

Developers Guide, API, Production and Deployment

NetBurner 3.5.6

NetBurner, Inc. 31-Oct-2025

1 NetBurner 3.5.6	1
1.1 Welcome to NetBurner Version 3!	1
1.2 Who Is This Guide For?	1
1.3 Recommended Starting Point for New Developers	2
1.4 Documentation Overview	2
1.4.1 The NetBurner Application Programming Interface (API)	2
1.4.2 Device Discovery and Configuration	3
1.4.3 The NBEclipse Getting Started Guide	3
1.4.4 Migration Guides	3
1.4.5 Example Programs	3
1.4.6 Programmers Guide	4
1.4.7 Platform References	4
1.4.8 System Diagnostics	4
1.4.9 Utilities	4
1.4.10 Production and Deployment	4
1.4.11 Location of Original Factory Program	5
1.4.12 Experienced NetBurner Customers	5
2 Build System	7
2.1 Introduction	7
2.2 GCC Compiler Flags	7
2.2.1 Generic	7
2.2.2 Architecture-Specific Compiler Flags	8
2.2.2.1 ARM Cortex-M7	8
2.2.2.2 ARM Cortex-M0+	8
2.2.2.3 ColdFire	8
2.2.3 CPU-Specific Compiler Flags	9
2.2.3.1 SAME70	9
2.2.3.2 MIMXRT11xx, MIMXRT10xx	9
2.2.3.3 SAMD20	9
2.2.3.4 MCF5441X	9
2.2.4 Platform-Specific Compiler Flags	9
2.2.4.1 MODM7AE70	9
2.2.4.2 SBE70LC	10
2.2.4.3 SOMRT1061	10
2.2.4.4 MOD5441X	10
2.2.4.5 NANO54415	10
2.2.4.6 SB800EX	10
2.3 Linker Flags	10
2.3.1 Generic	10
2.3.2 Architecture-Specific Linker Flags	11
2.3.3 CPU-Specific Linker Flags	11

2.3.3.1 SAME70	11
2.3.3.2 MIMXRT11xx, MIMXRT10xx	11
2.3.3.3 SAMD20	11
2.3.3.4 MCF5441X	12
2.3.4 Platform-Specific Linker Flags	12
2.4 Pack Binary	12
2.4.1 Generic	12
2.4.2 Architecture-Specific	12
2.4.3 CPU-Specific	13
2.4.3.1 MCF5441X	13
2.4.3.2 SAMD20	13
2.4.3.3 SAME70	13
2.4.3.4 MIMXRT11xx, MIMXRT10xx	13
2.4.4 Platform-Specific	13
2.4.4.1 MODM7AE70	13
2.4.4.2 SBE70LC	14
2.4.4.3 SOMRT1061	14
2.4.4.4 MOD5441X	14
2.4.4.5 NANO54415	14
2.4.4.6 SB800EX	14
3 Command Line Tools	15
3.1 Introduction	15
3.2 Command Line Summary	15
3.3 Command Line Environment Variables	15
3.4 Create a New Project From an Example	16
3.4.1 Edit the makefile	17
3.4.2 Edit main.cpp	17
3.5 Modifying System Files with Overload	18
3.5.1 Important Overload Rules	18
3.6 GNU Debugger (GDB)	19
3.6.1 Example GDB Session	19
3.7 Addr2line	21
3.7.1 ColdFire platforms	22
3.7.2 ARM platforms	22
4 Device Discovery and Configuration	23
4.1 Introduction	23
4.1.1 Device Discovery Methods:	23
4.1.2 Device Configuration methods:	23
4.2 Configuration Procedure	24
4.2.1 Configuration Settings	26
4.2.1.1 Config	26

4.2.1.2 Update Application	26
4.2.1.3 Config > Sys	26
4.2.1.4 Config > Sys > BOOT	26
4.2.1.5 Config > Sys > NetIf	27
4.2.1.6 Config > Sys > NetIf > Ethernet0	27
4.2.1.7 Config > Sys > NetIf > Ethernet0 > IPv4	27
4.2.1.8 Config > Sys > NetIf > Ethernet0 > IPv6	28
4.3 The JSON Object	29
4.3.1 Developer Notes	30
4.4 Configuration Security	31
4.5 Serial Configuration Server	31
4.5.1 Serial Configuration	32
4.5.2 Serial App Downloads	37
4.5.2.1 Start of Serial Configuration Server.	38
4.5.2.2 Optional, type "help" to see a list of commands.	38
4.5.2.3 Type "flash" command	38
4.5.2.4 Send Application File	39
4.5.3 Serial Config Settings	39
5 Migration Guides	41
5.1 Release 2.x to 3.x Overview	41
5.1.1 Hardware	42
5.1.2 Configuration	42
5.1.3 RTOS	42
5.1.4 TCP	43
5.1.5 Network Interfaces	43
5.1.6 SSL/TLS	43
5.1.7 System Initialization	43
5.1.8 NBEclipse	43
5.1.9 GCC	44
5.2 Release 2.x to 3.x Porting Guide	44
5.2.1 Device Configuration	44
5.2.2 Configuration Procedure	44
5.2.3 Recommended Examples	45
5.2.4 Configuration Security	45
5.2.4.1 Cautions When Using the Jumper Recover Procedure on a Device	46
5.2.5 Device Application Updates	46
5.2.6 Eclipse and Development Tools Updates	46
5.2.7 SSL/TLS	47
5.2.8 Notes on Porting From Previous Revisions	47
5.2.9 Porting I2C From MCF52xx Based Products to MODM7AE70	48
5.3 Upgrade 5441x Platforms to 3.x	50

5.3.1 Introduction	50
5.3.2 5441x Product Models Numbers	50
5.3.3 3.x Update Procedures	50
5.3.3.1 Procedure For a New 5441x Device Running The NetBurner Factory App	51
5.3.3.2 Procedure Using the 2.x to 3.x Conversion Application: xxxx-3p0-Update_APP.s19	51
5.3.3.3 Procedure Using Alternate Boot Monitor	51
5.3.4 Procedure to Revert Back to 2.x	52
5.3.4.1 Serial Port Procedure	52
5.3.4.2 Hardware Reset Jumper Procedure	52
5.3.5 Note on IPSetup utility and 3.x Devices	53
6 NBEclipse	55
6.1 Getting Started Guide	55
6.1.1 Introduction	55
6.1.1.1 How to Use This Guide	55
6.1.1.2 Source Code for Example Programs	56
6.1.1.3 Hardware Setup	56
6.1.1.4 Software Installation	56
6.1.1.5 Upgrading From a Previous Installation	56
6.1.1.6 Java Installation	56
6.1.1.7 Debug Port	57
6.1.2 Platform Overview	57
6.1.2.1 NetBurner Development Platform Choices	57
6.1.3 Project Management	57
6.1.3.1 NBEclipse Key Points	58
6.1.4 Creating Projects and Importing Files	58
6.1.4.1 Create a New Project	59
6.1.4.2 Select the NetBurner Project Type	59
6.1.4.3 Specify Project Name and Executable Option	60
6.1.4.4 Project Configurations	61
6.1.4.5 Select Your NetBurner Target Device	62
6.1.4.6 Application Wizard	64
6.1.4.7 New Project Created	65
6.1.4.8 Import Example Source Files to the Project SRC Folder	66
6.1.4.9 Open your main.cpp source file	70
6.1.4.10 Project Import Complete	71
6.1.4.11 Download the Application to Your Device	73
6.1.4.12 View the Device Web Page	76
6.1.4.13 View Serial Port Status Messages with MTTTY	77
6.1.5 Debugger	78
6.1.5.1 Starting a Debug Session	78
6.1.6 Rebuilding Projects & Libraries	81

6.1.6.1 Rebuild Project Source Files	81
6.1.6.2 Rebuild Library Files	82
6.1.7 Overload Directory	83
6.2 Add a Library to a Project	90
6.3 Change The IP Targeted By A Project	91
6.4 Change CompCode Settings for EDFS	91
7 PC Tools and Utilities	95
7.1 Multi-threaded TTY Serial Terminal (MTTTY)	95
7.1.1 MTTY FAQ	96
7.2 Wget	96
7.3 NBUdate	97
7.4 Smart Traps	97
7.4.1 Trap Information	98
7.4.2 Register Information	99
7.4.3 RTOS Information	99
7.4.4 Task Information	99
7.5 Task Scan	99
7.5.1 TaskScan FAQ	100
7.6 WinAddr2Line	101
7.6.1 Using WinAddr2Line	102
7.7 IPSetup	102
7.8 AutoUpdate	102
7.9 Virtual Comm Port	103
7.10 CompHtml	103
7.11 CompCode	103
7.12 flashpack	103
8 Platform References	105
8.1 MODM7AE70 Platform Reference	105
8.1.1 Introduction	105
8.1.2 Processor Information	105
8.1.2.1 Definitions	105
8.1.3 Datasheet	105
8.1.4 Development Board Schematic	106
8.1.5 Memory Operation	106
8.1.6 Memory Map	106
8.1.7 External Bus Interface	106
8.2 MOD54415, MOD54417 Platform Reference	107
8.2.1 Introduction	107
8.2.2 Processor Information	107
8.2.2.1 Definitions	107
8.2.3 Datasheet	107

8.2.4 Development Board Schematic	107
8.2.5 Memory Operation	107
8.2.6 Memory Map	108
8.3 NANO54415 Platform Reference	108
8.3.1 Introduction	108
8.3.2 Processor Information	108
8.3.2.1 Definitions	109
8.3.3 Datasheet	109
8.3.4 Development Board Schematic	109
8.3.5 Memory Operation	109
8.3.6 Processor Runtime Memory Map	109
8.3.7 Application SPI Flash Memory	110
8.4 SB800EX Platform Reference	110
8.4.1 Introduction	110
8.4.2 Processor Information	110
8.4.2.1 Definitions	110
8.4.3 Datasheet	110
8.4.4 Memory Operation	110
8.4.5 Processor Runtime Memory Map	111
8.4.6 Application SPI Flash Memory	111
8.5 SBE70LC Platform Reference	112
8.5.1 Introduction	112
8.5.2 Processor Information	112
8.5.2.1 Definitions	112
8.5.3 Datasheet	112
8.5.4 Development Board Schematic	112
8.5.5 Memory Operation	112
8.5.6 Memory Map	112
8.6 SOMRT1061 Platform Reference	113
8.6.1 Introduction	113
8.6.2 Processor Information	113
8.6.2.1 Definitions	113
8.6.3 Datasheet and Pins	113
8.6.4 Development Board Schematic	113
8.6.5 SOMRT1061 Platform General Information	114
8.6.5.1 The 8MB of Flash uses a Flash File System and is used for all storage purposes:	114
8.6.5.2 External Memory Bus	114
8.6.6 Boot Sequence	114
8.6.7 UART Signals and Port Number Mapping	115
8.7 Recovery: MODM7AE70, SBE70LC	115
8.7.1 Introduction	115
8.7.2 Repeating Traps or Resets	115

8.7.2.1 Step 1: Abort to the Configuration Server	115
8.7.2.2 Step 2: Download a New Application	115
8.7.3 Unresponsive Device or No Serial Port Access	116
8.7.3.1 Recovery Jumper Locations	116
8.8 Recovery: MOD5441x, NANO54415, SB800EX	118
8.8.1 Step 1: Abort to the Alternate Boot Monitor	118
8.8.2 Recovery Jumper Locations	119
8.8.2.1 NANO54415	119
8.8.2.2 MOD5441x	119
8.8.2.3 SB800EX	120
8.8.3 Step 2: Download a New Application	121
8.8.3.1 Network	121
8.8.3.2 Serial Port	121
8.9 Recovery: SOMRT1061	122
8.9.1 Introduction	122
8.9.2 Boot Components and Features Overview	122
8.9.3 Boot Sequence Overview	122
8.9.3.1 Normal Boot	122
8.9.3.2 Incorrect Network Settings	122
8.9.3.3 Application Starts, But Traps After Application Initialization	123
8.9.3.4 Application Starts, But Traps Before Application Initialization	123
8.9.4 Procedure to Abort to the Configuration Server	123
8.9.5 Uploading a New Application	123
8.9.5.1 Web Page Upload	123
8.9.5.2 NBUpdate	123
8.9.5.3 Serial Console Interface	123
8.9.6 Procedures to Abort to the Alternate Boot Monitor	124
8.9.6.1 No Valid Application	124
8.9.6.2 Configuration Server Access Operational	124
8.9.6.3 Application Traps Before UserMain() Starts	124
8.9.7 Hardware Jumper Recovery	124
8.9.7.1 Recovery Jumper Operation	124
8.9.7.2 Procedure	125
8.9.7.3 Recovery Jumper Location	125
8.10 ARM Cache Management	126
8.10.1 Details	126
8.10.2 Instructions	126
8.10.2.1 Turning cache on/off	126
8.10.2.2 Declaring static objects non cachable	126
8.10.2.3 Cleaning Cache	126
8.10.2.4 Invalidating Cache	126

