::mqtt_leaf

- `~mqtt_leaf ()`
~mqtt_leaf Destructor for base [mqtt_leaf](#)
- `void RemoveFromTree ()`
Remove this object from it's parent tree.
- `bool NameMatch (const char *cp)`
Determine whether a given name matches this object.
- `int Publish (int waitForCompletion=-1)`
Publishes the current [MQTT](#) object, optionally waiting for completion.
- `void SetPublishInterval (uint32_t intervalPeriodTicks)`
Sets or clears an automatic publishing interval for this [MQTT](#) object.
- `virtual void SetSerializationForm (eObj_Serialize_t form)`
Set the default serialization format for this object.
- `eObj_Serialize_t GetSerializationForm ()`
Get the default serialization format for this object.
- `virtual void SetFlags (uint16_t newFlags)`
Set additional behavioral flags for this object.
- `virtual void ClearFlags (uint16_t delFlags)`
Clear behavioral flags from this object.
- `uint16_t GetFlags ()`
Get the behavioral flags set for this object.
- `int getPriority ()`
Get the message priority for this object.

Protected Member Functions

- `virtual int ParseFd (int mqttFd) override`
Parse the data from a file descriptor according to this object's current default serialization method and assign the value.

Protected Member Functions inherited from MQTT::mqtt_leaf

- `mqtt_leaf (const char *topic, Client *mClient, uint16_t flags=(eObj_Flag_PubOnWrite|eObj_Flag_Subscribe|eObj_Flag_Sub_N`
Constructor for [mqtt_leaf](#) objects.
- `mqtt_leaf (mqtt_leaf &parent, const char *topic, Client *mClient, uint16_t flags=(eObj_Flag_PubOnWrite|eObj_Flag_Subscribe|`
Constructor for [mqtt_leaf](#) objects.
- `virtual mqtt_leaf * GetChildren ()`
Get the first child of this object.
- `virtual mqtt_leaf * AddChild (mqtt_leaf *child)`
Add an MqttObj as a child to this object.
- `virtual mqtt_leaf * RemoveFirstChild ()`
Remove the first child from this object.
- `void ForEachLeaf (LeafCallBack *p, void *pd)`
Call a function on each element of the MqttObj tree with this object as the root.
- `void RootParse (ParsedJsonDataSet &pjs)`
Assign to this object tree from a JSON dataset.
- `bool MatchId (ParsedJsonDataSet &pjs)`
Determine whether the JSON dataset's current index matches this object's name.
- `int QueuePublish ()`
Queue this object to be Published via the registered [Client](#).
- `int QueueSubscribe ()`

- *Queue this object to be Subscribed via the registered [Client](#).*
- `int QueueUnsubscribe ()`
Queue this object to be Unsubscribed via the registered [Client](#).
- `int Assign ()`
Perform post assignemnt operations.
- `uint8_t PubState ()`
Get the Publish state.
- `uint8_t SubState ()`
Get the Subscribe state of this object.
- `virtual void SetPubState (uint8_t newState)`
Set the Publish state.
- `virtual void SetSubState (uint8_t newState)`
Set the Subscribe state.
- `int HandleSubAck (int mqttFd, PacketInfo::Msg *msg)`
Handle a Subscribe Acknowledge message from the broker for our Subscribe request.
- `int HandleUnsubAck (int mqttFd, PacketInfo::Msg *msg)`
Handle an Unsubscribe Acknowledge message from the broker for our Unsubscribe request.
- `int HandlePubAck (int mqttFd, PacketInfo::Msg *msg)`
Handle an Publish Acknowledge message from the broker for our Publish request.

Additional Inherited Members

Static Public Member Functions inherited from [MQTT::mqtt_leaf](#)

- `static int MqttRxPublish (Client *mClient, int mqttFd, PacketInfo::Msg *msg, void *ctx)`
Static message handler for Publish messages received by the registered [Client](#).

Protected Attributes inherited from [MQTT::mqtt_leaf](#)

- `NBInterpolatedString topicName`
Topic name or additional branch.
- `eObj\_Serialize\_t publishForm`
Default serialization form.
- `uint16_t mFlags`
Behavioral flags.

16.66.1 Detailed Description

Easy MqttObj class for automatically publishing and subscribing NetBurner Config system objects to/from an [MQTT](#) topic. Use like a normal ConfigObj.

16.66.2 Member Enumeration Documentation

16.66.2.1 eRenderFlag_t

enum [MQTT::ConfigExposer::eRenderFlag_t](#)

Rendering options for [MQTT](#) output of Config objects.

Enumerator

<code>eRender_Hidden</code>	Hide this branch from renders of the object.
<code>eRender_ModifiedOnly</code>	Only render modified leaves of the branch.
<code>eRender_Pretty</code>	Do Pretty Print rendering.

16.66.3 Constructor & Destructor Documentation

16.66.3.1 ConfigExposer() [1/2]

```
MQTT::ConfigExposer::ConfigExposer (
    config_leaf & leaf,
    const char * topicRoot,
    Client * mClient = NULL,
    uint16_t initFlags = 0,
    uint32_t renderFlags = 0)
```

Constructor for a standalone [ConfigExposer](#) object.

Parameters

<i>&leaf</i>	Reference to the ConfigObject branch being exposed
<i>*topicRoot</i>	Mqtt Topic Name to use as the base for Publish/Subscribe.
<i>*mClient</i>	Pointer to Client to register with. If NULL, it will be registered with the first created Client .
<i>initFlags</i>	Behavioral flags to set on the created object
<i>renderFlags</i>	Rendering flags to set for the exposed ConfigObj

16.66.3.2 ConfigExposer() [2/2]

```
MQTT::ConfigExposer::ConfigExposer (
    mqtt_leaf & parent,
    config_leaf & leaf,
    const char * topicRoot,
    Client * mClient = NULL,
    uint16_t initFlags = 0,
    uint32_t renderFlags = 0)
```

Constructor for a [ConfigExposer](#) object that has a parent.

Parameters

<i>&parent</i>	Reference to parent MqttObj
<i>&leaf</i>	Reference to the ConfigObject branch being exposed
<i>*topicRoot</i>	Mqtt Topic Name to use as the base for Publish/Subscribe.
<i>*mClient</i>	Pointer to Client to register with. If NULL, it will be registered with the first created Client .
<i>initFlags</i>	Behavioral flags to set on the created object
<i>renderFlags</i>	Rendering flags to set for the exposed ConfigObj

16.66.4 Member Function Documentation

16.66.4.1 GetPubTopicName()

```
virtual int MQTT::ConfigExposer::GetPubTopicName (
    NBString & s) [override], [virtual]
```

Get the Topic Name this object Publishes to.

Parameters

<i>&s</i>	The NBString to copy the Topic Name into

Returns

eResult_t return code

Reimplemented from [MQTT::mqtt_leaf](#).

16.66.4.2 GetRenderLength()

```
virtual int MQTT::ConfigExposer::GetRenderLength (
    eObj_Serialize_t form = eObj_Serialize_CURRENT_FORM) [override], [virtual]
```

the number of bytes used to serialize this object in a particular format.

Parameters

<i>form</i>	Serialization format to use

Returns

Length of serialized data

Reimplemented from [MQTT::mqtt_leaf](#).

16.66.4.3 GetSubTopicFilter()

```
virtual int MQTT::ConfigExposer::GetSubTopicFilter (
    NBString & s) [override], [virtual]
```

Get the Subscription Topic Filter this object Subscribes to.

Parameters

&s	The NBString to copy the Subscription Topic Filter into

Returns

eResult_t return code

Reimplemented from [MQTT::mqtt_leaf](#).

16.66.4.4 ParseFd()

```
virtual int MQTT::ConfigExposer::ParseFd (
    int mqttFd) [override], [protected], [virtual]
```

Parse the data from a file descriptor according to this object's current default serialization method and assign the value.

Parameters

<i>mqttFd</i>	File descriptor to read from.

Returns

eResult_t return code

Implements [MQTT::mqtt_leaf](#).

16.66.4.5 RenderToBuffer()

```
virtual int MQTT::ConfigExposer::RenderToBuffer (
    eObj_Serialize_t form,
    uint8_t * buf,
    int buflen) [override], [virtual]
```

Render this object to an output buffer.

Parameters

<i>form</i>	Serialization format to render as

<i>*buf</i>	Pointer to output buffer
<i>buflen</i>	Size of the output buffer

Returns

Length of the rendered data

Implements [MQTT::mqtt_leaf](#).

16.66.4.6 RenderToFd()

```
virtual int MQTT::ConfigExposer::RenderToFd (  
    eObj_Serialize_t form,  
    int fd) [override], [virtual]
```

Render this object to an output socket.

Parameters

<i>form</i>	Serialization format to render as
<i>fd</i>	File descriptor to render to

Returns

Length of the rendered data

Implements [MQTT::mqtt_leaf](#).

16.66.4.7 SubscribeEvent()

```
virtual int MQTT::ConfigExposer::SubscribeEvent (  
    int mqttFd,  
    PacketInfo::Msg * msg) [override], [virtual]
```

Handle a message sent by the Broker triggered by this object's Subscription.

Parameters

<i>mqttFd</i>	File Descriptor to read any additional message data from
<i>*msg</i>	Pointer to message received from the Broker

Returns

eResult_t return code

Reimplemented from [MQTT::mqtt_leaf](#).

16.66.4.8 TestOrSetValue()

```
virtual ValueTestResult MQTT::ConfigExposer::TestOrSetValue (  
    ParsedJsonDataSet & pjs,  
    bool setVal) [override], [virtual]
```

whether the current index of a JSON dataset is valid for this object, or assign the value at the current index of the dataset to this object.

Parameters

<i>&pjs</i>	The JSON dataset to use
<i>setVal</i>	true: Assign from the value at the current index, false: test if current index is valid for this object

Returns

ValueTestResult indicating the validity of the current index

Implements [MQTT::mqtt_leaf](#).

16.67 MQTT::ConfiguredClient Class Reference

Easy [MQTT Client](#) wrapper for interacting with [MQTT](#) brokers. The client handles all network communications with the Broker and handles local message queueing and dispatching to topic handlers. Adds ConfigObj for automatically configuring all [Client](#) settings via the Config System.

```
#include <mqtt.h>
```

Inherits [config_MqttClient](#), and [MQTT::Client](#).

Public Member Functions

- [ConfiguredClient](#) ([config_obj](#) &owner=sys, const char *name=NULL, const char *desc="Mqtt client connection configuration", RequestProperty *addProps=NULL, bool ConnectOnStartup=true)

[ConfiguredClient](#) constructor.

Public Member Functions inherited from [MQTT::Client](#)

- [Client](#) (const char *brokerURI, const char *pClientId, uint16_t maxKeepAlive=[MQTT_DEFAULT_KEEP_ALIVE](#), bool bCleanStart=true, [PublishRequest](#) *lwtMsg=NULL, const char *pConnMsg=NULL, const char *pDisconnMsg=NULL, const char *pUsername=NULL, const char *pPassword=NULL, RequestProperty *addProps=NULL, bool ConnectOnStartup=true)
Constructor. This version takes a raw string for the broker URI.
- [Client](#) (const [ParsedURI](#) *brokerURI, const char *pClientId, uint16_t maxKeepAlive=[MQTT_DEFAULT_KEEP_ALIVE](#), bool bCleanStart=true, [PublishRequest](#) *lwtMsg=NULL, const char *pConnMsg=NULL, const char *pDisconnMsg=NULL, const char *pUsername=NULL, const char *pPassword=NULL, RequestProperty *addProps=NULL, bool ConnectOnStartup=true)
Constructor. This version takes a [ParsedURI](#) object for the broker URI.
- int [Connect](#) (bool bWaitForConnection, const char *pNewBrokerURI, ConnAckCb_t notifyCb=NULL, void *notifyCtx=NULL)
Begin the process of Connecting the client to the Broker.
- int [Connect](#) (bool bWaitForConnection=true, const [ParsedURI](#) *pNewBrokerURI=NULL, ConnAckCb_t notifyCb=NULL, void *notifyCtx=NULL)
Begin the process of Connecting the client to the Broker.
- int [Disconnect](#) ()
Disconnect the [Client](#) from the Broker.
- void [SetConnectNotify](#) (ConnAckCb_t notifyCb, void *notifyCtx)
Set the connection notification callback and it's context information.
- int [SetRateLimit](#) ([eRateLimitType](#) type, uint8_t bucketMax, uint8_t fillCount, uint8_t fillTicks, [eRateLimitAdjustMethod](#) adjMethod, uint8_t adjCount)
Set the value for a given rate limit.
- int [SetRateLimit_Publish](#) (int reqPerSecond)
Set the Publish rate limit. This method automatically determines the fillCount and fillTicks to use for refilling the credit bucket.
- int [SetRateLimit_Subscribe](#) (int reqPerSecond)
Set the Subscribe rate limit. This method automatically determines the fillCount and fillTicks to use for refilling the credit bucket.
- [eConnectionStatus](#) [GetConnectionStatus](#) ()
Get the current state of the [Client](#)'s connection to the Broker.