9 Production & Deployment	127
9.1 Production Releases and Customer Deployment	127
9.2 Finding a Device on a Network	127
9.3 Application Programming	127
9.3.1 Configuration Web Page	128
9.3.2 nbupdate Utility	128
9.3.3 wget Utility	128
9.3.3.1 Program an Application	128
9.3.3.2 Read The Configuration	129
9.3.3.3 Program New Configuration Settings	129
9.4 NetBurner SSL Certificate Upload Commands	129
9.4.1 Overview	129
9.4.2 Requirements	129
9.4.3 Linux/Unix Commands	129
9.4.3.1 Using curl (Recommended)	129
9.4.3.2 Using wget (Simple approach)	129
9.4.4 Windows PowerShell Commands	130
9.4.4.1 Method 1: Using Invoke-RestMethod (Recommended)	130
9.4.4.2 Method 2: Using Invoke-WebRequest	130
9.4.4.3 Method 3: Manual multipart construction	130
9.4.5 Windows Command Prompt	130
9.4.5.1 Method 1: Using curl (Windows 10/11)	130
9.4.5.2 Method 2: PowerShell one-liner from Command Prompt	131
9.4.5.3 Method 3: Batch file approach	131
9.4.6 Usage Notes	131
9.4.7 Recommended Approaches	131
9.4.8 Troubleshooting	131
9.4.9 Security Considerations	132
9.5 Customer Configuration	132
10 Programmers Guide	133
10.1 Overview	133
10.2 Table of Contents	133
10.3 About This Guide	133
10.3.1 Guide Navigation	133
10.3.1.1 Quick Start Path	133
10.3.1.2 By Use Case	134
10.3.2 Document Descriptions	135
10.3.2.1 Introduction to NetBurner Programming	135
10.3.2.2 Configuration Server	135
10.3.2.3 Custom Branding	135
10.3.2.4 IPv4-IPv6 Dual Stack	136

10.3.2.5	EFFS File System	136
10.3.2.6	File Descriptors	137
10.3.2.7	HTML Processing	137
10.3.2.8	Interrupt Handling	137
10.3.2.9	JSON Lexer	138
10.3.2.10	NetBurner RTOS	138
10.3.2.11	Network Protocols	139
10.3.2.12	SSL-TLS Security	139
10.3.2.13	SSH Protocol	139
10.3.2.14	Web Server	140
10.3.3	Development Workflow	140
10.3.3.1	Typical Application Development Process	140
10.3.4	Common Implementation Patterns	141
10.3.4.1	Pattern 1: Web-Based Device Control	141
10.3.4.2	Pattern 2: Network Data Logger	141
10.3.4.3	Pattern 3: Secure Remote Monitoring	142
10.3.5	Cross-Reference Guide	142
10.3.5.1	By Task	142
10.3.6	Quick Start Checklist	143
10.3.6.1	Essential Reading for New Developers	143
10.3.6.2	Advanced Topics Preparation	143
10.3.7	Document Conventions	144
10.3.7.1	Code Examples	144
10.3.7.2	Platform References	144
10.3.8	Getting Help	144
10.3.8.1	Documentation Resources	144
10.3.9	Version Information	144
10.3.10	Next Steps	145
10.4	Introduction	145
10.4.1	Intro to NetBurner Programming	145
10.4.2	Overview	145
10.4.3	Prerequisites	145
10.4.4	Learning Approach	145
10.4.5	Source Code Location	145
10.4.6	Creating Your First Application	146
10.4.6.1	Using the NBEclipse Application Wizard	146
10.4.6.2	Template Application Structure	146
10.4.6.3	Application Execution Flow	146
10.4.7	Key System Functions	147
10.4.7.1	init()	147
10.4.7.2	WaitForActiveNetwork()	147
10.4.7.3	StartHttp()	147

10.4.8 Output Functions	147
10.4.8.1 printf() vs printf()	147
10.4.9 Application Design Principles	148
10.4.9.1 The Main Loop	148
10.4.9.2 Timing Considerations	148
10.4.9.3 Resource Management	148
10.4.10 Next Steps	148
10.4.11 Quick Reference	148
10.4.11.1 Critical Constants	148
10.4.11.2 Core Functions	148
10.4.12 Architecture Overview	149
10.5 Config Server Programming Guide	149
10.5.1 Configuration Server Programming Guide	149
10.5.2 Introduction	149
10.5.2.1 Configuration System Overview	149
10.5.2.2 Access Methods	149
10.5.2.3 Key Features	149
10.5.3 Configuration Structure	150
10.5.3.1 Configuration Tree Hierarchy	150
10.5.3.2 Root Level: Config	150
10.5.4 Config.AppData	150
10.5.4.1 Purpose and Usage	150
10.5.4.2 Available Configuration Objects	151
10.5.4.3 Example: Application Settings	151
10.5.4.4 Configuration Object Hierarchy	151
10.5.5 Config.Sys - System Settings	151
10.5.5.1 System Configuration Tree	151
10.5.6 Config.Sys.Boot - Boot Settings	151
10.5.6.1 Boot Configuration Parameters	151
10.5.6.2 Boot Process Flow	152
10.5.6.3 Serial Config Server Modes	152
10.5.6.4 Security Configuration	153
10.5.7 Config.Sys.NetIf - Network Interfaces	153
10.5.7.1 Network Interface Tree	153
10.5.7.2 Common Interface Parameters	153
10.5.7.3 Discovery Configuration	153
10.5.8 Config.Sys.NetIf.Ethernet0.IPv4	154
10.5.8.1 IPv4 Settings Overview	154
10.5.8.2 IPv4 Parameters	154
10.5.8.3 IPv4 Mode Selection	155
10.5.9 Config.Sys.NetIf.Ethernet0.IPv6	155
10.5.9.1 IPv6 Settings Overview	155

10.5.9.2 IPv6 Parameters	156
10.5.9.3 IPv6 Mode Selection	156
10.5.10 Configuration Web Interface	156
10.5.10.1 Accessing the Web Interface	156
10.5.10.2 Web Interface Features	157
10.5.10.3 Application Update Feature	157
10.5.11 Serial Configuration Interface	157
10.5.11.1 Accessing Serial Config	158
10.5.11.2 Serial Config Prompt	158
10.5.11.3 Navigation Model	158
10.5.11.4 Serial Config Commands	158
10.5.11.5 Command Examples	158
10.5.11.6 Uploading Application via Serial	159
10.5.12 Creating a Custom Web Interface	160
10.5.12.1 Customization Workflow	160
10.5.12.2 Steps to Customize	160
10.5.12.3 Custom Interface Example	160
10.5.13 Configuration API Examples	161
10.5.13.1 Example Projects Overview	161
10.5.13.2 Available Examples	161
10.5.13.3 Example Selection Guide	162
10.5.14 Best Practices	163
10.5.14.1 Configuration Design Principles	163
10.5.15 Troubleshooting	164
10.5.15.1 Common Issues and Solutions	164
10.5.15.2 Debug Checklist	165
10.5.16 Advanced Topics	166
10.5.16.1 Custom Configuration Objects	166
10.5.16.2 Configuration Callbacks	166
10.5.16.3 Configuration Persistence	167
10.5.17 API Quick Reference	167
10.5.17.1 Core Configuration Functions	167
10.5.17.2 Configuration Object Types	167
10.5.17.3 Accessing Values	167
10.5.18 Summary	168
10.5.18.1 Key Features Recap	168
10.5.18.2 Access Methods Summary	168
10.5.18.3 Configuration Hierarchy	168
10.5.18.4 Best Practices Checklist	168
10.5.18.5 Getting Started	169
10.6 Custom Branding	169
10.6.1 Custom Branding	169

10.6.2 Overview	169
10.6.3 Branding Capabilities Options	169
10.6.4 Customization Options	170
10.6.4.1 1. Configuration Server Logo Replacement	170
10.6.4.2 2. Custom Configuration Interface	170
10.6.4.3 3. Physical Device Labeling	171
10.6.4.4 4. Discovery Utility Customization	171
10.6.4.5 5. Custom Cloud Server Infrastructure	172
10.6.5 Implementation Strategy	173
10.6.5.1 Planning Your Customization	173
10.6.5.2 Recommended Path	174
10.6.6 Best Practices	174
10.6.6.1 Visual Consistency	174
10.6.6.2 Configuration Access Patterns	174
10.6.6.3 Testing Checklist	175
10.6.7 Resources and Support	175
10.6.7.1 Example Code Locations	175
10.6.7.2 Getting Started	175
10.6.7.3 Support Channels	175
10.6.8 Security Considerations	176
10.7 IPv4/IPv6 Dual Stack Guide	176
10.7.1 Overview	176
10.7.1.1 Key Changes in 2.8.0+	176
10.7.2 IPv6 Address Assignment	176
10.7.2.1 Address Assignment Flow	176
10.7.2.2 Link-Local Addresses	177
10.7.2.3 Router Auto-Configuration (SLAAC)	177
10.7.2.4 DHCPv6 Configuration	177
10.7.2.5 Static IP Addresses	178
10.7.2.6 Complete Address Assignment Hierarchy	178
10.7.3 IPADDR Class Migration	178
10.7.3.1 Storage Considerations	178
10.7.3.2 Null Value Checking	179
10.7.3.3 Null IP in Function Parameters	179
10.7.4 IPADDR Member Functions	179
10.7.4.1 Function Types	179
10.7.4.2 Setting IP Address Values	179
10.7.4.3 Reading and Checking IP Address Values	179
10.7.4.4 Output Functions	180
10.7.5 Domain Name Service (DNS)	180
10.7.5.1 DNS Function Variants	180
10.7.5.2 Universal DNS Code Pattern	181

10.7.5.3 DNS Record Types	181
10.7.5.4 IPv6 DNS Priority Control	181
10.7.5.5 DNS Resolution Strategy Matrix	182
10.7.6 Platform-Specific Considerations	182
10.7.6.1 macOS and BSD Systems	182
10.7.7 Migration Checklist	182
10.7.7.1 Code Audit	182
10.7.7.2 Storage Migration	183
10.7.7.3 Testing Strategy	183
10.7.8 Best Practices	183
10.7.8.1 Portable Code Patterns	183
10.7.8.2 Storage Design	183
10.7.8.3 DNS Resolution	184
10.7.9 Summary	184
10.7.9.1 Key Takeaways	184
10.7.9.2 Migration Path	184
10.8 EDFS Programming Guide	184
10.8.1 NetBurner EDFS Programming Guide	184
10.8.2 Overview	184
10.8.2.1 Topics Covered	185
10.8.3 System Architecture	185
10.8.4 Supported Platforms	185
10.8.4.1 Platform Capabilities Matrix	185
10.8.4.2 Interface Types	185
10.8.5 Example Programs	186
10.8.5.1 EDFS-FAT Examples	186
10.8.5.2 EDFS-FAT Security Examples	186
10.8.5.3 EDFS-STD Examples	186
10.8.6 Flash Card Hardware Interface	187
10.8.6.1 SD/MMC Hardware Connection Diagram	187
10.8.6.2 Signal Connection Table	187
10.8.6.3 Hardware Specifications	187
10.8.6.4 GPIO Pin Configuration	188
10.8.6.5 Interrupt-Driven SPI (ColdFire Platforms Only)	188
10.8.7 EDFS-FAT File System Operation	188
10.8.7.1 Typical Operation Flow	188
10.8.7.2 Common EDFS-FAT Function Calls	189
10.8.7.3 File Time and Date Stamps	189
10.8.7.4 File System Utilities	189
10.8.8 EDFS-FAT Project Configuration	190
10.8.8.1 NBEclipse Project Setup	190
10.8.8.2 Makefile Configuration	190

10.8.9	FFFS-STD File System (On-Chip Flash)	190
10.8.9.1	FFFS-FAT vs EDFS-STD Comparison	190
10.8.9.2	Flash Memory Layout	190
10.8.9.3	Memory Allocation Considerations	190
10.8.10	FFFS-STD Project Configuration	191
10.8.10.1	NBEclipse Configuration	191
10.8.11	FFFS-STD Makefile Configuration	192
10.8.11.1	Step 1: Add EDFS-STD Library	192
10.8.11.2	Step 2: Platform-Specific Configuration	192
10.8.12	Flash Memory Address Configuration	192
10.8.12.1	Platform Memory Map	192
10.8.12.2	Memory Region Diagram	192
10.8.12.3	Configuration File Reference	192
10.8.13	Debug Port Configuration	193
10.8.13.1	Overview	193
10.8.13.2	Default Configuration	193
10.8.13.3	Supported Functions	193
10.8.13.4	Custom Configuration	193
10.8.14	API Reference Documentation	193
10.8.14.1	FFFS-FAT API Reference	193
10.8.14.2	FFFS-STD API Reference	193
10.8.14.3	Key Function Mapping	194
10.8.15	Best Practices	194
10.8.15.1	General Guidelines	194
10.8.15.2	FFFS-FAT Specific	194
10.8.15.3	FFFS-STD Specific	194
10.8.15.4	Performance Optimization	194
10.8.16	Troubleshooting	195
10.8.16.1	Common EDFS-FAT Issues	195
10.8.16.2	Common EDFS-STD Issues	195
10.8.17	Additional Resources	196
10.8.17.1	Documentation References	196
10.8.17.2	Support Files	196
10.8.17.3	Example Locations	196
10.8.18	Summary	196
10.9	File Descriptors	196
10.9.1	File Descriptors	196
10.9.2	Overview	196
10.9.3	File Descriptor Architecture	197
10.9.4	File Descriptor Allocation	197
10.9.4.1	Allocation Map	197
10.9.4.2	Detailed Breakdown	197

10.9.4.3 Expansion Pool Usage	197
10.9.5 Creating Custom I/O Drivers	198
10.9.5.1 Driver Architecture	198
10.9.5.2 Core Header File	198
10.9.5.3 State Management Functions	198
10.9.6 IoExpandStruct Definition	198
10.9.6.1 Structure Members	198
10.9.6.2 Data Flow	199
10.9.7 File Descriptor Management API	199
10.9.7.1 Core Functions	199
10.9.7.2 Function Details	199
10.9.8 TCP Socket Notifications	200
10.9.8.1 Callback System	200
10.9.8.2 Callback Definition	200
10.9.8.3 Callback Parameters	200
10.9.8.4 Implementation Example	201
10.9.9 Using select() with File Descriptors	201
10.9.9.1 Multiplexing Multiple I/O Sources	201
10.9.9.2 select() Usage Pattern	201
10.9.9.3 Mixing Device Types	202
10.9.10 Complete Implementation Example	202
10.9.10.1 Custom Ring Buffer Device	202
10.9.10.2 Usage of Custom Device	203
10.9.11 Best Practices	204
10.9.11.1 Resource Management	204
10.9.11.2 Guidelines	204
10.9.12 Troubleshooting	205
10.9.12.1 Common Issues	205
10.9.12.2 Debugging Tips	205
10.9.13 Summary	205
10.9.13.1 Key Concepts	205
10.9.13.2 Quick Reference	206
10.10 HTML Processing	206
10.10.1 HTML Processing	206
10.10.2 Introduction	206
10.10.2.1 Quick Start	206
10.10.2.2 Web Server Initialization	206
10.10.2.3 Content Sources	206
10.10.3 Dynamic Content Overview	206
10.10.3.1 Dynamic Content Methods	207
10.10.4 HTML Tags	207
10.10.4.1 Tag Overview	207

10.10.4.2 Tag Syntax	207
10.10.5 The CPPCALL Tag	208
10.10.5.1 Function Flow	208
10.10.5.2 Function Signature	208
10.10.5.3 Example: Display Client Information	208
10.10.6 The VARIABLE Tag	208
10.10.6.1 Use Case 1: Display Variables	208
10.10.6.2 Supported Variable Types	209
10.10.6.3 Use Case 2: Parameterized Function Calls	209
10.10.7 The INCLUDE Tag and htmlvar.h	209
10.10.7.1 Two Methods for Include Resolution	209
10.10.7.2 Method 1: INCLUDE Tag in HTML	209
10.10.7.3 Method 2: htmlvar.h Header File	210
10.10.7.4 Include Resolution Flow	210
10.10.8 Extending VARIABLE Tag Support	210
10.10.8.1 Custom Type Example	210
10.10.8.2 System Example: MAC Address Display	210
10.10.9 Configuration System Tags	211
10.10.9.1 Configuration Tag Types	211
10.10.9.2 Configuration Tree Structure	211
10.10.9.3 Example: Display Configuration Values	211
10.10.9.4 Configuration Access Flow	211
10.10.10 HTTP GET Request Handler	211
10.10.10.1 When to Use GET Handlers	211
10.10.10.2 GET Handler Flow	212
10.10.10.3 Creating a GET Handler	212
10.10.10.4 CallbackFunctionPageHandler Parameters	212
10.10.10.5 URL Encoding Example	213
10.10.11 HTTP Form POST Handler	213
10.10.11.1 Creating a POST Handler	213
10.10.11.2 Step 1: Create HTML Form	213
10.10.11.3 Step 2: Create Callback Function	213
10.10.11.4 Step 3: Register Handler	214
10.10.11.5 POST Event Flow	214
10.10.11.6 POST Events	215
10.10.11.7 Multiple Form Handling	215
10.10.12 Complete Examples	215
10.10.12.1 Example 1: System Status Page with Mixed Tags	215
10.10.12.2 Example 2: Interactive Control Panel	215
10.10.13 Best Practices	216
10.10.13.1 Tag Usage Guidelines	216
10.10.13.2 Performance Considerations	217

10.10.13.3 Security Guidelines	217
10.10.13.4 Code Organization	217
10.10.14 Troubleshooting	218
10.10.14.1 Common Issues and Solutions	218
10.10.14.2 Debug Checklist	218
10.10.15 Additional Resources	218
10.10.15.1 Related Documentation	218
10.10.15.2 Key Header Files	219
10.10.15.3 Quick Reference	219
10.10.16 Summary	219
10.11 Interrupt Handling	220
10.11.1 interrupt_handling Interrupt Handling in NetBurner Applications	220
10.11.2 interrupt_overview Overview	220
10.11.2.1 interrupt_sources Common Interrupt Sources	220
10.11.2.2 interrupt_platform_variations Platform Variations	220
10.11.3 core_interrupt_functions Core Interrupt Functions	221
10.11.3.1 interrupt_header_requirements Header Requirements	221
10.11.3.2 interrupt_function_overview Function Overview	221
10.11.3.3 interrupt_setpinirq SetPinIrq() - Configure Interrupt Pin	221
10.11.3.4 interrupt_enableirq EnableIrq() - Activate Interrupt	222
10.11.3.5 interrupt_disableirq DisableIrq() - Deactivate Interrupt	222
10.11.4 isr_restrictions ISR Restrictions	222
10.11.4.1 isr_critical_constraints Critical Constraints	222
10.11.4.2 isr_prohibited_rtos Prohibited RTOS Functions	222
10.11.4.3 isr_prohibited_io Prohibited I/O Functions	223
10.11.4.4 isr_prohibited_memory Prohibited Memory Functions	223
10.11.4.5 isr_recommended_pattern Recommended ISR Pattern	223
10.11.5 platform_specific_implementations Platform-Specific Implementations	223
10.11.6 same70_platforms SAME70 Platforms (MODM7AE70 and SBE70LC)	224
10.11.6.1 same70_architecture Architecture Overview	224
10.11.6.2 same70_port_priority Port Priority Configuration	224
10.11.6.3 same70_port_mapping Port Priority Mapping	225
10.11.6.4 same70_workflow Configuration Workflow	225
10.11.6.5 same70_example Complete SAME70 Example	225
10.11.7 mcf5441x_platforms MCF5441x Platforms (MOD54415, MOD54417, NANO54415 and SB800EX)	225
10.11.7.1 mcf5441x_architecture Architecture Overview	225
10.11.7.2 mcf5441x_interrupt_macro INTERRUPT() Macro	226
10.11.7.3 mcf5441x_setintc SetIntc() Function	227
10.11.7.4 mcf5441x_example Complete MCF5441x Example: 1-Wire Interface	228
10.11.7.5 mcf5441x_workflow MCF5441x Configuration Workflow	229
10.11.7.6 mcf5441x_best_practices Best Practices for MCF5441x	229

10.11.8 somrt1061_platform SOMRT1061 Platform	230
10.11.8.1 somrt1061_overview Overview	230
10.11.8.2 somrt1061_configuration Configuration Approach	230
10.11.8.3 somrt1061_notes Platform-Specific Notes	230
10.11.8.4 somrt1061_example SOMRT1061 Example	230
10.11.9 interrupt_summary Summary and Best Practices	231
10.11.9.1 interrupt_cross_platform Cross-Platform Compatibility	231
10.11.9.2 interrupt_platform_selection Platform Selection Guide	231
10.11.9.3 interrupt_general_best_practices General Best Practices	231
10.11.9.4 interrupt_debugging Debugging Interrupts	232
10.11.9.5 interrupt_error_prevention Error Prevention	232
10.11.10 interrupt_resources Additional Resources	232
10.12 JSON Lexer	232
10.12.1 JSON Lexer Programming Guide	232
10.12.2 Overview	232
10.12.2.1 Core Components	232
10.12.2.2 Version Notes	233
10.12.3 Loading JSON Data	233
10.12.3.1 Method 1: From Text Blob	233
10.12.3.2 Method 2: From Web Server	233
10.12.3.3 Method 3: From File Descriptor	233
10.12.4 Data Flow Diagram	233
10.12.5 Accessing JSON Data	234
10.12.5.1 Example JSON Structure	234
10.12.5.2 Basic Access Patterns	234
10.12.6 Access Operator Summary	234
10.12.6.1 Navigation Example	234
10.12.7 Type Conversion Operators	235
10.12.8 Validation Functions	235
10.12.8.1 IsValid() Method	235
10.12.8.2 Type Checking Functions	235
10.12.8.3 Validation Flow	235
10.12.9 Example References	235
10.12.9.1 Earthquake Example Application	235
10.12.9.2 Source Code	236
10.12.9.3 JSON Structure Navigation	236
10.12.9.4 Data Extraction Flow	237
10.12.9.5 Example Output	237
10.12.10 USGS JSON Response Structure	237
10.12.10.1 Response Schema	237
10.12.10.2 Metadata Section	237
10.12.10.3 Features Array	237

10.12.10.4 Parsing Strategy	238
10.12.11 Complete JSON Sample	238
10.12.11.1 Sample Structure	238
10.12.12 Best Practices	239
10.12.12.1 Memory Management	239
10.12.12.2 Error Handling	239
10.12.12.3 Performance Considerations	239
10.12.12.4 Type Safety	239
10.12.13 Advanced Usage	239
10.12.13.1 Nested Array Navigation	239
10.12.13.2 Dynamic Key Access	239
10.12.13.3 Array Iteration Patterns	239
10.12.14 Summary	240
10.13 NetBurner RTOS	240
10.13.1 Introduction	240
10.13.2 Priority Levels	240
10.13.3 What is a Preemptive RTOS?	241
10.13.4 Core Principle	241
10.13.5 Task Execution Flow	241
10.13.6 Blocking Scenarios	241
10.13.7 Function Categories	242
10.13.7.1 RTOS Blocking Functions	242
10.13.7.2 I/O Functions That Block	242
10.13.7.3 Network Functions That Block	242
10.13.7.4 Functions That Unblock Tasks	242
10.13.8 System Task Priorities	242
10.13.9 Task Creation	243
10.13.10 Entry Point: UserMain()	243
10.13.11 Task Creation Methods	243
10.13.11.1 Method 1: OSTaskCreatewName() - Full Control	243
10.13.11.2 Method 2: OSSimpleTaskCreatewName() - Simplified	243
10.13.12 Priority Selection Helper	243
10.13.13 Complete Example	244
10.13.14 Protecting Shared Data	245
10.13.15 Mechanism Selection Guide	245
10.13.16 Protection Mechanisms (Ordered by System Impact)	245
10.13.17 Detailed Mechanism Comparison	245
10.13.18 Important Considerations	246
10.13.18.1 Queue vs. FIFO	246
10.13.19 Semaphores	246
10.13.20 Concept	246
10.13.21 Operation Flow	246

10.13.22 Usage Pattern	246
10.13.23 Timeout Specification	247
10.13.24 Resource Protection Example	247
10.13.25 Message Queues	247
10.13.26 Concept	247
10.13.27 Queue Structure	247
10.13.28 Message Flow	247
10.13.29 Usage Example	248
10.13.30 FIFOs	248
10.13.31 Concept	248
10.13.32 Structure Requirements	248
10.13.33 FIFO Architecture	249
10.13.34 Memory Management Strategies	249
10.13.34.1 Strategy 1: Static Pool (Recommended)	249
10.13.34.2 Strategy 2: Dynamic Allocation (Not Recommended)	249
10.13.35 Queue vs. FIFO Decision	249
10.13.36 FIFO Functions	249
10.13.37 Critical Sections	250
10.13.38 OSCrit - Counted Critical Section	250
10.13.39 Operation Flow	250
10.13.40 Counting Behavior	250
10.13.41 Usage Examples	250
10.13.41.1 Manual Enter/Exit	250
10.13.41.2 C++ Scoped Object (Recommended)	250
10.13.42 OSCrit vs. OSLock	251
10.13.43 OSLock Usage Pattern	251
10.13.44 OS Flags	251
10.13.45 Concept	251
10.13.46 Flag Bitmap Structure	251
10.13.47 Flag Operations	251
10.13.48 Pending Modes	252
10.13.49 Flag Functions Summary	252
10.13.50 Usage Example	252
10.13.51 System Configuration	253
10.13.52 Predef.h and Predef-overload.h	253
10.13.53 Configuration Architecture	253
10.13.54 Why Use Predef-overload.h?	253
10.13.55 Setup Methods	254
10.13.55.1 NBEclipse Setup	254
10.13.55.2 Command Line Tools Setup	254
10.13.56 Predef-overload.h Best Practices	254
10.13.57 Configuration Workflow	254

10.13.58 Common Configuration Overrides	254
10.13.59 Verification After Changes	255
10.13.60 Summary	255
10.13.61 Key Takeaways	255
10.13.62 Quick Reference	256
10.13.63 Further Reading	256
10.14 Network Protocols TCP and UDP	256
10.14.1 TCP vs UDP Comparison	256
10.14.1.1 Protocol Characteristics	256
10.14.1.2 Protocol Comparison Diagram	257
10.14.1.3 Real-World Analogies	257
10.14.1.4 Decision Factors	257
10.14.1.5 Common Protocol Usage	258
10.14.1.6 Performance Considerations	258
10.14.1.7 Key Takeaways	258
10.14.1.8 Additional Resources	259
10.14.1.9 Quick Reference	259
10.14.2 TCP Protocol	260
10.14.2.1 TCP Protocol	260
10.14.2.2 TCP Stream Behavior	260
10.14.2.3 TCP Connection Requirements	260
10.14.2.4 Well-Known Port Numbers	261
10.14.2.5 TCP Server Implementation	261
10.14.2.6 TCP Client Implementation	268
10.14.2.7 TCP Error Handling	271
10.14.3 UDP Protocol	277
10.14.3.1 UDP Protocol	277
10.14.3.2 UDP Implementation Comparison	277
10.14.3.3 UDP Class Interface	278
10.14.3.4 UDP Sockets Interface	280
10.15 SSL/TLS and Certificates	289
10.15.1 Introduction	289
10.15.2 Understanding SSL/TLS Fundamentals	289
10.15.3 The Security Problem	290
10.15.4 How SSL/TLS Solves These Problems	290
10.15.5 The Trust Chain: How Authentication Works	290
10.15.5.1 Real-World Analogy: Trusting a Doctor	290
10.15.5.2 SSL/TLS Certificate Chain	290
10.15.6 Public Key Cryptography Simplified	291
10.15.7 Certificate Types at a Glance	291
10.15.8 Quick Start Guide	291
10.15.9 For SSL Servers (Your NetBurner Device)	291