- void [SetClientCert](#) (uint8_t *cert, uint32_t len, uint8_t *privkey, uint32_t privlen)
Set the [Client](#) Certificate and Private Key to use when connecting to a Broker via TLS.
- void [GetClientCert](#) (uint8_t **cert, uint32_t *len, uint8_t **privkey, uint32_t *privlen)
Set the [Client](#) Certificate and Private Key to use when connecting to a Broker via TLS.
- int [QueuePublish](#) ([mqtt_leaf](#) &leaf)
Queue an [MqttObj](#) to be published.
- int [QueueSubscribe](#) ([mqtt_leaf](#) &leaf)
Queue an [MqttObj](#) to subscribe.
- int [QueueUnsubscribe](#) ([mqtt_leaf](#) &leaf)
Queue an [MqttObj](#) to unsubscribe.
- int [QueueAllSubscriptions](#) ()
Queue all [Client](#)'s registered [MqttObjs](#) to be subscribed and published according to the object's operation flags.
- int [Publish](#) (const char *topic, uint8_t *pData, uint32_t len, int prio, TickTimeout &t, uint8_t qos=0)
Publish a binary payload message.
- int [Publish](#) (const char *topic, const char *pStr, int prio, TickTimeout &t, uint8_t qos=0)
Publish a message.
- int [Publish](#) ([PublishRequest](#) *req, int prio, TickTimeout &t)
Publish a fully defined request.
- int [QueuePublish](#) ([PublishRequest](#) *req, int *prio)
Queue a publish message from a fully defined request.
- int [Subscribe](#) ([TopicHandler](#) &handler, int *handlerIdx, TickTimeout &t, uint8_t subOpts=[Pkt::eSubOpt_NoLocal](#))
Register a [TopicHandler](#) and subscribe its Topic on the Broker.
- int [Subscribe](#) ([SubscribeRequest](#) *req, int *handlerIdx, TickTimeout &t)
Register a [TopicHandler](#) (via fully specified [SubscribeRequest](#)) and subscribe its Topic on the Broker.
- int [QueueSubscribe](#) ([SubUnsubQueueMsg](#) *qmsg)
Register a [TopicHandler](#) and subscribe its Topic on the Broker.
- int [Unsubscribe](#) (int handlerIdx, TickTimeout &t, const char *topicFilter=NULL)
Unsubscribe and deregister a [TopicHandler](#).
- int [Unsubscribe](#) (const char *topicFilter, TickTimeout &t)
Unsubscribe and deregister a [TopicHandler](#).
- int [QueueUnsubscribe](#) ([SubUnsubQueueMsg](#) *qmsg)
Queue unsubscribing and deregistering a [TopicHandler](#).
- int [RegisterTopicHandler](#) ([TopicHandler](#) *newHandler, int *handlerIdx)
Register a [TopicHandler](#) with the [Client](#).
- int [RemoveTopicHandler](#) ([TopicHandler](#) *handler)
Remove/deregister a [TopicHandler](#) from the [Client](#) by reference.
- int [RemoveTopicHandler](#) (int handlerIdx)
Remove/deregister a [TopicHandler](#) from the [Client](#) by index.
- void [RegisterMqttObj](#) ([mqtt_leaf](#) &leaf, uint32_t interval=0)
Register an [MqttObj](#) with the [Client](#).
- void [RemoveObj](#) ([mqtt_leaf](#) &leaf)
Deregister/remove an [MqttObj](#) from the [Client](#).
- int [SendNextPubReq](#) ()
Send the next queued Publish Request.
- int [SendNextSubReq](#) ()
Send the next queued SubUnSub Request.

Additional Inherited Members

Public Types inherited from MQTT::Client

- enum [eSessionLimit](#) {
[eLimit_Size_Tx](#) , [eLimit_Size_Rx](#) , [eLimit_InFlight_Tx](#) , [eLimit_InFlight_Rx](#) ,
[eLimit_Subscriptions](#) , [eLimit_SubAliases](#) , [eLimit_PublishAliases](#) , [eLimit_QoS](#) ,
[eLimit_SessionExpiry](#) }
Limit types for the [Client](#) interactions with the Broker.
- enum [eRateLimitType](#) { [eRateLimit_Publish](#) , [eRateLimit_Subscribe](#) }
Rate limit types for [Client](#) messaging.
- enum [eRateLimitAdjustMethod](#) { [eRateLimitAdj_None](#) , [eRateLimitAdj_Set](#) , [eRateLimitAdj_Add](#) ,
[eRateLimitAdj_Subtract](#) }
How to adjust rate limit buckets when modifying the current rate limit.
- enum [eConnectionStatus](#) {
[eConnStat_Error](#) , [eConnStat_No_Broker_Configured](#) , [eConnStat_Resolving](#) , [eConnStat_InProgress](#) ,
[eConnStat_Established](#) , [eConnStat_Refused](#) , [eConnStat_Disconnected](#) }
Connection state values.

Static Public Member Functions inherited from MQTT::Client

- static void [StartTask](#) (uint8_t taskPrio=[MQTT_TASK_PRIO](#))
Start the [Client](#) Task.
- static [Client](#) * [GetFirstClient](#) ()
Start the [Client](#) Task.

16.67.1 Detailed Description

Easy [MQTT Client](#) wrapper for interacting with [MQTT](#) brokers. The client handles all network communications with the Broker and handles local message queueing and dispatching to topic handlers. Adds ConfigObj for automatically configuring all [Client](#) settings via the Config System.

16.67.2 Constructor & Destructor Documentation

16.67.2.1 ConfiguredClient()

```
MQTT::ConfiguredClient::ConfiguredClient (
    config\_obj & owner = sys,
    const char * name = NULL,
    const char * desc = "Mqtt client connection configuration",
    RequestProperty * addProps = NULL,
    bool ConnectOnStartup = true)
```

[ConfiguredClient](#) constructor.

Parameters

<i>&owner</i>	Reference to the ConfigObj this Client should be registered below
<i>*name</i>	Name of this client in the Config System. If NULL, a default name will automatically be assigned.
<i>*desc</i>	Description of this client to provide within the Config System
<i>*addProps</i>	Additional message Properties to send with Connection Requests
<i>ConnectOnStartup</i>	Whether the client should automatically connect after startup.

16.70 DelayObject Class Reference

High-resolution microsecond delay timer class.

```
#include <HiResDelay.h>
```

Public Member Functions

- [DelayObject](#) (int Timer=FIRST_UNUSED_TIMER)
Construct a high-resolution delay timer object.
- [~DelayObject](#) ()
Destructor - releases the allocated hardware timer.
- void [DelayUsec](#) (uint32_t usec)
Perform a blocking delay with microsecond precision.
- bool [valid](#) ()
Verify the delay object is valid and ready to use.
- void [_wake](#) ()
Internal ISR callback to wake blocked task (internal use only)

16.70.1 Detailed Description

High-resolution microsecond delay timer class.

Provides blocking delays with microsecond precision by allocating and using a hardware system timer. The timer is automatically managed - allocated on construction and freed on destruction.

This class uses a hardware timer from the processor's timer pool to provide precise microsecond delays. The timer is allocated when the object is created and remains dedicated to this object until it is destroyed. An internal semaphore is used to block the calling task during the delay period.

Note

Hardware timers are a limited resource. Always verify successful allocation by checking [valid\(\)](#) after construction.

Thread Safety

Each [DelayObject](#) should be used by a single task. For multi-task use, create separate [DelayObject](#) instances or protect with a mutex.

Performance Considerations

- Object creation allocates a timer (overhead on first use)
- Use static or member variables to avoid repeated allocation
- Very short delays (<10us) have relatively higher overhead
- Delay accuracy affected by interrupt latency and system load

Example: Basic Usage

```
DelayObject delay;

if (delay.valid()) {
    delay.DelayUsec(500); // 500 microsecond delay
}
```

Example: Pulse Generation

```
static DelayObject pulseDelay;

void generatePulse(int pin, uint32_t pulseWidthUs) {
    Pins[pin].set(); // Set pin high
    pulseDelay.DelayUsec(pulseWidthUs); // Precise pulse width
    Pins[pin].clr(); // Set pin low
}
```

Example: Protocol Timing

```

static DelayObject protocolDelay;

void sendI2CStart() {
    SDA.set();
    protocolDelay.DelayUsec(5);    // Setup time
    SCL.set();
    protocolDelay.DelayUsec(5);    // High time
    SDA.clr();
    protocolDelay.DelayUsec(5);    // Hold time
}

```

[Interval Timer](#) For non-blocking periodic timers

[Stopwatch Timer](#) For measuring elapsed time

[OSTimeDly\(\)](#) For standard RTOS delays

16.70.2 Constructor & Destructor Documentation**16.70.2.1 DelayObject()**

```

DelayObject::DelayObject (
    int Timer = FIRST_UNUSED_TIMER)

```

Construct a high-resolution delay timer object.

Allocates a hardware system timer from the processor's timer pool. The timer remains allocated for the lifetime of this object.

Parameters

<i>Timer</i>	Timer number to use. Default is FIRST_UNUSED_TIMER which automatically selects the first available timer. Specific timer numbers can be used for advanced applications but this is not recommended for general use.

Note

Always check [valid\(\)](#) after construction to ensure a timer was successfully allocated.

Warning

If no timers are available, the object will be invalid and [DelayUsec\(\)](#) should not be called. Check [valid\(\)](#) first.

Example

```

DelayObject delay; // Allocates first free timer
if (!delay.valid()) {
    iprintf("ERROR: No hardware timers available\n");
    return;
}

```

See also

[valid\(\)](#) To verify successful timer allocation

FIRST_UNUSED_TIMER Default timer selection constant

16.70.2.2 ~DelayObject()

```

DelayObject::~~DelayObject ()

```

Destructor - releases the allocated hardware timer.

Automatically frees the hardware timer back to the system pool when the object is destroyed or goes out of scope.

Note

The timer is freed even if a delay is in progress, though this should be avoided in normal operation.

16.70.3 Member Function Documentation

16.70.3.1 `_wake()`

```
void DelayObject::_wake () [inline]
```

Internal ISR callback to wake blocked task (internal use only)

This function is called by the timer interrupt service routine when the delay period expires. It posts the internal semaphore to unblock the task waiting in [DelayUsec\(\)](#).

Warning

This function is for internal use only and should never be called by user code. It is public only for ISR access.

Note

The leading underscore indicates internal/private usage

16.70.3.2 `DelayUsec()`

```
void DelayObject::DelayUsec (
    uint32_t usec)
```

Perform a blocking delay with microsecond precision.

Blocks the calling task for the specified number of microseconds using a hardware timer. The task is suspended until the timer expires.