10.15.9.1 Option 1: Automatic (Recommended for Production)	291
10.15.10 For SSL Clients (Connecting to Servers)	292
10.15.11 Certificate Types and Use Cases	292
10.15.12 Decision Matrix	292
10.15.13 1. Self-Signed Certificates	292
10.15.14 2. Private Certificate Authority (CA)	293
10.15.15 3. Public CA Certificates	294
10.15.16 4. ACME (Automated Certificate Management)	295
10.15.17 Use Case Decision Table	296
10.15.18 Implementation Methods	296
10.15.19 Method 1: Automatic Onboard Certificate Generation	296
10.15.19.1 How It Works	297
10.15.19.2 Basic Implementation	297
10.15.19.3 Advanced: Auto-Regeneration	297
10.15.19.4 Customizing Certificate Generation	297
10.15.20 Method 2: ACME Automated Certificates	298
10.15.20.1 Complete ACME Example	298
10.15.20.2 ACME Troubleshooting Checklist	298
10.15.21 Method 3: Manual Certificate Installation	298
10.15.21.1 Step-by-Step Process	298
10.15.21.2 Installing Certificate Chain	299
10.15.22 Method 4: SSL Client Implementation	300
10.15.22.1 Basic SSL Client	300
10.15.22.2 Advanced: Certificate Verification	300
10.15.22.3 Loading CAs from Storage	301
10.15.23 Troubleshooting	301
10.15.24 Common Browser Warning Messages	301
10.15.24.1 1. "Your Connection is Not Private"	301
10.15.24.2 2. "Certificate Name Mismatch"	301
10.15.24.3 3. "Certificate Expired"	302
10.15.24.4 4. "Certificate Not Yet Valid"	302
10.15.25 SSL Handshake Failures	302
10.15.25.1 Debugging Connection Issues	302
10.15.25.2 Common Error Codes	303
10.15.26 Certificate Verification Issues	303
10.15.26.1 Verification Flowchart	303
10.15.26.2 Bypass Verification (Development Only!)	304
10.15.27 Memory and Resource Issues	304
10.15.27.1 Memory Requirements	304
10.15.27.2 Checking Memory	304
10.15.28 Performance Optimization	304
10.15.28.1 Cipher Suite Selection	304

10.15.28.2 Connection Reuse	305
10.15.29 Best Practices	305
10.15.30 Security Principles	305
10.15.30.1 1. Private Key Protection	305
10.15.30.2 2. Certificate Validation	306
10.15.30.3 3. Protocol and Cipher Configuration	306
10.15.31 Production Checklist	306
10.15.31.1 Pre-Deployment	306
10.15.31.2 Post-Deployment Monitoring	306
10.15.32 Development Workflow	307
10.15.32.1 Recommended Development Cycle	307
10.15.32.2 Configuration Management	307
10.15.33 Common Pitfalls to Avoid	308
10.15.33.1 1. Time Synchronization	308
10.15.33.2 2. Certificate Chain Issues	308
10.15.33.3 3. Resource Leaks	308
10.15.33.4 4. Hardcoded Credentials	308
10.15.34 Additional Resources	309

10.16.10.5 Migration Checklist	326
10.16.11 Summary	327
10.16.11.1 Key Takeaways	327
10.17 Web Server	328
10.17.1 NetBurner Web Server Guide	328
10.17.2 Overview	328
10.17.2.1 Key Features	328
10.17.3 Basic Web Server Setup	328
10.17.3.1 Project Structure	328
10.17.3.2 Initial index.html	329
10.17.3.3 Static Content	329

10.17.3.4 Adding Resources	329
10.17.3.5 Editing HTML Files in NBEclipse	330
10.17.4 Dynamic Web Content	330
10.17.4.1 CPPCALL Tag - C++ Callback Functions	330
10.17.4.2 VARIABLE Tag - Displaying Variables	331
10.17.4.3 INCLUDE Tag - Linking Variables	333
10.17.5 Advanced Techniques	334
10.17.5.1 Function Callbacks with Parameters	334
10.17.5.2 Custom Data Types	337
10.17.6 Best Practices	339
10.17.6.1 Project Organization	339
10.17.6.2 Code Organization	339
10.17.6.3 Performance Optimization	339
10.17.6.4 Security Considerations	340
10.17.6.5 Error Handling	340
10.17.6.6 HTML Best Practices	341
10.17.6.7 Testing Strategy	341
10.17.6.8 Debugging Tips	342
10.17.6.9 Common Pitfalls to Avoid	342
10.17.7 Quick Reference	342
10.17.7.1 Tag Summary	342
10.17.7.2 Function Signatures	343
10.17.7.3 Common Patterns	343
10.17.8 Summary	343
10.17.8.1 Key Takeaways	343
10.18 Web Sockets	344
10.18.1 WebSocket Protocol Implementation for Real-Time Bidirectional Communication	344
10.18.2 Overview	344
10.18.3 Typical WebSocket Workflow	344
10.18.4 WebSocket Frame Types	345
10.18.5 Buffering and Flow Control	345
10.18.6 Connection Health Monitoring	345
10.18.7 Graceful Connection Closure	345
10.18.8 Thread Safety	346
10.18.9 Resource Limits	346
10.18.10 Error Handling	346
10.18.11 Security Considerations	347
10.18.12 Performance Optimization	347
10.18.13 Debugging WebSocket Issues	347
10.18.14 Configuration and Return Code Definitions	352
10.18.14.1 Number of buffer segments allocated for each WebSocket connection.	352
10.18.14.2 Maximum number of simultaneous WebSocket connections supported.	353

10.18.14.3 Minimum buffer space threshold before triggering buffer management actions.	354
10.18.14.4 Accumulation delay for batching small writes before transmission.	354
10.18.14.5 Timeout value for flush operations (in system ticks).	355
10.18.14.6 WebSocket frame FIN bit mask indicating final fragment.	355
10.18.14.7 WebSocket continuation frame opcode.	356
10.18.14.8 WebSocket text frame opcode for UTF-8 encoded text data.	357
10.18.14.9 WebSocket binary frame opcode for raw binary data.	357
10.18.14.10 WebSocket close frame opcode for connection termination.	359
10.18.14.11 WebSocket ping frame opcode for connection liveness check.	360
10.18.14.12 WebSocket pong frame opcode for ping response.	361
10.18.14.13 WebSocket socket option to enable text frame mode.	361
11 System Diagnostics	365
11.1 Introduction	365
11.2 Server Page with Diagnostics Enabled	365
11.3 Configuration Web Page Display	366
11.4 Adding Your Own Diagnostic Information	369
12 Example Applications	371
12.1 Example Applications Main Page	371
12.2 AES	373
12.3 Application Image Security	374
12.3.1 Examples for application image security, including:	374
12.3.1.1 Examples	374
12.3.2 Application Image Checksum	374
12.3.2.1 Application Image Checksum	374
12.3.3 Board Lock	376
12.3.3.1 Lock an Application to a Specific Device (board)	376
12.3.3.2 Check Lock	376
12.3.3.3 Key Blob	378
12.3.3.4 Sign Board	380
12.3.4 Signed Application	382
12.3.4.1 Signed Application Example	382
12.4 Clear Configuration Flash	385
12.4.1 NetBurner Clear Configuration Flash	385
12.4.1.1 Overview	385
12.4.1.2 Purpose	385
12.4.1.3 Important Limitations	385
12.4.1.4 Reboot Requirement	385
12.4.1.5 How It Works	386
12.4.1.6 Usage Instructions	386
12.4.1.7 Technical Details	386
12.4.1.8 Safety Considerations	386

12.4.1.9 Development Notes	386
12.5 Configuration	387
12.5.1 Application Data	387
12.5.1.1 Basic Config Variables	387
12.5.1.2 Config Class	391
12.5.1.3 Custom Range Limit Config Variables	393
12.5.1.4 Nesting Config Objects	396
12.5.1.5 FS_BulkStore	399
12.5.2 Config and System Params	402
12.5.2.1 Disable System Features	402
12.5.2.2 Modify Boot	405
12.5.2.3 Modify Ethernet Interface	407
12.5.2.4 Show Configuration	414
12.5.3 Config Web Interfaces	416
12.5.3.1 Basic Web Config	417
12.5.3.2 Basic Web Config with SSL/TLS	417
12.5.3.3 Config Tags	418
12.5.3.4 Custom Web Config	422
12.5.3.5 Custom Web System Config	425
12.5.3.6 HTML Only Configuration	427
12.5.4 Detached Config Object	430
12.5.4.1 Detached Config Example	430
12.5.5 Change Notify	432
12.5.5.1 Config Notify Application	432
12.5.6 Config Class Receive Notification	434
12.5.6.1 Config Notify Class Example	434
12.6 DNS Device Name	437
12.6.1 DNS Device Name Application	437
12.6.1.1 Overview	437
12.6.1.2 Features	437
12.6.1.3 How It Works	437
12.6.1.4 Device Naming	437
12.6.1.5 Network Integration	438
12.6.1.6 Sample Output	438
12.6.1.7 Key Functions	438
12.6.1.8 Important Notes	439
12.6.1.9 Building and Deployment	439
12.6.1.10 Use Cases	439
12.6.1.11 Additional Information on DNS Naming	439
12.7 DHCP	440
12.7.1 DHCP Client - Change IP Address	440
12.7.1.1 DHCP Client - Change IP Address Application	440

12.7.2 DHCP Client - Test DHCP	443
12.7.2.1 DHCP Test Application	443
12.7.3 DHCP Server (DHCPD)	446
12.7.3.1 DHCP Server Application (DHCPD)	446
12.7.4 DHCP Client - Change IP Address Via Webpage	448
12.7.4.1 DHCP Client - Change IP Address Via Webpage	448
12.8 DNS Client	451
12.8.1 DNS Client Application	451
12.8.1.1 Overview	451
12.8.1.2 Features	452
12.8.1.3 Application Functions	452
12.8.1.4 Prerequisites	452
12.8.1.5 Usage Instructions	453
12.8.1.6 Error Handling	453
12.8.1.7 Network Interface Diagnostics	453
12.8.1.8 Compilation Options	453
12.8.1.9 Technical Details	453
12.8.1.10 Troubleshooting	454
12.8.1.11 Application Flow	454
12.9 Embedded Flash File System (EFFS)	454
12.9.1 FAT File System (EFFS-FAT)	455
12.9.1.1 Application Update	455
12.9.1.2 Basic	455
12.9.1.3 FTP	458
12.9.1.4 HTTP	461
12.9.1.5 HTML Variables	465
12.9.1.6 Multiple Tasks	466
12.9.1.7 Performance Tests	466
12.9.1.8 RAM Drive	467
12.9.2 Standard File System (EFFS-STD)	467
12.9.2.1 EFFS-STD HTTP	467
12.10 Ethernet	470
12.10.1 Manual Configuration	471
12.10.1.1 Ethernet Manual Configuration Test Application	471
12.11 Exception Try/Catch	473
12.11.1 Exception Try/Catch Application	473
12.11.1.1 Overview	473
12.11.1.2 Application Details	473
12.11.1.3 Key Features	473
12.11.1.4 Output	474
12.11.1.5 Compilation Requirements	474
12.11.1.6 Dependencies	474

12.11.1.7 Usage	474
12.11.1.8 Development Notes	474
12.12 External IRQ	474
12.12.1 External IRQ Example	474
12.12.1.1 Overview	474
12.12.1.2 Supported Platforms	475
12.12.1.3 Hardware Setup	475
12.12.1.4 How It Works	476
12.12.1.5 User Interface	476
12.12.1.6 Configuration Options	476
12.12.1.7 Building and Running	477
12.12.1.8 Key Functions Used	477
12.12.1.9 Important Notes	477
12.12.1.10 Troubleshooting	477
12.13 Extra FD Circular Buffer	477
12.13.1 NetBurner Extra File Descriptor Circular Buffer	477
12.13.1.1 Overview	477
12.13.1.2 Key Features	478
12.13.1.3 Architecture	478
12.13.1.4 Configuration Options	478
12.13.1.5 Usage Example	479
12.13.1.6 Test Functions	479
12.13.1.7 File Descriptor Status Management	479
12.13.1.8 Thread Safety	479
12.13.1.9 Debug Features	479
12.13.1.10 Configuration	479
12.13.1.11 Integration Notes	480
12.13.1.12 Files	480
12.14 FileDescriptor	480
12.15 Extra FD Circular Buffer	480
12.15.1 NetBurner Extra File Descriptor Circular Buffer	480
12.15.1.1 Overview	480
12.15.1.2 Key Features	480
12.15.1.3 Architecture	481
12.15.1.4 Configuration Options	481
12.15.1.5 Usage Example	481
12.15.1.6 Test Functions	482
12.15.1.7 File Descriptor Status Management	482
12.15.1.8 Thread Safety	482
12.15.1.9 Debug Features	482
12.15.1.10 Configuration	482
12.15.1.11 Integration Notes	482

12.15.1.12 Files	483
12.15.2 FDBuffer	483
12.15.2.1 NetBurner FDBuffer Example	483
12.15.3 fdprintf - printf to file descriptor	485
12.15.3.1 fdprintf Example Application	485
12.15.4 FdToNBString	487
12.15.4.1 File Descriptor to NBString Example	487
12.16 FTP	489
12.16.1 FTP Client	490
12.16.1.1 FTP Client Example	490
12.16.2 Display HTML Files (FTPD)	493
12.16.2.1 FTPD HTML Expose Application	493
12.16.3 Simple FTP Server (FTPD)	496
12.16.3.1 Simple FTP Server (FTPD) - Trivial Implementation	496
12.17 GDB Debugger	499
12.17.1 NetBurner GDB Demo Application	499
12.17.1.1 Overview	499
12.17.1.2 Application Description	499
12.17.1.3 Features	499
12.17.1.4 Hardware Requirements	499
12.17.1.5 Software Requirements	500
12.17.1.6 Application Behavior	500
12.17.1.7 Console Output	500
12.17.1.8 Usage	500
12.17.1.9 Development Notes	500
12.17.1.10 File Structure	500
12.17.1.11 Building and Deployment	500
12.18 General Purpose I/O	501
12.18.1 GPIO Blink	501
12.18.1.1 GPIO Blink Application	501
12.18.2 General Purpose I/O Service	503
12.18.2.1 GPIO Service Application	503
12.19 I2C	506
12.19.1 PAC193X	506
12.19.1.1 PAC193x Energy Monitor	506
12.19.2 PicKit Serial I2C Demo Board	509
12.19.2.1 PicKit I2C Serial Demo Board Application	509
12.19.3 RV3032 I2C Real-Time Clock	512
12.19.3.1 There are multiple I2C peripherals on each NetBurner platform as indicated in the tables below. The first	512
12.19.4 Wire Address Scan	513
12.19.4.1 I2C Wire Scan Application	513