Parameters

<i>usec</i>	Number of microseconds to delay (range: 0 to 4,294,967,295)

Precondition

The [DelayObject](#) must be valid (check with [valid\(\)](#))

Postcondition

The calling task resumes after approximately usec microseconds

Warning

Do not call this function if [valid\(\)](#) returns false

Very short delays (<10us) may have reduced accuracy due to function call and setup overhead

Note

The actual delay may be slightly longer than requested due to:

- Interrupt latency
- Task scheduling overhead
- System load

Delay Range Guidelines

- 1-10 us: Use only if hardware timing is critical
- 10-999 us: Ideal range for high-resolution delays
- 1-20 ms: Consider using [OSTimeDly\(\)](#) instead for efficiency
- >20 ms: Strongly recommend [OSTimeDly\(\)](#) to free hardware timer

Example: Short Delays

```
static DelayObject delay;
delay.DelayUsec(50);    // 50 microsecond delay
delay.DelayUsec(100);   // 100 microsecond delay
```

Example: Millisecond Delays

```
static DelayObject delay;
delay.DelayUsec(1000);  // 1 millisecond = 1000 microseconds
delay.DelayUsec(2500);  // 2.5 milliseconds
```

See also

[OSTimeDly\(\)](#) For delays ≥ 20 ms (more efficient)

[valid\(\)](#) Check before calling this function

16.70.3.3 [valid\(\)](#)

```
bool DelayObject::valid () [inline]
```

Verify the delay object is valid and ready to use.

Checks whether a hardware timer was successfully allocated during construction. Must be called before using [DelayUsec\(\)](#) to avoid undefined behavior.

Returns

true if a hardware timer was successfully allocated

false if no timer was available or allocation failed

Postcondition

If false is returned, [DelayUsec\(\)](#) must not be called

Note

A return value of false indicates all hardware timers are currently allocated. Consider:

- Freeing unused [DelayObject](#) instances
- Using [OSTimeDly\(\)](#) for less critical timing
- Redesigning to share timers between operations

Example: Proper Error Checking

```
DelayObject delay;

if (delay.valid()) {
    delay.DelayUsec(100); // Safe to use
} else {
    iprintf("WARNING: No hardware timers available\n");
    OSTimeDly(1); // Fallback to standard delay
}
```

Example: Critical Operation Guard

```
static DelayObject criticalDelay;

void performCriticalTiming() {
    if (!criticalDelay.valid()) {
        iprintf("FATAL: Cannot perform critical timing\n");
        return; // Abort operation
    }
    // Proceed with timing-critical code
    criticalDelay.DelayUsec(50);
}
```

Returns number of seconds remaining before the lease will be renewed.

- uint32_t [GetDhcpRebindTime](#) ()

Returns number of seconds remaining before the current lease will have to rebind.

- uint32_t [GetDhcpExpirationTime](#) ()

Returns number of seconds remaining before the current lease will expire.

- int32_t [GetDHCPState](#) ()

Returns current state of the [DHCP](#) lease.

16.74.1 Detailed Description

[DHCP](#) client class.

16.74.2 Member Function Documentation

16.74.2.1 bDoFallBack()

```
bool DhcpObject::bDoFallBack ()
```

Returns true if a [DHCP](#) fallback event has occurred.

The [init\(\)](#) function called at the beginning of an application will handle [DHCP](#) client services for all network interfaces.

It is rare that you would need to call these functions manually.

If the fallback functionality has been enabled in the device configuration, this function can be used to determine if a fallback to a static IP settings has occurred.

Returns

True if a fallback condition has occurred.

16.74.2.2 GetDhcpExpirationTime()

```
uint32_t DhcpObject::GetDhcpExpirationTime () [inline]
```

Returns number of seconds remaining before the current lease will expire.

Returns

The number of seconds remaining before the current lease will expire.

16.74.2.3 GetDhcpRebindTime()

```
uint32_t DhcpObject::GetDhcpRebindTime () [inline]
```

Returns number of seconds remaining before the current lease will have to rebind.

Returns

The number of seconds remaining before the current lease will have to rebind.

See also

[GetRemainingDhcpLeaseTime\(\)](#), [GetDhcpRenewTime\(\)](#), [GetDhcpExpirationTime\(\)](#)

16.74.2.4 GetDhcpRenewTime()

```
uint32_t DhcpObject::GetDhcpRenewTime () [inline]
```

Returns number of seconds remaining before the lease will be renewed.

Returns

The number of seconds remaining before the lease will be renewed.

See also

[GetRemainingDhcpLeaseTime\(\)](#), [GetDhcpRebindTime\(\)](#), [GetDhcpExpirationTime\(\)](#)

16.74.2.5 GetDHCPState()

```
int32_t DhcpObject::GetDHCPState ()
```

Returns current state of the [DHCP](#) lease.

Returns

[DHCP State](#)

See also

[ValidDhcpLease\(\)](#)

16.74.2.6 GetRemainingDhcpLeaseTime()

```
uint32_t DhcpObject::GetRemainingDhcpLeaseTime ()
```

Returns number of seconds remaining for current lease.

Returns

The number of seconds remaining for current lease.

See also

[GetDhcpRenewTime\(\)](#), [GetDhcpRebindTime\(\)](#), [GetDhcpExpirationTime\(\)](#)

16.74.2.7 RebindDHCP()

```
void DhcpObject::RebindDHCP ()
```

Manually force a [DHCP](#) rebind of a lease.

The [init\(\)](#) function called at the beginning of an application will handle [DHCP](#) client services for all network interfaces.

It is rare that you would need to call these functions manually.

See also

[RenewDHCP\(\)](#)

16.74.2.8 RenewDHCP()

```
void DhcpObject::RenewDHCP ()
```

Manually force a [DHCP](#) renew of a lease.

The [init\(\)](#) function called at the beginning of an application will handle [DHCP](#) client services for all network interfaces.

It is rare that you would need to call these functions manually.

See also

[RebindDHCP\(\)](#)

16.74.2.9 RestartDHCP()

```
void DhcpObject::RestartDHCP ()
```

Manually stop are resetar the [DHCP](#) client.

The [init\(\)](#) function called at the beginning of an application will handle [DHCP](#) client services for all network interfaces. It is rare that you would need to call these functions manually.

See also

[DhcpObject::StartDHCP\(\)](#), [DhcpObject::StopDHCP\(\)](#)

16.74.2.10 StartDHCP()

```
void DhcpObject::StartDHCP ()
```

Manually start the [DHCP](#) Client.

The [init\(\)](#) function called at the beginning of an application will handle [DHCP](#) client services for all network interfaces. It is rare that you would need to call these functions manually.

This function will start the [DHCP](#) client and return immediately. Check the [DHCP](#) status to verify you have successfully obtained a lease via [GetDHCPState\(\)](#)

See also

[DhcpObject::StopDHCP\(\)](#)

16.74.2.11 StopDHCP()

```
void DhcpObject::StopDHCP ()
```

Manually stop the [DHCP](#) client and release the [DHCP](#) lease.

The [init\(\)](#) function called at the beginning of an application will handle [DHCP](#) client services for all network interfaces. It is rare that you would need to call these functions manually.

See also

[DhcpObject::StartDHCP\(\)](#)

16.74.2.12 ValidDhcpLease()

```
BOOL DhcpObject::ValidDhcpLease ()
```

Returns the status of a [DHCP](#) lease.

Returns

True if the interface has a valid lease.

See also

[RenewDHCP\(\)](#)

16.75 DiagCallBack Class Reference

Callback-based diagnostic item that calls a custom function to generate diagnostic content.

```
#include <diagnostics.h>
```

Inherits [DiagItemClass](#).

Public Member Functions

- [DiagCallBack](#) (const char *name, [diagcallback](#) *pFunc)

Constructor for callback-based diagnostic item.

16.75.1 Detailed Description

Callback-based diagnostic item that calls a custom function to generate diagnostic content.

16.75.2 Constructor & Destructor Documentation

16.75.2.1 DiagCallBack()

```
DiagCallBack::DiagCallBack (
    const char * name,
    diagcallback * pFunc) [inline]
```

Constructor for callback-based diagnostic item.

Parameters

<i>name</i>	Name of the diagnostic item that will appear in the JSON output
<i>pFunc</i>	Pointer to the callback function that will generate the diagnostic content

The documentation for this class was generated from the following file:

- diagnostics.h

16.76 DiagItemClass Class Reference

Base class for all diagnostic items.

```
#include <diagnostics.h>
```

Inherited by [AcmeServletObject](#), [DiagCallBack](#), [DiagPtrMon](#), [DiagStrMon](#), and [DiagVarMon](#).

16.76.1 Detailed Description

Base class for all diagnostic items.

The documentation for this class was generated from the following file:

- diagnostics.h

16.77 DiagPtrMon Class Reference

Monitor and report pointer values.

```
#include <diagnostics.h>
```

Inherits [DiagItemClass](#).

Public Member Functions

- [DiagPtrMon](#) (const char *name, void *p)
Constructor for monitoring pointer values.
- virtual void **ServeContent** (int fd)
Output the pointer value as a hexadecimal string.

16.77.1 Detailed Description

Monitor and report pointer values.

16.77.2 Constructor & Destructor Documentation

16.77.2.1 DiagPtrMon()

```
DiagPtrMon::DiagPtrMon (  
    const char * name,  
    void * p) [inline]
```

Constructor for monitoring pointer values.

Parameters

<i>name</i>	Display name for this pointer in the diagnostic output
<i>p</i>	Pointer value to monitor

The documentation for this class was generated from the following file:

- `diagnostics.h`

16.78 DiagStrMon Class Reference

Monitor and report string values.

```
#include <diagnostics.h>
```

Inherits [DiagItemClass](#).

Public Member Functions

- [DiagStrMon](#) (const char *name, const char *pstr)
Constructor for monitoring C-style string.
- [DiagStrMon](#) (const char *name, [NBString](#) &s)
Constructor for monitoring [NBString](#) object.
- virtual void **ServeContent** (int fd)
Output the string value to the diagnostic stream.

16.78.1 Detailed Description

Monitor and report string values.

16.78.2 Constructor & Destructor Documentation

16.78.2.1 DiagStrMon() [1/2]

```
DiagStrMon::DiagStrMon (  
    const char * name,  
    const char * pstr) [inline]
```

Constructor for monitoring C-style string.

Parameters

<i>name</i>	Display name for this string in the diagnostic output
<i>pstr</i>	Pointer to the C-style string to monitor

16.78.2.2 DiagStrMon() [2/2]

```
DiagStrMon::DiagStrMon (  
    const char * name,  
    NBString & s) [inline]
```

Constructor for monitoring [NBString](#) object.

Parameters

<i>name</i>	Display name for this string in the diagnostic output
<i>s</i>	Reference to the NBString object to monitor

The documentation for this class was generated from the following file:

- `diagnostics.h`

16.79 DiagVarMon Class Reference

Monitor and report the value of numeric variables.

#include <diagnostics.h>

Inherits [DiagItemClass](#).

Public Member Functions

- [DiagVarMon](#) (const char *name, uint32_t &v)
Constructor for monitoring numeric variables.
- virtual void **ServeContent** (int fd)
Pure virtual function to output diagnostic content.

16.79.1 Detailed Description

Monitor and report the value of numeric variables.

16.79.2 Constructor & Destructor Documentation

16.79.2.1 DiagVarMon()

```
DiagVarMon::DiagVarMon (
    const char * name,
    uint32_t & v) [inline]
```

Constructor for monitoring numeric variables.

Creates a diagnostic monitor for various numeric data types. The constructor automatically determines the appropriate formatting based on the variable type:

- Signed integers are displayed as signed decimal numbers
- Unsigned integers are displayed as unsigned decimal numbers
- Floating point numbers are displayed in general format (g)

Parameters

<i>name</i>	Display name for this variable in the diagnostic output
<i>v</i>	Reference to the variable to monitor

The documentation for this class was generated from the following file:

- diagnostics.h

16.80 NB::Wifi::driverStatusStruct Struct Reference

#include <wifiDriver.h>

Public Attributes

- uint8_t **connected**
1 if connected, 0 if disconnected
- uint8_t **ssidLength**
Length of the SSID string.
- uint16_t **txPower**
Transmit power.
- int16_t **rss**

- *Recieved Signal Strength Indicator.*
- uint8_t **band**
Frequency band.
- uint8_t **channel**
802.11 channel
- uint32_t **maxTxRate**
Max transmit data throughput.
- uint8_t **security**
Security used: WEP, WPA, WPA2, open, unknown.
- uint8_t **cipher**
refer to [OPTIONLISTCIPH](#) for defenitions
- [MACADR](#) **bssid**
Basic Service Set Identifier.
- uint8_t **bssType**
refer to [OPTIONLISTBSSTYPE](#) for defenitions
- char **ssid** [SSID_MAX_LEN+1]
Placeholder for char array pointer.
- uint32_t **tickLastUpdated**
CPU tick count of when this struct was last updated.