12.19.5 SparkFun Qwiic Alphanumeric Display	515
12.19.5.1 SparkFun Qwiic Alphanumeric Display Application	515
12.19.6 SparkFun Qwiic Joystick	517
12.19.6.1 SparkFun Qwiic Alphanumeric Display Application	517
12.19.7 SparkFun Qwiic KeyPad	521
12.19.7.1 SparkFun Qwiic KeyPad Application	521
12.19.8 SparkFun Qwiic OLED Display	523
12.19.8.1 SparkFun Qwiic OLED Display - Analog Clock	523
12.20 IP Address Object (IPADDR)	526
12.20.1 FunWithIPADDR - NetBurner IP Address Object Example	526
12.20.1.1 Overview	526
12.20.1.2 What is IPADDR?	526
12.20.1.3 Application Functionality	526
12.20.1.4 Code Examples	527
12.20.1.5 Important Notes	527
12.20.1.6 Application Flow	527
12.20.1.7 Build Requirements	527
12.20.1.8 System Features Used	528
12.21 IPv6	528
12.21.1 DHCPv6	528
12.21.1.1 DHCPv6 Client Application	528
12.22 JSON	531
12.22.1 JSON Lexer	532
12.22.1.1 JSON Array	532
12.22.1.2 JSON Array with Objects	534
12.22.1.3 Parse Test	535
12.22.2 NetBurner Demo Server for JSON Client Examples	538
12.22.2.1 NetBurner Demo Server	538
12.22.3 Get JSON Object From Server	541
12.22.3.1 Get JSON From Server Application	541
12.22.4 Get Non-JSON Object From Server	544
12.22.4.1 Get Non-JSON From Server	544
12.22.5 JSON Linter Test	546
12.22.5.1 JSON Linter Test Application	546
12.22.6 Post JSON to Server and Display Result	550
12.22.6.1 JSON POST Application	550
12.22.7 Post JSON to Server	552
12.22.7.1 NetBurner JSON POST Application	552
12.22.8 Get Application Image and Load it From a Web Server	555
12.22.8.1 LoadCodeFromServer	555
12.22.9 Simple JSON HTML Example	557
12.22.9.1 NetBurner Simple JSON HTML Example	557

12.22.10 Simple JSON Post Receiver Example	560
12.22.10.1 Simple JSON Post Receiver Example	560
12.23 malloc	563
12.23.1 Malloc Example Application	563
12.23.1.1 Overview	563
12.23.1.2 Purpose	563
12.23.1.3 Key Features	563
12.23.1.4 Application Flow	564
12.23.1.5 Memory Fragmentation Example	564
12.23.1.6 Key Observations	564
12.23.1.7 Code Structure	565
12.23.1.8 Usage Notes	565
12.23.1.9 Educational Value	565
12.23.1.10 Platform Requirements	565
12.24 MQTT Examples	565
12.24.1 MQTT Config Object Example	566
12.24.1.1 MQTT Config Object Application	566
12.24.2 MQTT Custom Object Example	569
12.24.2.1 MQTT Custom Object Example	569
12.24.3 MQTT Object I/O Example	571
12.24.3.1 MQTT Object I/O Application	571
12.24.4 MQTT Simple Object Pub/Sub Example	574
12.24.4.1 MQTT Simple Object Pub/Sub Application	574
12.24.5 MQTT SubHandler GPIO Example	576
12.24.6 Advanced MQTT Periodic Example	576
12.24.6.1 MQTT Periodic Publish Example	576
12.24.7 Advanced MQTT Pub/Sub Example	578
12.24.7.1 MQTT Advanced Pub/Sub Example	578
12.24.8 Advanced MQTT Echo Example	581
12.24.8.1 MQTT Echo Application	581
12.25 Multicast	584
12.25.1 Multicast Example Application	584
12.25.1.1 Overview	584
12.25.1.2 Features	584
12.25.1.3 Application Components	584
12.25.1.4 How It Works	585
12.25.1.5 Usage Instructions	585
12.25.1.6 Technical Details	585
12.25.1.7 Important Notes	586
12.25.1.8 Troubleshooting	586
12.25.1.9 Dependencies	586
12.26 Multihome	586

12.26.1 Multihome Application	586
12.26.1.1 Overview	586
12.26.1.2 Features	587
12.26.1.3 Prerequisites	587
12.26.1.4 Application Behavior	587
12.26.1.5 Code Structure	588
12.26.1.6 Usage	588
12.26.1.7 Network Configuration	588
12.26.1.8 Error Handling	588
12.26.1.9 System Requirements	588
12.27 NB Approve Shutdown	589
12.27.1 NBApproveShutdown Application	589
12.27.1.1 Overview	589
12.27.1.2 Purpose	589
12.27.1.3 System Requirements	589
12.27.1.4 Application Features	589
12.27.1.5 How It Works	590
12.27.1.6 Usage Instructions	590
12.27.1.7 Code Structure	590
12.27.1.8 Implementation Notes	591
12.27.1.9 Example Output	591
12.27.1.10 Development Guidelines	591
12.28 NSString Class	591
12.29 Network Time Server (NTP) Client	592
12.29.1 NTP Client Example Application	592
12.29.1.1 Overview	592
12.29.1.2 Features	592
12.29.1.3 Prerequisites	592
12.29.1.4 Time Zone Features	592
12.29.1.5 Application Flow	593
12.29.1.6 Time Display Format	593
12.29.1.7 Output Examples	593
12.29.1.8 Key Functions	593
12.29.1.9 Technical Details	594
12.29.1.10 Usage Instructions	594
12.29.1.11 Status Information	594
12.29.1.12 Troubleshooting	594
12.29.1.13 Development Notes	594
12.30 NTP & Real-Time Clock	595
12.30.1 NTP-System-RTC Demo Application	595
12.30.1.1 Overview	595
12.30.1.2 Hardware Requirements	595

12.30.1.3 Features	595
12.30.1.4 Application Menu	596
12.30.1.5 Technical Details	596
12.30.1.6 Network Requirements	596
12.30.1.7 Time Zone Configuration	597
12.30.1.8 Build and Deployment	597
12.30.1.9 Usage Scenarios	597
12.30.1.10 Limitations	597
12.30.1.11 Applications	597
12.31 Overload Directory & System Files	598
12.31.1 NetBurner Overload Directory Example	598
12.31.1.1 Overview	598
12.31.1.2 Application Description	598
12.31.1.3 Key Features	598
12.31.1.4 Directory Structure	599
12.31.1.5 Files in This Example	599
12.31.1.6 Setup Instructions for NBEclipse Projects	599
12.31.1.7 Building and Maintenance	600
12.31.1.8 Application Behavior	600
12.31.1.9 Important Notes	600
12.32 Ping	600
12.32.1 Ping Example	600
12.32.1.1 Overview	600
12.32.1.2 Features	600
12.32.1.3 How It Works	601
12.32.1.4 Key Functions	601
12.32.1.5 Technical Details	601
12.32.1.6 Usage Example	602
12.32.1.7 Error Handling	602
12.32.1.8 System Requirements	602
12.32.1.9 Development Notes	602
12.32.1.10 Purpose	602
12.33 PLATFORM SPECIFIC	603
12.33.1 MOD5441x, NANO54415, SB800EX	603
12.33.1.1 1-Wire	604
12.33.1.2 Analog to Digital	607
12.33.1.3 CAN to Serial	617
12.33.1.4 Digital to Analog (DAC)	624
12.33.1.5 DSPI to Serial	629
12.33.1.6 Load Application From Flash Card	635
12.33.1.7 SDHC Flash Card	640
12.33.1.8 EMI Emissions Reduction	648

12.33.1.9 External NMI IRQ 7	650
12.33.1.10 RTC - External	655
12.33.1.11 I2C	655
12.33.1.12 RTC - On Chip	669
12.33.1.13 Periodic Interrupt Timer	669
12.33.1.14 Pulse Generator and Counter	669
12.33.1.15 PWM	670
12.33.1.16 Core Watchdog Timer (CWT)	670
12.33.1.17 WAV File Audio Player	670
12.33.1.18 MOD5441x Only	671
12.33.1.19 NANO54415 Only	703
12.33.1.20 SB800EX Only	703
12.33.2 MODM7AE70, SBE70LC	704
12.33.2.1 GPIO Command Server	704
12.33.2.2 I2C	704
12.33.2.3 Serial Callback Function	711
12.33.2.4 Timers	711
12.33.2.5 Watchdog Timer	720
12.33.2.6 MODM7AE70	720
12.33.2.7 SBE70LC	725
12.33.3 SOMRT1061	726
12.33.3.1 CAN	726
12.33.3.2 Clock Module Example	729
12.33.3.3 EDFS Multiple Partitions	734
12.33.3.4 External Real Time Clock	734
12.33.3.5 Periodic Interrupt Timer (PIT)	734
12.33.3.6 Open All UARTs	735
12.33.3.7 SOMRT1061 Pin IRQ Example	736
12.33.3.8 PWM	738
12.33.3.9 SEMC Simple	739
12.33.3.10 SEMC to SRAM, FPGA, LCD	742
12.33.3.11 Analog to Digital (ADC)	773
12.33.3.12 SPI PickIt Demo Board	773
12.33.3.13 On-Chip Temperature Sensor (TEMPMON)	776
12.33.3.14 Dev Board Temperature Sensor and ADC	776
12.34 PPP	776
12.34.1 PPP Server Application	776
12.34.1.1 Overview	776
12.34.1.2 Features	776
12.34.1.3 Hardware Requirements	776
12.34.1.4 Connection Types	777
12.34.1.5 Configuration	777

12.34.1.6 Authentication	777
12.34.1.7 Interactive Commands	777
12.34.1.8 PPP State Machine	778
12.34.1.9 Error Handling	778
12.34.1.10 IP Address Utilities	778
12.34.1.11 Web Interface	779
12.34.1.12 File Structure	779
12.34.1.13 Build Requirements	779
12.34.1.14 Usage Instructions	779
12.34.1.15 Testing PPP Connections	780
12.34.1.16 Development Notes	780
12.34.1.17 Troubleshooting	780
12.35 Profiler	781
12.35.1 Profiler Example Application	781
12.35.1.1 Overview	781
12.35.1.2 Features	781
12.35.1.3 Profiling Functionality	781
12.35.1.4 Menu Commands	781
12.35.1.5 Setup and Configuration	781
12.35.1.6 Application Flow	782
12.35.1.7 Network Features	782
12.35.1.8 Development Notes	782
12.35.1.9 Output Examples	782
12.35.1.10 Compilation Requirements	782
12.35.1.11 Usage	783
12.36 RTOS	783
12.36.1 MaxTasks	783
12.36.1.1 MaxTasks RTOS Example	783
12.36.2 OSCrit - Critical Section	786
12.36.2.1 OSCrit - Critical Section Example	786
12.36.3 OSFifo - FIFO	788
12.36.3.1 RTOS FIFO Example Application	788
12.36.4 OSFlags	790
12.36.4.1 OSFlags RTOS Example	790
12.36.5 OSMailbox	793
12.36.5.1 RTOS Mailbox Example	793
12.36.6 OSQueue	794
12.36.7 OSSemaphore	795
12.36.8 OSTaskCreate	795
12.36.9 Round Robin Task Sheduler	795
12.37 Serial	795
12.37.1 Dual TCP To Serial	795

12.37.1.1 DualTCP2Serial Example	795
12.37.2 Serial To Ethernet	798
12.37.2.1 Serial to Ethernet Bridge Application	798
12.37.3 Serial HTTP Get Request	801
12.37.4 Serial Receive Callback	801
12.37.4.1 Serial Receive Callback Example	801
12.37.5 Serial to Serial	803
12.37.5.1 Serial to Serial Example	803
12.37.6 Serial Application Update	805
12.37.6.1 Overview	805
12.37.6.2 Methods	805
12.37.7 TCP to Serial	805
12.37.7.1 TCP to Serial Bridge	805
12.37.8 Serial Webserver	808
12.37.8.1 Serial Webserver	808
12.38 SHA1 Digest	809
12.39 Show Network Interfaces	810
12.39.1 Show Network Interfaces Example	810
12.39.1.1 Overview	810
12.39.1.2 Application Architecture	810
12.39.1.3 Key Features	810
12.39.1.4 Implementation Details	811
12.39.1.5 Web Interface Structure	814
12.39.1.6 Network Information Display	814
12.39.1.7 Usage Instructions	815
12.39.1.8 Advanced Features	816
12.39.1.9 Troubleshooting	817
12.39.1.10 Performance Considerations	818
12.39.1.11 Build Configuration	819
12.39.1.12 Learning Objectives	819
12.39.1.13 Related Examples	820
12.40 SOCKS5 Client	820
12.41 SPI	820
12.41.1 DSPI Multiplex	820
12.41.2 Serial to SPI	820
12.41.3 SPI PicKit Demo Board	820
12.42 SSH	821
12.42.1 SSH Server	821
12.42.1.1 SSH Minimal Server Example	821
12.42.2 SSH Server with User Key	824
12.42.2.1 SSH Server with User Key Example	824
12.42.3 SSH Client	827

12.42.3.1 SSH Minimal Client Example	827
12.42.4 SSH Server with User Authorization	830
12.42.4.1 SSH Server with User Authorization	830
12.42.5 SecureSerToEthFactoryApp	834
12.42.5.1 NetBurner Secure Serial-to-Ethernet Factory Application	834
12.43 SSL/TLS	838
12.43.1 Easy SSL/TLS Onboard Certificates	839
12.43.1.1 ACME Certificate Generation (Easy Servlet)	839
12.43.1.2 On-board Cert Generation - Simple	842
12.43.1.3 On-board Cert Generation - Advanced	845
12.43.1.4 On-board Cert Generation - Compiled Certificate Authority	849
12.43.1.5 ACME Certificate Generation (Easy Servlet)	852
12.43.2 FTPS Server	855
12.43.2.1 FTPS Server Example	855
12.43.3 HTML File Post	859
12.43.3.1 SSL/TLS File Post with Multipart Form	859
12.43.4 HTML Form Post	862
12.43.4.1 NetBurner SSL HTML Form Post Example	862
12.43.5 HTTPS Dual Cert	865
12.43.5.1 NetBurner HTTPS Dual Certificate Server	865
12.43.6 HTTPS Upload Cert	869
12.43.6.1 NetBurner SSL Certificate Upload Application	869
12.43.7 HTTPS Web Server Demo	875
12.43.7.1 SSL/TLS Web Server Demo	875
12.43.8 HTTPS GET Request	878
12.43.8.1 SSL HTTPS GET Example	878
12.43.9 SSL/TLS Client	880
12.43.9.1 SSL/TLS Client Example	880
12.43.10 SSL/TLS Client Certificate	882
12.43.10.1 SSL Client Certificate Example	882
12.43.11 SSL/TLS Client Verify Peer - Basic	885
12.43.11.1 SSL/TLS Client Verify Peer - Basic	885
12.43.12 SSL/TLS Client Verify Peer - EDFS-STD	888
12.43.12.1 SSL/TLS Client Verify Peer - EDFS-STD	888
12.43.13 SSL/TLS Receive Mail (POP3)	892
12.43.13.1 SSL POP3 Mail Example	892
12.43.14 SSL/TLS Send Mail	894
12.43.14.1 SSL/TLS Send Mail Example	894
12.43.15 SSL/TLS Send Mail w/ Attachment	898
12.43.15.1 SSL/TLS SendMail with Attachment	898
12.43.16 SSL/TLS Send Mail w/ EDFS Atchment	901
12.43.16.1 SSL Send Mail with EDFS Attachment	901

12.43.17 SSL/TLS Server	904
12.43.17.1 NetBurner SSL/TLS Server Example	904
12.43.18 HTTPS Configuration Mirror	907
12.43.18.1 SSL Configuration Mirror	907
12.44 Stack Protection	910
12.44.1 Stack Protection Example	910
12.44.1.1 Overview	911
12.44.1.2 Features	911
12.44.1.3 Architecture Support	911
12.44.1.4 Prerequisites	911
12.44.1.5 Application Structure	912
12.44.1.6 Usage	912
12.44.1.7 Expected Output	912
12.44.1.8 Safety Features	912
12.44.1.9 Development Notes	912
12.44.1.10 Important Warnings	913
12.44.1.11 Build Instructions	913
12.44.1.12 Troubleshooting	913
12.45 Syslog	913
12.45.1 NetBurner Syslog Demo	913
12.45.1.1 Overview	913
12.45.1.2 Features	913
12.45.1.3 How It Works	913
12.45.1.4 Setup Instructions	914
12.45.1.5 Code Structure	914
12.45.1.6 Expected Output	915
12.45.1.7 Network Requirements	915
12.45.1.8 Production Considerations	915
12.45.1.9 Troubleshooting	915
12.46 System Diagnostics	915
12.46.1 System Diagnostics Example	915
12.46.1.1 Overview	915
12.46.1.2 Features	915
12.46.1.3 Application Components	916
12.46.1.4 Code Structure	916
12.46.1.5 Usage Instructions	916
12.46.1.6 Adding Custom Variables	916
12.46.1.7 Important Notes	917
12.46.1.8 Output Example	917
12.47 TCP	917
12.47.1 TCP Client	918
12.47.1.1 TCP Client Example Application	918

12.47.2 TCP No Block Connect Test	920
12.47.2.1 TCP No Block Connect Test	920
12.47.3 TCP Keepalive Simple	923
12.47.3.1 TCP Keep-Alive Server	923
12.47.4 TCP Keepalive Multiple	925
12.47.4.1 TCP Multi-Socket Server with Keep-Alive	925
12.47.5 Multiple TCP Interface Test	929
12.47.5.1 TCP Multiple Interface Test	929
12.47.6 TCP Multi-Socket Server	931
12.47.6.1 TCP Multi-Socket Server	931
12.47.7 TCP Resource Information	933
12.47.7.1 TCP Resource Information	933
12.47.8 TCP Server	935
12.47.8.1 Simple TCP Server Example	935
12.47.9 TCP Server Using Via	937
12.47.9.1 TCP Server Via Example	937
12.47.10 TCP Speed Test	940
12.47.10.1 TCP Speed Test Application	940
12.47.11 TCP Stress Test	943
12.47.11.1 TCP Stress Test Application	943
12.48 Telnet Command	945
12.48.1 NetBurner Telnet Command Example	945
12.48.1.1 Overview	945
12.48.1.2 Features	945
12.48.1.3 Configuration	946
12.48.1.4 Callback Functions	946
12.48.1.5 Connection Types and Prompts	947
12.48.1.6 Disconnect Handling	947
12.48.1.7 SSH Support (Optional)	947
12.48.1.8 Usage	947
12.48.1.9 Build Requirements	948
12.48.1.10 System Integration	948
12.48.1.11 Customization	948
12.48.1.12 Security Notes	948
12.48.1.13 Related Documentation	948
12.49 TFTP Client	948
12.49.1 TFTP Client Application	948
12.49.1.1 Overview	948
12.49.1.2 Features	949
12.49.1.3 Requirements	949
12.49.1.4 Application Flow	949
12.49.1.5 Code Structure	949

12.49.1.6 Return Codes	950
12.49.1.7 Usage Instructions	950
12.49.1.8 Test Files	951
12.49.1.9 Network Requirements	951
12.49.1.10 Troubleshooting	951
12.49.1.11 Customization Options	951
12.49.1.12 Development Notes	951
12.50 TFTP Server	952
12.50.1 TFTP Server Application	952
12.50.1.1 Overview	952
12.50.1.2 Application Description	952
12.50.1.3 Key Components	952
12.50.1.4 Functionality	953
12.50.1.5 System Requirements	953
12.50.1.6 Usage	953
12.50.1.7 Development Notes	954
12.50.1.8 File Structure	954
12.50.1.9 Output Information	954
12.50.1.10 Protocol Support	954
12.51 Time Functions	954
12.51.1 Time Functions Application	954
12.51.1.1 Overview	954
12.51.1.2 Features	954
12.51.1.3 File Structure	955
12.51.1.4 Key Time Functions Demonstrated	956
12.51.1.5 Time Zone Support	956
12.51.1.6 Usage Requirements	956
12.51.1.7 Time Precision and Accuracy	957
12.51.1.8 Error Handling	957
12.51.1.9 Example Output	957
12.51.1.10 Development Notes	957
12.51.1.11 Integration	958
12.52 Timers	958
12.52.1 Timer	958
12.52.1.1 HiRes Delay Timer Example	958
12.52.2 Interval Timer	961
12.52.2.1 Interval Timer Example Application	961
12.52.3 Stopwatch Timer	963
12.52.3.1 Stopwatch Example Application	963
12.53 UDP	965
12.53.1 UDP to Serial	965
12.53.1.1 NetBurner UDP to Serial Bridge	965

12.53.2 UDP Notify Callback Function	969
12.53.2.1 UDP Notify Example	969
12.53.3 UDP C++ Packet Class	971
12.53.4 UDP Echo	971
12.53.4.1 UDP C++ Packet Class Example	971
12.53.5 UDP Send/Receive	973
12.53.5.1 UDP Send/Receive Example	973
12.53.6 UDP Sockets	976
12.53.6.1 UDP Sockets Example Application	976
12.53.7 UDP Sockets Via	978
12.53.7.1 UDP Sockets Via Example	978
12.54 VLAN	981
12.54.1 VLAN Example Application	981
12.54.1.1 Overview	981
12.54.1.2 Features	981
12.54.1.3 VLAN Configuration	981
12.54.1.4 Prerequisites	981
12.54.1.5 Serial Console Commands	981
12.54.1.6 Network Interface Information	982
12.54.1.7 Web Interface	983
12.54.1.8 File Structure	983
12.54.1.9 Key Functions	983
12.54.1.10 Building and Deployment	983
12.54.1.11 Network Setup Requirements	983
12.54.1.12 Troubleshooting	984
12.54.1.13 Platform Compatibility	984
12.54.1.14 IPv6 Support	984
12.55 Web Server	984
12.55.1 Ajax Graph	985
12.55.1.1 NetBurner AJAX Graph Application	985
12.55.2 Bootstrap Hello World	987
12.55.2.1 NetBurner Bootstrap HelloWorld Example	987
12.55.3 HTML File Post	990
12.55.3.1 File Post with Multipart Form	990
12.55.4 HTML File Post Task Handoff	992
12.55.4.1 File Post Task Handoff Example	992
12.55.5 Flash Form	995
12.55.5.1 FlashForm Example Application	995
12.55.6 GIF Canvas	997
12.55.6.1 GIF Canvas Example	997
12.55.7 HTML Application File Post	1000
12.55.7.1 NetBurner Application Update Server	1000

12.55.8 HTML Cookie	1002
12.55.8.1 NetBurner HTML Cookie Example	1002
12.55.9 HTML Form Post	1005
12.55.9.1 HtmlFormPost Example	1005
12.55.10 HTML Form Post 2.X Compatible	1014
12.55.10.1 NetBurner HTML Form POST Example	1014
12.55.11 HTML Password	1017
12.55.11.1 Methods to Set an Access Group	1017
12.55.11.2 ACCESSGROUP HTML Tags	1018
12.55.12 HtmlPostDateTime	1018
12.55.12.1 HTML Date Time Post Application	1018
12.55.13 HTML Server GET Request	1021
12.55.13.1 HtmlServerGetRequest Example	1021
12.55.14 HTMLVariables	1030
12.55.14.1 HtmlVariables Example	1030
12.55.15 Ping From Web	1038
12.55.15.1 NetBurner Ping From Web Example	1038
12.55.16 Raw Form Post 2pX	1041
12.55.16.1 Raw Post Callback 2pX	1041
12.55.17 Remote Web Console for Serial/stdout	1043
12.55.17.1 NetBurner Remote Web Console Example	1043
12.55.18 Serial Webserver	1046
12.55.18.1 Serial Webserver	1046
12.55.19 Simple HTML	1048
12.55.19.1 NetBurner Simple HTML Example	1048
12.55.20 TicTacToe	1050
12.55.20.1 NetBurner TicTacToe Web Application	1050
12.56 Web Client	1053
12.56.1 Earthquake	1053
12.56.1.1 Earthquake Monitor Application	1053
12.56.2 Find My IP	1055
12.56.2.1 FindMyIP Application	1055
12.56.3 Find My IP Task	1056
12.56.3.1 Find My IP Application	1056
12.56.4 WebClient Http Request Methods	1058
12.56.4.1 HTTP Methods Test Application	1058
12.56.5 Message Passer	1062
12.56.5.1 MessagePasser	1062
12.56.6 MessagePasserTask JSON	1064
12.56.6.1 MessagePasserTask Application	1064
12.57 Web Sockets	1067
12.57.1 Web Socket Connect	1067

12.57.1.1 WebSocket Connect Application	1067
12.57.2 Web Socket Console	1069
12.57.2.1 WebSocket Console	1069
12.57.3 Web Socket DIP Switch	1072
12.57.3.1 Real-Time DIP Switch States via WebSocket	1072
12.57.4 Web Socket Echo	1075
12.57.4.1 WebSocket Echo Application	1075
12.57.5 HTTPS WebSocket Demo	1078
12.57.5.1 SSL/TLS WebSocket Demo	1078
12.58 WiFi Examples	1081
12.58.1 Wifi Config AP	1081
12.58.1.1 NetBurner WiFi Configuration Access Point	1081
12.58.2 Configure AP with JSON	1084
12.58.2.1 WiFi Configuration Access Point with JSON	1084
12.58.3 Wifi Firmware Update	1087
12.58.3.1 WiFi Firmware Update Application	1087
12.58.4 Wifi Access Point	1088
12.58.4.1 WiFi Access Point Application	1088
12.58.5 Wifi Client	1091
12.58.5.1 WiFi Client Application	1091
12.58.6 Wifi Scan	1093
12.58.6.1 WiFi Scan Application	1093
13 Deprecated List	1097
14 NetBurner API	1099
14.1 AES - Advanced Encryption Standard	1099
14.1.1 Detailed Description	1099
14.1.2 Function Documentation	1099
14.1.2.1 aes_cbc_decrypt()	1099
14.1.2.2 aes_cbc_encrypt()	1101
14.1.2.3 aes_decrypt()	1101
14.1.2.4 aes_encrypt()	1101
14.1.2.5 aes_self_test()	1102
14.1.2.6 aes_set_key()	1102
14.2 ARP - Address Resolution Protocol	1102
14.2.1 Detailed Description	1103
14.2.2 How ARP Works	1104
14.2.3 ARP Cache Management	1104
14.2.4 Function Categories	1104
14.2.5 Example Usage	1104
14.2.5.1 Querying the ARP Cache	1104
14.2.5.2 Displaying ARP Cache Contents	1104