16.80.1 Detailed Description

A struct used to describe the status of the current network connection.
The documentation for this struct was generated from the following file:

- wifiDriver.h

16.81 dspiDMAStruct Struct Reference

DSPI DMA structure.
`#include <dspi.h>`

Public Attributes

- bool **enabled**
Whether or not the driver is using DMA for the transfer.
- uint8_t **byteCount**
The bytes transferred per DMA call.
- bool **rxPresent**
Is a receive buffer present?
- bool **txPresent**
Is a transmit buffer present?
- dspistruct **savedDSPI**
- bool **csState**
- uint8_t **bytesLastRead**
- bool **isThereExtraRxBytes**
- DmaCh * **rxDma**
- DmaCh * **txDma**

- LPSPI_Type **savedSPI**
- bool **isPcsContinuous**
- uint32_t **extraBytesTCR**
Used to write SPI TCR via DMA for extra 1 or 2 data byte transfer. Used to de-assert CS if DEASSERT_AFTER_LAST.
- uint32_t **extraThirdByteTCR**
Used to write SPI TCR via DMA for extra 3rd data byte transfer. Used to de-assert CS if DEASSERT_AFTER_LAST.
- uint32_t **pcsTCR**
Used to write SPI TCR via DMA to de-assert CS if DEASSERT_AFTER_LAST at the end of the transfer.
- DmaTcd **softwareTCD** [6]
SoftwareTCD, used for scatter/gather to de-assert CS, internally used.

16.81.1 Detailed Description

DSPI DMA structure.

The documentation for this struct was generated from the following files:

- coldfire/cpu/MCF5441X/include/dspi.h
- cortex-m7/cpu/MIMXRT10xx/include/dspi.h

16.82 dspiDriverStruct Struct Reference

Major variables/configurations used for a DSPI transfer.

```
#include <dspi.h>
```

Public Attributes

- volatile uint8_t * **pDSPIRxbuf**
Track memory location where data will be read or written to the peripheral.
- volatile uint8_t * **pDSPITxbuf**
Track memory location where data will be read or written to the peripheral.
- uint8_t **BitsPerQueue**
Number of bits per transfer, (value = 8 - 32)
- uint32_t **DSPI_SizeLeft**
Number of bytes left in the transfer.
- uint16_t **Command_Mask**
Partial configuration for the queue's command reg.
- [csReturnType](#) **csReturnToInactive**
- OS_SEM * **DSPI_Sem**
Pointer to an external semaphore provided by [DSPIStart\(\)](#)
- volatile uint8_t **DSPI_INT_STATUS**
Status of the spi device.
- uint32_t **WordsToWrite**
Number of words to write to the command/TX Queues and Read from RX.
- uint32_t **LastWordsToWrite**
The amount from the previous ISR.
- volatile BOOL **DSPIfinished**
- [dspiDMAStruct](#) **dma**

16.82.1 Detailed Description

Major variables/configurations used for a DSPI transfer.

The documentation for this struct was generated from the following file:

- coldfire/cpu/MCF5441X/include/dspi.h

16.83 DSPIModule Class Reference

DSPIModule is a SPI communications driver. It is an object based driver, which allows for low overhead multiplexing between peripherals with different bus configurations.

```
#include <dspi.h>
```

Public Member Functions

- **DSPIModule** (uint8_t **SPIModule**)
*The minimum **DSPIModule** Constructor. Requires that configuration settings be applied after construction before use.*
- **DSPIModule** (uint8_t **SPIModule**, uint32_t baudRateInBps, uint8_t transferSizeInBits=8, uint8_t peripheralChipSelects=0x00, uint8_t chipSelectPolarity=0x0F, uint8_t clockPolarity=0, uint8_t clockPhase=1, BOOL doutHiz=TRUE, uint8_t csToClockDelay=0, uint8_t delayAfterTransfer=0)
***DSPIModule** Full **DSPIModule** Constructor. Will initialize all hardware settings.*
- uint8_t **Init** (uint32_t baudRateInBps=2000000, uint8_t transferSizeInBits=8, uint8_t peripheralChipSelects=0x00, uint8_t chipSelectPolarity=0x0F, uint8_t clockPolarity=0, uint8_t clockPhase=1, BOOL doutHiz=TRUE, uint8_t csToClockDelay=0, uint8_t delayAfterTransfer=0)
***DSPIModule** Full **DSPIModule** Constructor. Will initialize all hardware settings.*
- uint8_t **Start** (uint8_t *transmitBufferPtr, volatile uint8_t *receiveBufferPtr, uint32_t byteCount, int csReturnToInactive=**DEASSERT_AFTER_LAST**)
Start begins a SPI transaction using the provided buffers.
- uint8_t **Tx** (uint8_t *transmitBufferPtr, uint32_t byteCount, int csReturnToInactive=**DEASSERT_AFTER_LAST**)
Tx begins a transmit only SPI transaction using the provided buffer. Silently discards the received data.
- uint8_t **Rx** (uint8_t *receiveBufferPtr, uint32_t byteCount, int csReturnToInactive=**DEASSERT_AFTER_LAST**)
Rx begins a receive only SPI transaction using the provided buffer. Holds output line low during transfers.
- bool **EnableDMA** (bool enableDMA=true)
EnableDMA configures whether DMA is allowed for qualifying transactions.
- bool **DisableDMA** ()
DisableDMA disables DMA for all transactions.
- bool **RegisterSem** (OS_SEM *finishedSem)
Registers a semaphore to be posted to upon completion of transactions.
- bool **ClrSem** ()
Clears the semaphore registration.
- OS_SEM * **GetSem** ()
Gets a pointer to the registered Semaphore.
- bool **Done** ()
Returns whether the previously started transaction is complete.
- uint32_t **GetActualBaudrate** ()
Returns the actual bus speed to be used.
- bool **SetCS** (uint8_t CS)
Modifies the chip select configuration for the driver context such that only the requested chip select is active during transfers.

Static Public Member Functions

- static BOOL **Done** (uint8_t **SPIModule**)
Returns whether the previously started transaction for a given hardware module is complete.

Friends

- uint8_t [DSPIInit](#) (uint8_t [SPIModule](#)=[DEFAULT_DSPI_MODULE](#), uint32_t Baudrate=2000000, uint8_t QueueBitSize=8, uint8_t CS=0x00, uint8_t CSPol=0x0F, uint8_t ClkPolarity=0, uint8_t ClkPhase=1, BOOL Douthiz=TRUE, uint8_t QCD=0, uint8_t DTL=0)

Initialize a DSPI module.

16.83.1 Detailed Description

[DSPIModule](#) is a SPI communications driver. It is an object based driver, which allows for low overhead multiplexing between peripherals with different bus configurations.

16.83.2 Constructor & Destructor Documentation**16.83.2.1 DSPIModule() [1/2]**

```
DSPIModule::DSPIModule (
    uint8_t SPIModule)
```

The minimum [DSPIModule](#) Constructor. Requires that configuration settings be applied after construction before use.

Parameters

SPIModule	The DSPI module to use, from 1 to 3. Default is 1.

See also

[DSPIModule::DSPIModule\(uint8_t \[SPIModule\]\(#\), uint32_t baudRateInBps, uint8_t transferSizeInBits, uint8_t peripheralChipSelects\)](#)

16.83.2.2 DSPIModule() [2/2]

```
DSPIModule::DSPIModule (
    uint8_t SPIModule,
    uint32_t baudRateInBps,
    uint8_t transferSizeInBits = 8,
    uint8_t peripheralChipSelects = 0x00,
    uint8_t chipSelectPolarity = 0x0F,
    uint8_t clockPolarity = 0,
    uint8_t clockPhase = 1,
    BOOL douthiz = TRUE,
    uint8_t csToClockDelay = 0,
    uint8_t delayAfterTransfer = 0)
```

[DSPIModule](#) Full [DSPIModule](#) Constructor. Will initialize all hardware settings.

Parameters

SPIModule	The DSPI module to use, from 1 to 3. Default is 1.
baudRateInBps	Maximum master clock frequency for SPI Bus in bits per second.
transferSizeInBits	Bit width of the transfers to be made.
peripheralChipSelects	Bit mask of which chipselects are active during transfers.
chipSelectPolarity	Bit mask of the inactive state of chipselects.
clockPolarity	Inactive level for the clock signal.
clockPhase	Clock phase: • 0: data captured on leading edge of DSPI_CLK, changed on following edge. • 1: data changed on leading edge of DSPI_CLK, captured on following edge.

Parameters

<i>doutHiz</i>	Data output is high impedance between transfers (instead of driven).
<i>csToClockDelay</i>	Delay from chip select to valid clock. The default of 0 will set the delay as close to 1/2 DSPI_CLK without going under, keeping with the interface to QSPI driver.
<i>delayAfterTransfer</i>	Delay between data transfers. The default of 0 is 17/(system clock / 2), in keeping with interface to QSPI

16.83.3 Member Function Documentation

16.83.3.1 ClrSem()

```
bool DSPIModule::ClrSem () [inline]
```

Clears the semaphore registration.

Returns

Returns whether the registration was successfully cleared.

16.83.3.2 DisableDMA()

```
bool DSPIModule::DisableDMA () [inline]
```

DisableDMA disables DMA for all transactions.

Returns

Returns whether DMA is allowed

16.83.3.3 Done() [1/2]

```
bool DSPIModule::Done () [inline]
```

Returns whether the previously started transaction is complete.

Returns

Whether the previously started transaction is complete

16.83.3.4 Done() [2/2]

```
static BOOL DSPIModule::Done (
    uint8_t SPIModule) [static]
```

Returns whether the previously started transaction for a given hardware module is complete.

Parameters

SPIModule	The hardware instance to check the transaction state for.

Returns

Whether the previously started transaction is complete

16.83.3.5 EnableDMA()

```
bool DSPIModule::EnableDMA (  
    bool enableDMA = true)
```

EnableDMA configures whether DMA is allowed for qualifying transactions.

Parameters

<i>enableDMA</i>	Whether DMA is allowed

Returns

Returns whether DMA is allowed

16.83.3.6 GetActualBaudrate()

```
uint32_t DSPIModule::GetActualBaudrate () [inline]
```

Returns the actual bus speed to be used.

Returns

The actual bus speed to be used.

16.83.3.7 GetSem()

```
OS_SEM * DSPIModule::GetSem () [inline]
```

Gets a pointer to the registered Semaphore.

Returns

Pointer to the registered Semaphore

16.83.3.8 Init()

```
uint8_t DSPIModule::Init (
    uint32_t baudRateInBps = 2000000,
    uint8_t transferSizeInBits = 8,
    uint8_t peripheralChipSelects = 0x00,
    uint8_t chipSelectPolarity = 0x0F,
    uint8_t clockPolarity = 0,
    uint8_t clockPhase = 1,
    BOOL doutHiz = TRUE,
    uint8_t csToClockDelay = 0,
    uint8_t delayAfterTransfer = 0)
```

[DSPIModule](#) Full [DSPIModule](#) Constructor. Will initialize all hardware settings.

param [SPIModule](#) The instance number of the hardware module to use with this driver context.

Parameters

<i>baudRateInBps</i>	Maximum master clock frequency for SPI Bus
<i>transferSizeInBits</i>	Bit width of the transfers to be made
<i>peripheralChipSelects</i>	Bit mask of which chipselects are active during transfers
<i>chipSelectPolarity</i>	Bit mask of the inactive state of chipselects
<i>clockPolarity</i>	Inactive level for the clock signal
<i>clockPhase</i>	• 0: data captured on leading edge of DSPI_CLK, changed on following edge • 1: data changed on leading edge of DSPI_CLK, captured on following edge

Parameters

<i>doutHiz</i>	Data output is high impedance between transfers (instead of driven)

Parameters

<i>csToClockDelay</i>	Delay form chip select to valid clock. The default of 0 will set the delay as close to 1/2 DSPI_CLK without going under, keeping with the interface to QSPI driver.
<i>delayAfterTransfer</i>	Delay between data transfers. The default of 0 is 17/(system clock / 2), in keepin with interface to QSPI

See also

[DSPIModule::DSPIModule\(uint8_t SPIModule, uint32_t baudRateInBps, uint8_t transferSizeInBits, uint8_t peripheralChipSelect\)](#)

16.83.3.9 RegisterSem()

```
bool DSPIModule::RegisterSem (
    OS_SEM * finishedSem)
```

Registers a semaphore to be posted to upon completion of transactions.

Parameters

<i>finishedSem</i>	A pointer to the semaphore to be posted to.

Returns

Returns whether the semaphore was successfully registered.

16.83.3.10 Rx()

```
uint8_t DSPIModule::Rx (
    uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    int csReturnToInactive = DEASSERT_AFTER_LAST) [inline]
```

Rx begins a receive only SPI transaction using the provided buffer. Holds output line low during transfers.

Parameters

<i>receiveBufferPtr</i>	A pointer to the buffer to write received data to. If the buffer is NULL, then receive data will silently be discarded.
<i>byteCount</i>	The number of bytes to send and receive in this transaction. The value must be a multiple of the number of bytes in each individual transfer.
<i>csReturnToInactive</i>	Configures when the ChipSelect that is used for the transaction should be deasserted and return to being inactive.

See also

[csReturnType](#)

Returns

Non-zero on error

16.83.3.11 SetCS()

```
bool DSPIModule::SetCS (
    uint8_t CS) [inline]
```

Modifies the chip select configuration for the driver context such that only the requested chip select is active during transfers.

Parameters

CS	The chip select number to assert during transfers.

Returns

Whether the active chip select was successfully updated.

16.83.3.12 Start()

```
uint8_t DSPIModule::Start (
    uint8_t * transmitBufferPtr,
    volatile uint8_t * receiveBufferPtr,
    uint32_t byteCount,
    int csReturnToInactive = DEASSERT_AFTER_LAST)
```

Start begins a SPI transaction using the provided buffers.

Parameters

<i>transmitBufferPtr</i>	A pointer to the buffer containing data to be sent out. If the buffer is NULL, the bus will be held low instead.
<i>receiveBufferPtr</i>	A pointer to the buffer to write received data to. If the buffer is NULL, then receive data will silently be discarded.
<i>byteCount</i>	The number of bytes to send and receive in this transaction. The value must be a multiple of the number of bytes in each individual transfer.
<i>csReturnToInactive</i>	Configures when the ChipSelect that is used for the transaction should be deasserted and return to being inactive.

See also

[csReturnType](#)

Returns

Non-zero on error

16.83.3.13 Tx()

```
uint8_t DSPIModule::Tx (
    uint8_t * transmitBufferPtr,
    uint32_t byteCount,
    int csReturnToInactive = DEASSERT_AFTER_LAST) [inline]
```

Tx begins a transmit only SPI transaction using the provided buffer. Silently discards the received data.

Parameters

<i>transmitBufferPtr</i>	A pointer to the buffer containing data to be sent out. If the buffer is NULL, the bus will be held low instead.
<i>byteCount</i>	The number of bytes to send and receive in this transaction. The value must be a multiple of the number of bytes in each individual transfer.
<i>csReturnToInactive</i>	Configures when the ChipSelect that is used for the transaction should be deasserted and return to being inactive.

See also

[csReturnType](#)

Returns

Non-zero on error

16.83.4 Friends And Related Symbol Documentation

16.83.4.1 DSPIInit

```
uint8_t DSPIInit (
    uint8_t SPIModule = DEFAULT_DSPI_MODULE,
    uint32_t Baudrate = 2000000,
    uint8_t QueueBitSize = 8,
    uint8_t CS = 0x00,
    uint8_t CSPol = 0x0F,
    uint8_t ClkPolarity = 0,
    uint8_t ClkPhase = 1,
    BOOL DoutHiz = TRUE,
    uint8_t QCD = 0,
    uint8_t DTL = 0) [friend]
```

Initialize a DSPI module.

Notes:

- The maximum baud rate is CPU_CLOCK / 3
- Will initialize to the highest available baud rate that does not exceed the maximum
- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for greater than 8 bits per transfer then the data must be uint16_t aligned
- If configured for greater than 16 bits per transfer then the data must be uint32_t aligned
- Chip select is based on chipSelectPolarity
- 0 data captured leading edge of DSPI_CLK, changed following edge.
- 1 data changed leading edge of DSPI_CLK, captured following edge.
- 0 default is as close to 1/2 DSPI_CLK without going under, keeping with the interface to SPI
- 0 default is 17/(system clock / 2), in keeping with interface to QSPI

Parameters

<i>SPIModule</i>	SPI module number, 0 - 1
<i>Baudrate</i>	Maximum baud rate requested
<i>QueueBitSize</i>	Number of bits per transfer: 8, 16 or 32
<i>CS</i>	SPI chip selects to use for transfer
<i>CSPol</i>	0 = inactive logic level low, 1 = high
<i>ClkPolarity</i>	0 = inactive logic level low, 1 = high
<i>ClkPhase</i>	0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge.
<i>DoutHiz</i>	Data output high impedance between transfers
<i>QCD</i>	Delay from chip select to valid clock (default is 0). QCD is a value in the QDLYR register and will change the delay between the assertion of the chip select and the start of the DSPI clock. Default setting of one half DSPI clk will be used if parameter is specified as 0x0 or not included.
<i>DTL</i>	DTL is a value in the QDLYR register and will change the delay following a transfer of a single uint16_t in the DSPI queue. Default reset value of 17/(fsys/2) will be used if parameter is specified 0 or not included.

Returns

Current stat of DSPI bus [MOD5441xDspiStates](#)

Notes:

- The maximum baud rate is CPU_CLOCK / 3
- Will initialize to the highest available baud rate that does not exceed the maximum
- If configured for 8 bits per transfer then the data must be uint8_t aligned
- If configured for greater than 8 bits per transfer then the data must be uint16_t aligned
- If configured for greater than 16 bits per transfer then the data must be uint32_t aligned
- Chip select is based on chipSelectPolarity
- 0 data captured leading edge of DSPI_CLK, changed following edge.
- 1 data changed leading edge of DSPI_CLK, captured following edge.
- 0 default is as close to 1/2 DSPI_CLK without going under, keeping with the interface to SPI
- 0 default is 17/(system clock / 2), in keeping with interface to QSPI

Parameters

SPIModule	SPI module number, 0 - 1
<i>Baudrate</i>	Maximum baud rate requested
<i>QueueBitSize</i>	Number of bits per transfer: 8, 16 or 32
<i>CS</i>	SPI chip selects to use for transfer
<i>CSPol</i>	0 = inactive logic level low, 1 = high
<i>ClkPolarity</i>	0 = inactive logic level low, 1 = high
<i>ClkPhase</i>	0 = data captured leading edge clock, changed following edge. 1 = data changed leading edge clock, captured following edge.
<i>DoutHiz</i>	Data output high impedance between transfers
<i>QCD</i>	Delay from chip select to valid clock (default is 0)
<i>DTL</i>	Chip select mode dspicChipSelectMode

Returns

Current stat of DSPI bus [dspicState](#)

16.85.1 Detailed Description

Configuration structure for an External Bus Interface (EBI) chip select.

This structure defines all timing and control parameters for a single chip select on the External Bus Interface. It controls setup times, pulse widths, cycle lengths, and operational modes for interfacing with external memory or peripheral devices.

The timing parameters are specified in clock cycles and use formulas to extend the range of values that can be represented in the limited bit fields.

Note

All timing values are expressed in EBI clock cycles. Calculate actual times by dividing by your EBI clock frequency.

Setup + Pulse widths should not exceed the total cycle length. The hold time is implicitly: $\text{Hold} = \text{Total\_Cycles} - (\text{Setup} + \text{Pulse})$

Warning

Incorrect timing configuration can result in data corruption, device malfunction, or bus hangs. Always consult your external device datasheet for minimum timing requirements.

Expand for Example Usage

Examples

Example 1: Fast SRAM configuration (70ns access time)

```
// Assuming 150 MHz EBI clock (6.67 ns per cycle)
// SRAM requires: 10ns setup, 70ns pulse, 10ns hold

EBI_CS_cfg_t sramConfig = {
    // Read timing
    .ncs_rd_setup = 2,          // ~13ns (2 cycles)
    .nrd_setup = 2,            // ~13ns
    .ncs_rd_pulse = 11,        // ~73ns (11 cycles)
    .nrd_pulse = 11,           // ~73ns
    .nrd_cycles = 15,          // ~100ns total (15 cycles)

    // Write timing (same as read for this SRAM)
    .ncs_wr_setup = 2,         // ~13ns
    .nwe_setup = 2,            // ~13ns
    .ncs_wr_pulse = 11,        // ~73ns
    .nwe_pulse = 11,           // ~73ns
    .nwe_cycles = 15,          // ~100ns total

    // Additional parameters
    .tdf_cycles = 2,           // 2 cycles data float time
    .busWidth = EBI_BUS_WIDTH_16,
    .byteAccess = EBI_BYTE_ACCESS_WRITE,
    .nWait = EBI_NWAIT_DISABLED,
    .wrMode = EBI_WRITE_MODE_NWE,
    .rdMode = EBI_READ_MODE_NRD
};

iprintf("Fast SRAM configured: 70ns access time\r\n");
```

Example 2: Slow flash memory configuration (120ns access)

```
// Assuming 100 MHz EBI clock (10 ns per cycle)
// Flash requires: 20ns setup, 120ns pulse, 20ns hold

EBI_CS_cfg_t flashConfig = {
    // Read timing
    .ncs_rd_setup = 2,          // 20ns (2 cycles)
    .nrd_setup = 2,            // 20ns
    .ncs_rd_pulse = 12,        // 120ns (12 cycles)
    .nrd_pulse = 12,           // 120ns
    .nrd_cycles = 16,          // 160ns total (16 cycles)

    // Write timing (flash writes are slower)
    .ncs_wr_setup = 3,         // 30ns
    .nwe_setup = 3,            // 30ns
    .ncs_wr_pulse = 20,         // 200ns (longer for programming)
    .nwe_pulse = 20,           // 200ns
    .nwe_cycles = 26,          // 260ns total

    // Additional parameters
    .tdf_cycles = 3,           // 3 cycles data float
    .busWidth = EBI_BUS_WIDTH_8,
    .byteAccess = EBI_BYTE_ACCESS_SELECT,
    .nWait = EBI_NWAIT_FROZEN, // Flash can extend cycles
    .wrMode = EBI_WRITE_MODE_NWE,
    .rdMode = EBI_READ_MODE_NRD
};

iprintf("Flash memory configured with NWAIT support\r\n");
```

Example 3: Simple 8-bit I/O device (minimal timing)

```
// Assuming 120 MHz EBI clock (8.33 ns per cycle)
// Simple device with relaxed timing: 25ns setup, 50ns pulse

EBI_CS_cfg_t ioConfig = {
    // Read timing
    .ncs_rd_setup = 3,          // ~25ns (3 cycles)
    .nrd_setup = 3,            // ~25ns
    .ncs_rd_pulse = 6,         // ~50ns (6 cycles)
    .nrd_pulse = 6,            // ~50ns
    .nrd_cycles = 10,          // ~83ns total

    // Write timing (same as read)
    .ncs_wr_setup = 3,         // ~25ns
    .nwe_setup = 3,            // ~25ns
    .ncs_wr_pulse = 6,         // ~50ns
    .nwe_pulse = 6,            // ~50ns
    .nwe_cycles = 10,          // ~83ns total

    // Additional parameters
    .tdf_cycles = 1,           // Minimal data float
    .busWidth = EBI_BUS_WIDTH_8,
    .byteAccess = EBI_BYTE_ACCESS_SELECT,
    .nWait = EBI_NWAIT_DISABLED,
    .wrMode = EBI_WRITE_MODE_NCS, // Use CS for control
    .rdMode = EBI_READ_MODE_NCS
};

iprintf("Simple I/O device configured\r\n");
```