14.2.5.3 Sending Gratuitous ARP	1105
14.2.5.4 IP Address Conflict Detection	1105
14.2.5.5 Network Device Monitoring	1105
14.2.6 Best Practices	1106
14.2.7 Troubleshooting	1106
14.2.8 Important Notes	1106
14.2.9 Protocol Specifications	1106
14.2.10 Typedef Documentation	1107
14.2.10.1 PARP	1107
14.2.11 Function Documentation	1107
14.2.11.1 fShowArp()	1107
14.2.11.2 GetArpMacFromIp()	1108
14.2.11.3 GetProperInterface4()	1110
14.2.11.4 IsMyAddressUsedArpDetect()	1111
14.2.11.5 sendGratuitousArp()	1113
14.2.11.6 ShowArp()	1115
14.2.12 Variable Documentation	1117
14.2.12.1 hard_size	1117
14.2.12.2 hard_Type	1117
14.2.12.3 op_code	1117
14.2.12.4 prot_size	1117
14.2.12.5 prot_Type	1117
14.2.12.6 sender_ip	1117
14.2.12.7 sender_phy	1117
14.2.12.8 target_ip	1117
14.2.12.9 target_phy	1118
14.3 AT Commands	1118
14.3.1 Detailed Description	1119
14.3.2 Typedef Documentation	1119
14.3.2.1 ProcessATcommandFunc	1119
14.4 Base64	1119
14.4.1 Detailed Description	1119
14.4.2 Function Documentation	1120
14.4.2.1 Base64Decode()	1120
14.4.2.2 Base64Encode()	1120
14.4.2.3 Base64StreamEncode()	1121
14.4.2.4 Base64UrlDecode()	1121
14.4.2.5 Base64UrlEncode()	1122
14.4.2.6 Base64UrlStreamEncode()	1122
14.5 Buffers - System Buffer Pool	1123
14.5.1 Detailed Description	1123
14.5.2 Function Documentation	1123

14.5.2.1 FreeBuffer()	1123
14.5.2.2 FreeBufferList()	1124
14.5.2.3 GetBuffer()	1124
14.5.2.4 GetFastBuffer()	1124
14.5.2.5 GetFreeCount()	1125
14.5.2.6 IncUsageCount()	1125
14.5.2.7 InitBuffers()	1125
14.5.2.8 ShowBuffer()	1125
14.5.3 Buffer Ownership States	1126
14.5.3.1 Detailed Description	1126
14.5.4 Buffer State Flags	1126
14.5.4.1 Detailed Description	1126
14.6 CAN	1127
14.6.1 Detailed Description	1127
14.6.2 FlexCAN SOMRT1061	1127
14.6.2.1 Detailed Description	1132
14.6.2.2 Macro Definition Documentation	1132
14.6.2.3 Typedef Documentation	1137
14.6.2.4 Enumeration Type Documentation	1138
14.6.2.5 Function Documentation	1141
14.6.3 MOD5441x, NANO54415, SB800EX	1153
14.6.3.1 Detailed Description	1153
14.6.4 MODM7AE70	1153
14.6.4.1 Detailed Description	1154
14.6.4.2 Macro Definition Documentation	1155
14.6.4.3 MCAN Driver Internals	1155
14.7 Command Processor	1159
14.7.1 Detailed Description	1160
14.7.2 Function Documentation	1160
14.7.2.1 CmdAddCommandFd()	1160
14.7.2.2 CmdListenOnSshPort()	1161
14.7.2.3 CmdListenOnTcpPort()	1161
14.7.2.4 CmdListenQuietOnSshPort()	1161
14.7.2.5 CmdListenQuietOnTcpPort()	1162
14.7.2.6 CmdRemoveCommandFd()	1162
14.7.2.7 CmdStartCommandProcessor()	1163
14.7.2.8 CmdStopListeningOnSshPort()	1164
14.7.2.9 CmdStopListeningOnTcpPort()	1164
14.7.2.10 SendToAll()	1164
14.7.3 Variable Documentation	1165
14.7.3.1 CmdAuthenticateFunc	1165
14.7.3.2 CmdAuthenticateSshFunc	1165

14.7.3.3 CmdChar_func	1166
14.7.3.4 CmdCmd_func	1166
14.7.3.5 CmdConnect_func	1167
14.7.3.6 CmdDisconnect_func	1167
14.7.3.7 CmdIdleTimeout	1167
14.7.3.8 CmdPrompt_func	1167
14.7.4 Command Processor Disconnect Causes	1168
14.7.4.1 Detailed Description	1168
14.7.5 Command Processor Listen Channels	1168
14.7.5.1 Detailed Description	1168
14.7.5.2 Enumeration Type Documentation	1168
14.7.6 Command Processor Response Codes	1168
14.7.6.1 Detailed Description	1169
14.8 Configuration System	1169
14.8.1 Detailed Description	1169
14.8.2 Configuration Network Objects	1169
14.8.2.1 Detailed Description	1169
14.8.3 Configuration Server	1170
14.8.3.1 Detailed Description	1170
14.8.3.2 Function Documentation	1170
14.8.4 Configuration Time Objects	1171
14.8.4.1 Detailed Description	1171
14.8.5 Configuration Variables	1171
14.8.5.1 Detailed Description	1172
14.8.5.2 Function Documentation	1172
14.8.5.3 Configuration Variable Flags	1173
14.9 Constants (constants.h)	1173
14.9.1 Detailed Description	1175
14.9.2 Macro Definition Documentation	1175
14.9.2.1 TICKS_PER_SECOND	1175
14.10 DHCP	1175
14.10.1 Detailed Description	1175
14.10.2 DHCP Server	1176
14.10.2.1 Detailed Description	1176
14.10.2.2 Function Documentation	1176
14.10.3 DHCPv4 Client	1177
14.10.3.1 Detailed Description	1177
14.10.3.2 Function Documentation	1177
14.10.3.3 DHCP State	1178
14.10.4 DHCPv6 Client	1178
14.10.4.1 Detailed Description	1179
14.10.4.2 Function Documentation	1179

14.11 DNS - Domain Name System	1180
14.11.1 Detailed Description	1181
14.11.2 Function Documentation	1181
14.11.2.1 AnyDNSInterFaceActive()	1181
14.11.2.2 CheckDnsCache()	1182
14.11.2.3 fd_dns_part1()	1182
14.11.2.4 fd_dns_processresult()	1182
14.11.2.5 fd_outstanding_Responses()	1183
14.11.2.6 GetHostByName()	1183
14.11.2.7 GetHostByNameVialfNum()	1184
14.11.2.8 IsNameIPAddress()	1185
14.11.3 DNS Record Types	1185
14.11.3.1 Detailed Description	1185
14.11.4 DNS Return Codes	1185
14.11.4.1 Detailed Description	1186
14.12 Device Interrupts	1186
14.12.1 Detailed Description	1186
14.12.2 Enumeration Type Documentation	1186
14.12.2.1 _DeviceInterruptTrigger	1186
14.12.3 Function Documentation	1187
14.12.3.1 DeviceAckInterrupt()	1187
14.12.3.2 DeviceDisableInterrupt()	1187
14.12.3.3 DeviceEnableInterrupt()	1187
14.12.3.4 DeviceGetI2cSem()	1187

14.45.4.2 SSL_clrsockoption	1508
14.45.4.3 SSL_GetRawSocket	1508
14.45.4.4 SSL_getsockoption	1508
14.45.4.5 SSL_setsockoption	1509
14.45.5 ACME Certificate Generation	1509
14.45.5.1 Detailed Description	1509
14.45.6 Onboard Self-Signed Certificate Generation	1510
14.45.6.1 Detailed Description	1511
14.45.6.2 Enumeration Type Documentation	1511
14.45.6.3 Function Documentation	1512
14.45.7 SSL Error Codes	1513
14.45.7.1 Detailed Description	1514
14.46 Serial Interfaces	1514
14.46.1 Detailed Description	1515
14.46.2 Macro Definition Documentation	1515
14.46.2.1 SimpleOpenSerial	1515
14.46.3 Enumeration Type Documentation	1515
14.46.3.1 parity_mode	1515
14.46.4 Function Documentation	1515
14.46.4.1 GetUartErrorReg()	1515
14.46.4.2 OpenDefaultSerial()	1516
14.46.4.3 OpenSerial()	1516
14.46.4.4 SendBreak()	1517
14.46.4.5 Serial485HalfDupMode()	1517
14.46.4.6 SerialClose()	1517
14.46.4.7 SerialEnableHwRxFlow()	1518
14.46.4.8 SerialEnableHwTxFlow()	1518
14.46.4.9 SerialEnableRxFlow()	1518
14.46.4.10 SerialEnableTxFlow()	1518
14.46.4.11 SerialExpandRxBuffer()	1519
14.46.4.12 SerialSendComplete()	1519
14.46.4.13 serwriteaddress()	1519
14.46.4.14 SetRTS()	1519
14.46.5 Serial Port Error Codes	1519
14.46.5.1 Detailed Description	1519
14.47 Shutdown Notifications	1520
14.47.1 Detailed Description	1520
14.47.2 Function Documentation	1520
14.47.2.1 NBApproveShutdown()	1520

14.47.2.2 NBFaultNotify()	1522
14.47.3 ShutdownReasons	1522
14.47.3.1 Detailed Description	1523
14.48 Signed Application Update	1523
14.48.1 Detailed Description	1523
14.48.2 Function Documentation	1523
14.48.2.1 ProgramApplication()	1523
14.48.2.2 RegisterAppSigningPublicKey()	1524
14.48.2.3 UpdateFromStream()	1524
14.48.3 NBUpdate Function Return Values	1524
14.48.3.1 Detailed Description	1525
14.49 Stream Update	1525
14.49.1 Detailed Description	1525
14.49.2 Function Documentation	1525
14.49.2.1 ReadBinaryApplicationCodeFromStream()	1525
14.49.2.2 ReadS19ApplicationCodeFromStream()	1526
14.49.3 Stream Update Return Values	1526
14.49.3.1 Detailed Description	1526
14.50 Synchronous Audio Interface (SOMRT1061)	1526
14.50.1 Detailed Description	1527
14.50.2 Variable Documentation	1527
14.50.2.1 sai	1527
14.50.3 SAI Callback Types	1527
14.50.3.1 Detailed Description	1527
14.50.3.2 Typedef Documentation	1527
14.50.4 SAI Configuration Enumerations	1528
14.50.4.1 Detailed Description	1529
14.50.4.2 Enumeration Type Documentation	1529
14.50.5 SAI Configuration Structures	1532
14.50.5.1 Detailed Description	1532
14.50.6 SAI Driver Class	1532
14.50.6.1 Detailed Description	1532
14.50.7 SAI Driver Constants	1532
14.50.7.1 Detailed Description	1533
14.50.7.2 Macro Definition Documentation	1533
14.50.8 SAI Predefined Configurations	1533
14.50.8.1 Detailed Description	1534
14.50.8.2 Variable Documentation	1534
14.51 Syslog	1535
14.51.1 Detailed Description	1536
14.51.2 Function Documentation	1536
14.51.2.1 SysLog()	1536

14.51.2.2 SysLogVia()	1538

Chapter 1

NetBurner 3.5.6

1.1 Welcome to NetBurner Version 3!

Last updated at October 31 2025 06:49:49

This Developers Guide details the capabilities of your NetBurner Development Software and Tools. If you are viewing this document from your development tools installation, the latest version is available at www.netburner.com. There is also a pdf version of this document available at the [PDF Version](#) link above.

Note

Version 3 is used as a development platform on all ARM based devices, as well as MOD5441x, NANO54415 and SB800EX devices. If you have an earlier ColdFire based device please refer to the version 2 development tools.

1.2 Who Is This Guide For?

NetBurner devices come in two forms:

- Devices pre-programmed with factory applications that can be used without any custom programming on the device itself. Serial to Ethernet devices are a good example of this.
- If you wish to customize any device, we provide development tools that enable you to create custom applications.

This guide is intended for software developers to create custom applications to run on NetBurner devices. If you are using a device that does not require custom programming, please refer to that device's product page for documentation and any appropriate software utilities.

1.3 Recommended Starting Point for New Developers

Your NetBurner development system is pre-programmed with a factory application. If connected to a network with Internet access and a DHCP server, you can open a web browser, go to <http://discover.netburner.com>, and access your device immediately: both the application web page and configuration interface are linked from the Discover page.

If you are connected directly, such as a laptop with a direct Ethernet connection, or on a network without a DHCP server and Internet access, please see the procedure below:

- Configure the development kit device/hardware (if necessary) as described in the [Quick Start Guide](#).
- Connect both your development computer and your NetBurner device to a network with Internet access. Internet access is not required for development, but will make the initial configuration of the device easier.
- If using a development kit with a USB interface, connect it from the development board to your computer. It will provide both power and a console/debug serial port. To view status and debug information, run a serial terminal program such as the included MTTY, although any serial terminal application should work.
- Your NetBurner device will be running a pre-programmed factory application. Open a web browser and type "discover.netburner.com" to identify your device. Links on the web page are available to go directly to the device's web page and configuration page.

Note

If you do not have an Internet connection, you can use a utility such as localdiscover. Please refer to the Device Discovery and Configuration section of this guide.

- Refer to the [NBEclipse](#) Getting Started Guide section of this document to learn how to create, build and download applications. If you prefer to use command line tools, they are available as well.
- Select one of the examples from the "nburn\examples" folder. Create a project and download per the NBEclipse Guide.
- Refer to the Programmers Guide and NetBurner API documents for additional information.

Note

NBEclipse provides auto-complete functionality by pressing cntl-space. This makes accessing the API functions much easier.

1.4 Documentation Overview

1.4.1 The NetBurner Application Programming Interface (API)

Description of the functions and capabilities in the NetBurner Library API. These functions include:

- Real-Time Operating System
- TCP/IP Stack
- Peripherals, such as SPI, [I2C](#), 1-Wire, UARTs, ADC, DAC, Timers, etc
- Description of objects, classes and structures
- Function error codes

1.4.2 Device Discovery and Configuration

How to locate your NetBurner device as well as configure system parameters.

1.4.3 The NBEclipse Getting Started Guide

Describes how to create projects and build applications.

1.4.4 Migration Guides

Information for those moving from tools revision 2.x to 3.x.

1.4.5 Example Programs

Well over 100 example programs on everything from web servers, TCP, UDP, Configuration to hardware peripherals. The examples are described in this guide, and located in the "nburn\examples" folder of your installation.