Example 4: Extended timing range using formula (slow device)

```
// Device requires very long access time: 1 microsecond
// Assuming 100 MHz EBI clock (10 ns per cycle)
// Need 100 cycles for 1us pulse

EBI_CS_cfg_t slowConfig = {
    // Using extended range formula for pulse:
    // nrd_pulse[6] = 0, nrd_pulse[5:0] = 100 won't work (max 63)
    // Need to use bit 6: pulse = 256*0 + 100 = 100 cycles
    // But 100 > 63, so we need bit 6 set
    // Actually: 256*0 + 100 still exceeds 6 bits
    // Correct approach: For 100 cycles, we can't fit in 6 bits alone
    // Let's use a realistic long pulse: 200 cycles = 2us

    .ncs_rd_setup = 10,        // 100ns
    .nrd_setup = 10,           // 100ns
    .ncs_rd_pulse = 200,        // 2us (bit 6 will be set automatically)
    .nrd_pulse = 200,          // 2us
    .nrd_cycles = 220,          // 2.2us total

    .ncs_wr_setup = 10,
    .nwe_setup = 10,
    .ncs_wr_pulse = 200,
    .nwe_pulse = 200,
    .nwe_cycles = 220,

    .tdf_cycles = 5,           // Longer data float time
    .busWidth = EBI_BUS_WIDTH_16,
    .byteAccess = EBI_BYTE_ACCESS_WRITE,
    .nWait = EBI_NWAIT_READY,
    .wrMode = EBI_WRITE_MODE_NWE,
    .rdMode = EBI_READ_MODE_NRD
};

iprintf("Very slow device configured: 2us access time\r\n");
```

Example 5: Helper function to calculate timing from nanoseconds

```
void CalculateEBITiming(uint32_t clockFreqMHz, uint32_t setupNs,
                        uint32_t pulseNs, uint32_t holdNs,
                        EBI_CS_cfg_t *config)
{
    // Calculate cycles needed (round up)
    float nsPerCycle = 1000.0f / clockFreqMHz;

    uint8_t setupCycles = (uint8_t)((setupNs + nsPerCycle - 1) / nsPerCycle);
    uint8_t pulseCycles = (uint8_t)((pulseNs + nsPerCycle - 1) / nsPerCycle);
    uint8_t holdCycles = (uint8_t)((holdNs + nsPerCycle - 1) / nsPerCycle);

    uint16_t totalCycles = setupCycles + pulseCycles + holdCycles;

    // Apply to both read and write (can be customized)
    config->ncs_rd_setup = setupCycles;
    config->nrd_setup = setupCycles;
```

```

    config->ncs_rd_pulse = pulseCycles;
    config->nrd_pulse = pulseCycles;
    config->nrd_cycles = totalCycles;

    config->ncs_wr_setup = setupCycles;
    config->nwe_setup = setupCycles;
    config->ncs_wr_pulse = pulseCycles;
    config->nwe_pulse = pulseCycles;
    config->nwe_cycles = totalCycles;

    iprintf("Calculated timing: %u setup, %u pulse, %u hold cycles\r\n",
            setupCycles, pulseCycles, holdCycles);
}

void UserMain(void *pd) {
    init();

    EBI_CS_cfg_t myConfig = {0};
    myConfig.busWidth = EBI_BUS_WIDTH_16;
    myConfig.wrMode = EBI_WRITE_MODE_NWE;
    myConfig.rdMode = EBI_READ_MODE_NRD;
    myConfig.nWait = EBI_NWAIT_DISABLED;
    myConfig.tdf_cycles = 2;

    // Calculate timing for 150 MHz clock, 20ns setup, 70ns pulse, 10ns hold
    CalculateEBI_Timing(150, 20, 70, 10, &myConfig);

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

Example 6: Validating timing configuration

```

bool ValidateEBI_Timing(const EBI_CS_cfg_t *config)
{
    // Check TDF cycles range
    if (config->tdf_cycles > 15) {
        iprintf("Error: tdf_cycles must be 0-15\r\n");
        return false;
    }

    // Verify read timing makes sense
    uint16_t rdSetup = config->ncs_rd_setup;
    uint16_t rdPulse = config->ncs_rd_pulse;
    if ((rdSetup + rdPulse) > config->nrd_cycles) {
        iprintf("Error: Read setup+pulse exceeds total cycles\r\n");
        return false;
    }

    // Verify write timing makes sense
    uint16_t wrSetup = config->ncs_wr_setup;
    uint16_t wrPulse = config->ncs_wr_pulse;
    if ((wrSetup + wrPulse) > config->nwe_cycles) {
        iprintf("Error: Write setup+pulse exceeds total cycles\r\n");
        return false;
    }

    iprintf("EBI timing configuration valid\r\n");
    return true;
}

void ConfigureEBI_WithValidation() {
    EBI_CS_cfg_t config = {
        .ncs_rd_setup = 2, .nrd_setup = 2,
        .ncs_rd_pulse = 10, .nrd_pulse = 10,
        .nrd_cycles = 15,
        .ncs_wr_setup = 2, .nwe_setup = 2,
        .ncs_wr_pulse = 10, .nwe_pulse = 10,

### 16.87.1 Detailed Description

FIFO buffer storage using linked pool buffers.

Manages a FIFO queue of data using a chain of [pool\\_buffer](#) structures. Provides stream-like read/write operations with automatic buffer allocation and deallocation. Used for serial ports and network I/O buffering.

### 16.87.2 Constructor & Destructor Documentation

#### 16.87.2.1 fifo\_buffer\_storage()

```
fifo_buffer_storage::fifo_buffer_storage (
 uint8_t max_buffers = 0,
 uint8_t use_fromisr = 1,
 uint8_t use_fast_buffs = 1)
```

Constructor.

Parameters

|                       |                                  |
|-----------------------|----------------------------------|
| <i>max_buffers</i>    | Maximum number of buffers to use |
| <i>use_fromisr</i>    | Enable ISR-safe operation        |
| <i>use_fast_buffs</i> | Prefer fast buffer pool          |

### 16.87.3 Member Function Documentation

#### 16.87.3.1 Empty()

```
BOOL fifo_buffer_storage::Empty ()
```

Check if buffer is empty.

Returns

TRUE if no data is stored

### 16.87.3.2 Full()

```
BOOL fifo_buffer_storage::Full ()
```

Check if buffer is full.

Returns

TRUE if no more data can be stored

### 16.87.3.3 Peek\_Begin()

```
PeekIterator fifo_buffer_storage::Peek_Begin ()
```

Get iterator for beginning of buffered data.

Returns

Iterator positioned at start of data

### 16.87.3.4 Peek\_End()

```
PeekIterator fifo_buffer_storage::Peek_End ()
```

Get iterator for end of buffered data.

Returns

Iterator positioned after last byte

### 16.87.3.5 PeekData()

```
uint8_t fifo_buffer_storage::PeekData (
 int idx = -1)
```

Peek at data without removing it.

Parameters

|            |                                          |
|------------|------------------------------------------|
| <i>idx</i> | Byte index to peek at (-1 for next byte) |
|------------|------------------------------------------|

Returns

Byte value at specified position

### 16.87.3.6 ReadData()

```
int fifo_buffer_storage::ReadData (
 uint8_t pCopyTo,
 int max_bytes)
```

Read data from the buffer.

Parameters

|                  |                       |
|------------------|-----------------------|
| <i>pCopyTo</i>   | Destination buffer    |
| <i>max_bytes</i> | Maximum bytes to read |

Returns

Number of bytes actually read

### 16.87.3.7 Reset()

```
void fifo_buffer_storage::Reset (
 uint8_t max_buffers)
```

Reset buffer storage and free all data.

## Parameters

|                    |                          |
|--------------------|--------------------------|
| <i>max_buffers</i> | New maximum buffer count |
|--------------------|--------------------------|

**16.87.3.8 SpaceAvail()**

```
uint16_t fifo_buffer_storage::SpaceAvail ()
```

Get number of bytes available for writing.

## Returns

Available space in bytes

**16.87.3.9 SpaceUsed()**

```
uint16_t fifo_buffer_storage::SpaceUsed ()
```

Get number of bytes currently stored.

## Returns

Used space in bytes

**16.87.3.10 WriteData()**

```
int fifo_buffer_storage::WriteData (
 uint8_t *pCopyFrom,
 int num_bytes)
```

Write data to the buffer.

## Parameters

|                  |                          |
|------------------|--------------------------|
| <i>pCopyFrom</i> | Source data buffer       |
| <i>num_bytes</i> | Number of bytes to write |

## Returns

Number of bytes actually written

## 16.88.1 Detailed Description

Base class for HTTP request handlers that process requests for specific URLs and HTTP methods.

This abstract base class provides the foundation for handling HTTP requests in NetBurner web applications. Derived classes implement specific request processing logic for particular URLs and HTTP methods (GET, POST, etc.). The class manages handler registration, URL matching, access control, and provides a linked-list structure for efficient handler lookup during request processing. Handlers can be configured to process requests before or after built-in file serving, allowing for custom processing or overriding of static content.

The handler system supports:

- URL pattern matching with wildcard support (NULL/empty string matches all URLs)
- HTTP method filtering (GET, POST, PUT, DELETE, etc.)
- Access group-based authorization
- Priority ordering for handler evaluation
- Integration with NetBurner's built-in file serving system

### Note

Despite the class name "HtmlPageHandler", this class handles all HTTP request types, not just HTML pages. The name is maintained for backward compatibility with existing NetBurner applications. Handlers are automatically registered upon construction and unregistered upon destruction.

## 16.88.2 Constructor & Destructor Documentation

### 16.88.2.1 HtmlPageHandler()

```
HtmlPageHandler::HtmlPageHandler (
 const char * url,
 HTTP_RequestTypes rt = tGet,
 int accessGroup = 0,
 bool Before_Files = false)
```

Constructs and registers an HTTP request handler for a specific URL pattern and method.

Creates a new request handler and automatically registers it in the global handler chain. The handler will be invoked when incoming requests match the specified URL pattern and HTTP method type, subject to access control restrictions.

#### Parameters

|                     |                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>url</i>          | URL pattern to handle. NULL or empty string creates a catch-all handler that matches any URL not handled by more specific handlers                                         |
| <i>rt</i>           | HTTP request type(s) to respond to from HTTP_RequestTypes enumeration (default: tGet for GET requests)                                                                     |
| <i>accessGroup</i>  | Access control group identifier for authorization (default: 0 for unrestricted access)                                                                                     |
| <i>Before_Files</i> | Handler priority relative to built-in file serving true: process before file serving (allows overriding static content) false: process after file serving (default: false) |

## 16.88.3 Member Function Documentation

### 16.88.3.1 FindHandler()

```
static HtmlPageHandler * HtmlPageHandler::FindHandler (
 HTTP_Request & req,
 bool bBeforeFiles) [static]
```

Locates the appropriate handler for an incoming HTTP request.

Searches the handler chain to find the first handler that matches the request's URL, HTTP method, and access requirements. Handlers are evaluated in priority order.

#### Parameters

|                     |                                                                                                                                        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <i>req</i>          | HTTP request object containing URL, method, and other request details                                                                  |
| <i>bBeforeFiles</i> | Handler priority group to search true: search handlers that run before file serving false: search handlers that run after file serving |

#### Returns

Pointer to matching handler if found, or NULL if no handler matches the request

### 16.88.3.2 GetGroup()

```
int HtmlPageHandler::GetGroup () [inline]
```

Returns the access control group identifier for this handler.

#### Returns

Access group identifier used for authorization checks, [HTTP\\_ACCESS](#)

#### See also

[CheckHttpAccess](#) for access control implementation details

### 16.88.3.3 MoveHandlerToLast()

```
void HtmlPageHandler::MoveHandlerToLast ()
```

Moves this handler to the end of the handler chain, making it function as a 404 handler.

Repositions the handler to be evaluated last, effectively creating a catch-all handler that processes requests not matched by any other handlers. This is commonly used to implement custom 404 error pages or fallback request processing.

### 16.88.3.4 ProcessRaw()

```
virtual int HtmlPageHandler::ProcessRaw (
 int sock,
 HTTP_Request & pd) [pure virtual]
```

Pure virtual method that must be implemented to process HTTP requests.

This method is called when a matching request is received and must contain the actual request processing logic. Implementations should read request data, perform necessary processing, and send appropriate HTTP responses.

#### Parameters

|             |                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------|
| <i>sock</i> | Socket file descriptor for the client connection                                              |
| <i>pd</i>   | HTTP request object containing parsed request details (headers, URL, method, body data, etc.) |

#### Returns

Non-zero if the request was successfully processed and a response was sent, or 0 if the request was not processed (allows fallback to other handlers)

Implemented in [CallBackFunctionPageHandler](#), and [CallBackFunctionPostHandler](#).

The documentation for this class was generated from the following file:

- [http.h](#)

## 16.89 HtmlPostVariableListCallback Class Reference

Implements the HtmlPostVariableListHandler class as a function pointer callback for HTTP POST submissions.

```
#include <httppost.h>
```

Inherits [HtmlPostVariableListHandler](#).

### Public Member Functions

- [HtmlPostVariableListCallback](#) (const char \*pUrl, postvarhandler \*pCallback, int accessGroup=0)  
*Custom HTTP POST handler callback function constructor.*
- [HtmlPostVariableListCallback](#) (const char \*pUrl, postvarhandler\_int \*pCallback, int accessGroup=0)  
*Custom HTTP POST handler callback function constructor.*

### 16.89.1 Detailed Description

Implements the HtmlPostVariableListHandler class as a function pointer callback for HTTP POST submissions.

### 16.89.2 Constructor & Destructor Documentation

#### 16.89.2.1 HtmlPostVariableListCallback() [1/2]

```
HtmlPostVariableListCallback::HtmlPostVariableListCallback (
 const char * pUrl,
 postvarhandler * pCallback,
 int accessGroup = 0) [inline]
```

Custom HTTP POST handler callback function constructor.

## Parameters

|                    |                                                         |
|--------------------|---------------------------------------------------------|
| <i>pUrl</i>        | Pointer to URL character string                         |
| <i>pCallback</i>   | Pointer to callback function that will process the POST |
| <i>accessGroup</i> | Password group access                                   |

**16.89.2.2 HtmlPostVariableListCallback() [2/2]**

```
HtmlPostVariableListCallback::HtmlPostVariableListCallback (
 const char * pUrl,
 postvarhandler_int * pCallback,
 int accessGroup = 0) [inline]
```

Custom HTTP POST handler callback function constructor.

## Parameters

|                    |                                                         |
|--------------------|---------------------------------------------------------|
| <i>pUrl</i>        | Pointer to URL character string                         |
| <i>pCallback</i>   | Pointer to callback function that will process the POST |
| <i>accessGroup</i> | Password group access                                   |

The documentation for this class was generated from the following file:

- httppost.h

**16.90 HTTP\_Request Struct Reference**

*Type of request [HTTP\\_RequestTypes](#).*

### 16.90.1 Detailed Description

HTTP Request Structure.

This structure is populated before a HTTP request is sent out.

### 16.90.2 Member Function Documentation

#### 16.90.2.1 GetBoundaryMarker()

```
const char * HTTP_Request::GetBoundaryMarker ()
```

Extracts the boundary marker string from multipart Content-Type headers.

This function searches through the previously parsed HTTP headers to locate and extract the boundary parameter from the Content-Type header when multipart content is present. The boundary marker is used to delimit individual parts within multipart HTTP content such as multipart/form-data or multipart/mixed. The function parses the Content-Type header according to RFC specifications to isolate the boundary value from other Content-Type parameters.

#### Returns

Pointer to null-terminated string containing the boundary marker value if found, or NULL if no multipart Content-Type header exists or no boundary parameter is specified in the Content-Type header

#### Note

The returned pointer references internal header data and remains valid as long as the header information is preserved. This function should only be called after HTTP headers have been successfully parsed. The boundary marker does not include the leading "--" prefix used in actual multipart delimiters. Multipart content requires a boundary parameter to be properly processed according to RFC standards.

#### See also

[ReadSimpleBody\(\)](#) for using the boundary marker during body parsing

RFC 2046 for multipart media type specifications

### 16.90.2.2 ReadSimpleBody()

```
int HTTP_Request::ReadSimpleBody (
 int socket,
 const char * boundary = NULL)
```

Reads the HTTP request body from a socket into the internal buffer and processes termination conditions. This function reads the remaining HTTP request body data from an established socket connection into the buffer backing the request object, preparing the `pData` member for access. The function handles different HTTP body termination scenarios including content-length bounded bodies, chunked transfer encoding, and boundary-delimited content such as multipart data. Reading continues until one of several termination conditions is met, allowing proper handling of various HTTP body formats.

#### Parameters

|                 |                                                                                                                                                                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>socket</i>   | File descriptor of the established HTTP connection Must be a valid socket with available data to read                                                                                                                                                             |
| <i>boundary</i> | Pointer to null-terminated string containing the boundary sequence that indicates the end of the request body (default: NULL) Used for multipart content or custom termination sequences If NULL, termination is determined by Content-Length or chunked encoding |

#### Returns

HTTP\_RRR\_END\_FOUND if the function successfully found the trailing termination sequence and completed reading the body

HTTP\_RRR\_FINISHED if all content was read as indicated by HTTP headers (Content-Length reached or chunked encoding completed)

HTTP\_RRR\_BUFF\_FULL if the internal buffer became full before the body was completely read, indicating more data remains available on the socket

HTTP\_RRR SOCK\_ERR if a socket error occurred during reading, typically indicating the connection was closed or experienced a network error

#### Note

This function modifies the internal buffer state and primes the `pData` member for access. The socket must have HTTP headers already processed before calling this function. For multipart or boundary-terminated content, the boundary parameter must be specified. Buffer overflow conditions require additional reads to retrieve remaining data. The function respects HTTP protocol specifications for body termination.

#### See also

*Read a number of 8-bit values from an [I2C](#) slave at the specified register address.*

## Friends

- class [WireIntf](#)
- class [TwoWire](#)

## 16.91.1 Detailed Description

[I2C](#) Peripheral Class.

For [I2C](#) communication, you can choose the [WireIntf](#) class, or the [I2C](#) class. The [WireIntf](#) class is simpler to use, while the [I2C](#) class provides more low level control.

Note that the system automatically instantiates [I2C](#) and [WireIntf](#) objects for each of the [I2C](#) peripheral modules. The [WireIntf](#) objects can be accessed with: [Wire](#), [Wire1](#) and [Wire2](#). The [I2C](#) objects can be accessed with [I2C\[0\]](#), [I2C\[1\]](#) and [I2C\[2\]](#).

## 16.91.2 Member Enumeration Documentation

### 16.91.2.1 Result\_t

enum [I2C::Result\\_t](#)

Return result types.

#### Enumerator

|                                 |                        |
|---------------------------------|------------------------|
| <a href="#">I2C_RES_ACK</a>     | Acknowledged.          |
| <a href="#">I2C_RES_NACK</a>    | Not acknowledged.      |
| <a href="#">I2C_RES_ARB_LST</a> | Arbitration listening. |
| <a href="#">I2C_RES_BUSY</a>    | Bus is busy.           |
| <a href="#">I2C_RES_ARG</a>     | Bad argument.          |

## 16.91.3 Constructor & Destructor Documentation

### 16.91.3.1 I2C()

```
I2C::I2C (
 int module)
```

Constructor for the [I2C](#) peripheral module.

#### Parameters

|               |                                                           |
|---------------|-----------------------------------------------------------|
| <i>module</i> | The <a href="#">I2C</a> module to instantiate (0, 1 or 2) |
|---------------|-----------------------------------------------------------|

## 16.91.4 Member Function Documentation

### 16.91.4.1 DoTransaction()

```
Result_t I2C::DoTransaction (
 I2CTxn_t * pTransaction,
 bool bRepeatedStart = false)
```

Start an [I2C](#) transaction.

Execute the transaction pointed to by pTransaction

#### Parameters

|                       |                                               |
|-----------------------|-----------------------------------------------|
| <i>*pTransaction</i>  | Pointer to the transaction to execute         |
| <i>bRepeatedStart</i> | Repeat the <a href="#">I2C</a> start sequence |

#### Returns

[Result\\_t](#)

### 16.91.4.2 readReg8()

```
Result_t I2C::readReg8 (
 uint8_t devAddr,
 uint32_t reg,
 uint8_t & data)
```

Read an 8-bit value form an [I2C](#) slave device register.

#### Parameters

|                |                                                           |
|----------------|-----------------------------------------------------------|
| <i>devAddr</i> | Address of <a href="#">I2C</a> device                     |
| <i>reg</i>     | Register address to read                                  |
| <i>data</i>    | Reference to variable in which to store the register data |

#### Returns

[Result\\_t](#)

### 16.91.4.3 readRegN()

```
Result_t I2C::readRegN (
 uint8_t devAddr,
 uint32_t reg,
 uint8_t * buf,
 uint32_t blen)
```

Read a number of 8-bit values from an [I2C](#) slave at the specified register address.

## Parameters

|                |                                          |
|----------------|------------------------------------------|
| <i>devAddr</i> | Address of <a href="#">I2C</a> device    |
| <i>reg</i>     | Register address to read                 |
| <i>*buf</i>    | Pointer to buffer to store received data |
| <i>blen</i>    | Number of bytes to read                  |

## Returns

[Result\\_t](#)**16.91.4.4 setNumAddressBytes()**

```
void I2C::setNumAddressBytes (
 uint8_t numAddressBytes = 1) [inline]
```

Specify the register address size for a read or write transaction. A number of bytes, from 0 to 3, can be sent to specify an address up to 24-bit (3 bytes): 0 = none, 1 = 8-bits, 2 = 16-bits, 3 = 24-bits.

If you are using a single [I2C](#) device, or all devices use the same address size, this function only needs to be called once. If you have multiple [I2C](#) devices with different address/register bit sizes, then this function should be called before each read/write operation for each different device.

## Parameters

|                        |                                                                          |
|------------------------|--------------------------------------------------------------------------|
| <i>numAddressBytes</i> | The number of address bytes to send: 0 - 3. The default value is 1 byte. |
|------------------------|--------------------------------------------------------------------------|

**16.91.4.5 setup()**

```
void I2C::setup (
 uint32_t busSpeed)
```

Setup the [I2C](#) peripheral interface.

## Parameters

|                 |                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------|
| <i>busSpeed</i> | Target bus speed. If the specified speed cannot be achieved, a lower bus speed may be enabled. |
|-----------------|------------------------------------------------------------------------------------------------|

**16.91.4.6 writeReg8()**

```
Result_t I2C::writeReg8 (
 uint8_t devAddr,
 uint32_t reg,
 uint8_t data)
```

Write an 8-bit value to a [I2C](#) slave device register.

## Parameters

|                |                                       |
|----------------|---------------------------------------|
| <i>devAddr</i> | Address of <a href="#">I2C</a> device |
| <i>reg</i>     | Register address to write             |
| <i>data</i>    | Data to write to register             |

## Returns

[Result\\_t](#)

### 16.91.4.7 writeRegN()

```
Result_t I2C::writeRegN (
 uint8_t devAddr,
 uint32_t reg,
 const uint8_t * buf,
 uint32_t blen)
```

Write a number of 8-bit values to an [I2C](#) slave to the specified register address.

Executing this function will send the following: a start bit, the slave device address and read/write bit, the 8-bit data bytes, and finally a stop bit. Note that the address is not incremented with each 8-bit data value.

#### Parameters

|                |                                            |
|----------------|--------------------------------------------|
| <i>devAddr</i> | Address of <a href="#">I2C</a> device      |
| <i>reg</i>     | Register address to write                  |
| <i>*buf</i>    | Pointer to buffer containing data to write |
| <i>blen</i>    | Number of bytes to write                   |

#### Returns

[Result\\_t](#)

*Read a number of 8-bit values from an [I2C](#) slave at the specified register address.*

### 16.92.1 Detailed Description

[I2C](#) Device Class (recommended)

For [I2C](#) communication, you can choose the [I2CDevice](#) class, the [I2C](#) class, or the [WireIntf](#) class. The recommended interface is the [I2CDevice](#) class.

For example, to create an object for an analog to digital converter:

```
I2CDevice AdcDevice(i2c[I2C_MODULE_NUM], I2C_ADC_ADDRESS);
```

To read a 16 bit value:

```
uint8_t I2CStat = AdcDevice.readRegN(0x00, buf, 2);
```

## 16.92.2 Constructor & Destructor Documentation

### 16.92.2.1 I2CDevice()

```
I2CDevice::I2CDevice (
 I2C & pInterface,
 uint8_t deviceAddress,
 uint8_t numAddressBytes = 1) [inline]
```

Initialize the I2C module.

#### Parameters

|                        |                                                                                                                                                                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>pInterface</i>      | Pointer to the I2C interface to use. This will normally be one of the preallocated I2C modules in the i2c[] array: i2c[0] (default), i2c[1] or i2c[2].                                                                                                                                                       |
| <i>deviceAddress</i>   | I2C device address                                                                                                                                                                                                                                                                                           |
| <i>numAddressBytes</i> | Number of address bytes to send to specify the register or address to access for a read or write operation. Refer to your I2C device data sheet to determine the correct number. The I2C address range is 24-bits maximum (3 bytes). The default value is 1 byte, representing an address range of 0 to 255. |

## 16.92.3 Member Function Documentation

### 16.92.3.1 getI2CAddress()

```
uint8_t I2CDevice::getI2CAddress () [inline]
```

Get device's I2C address.

Note that the return address will be just the I2C address bits, not including the read/write bit. If your device data sheet specifies the address byte to include the read/write bit, that value would be this address left shifted by 1. For example, if a device data sheet specifies the address as 0xA2 and includes the read/write bit, the actual address would be 0x51.

#### Returns

The device's I2C address

### 16.92.3.2 readReg8()

```
I2C::Result_t I2CDevice::readReg8 (
 uint32_t reg,
 uint8_t & data) [inline]
```

Read an 8-bit value form an I2C slave device register.

#### Parameters

|             |                                                           |
|-------------|-----------------------------------------------------------|
| <i>reg</i>  | Register address to read                                  |
| <i>data</i> | Reference to variable in which to store the register data |

#### Returns

I2C::Result\_t

### 16.92.3.3 readRegN()

```
I2C::Result_t I2CDevice::readRegN (
 uint32_t reg,
 uint8_t * buf,
 uint32_t blen) [inline]
```

Read a number of 8-bit values from an I2C slave at the specified register address.

## Parameters

|             |                                          |
|-------------|------------------------------------------|
| <i>reg</i>  | Register address to read                 |
| <i>*buf</i> | Pointer to buffer to store received data |
| <i>blen</i> | Number of bytes to read                  |

## Returns

[I2C::Result\\_t](#)

**16.92.3.4 setup()**

```
void I2CDevice::setup (
 uint32_t busSpeed) [inline]
```

Setup the [I2C](#) peripheral module.

## Parameters

|                 |                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------|
| <i>busSpeed</i> | Target bus speed. If the specified speed cannot be achieved, a lower bus speed may be enabled. |
|-----------------|------------------------------------------------------------------------------------------------|

**16.92.3.5 writeReg8()**

```
I2C::Result_t I2CDevice::writeReg8 (
 uint32_t reg,
 uint8_t data) [inline]
```

Write an 8-bit value to an [I2C](#) slave device register.

## Parameters

|             |                           |
|-------------|---------------------------|
| <i>reg</i>  | Register address to write |
| <i>data</i> | Data to write to register |

## Returns

[I2C::Result\\_t](#)

**16.92.3.6 writeRegN()**

```
I2C::Result_t I2CDevice::writeRegN (
 uint32_t reg,
 const uint8_t * buf,
 uint32_t blen) [inline]
```

Write a number of 8-bit values to an [I2C](#) slave to the specified register address.

Executing this function will send the following: a start bit, the slave device address and read/write bit, the 8-bit data bytes, and finally a stop bit. Note that the address is not incremented with each 8-bit data value.

## Parameters

|             |                                            |
|-------------|--------------------------------------------|
| <i>reg</i>  | Register address to write                  |
| <i>*buf</i> | Pointer to buffer containing data to write |
| <i>blen</i> | Number of bytes to write                   |

## Returns

[I2C::Result\\_t](#)

### 16.95.1 Detailed Description

[IEEE1588Timer](#) class - Encapsulates 1588 timer functionality for GPS PPS synchronization

This class manages the hardware 1588 timer on the ethernet controller for precise time synchronization with GPS PPS signals. It provides methods to:

- Initialize the 1588 timer hardware
- Capture PPS edges with precise timestamps
- Track GPS time synchronization validity
- Calculate precise NTP timestamps

### 16.95.2 Member Function Documentation

#### 16.95.2.1 [enablePPSCapture\(\)](#)

```
void IEEE1588Timer::enablePPSCapture ()
```

Enable PPS capture on channel 2 Configures interrupt handling for PPS edge detection

#### 16.95.2.2 [getConsecutiveValidSeconds\(\)](#)

```
uint32_t IEEE1588Timer::getConsecutiveValidSeconds () const [inline]
```

Get count of consecutive valid GPS seconds

Returns

Number of consecutive seconds with valid GPS time

#### 16.95.2.3 [getCurrentTime\(\)](#)

```
uint32_t IEEE1588Timer::getCurrentTime (
 EthernetVars & ev)
```

Get current 1588 timer value

Parameters

|                    |                                           |
|--------------------|-------------------------------------------|
| <a href="#">ev</a> | Reference to ethernet variables structure |
|--------------------|-------------------------------------------|

Returns

Current 1588 timer count

#### 16.95.2.4 [getPPSCapture\(\)](#)

```
uint32_t IEEE1588Timer::getPPSCapture (
 uint8_t index) const [inline]
```

Access PPS capture arrays for timestamp calculation These methods provide read-only access to internal arrays for use by [NtpTimeStamp::SetFrom](#) method

#### 16.95.2.5 [getPPSLoop\(\)](#)

```
uint32_t IEEE1588Timer::getPPSLoop () const [inline]
```

Get current PPS loop index

Returns

Current ring buffer write index

**16.95.2.6 init()**

```
bool IEEE1588Timer::init ()
```

Initialize the 1588 timer hardware Sets up the timer with proper clock source and enables PPS capture

**Returns**

true if initialization successful, false on error

**16.95.2.7 markValidTime()**

```
void IEEE1588Timer::markValidTime (
 uint8_t index,
 uint32_t ntpTime)
```

Mark a GPS time as valid for a specific PPS capture Called by GPS processing when GPRMC message provides valid time

**Parameters**

|                |                                         |
|----------------|-----------------------------------------|
| <i>index</i>   | Ring buffer index for the PPS capture   |
| <i>ntpTime</i> | NTP timestamp corresponding to this PPS |

**16.95.2.8 PPS\_1588\_TimeCapIsr()**

```
void IEEE1588Timer::PPS_1588_TimeCapIsr () [static]
```

Static ISR handler for PPS capture interrupt This must be static to be used as C-style function pointer

**16.95.2.9 resetConsecutiveSeconds()**

```
void IEEE1588Timer::resetConsecutiveSeconds () [inline]
```

Reset consecutive seconds tracking Called when GPS synchronization is lost

**16.95.2.10 ring\_diff\_forward()**

```
static uint32_t IEEE1588Timer::ring_diff_forward (
 uint32_t a,
 uint32_t b) [inline], [static]
```

Utility functions for ring buffer arithmetic These are used for calculating time differences in wrap-around scenarios

**16.95.2.11 updateConsecutiveSeconds()**

```
void IEEE1588Timer::updateConsecutiveSeconds (
 uint32_t currentTimeTick)
```

Update consecutive seconds tracking Called when new valid GPS time is received

**Parameters**

|                        |                       |
|------------------------|-----------------------|
| <i>currentTimeTick</i> | Current OS tick count |
|------------------------|-----------------------|

The documentation for this class was generated from the following files:

- IEEE1588Timer.h
- IEEE1588Timer.cpp

**16.96 InterfaceBlock Class Reference**

Network interface configuration block class for interface control and configuration.

```
#include <netinterface.h>
```

Inherits [config\\_obj](#).

Inherited by EtherLikeInterface, MultiHomeInterface, and PPPInterface.

## Public Member Functions

*This interface number.*
- `uint16_t netMss`  
*Network max segment size for this interface.*
- `uint8_t checksumOffload`  
*Non-zero if hardware interface support offloading checksum calculation.*
- `bool bHaveSeenLink`  
*True if a link has been present previously at least once.*
- `DhcpObject dhcpClient` {this}  
*DHCP client support.*
- `discover_servlet disco_servlet` {this}  
*The servlet that runs the NetBurner discovery server process.*
- `void(* MCastLinkNotify)(InterfaceBlock *pBlock, bool bLink)`  
*A function pointer called when link changes for multicast.*
- `IPADDR4 previous_addr`  
*Previous IPv4 address.*
- `IPADDR4 previous_mask`  
*Previous IPv4 mask.*
- `IPADDR4 previous_gate`  
*Previous IPv4 gateway.*
- `AutoIPClient AutoClient`  
*AutoIP client object for this interface.*

### 16.96.1 Detailed Description

Network interface configuration block class for interface control and configuration.

Network Interfaces are configured and controlled C++ [InterfaceBlock](#) objects. The [InterfaceBlock](#) contains variables and member functions for things such as:

- The Configuration Server interface
- IP settings for both IPv4 and IPv6 types
- Configuration to static or [DHCP](#), and [DHCP](#) status (both v4 and v6)
- Multihome
- Routing
- AutoIP

#### Note

While the recommended method for getting and setting network interface parameters is to obtain a pointer to an [InterfaceBlock](#), there are also non-member functions of the object that can be used for situations that are best served by a single function call, such as just getting a single IP address of an interface. When using those functions pay special attention to the return value type. While `IPADDR` should be used because it supports both `IPADDR4` and `IPADDR6` types automatically, some of these helper functions may specifically return an `IPADDR4` type.

## 16.96.2 Constructor & Destructor Documentation

### 16.96.2.1 InterfaceBlock() [1/2]

```
InterfaceBlock::InterfaceBlock (
 const char * name,
 const char * desc = NULL)
```

Constructor with interface name and description.

#### Parameters

|             |                                                      |
|-------------|------------------------------------------------------|
| <i>name</i> | Interface name.                                      |
| <i>desc</i> | Interface description. If not used, default is null. |

### 16.96.2.2 InterfaceBlock() [2/2]

```
InterfaceBlock::InterfaceBlock (
 config_obj & owner,
 const char * name,
 const char * desc = NULL)
```

Constructor with [config\\_obj](#) owner, interface name and description.

#### Parameters

|              |                                                                |
|--------------|----------------------------------------------------------------|
| <i>owner</i> | Reference to <a href="#">config_obj</a> owner of the interface |
| <i>name</i>  | Interface name.                                                |
| <i>desc</i>  | Interface description. If not used, default is null.           |

## 16.96.3 Member Function Documentation

### 16.96.3.1 EnableMulticast()

```
virtual void InterfaceBlock::EnableMulticast (
 MACADR macAddress,
 BOOL addAddress) [pure virtual]
```

Enable Multicast on this interface.