Note

NBEclipse provides an easy example import feature when you create a new project.

Interesting Starting Examples:

- ShowInterfaces: Displays all available network interface information on a web page and serial port
- SimpleHtml: Minimal web server
- IPADDR-IP Address: IPADDR object operations for assignment and display
- PlatformSpecific folder: Unique peripherals for each hardware platform, such as timers, ADC, DAC and unique I2C and SPI peripherals
- RTOS folder: How to use the various system RTOS capabilities

1.4.6 Programmers Guide

Textbook style guide on how to use the various features of your device and networking.

- Device configuration and the Configuration Server
- HTML Processing and Web Server
- NetBurner Real-Time Operating System (NBRTOS)
- Network Protocols such as TCP and UDP
- Security using SSL/TLS
- Embedded Flash File System (EFFS)

1.4.7 Platform References

The Platform References of this guide provide hardware information such as memory maps and device recovery should your application crash in a way that is not easily reset. Schematics for your NetBurner devices are located in the `\nburn\docs\NetBurner\platform` folder.

1.4.8 System Diagnostics

Information on how to enable and use built-in device diagnostics as well as customizing to add your own.

1.4.9 Utilities

Tools and Utilities that are run on a client computer, such as discover, configuration, and application updates.

1.4.10 Production and Deployment

Creating a great application and end product is just part of what needs to be done for a successful product. NetBurner provides deployment information and utilities that you can use in your production environment to program and configure modules in volume, as well as offer to your end customers.

1.4.11 Location of Original Factory Program

If at any time you wish to restore the original factory program that was running on your device, the pre-built application image is located in the `\nburn\platform\<your platform>\original` folder. For example, `\nburn\platform\MODM7AE70\original`. This path assumes a default install to a folder named `nburn`.

1.4.12 Experienced NetBurner Customers

A significant change you will notice from NBRTOS version 2 is how the device configuration is accomplished using a web interface. Please refer to the Migration Guide for a detailed description of the differences between release version 3 and previous releases.

Chapter 2

Build System

2.1 Introduction

The Build System section contains information on subjects such as the GCC Compiler and Build Environment.

2.2 GCC Compiler Flags

Compiler flags can be added or modified in both NBEclipse and command line makefiles.

2.2.1 Generic

Language	Mode	Flag	Description
C/C++	R, D	-gdwarf-2	Adds dwarf-2 debug symbols to the binary. This makes it easier to resolve symbols in gdb.
C/C++	R, D	-Wall	Enables all warnings.
C/C++	R, D	-Werror=return-type	Treats warnings as errors for functions that are missing a return statement.
C/C++	R, D	-Wno-unused	Suppresses warnings for unused variables.
C/C++	R, D	-falign-functions=4	Aligns functions to 4-byte boundaries for improved performance.
C/C++	R	-O2	Enables level 2 optimization for improved performance.
C/C++	D	-O0	Disables optimization for debugging.
C/C++	R, D	-D PLATFORM_↵ NAME=\$(PLATFORM_NAME)	Defines the PLATFORM_NAME macro with the value of the PLATFORM_NAME environment variable.
C/C++	R, D	\$(NBINCLUDE)	Includes the specified directories in the search path for header files.
C	R, D	-std=gnu17	Sets the C standard to GNU C17.

Language	Mode	Flag	Description
C	R, D	<code>-ffunction-sections</code>	Places each function in a separate section to enable linker optimizations.
C	R, D	<code>-fdata-sections</code>	Places each data object in a separate section to enable linker optimizations.
C++	R, D	<code>-std=gnu++17</code>	Sets the C++ standard to GNU C++17.
C++	R, D	<code>-fno-rtti</code>	Disables runtime type information (RTTI) for improved performance.
C++	R, D	<code>-fno-exceptions</code>	Disables C++ exceptions for improved performance.
C++	R, D	<code>-Wno-register</code>	Suppresses warnings for unused register variables.
C++	R, D	<code>-ffunction-sections</code>	Places each function in a separate section to enable linker optimizations.
C++	R, D	<code>-fdata-sections</code>	Places each data object in a separate section to enable linker optimizations.
Assembler	R, D	<code>\$(CPUFLAG)</code>	Specifies the CPU architecture flag.

2.2.2 Architecture-Specific Compiler Flags

2.2.2.1 ARM Cortex-M7

Language	Mode	Flag	Description
C/C++	R, D	<code>-fasynchronous-unwind-tables</code>	Enables asynchronous unwind tables
C/C++	R, D	<code>-D_C11_SOURCE</code>	Defines the <code>_C11_SOURCE</code> macro.
C/C++	R, D	<code>-DCORTEX_M7</code>	Defines the <code>CORTEX_M7</code> macro.

2.2.2.2 ARM Cortex-M0+

Language	Mode	Flag	Description
C/C++	R, D	<code>-fasynchronous-unwind-tables</code>	Enables asynchronous unwind tables
C/C++	D	<code>-fomit-frame-pointer</code>	Omit frame pointer for improved performance.
C/C++	R, D	<code>-D_C11_SOURCE</code>	Defines the <code>_C11_SOURCE</code> macro.
C/C++	R, D	<code>-DCORTEX_M0PLUS</code>	Defines the <code>CORTEX_M0PLUS</code> macro.

2.2.2.3 ColdFire

Language	Mode	Flag	Description
C/C++	R, D	<code>-fno-omit-frame-pointer</code>	Do not omit frame pointer for improved debugging
C/C++	R, D	<code>-fasynchronous-unwind-tables</code>	Enables asynchronous unwind tables
C/C++	R, D	<code>-DCOLDFIRE</code>	Defines the <code>COLDFIRE</code> macro
Assembler	D	<code>--defsym __DEBUG=1</code>	Defines the <code>__DEBUG</code> symbol.

2.2.3 CPU-Specific Compiler Flags

2.2.3.1 SAME70

Language	Mode	Flag	Description
C/C++	R, D	<code>-mcpu=cortex-m7</code>	Specifies the CPU architecture.
C/C++	R, D	<code>-mthumb</code>	Specifies the Thumb instruction set.
C/C++	R, D	<code>-mfpv=fpv5-d16</code>	Specifies the floating-point unit.
C/C++	R, D	<code>-mfloat-abi=\$(ABI_OPT)</code>	Specifies the floating-point ABI. Defaults to softfp
C/C++	R, D	<code>-D\$(CPU)</code>	Defines the <code>\$(CPU)</code> macro.
C++	R, D	<code>-fno-use-cxa-atexit</code>	Disables the use of <code>__cxa_atexit</code>
C++	R, D	<code>-falign-fuinctions=4</code>	Aligns functions to 4-byte boundaries for improved performance.

2.2.3.2 MIMXRT11xx, MIMXRT10xx

Language	Mode	Flag	Description
C/C++	R, D	<code>-mcpu=cortex-m7</code>	Specifies the CPU architecture.
C/C++	R, D	<code>-mthumb</code>	Specifies the Thumb instruction set.
C/C++	R, D	<code>-mfpv=fpv5-d16</code>	Specifies the floating-point unit.
C/C++	R, D	<code>-mfloat-abi=\$(ABI_OPT)</code>	Specifies the floating-point ABI. Defaults to softfp
C/C++	R, D	<code>-D\$(CPU)</code>	Defines the <code>\$(CPU)</code> macro.
C++	R, D	<code>-fno-use-cxa-atexit</code>	Disables the use of <code>__cxa_atexit</code>
C++	R, D	<code>-falign-fuinctions=8</code>	Aligns functions to 8-byte boundaries for improved performance.

2.2.3.3 SAMD20

Language	Mode	Flag	Description
C/C++	R, D	<code>-mcpu=cortex-m0plus</code>	Specifies the CPU architecture.
C/C++	R, D	<code>-mthumb</code>	Specifies the Thumb instruction set.
C++	R	<code>-fno-use-cxa-atexit</code>	Disables the use of <code>__cxa_atexit</code>
C++	R	<code>-falign-fuinctions=4</code>	Aligns functions to 4-byte boundaries for improved performance.

2.2.3.4 MCF5441X

Language	Mode	Flag	Description
C/C++	R, D	<code>-D\$(CPU)</code>	Defines the <code>\$(CPU)</code> macro.
C/C++	R, D	<code>-mcpu=54415</code>	Specifies the CPU architecture.

2.2.4 Platform-Specific Compiler Flags

2.2.4.1 MODM7AE70

Language	Mode	Flag	Description
C/C++	R, D	-D__SAME70Q21↔ __	Defines the __SAME70Q21__ macro.
C/C++	R, D	-DMODM7AE70	Defines the MODM7AE70 macro.

2.2.4.2 SBE70LC

Language	Mode	Flag	Description
C/C++	R, D	-D__SAME70Q21↔ __	Defines the __SAME70Q21__ macro.
C/C++	R, D	-DSBE70LC	Defines the SBE70LC macro.

2.2.4.3 SOMRT1061

Language	Mode	Flag	Description
C/C++	R, D	-D__MIMXRT106xx↔ __	Defines the __MIMXRT106xx__ macro.
C/C++	R, D	-D__MIMXRT1061↔ __	Defines the __MIMXRT1061__ macro.
C/C++	R, D	-DSOMRT1061	Defines the SOMRT1061 macro.

2.2.4.4 MOD5441X

Language	Mode	Flag	Description
C/C++	R, D	-DMOD5441X	Defines the MOD5441X macro.

2.2.4.5 NANO54415

Language	Mode	Flag	Description
C/C++	R, D	-DNANO54415	Defines the NANO54415 macro.

2.2.4.6 SB800EX

Language	Mode	Flag	Description
C/C++	R, D	-DSB800EX	Defines the SB800EX macro.

2.3 Linker Flags

2.3.1 Generic

Flag	Description
\$ (CPUFLAG)	Specifies the CPU architecture flag.
-Wl, -n	Disables linking to dyn
-T\$ (NNDK_ROOT) /platform/\$ (PLATFORM) /linker.ld	Specifies the linker script.
-Wl, -R\$ (NNDK_ROOT) /platform/\$ (PLATFORM) /linker.ld	Specifies the linker script.
-Wl, -Map=\$ (@:.elf=.map)	Generates a map file.
-Wl, --cref	Generates a cross-reference table.
-Wl, --gc-sections	Removes unused sections to reduce the size of the binary.
-Wl, --start-group, \$ (NBLIBS) \$ (XTRALIB) -lstdc++ -lc -Wl, --end-group	Specifies the libraries to link.

2.3.2 Architecture-Specific Linker Flags

None

2.3.3 CPU-Specific Linker Flags

2.3.3.1 SAME70

Flag	Description
-nostartfiles	Disables linking to the default startup files.
-mfloat-abi=\$ (ABI_OPT)	Specifies the floating-point ABI. Defaults to softfp
-Wl--thumb-entry=Reset_Handler	Specifies the entry point.
-Wl--thumb-entry=_start_	Specifies the entry point. (SOMRT1061)

2.3.3.2 MIMXRT11xx, MIMXRT10xx

Flag	Description
-nostartfiles	Disables linking to the default startup files.
-mfloat-abi=\$ (ABI_OPT)	Specifies the floating-point ABI. Defaults to softfp
-Wl--thumb-entry=Reset_Handler	Specifies the entry point.

2.3.3.3 SAMD20

Flag	Description
-nostartfiles	Disables linking to the default startup files.

<code>-Wl--thumb-entry=Reset_Handler</code>	Specifies the entry point.

2.3.3.4 MCF5441X

None

2.3.4 Platform-Specific Linker Flags

None

2.4 Pack Binary

2.4.1 Generic

None

2.4.2 Architecture-Specific

None

Executable	I/O	Flag	Description

2.4.3 CPU-Specific

2.4.3.1 MCF5441X

Executable	I/O	Flag	Description
m68k-elf-objcopy	.elf -> .s19	-O srec	Converts the elf file to s19
m68k-elf-objcopy	.elf -> .s19	-Wl,--gc-sections	Removes unused sections to reduce the size of the binary.
m68k-elf-objcopy	.elf -> .s19	--strip-all	Removes all symbols from the binary.
compcode	.s19 -> _APP.s19	-M \$(^↵ :.s19=.map)	Specifies the map file.
compcode	.s19 -> _APP.s19	-R	Print report.
compcode	.s19 -> _APP.s19	-P\$(PLATFORM)	Specifies the platform.
compcode	.s19 -> .bin	-O binary	Converts the s19 file to binary
compcode	.s19 -> .bin	-M \$(^↵ :.s19=.map)	Specifies the map file.
compcode	.s19 -> .bin	-B	Specifies binary output.
compcode	.s19 -> .bin	-P\$(PLATFORM)	Specifies the platform.
compcode	.s19 -> .bin	-R	Print report.

2.4.3.2 SAMD20

Executable	I/O	Flag	Description
nbfspace	.elf -> .bin	-output-target bin	Converts the elf file to binary

2.4.3.3 SAME70

Executable	I/O	Flag	Description
arm-none-eabi-size	.elf -> .bin		Displays the size of the binary.
nbfspace	.elf -> .bin	-output-target bin	Converts the elf file to binary
nbfspace	.elf -> .bin	-S	Show build statistics.
nbfspace	.elf -> .bin	-P \$(PLATFORM)	Specifies the platform.

2.4.3.4 MIMXRT11xx, MIMXRT10xx

Executable	I/O	Flag	Description
nbfspace	.elf -> .bin	-output-target bin	Converts the elf file to binary

2.4.4 Platform-Specific

2.4.4.1 MODM7AE70

Executable	I/O	Flag	Description
nbfspack	.elf -> .bin	-C	Compress program sections
nbfspack	.elf -> .bin	-cflag S:3	.
nbfspack	.elf -> .bin	-cflag S:0	.
nbfspack	.elf -> .bin	-cflag S:1	.

2.4.4.2 SBE70LC

Executable	I/O	Flag	Description
nbfspack	.elf -> .bin	-C	Compress program sections
nbfspack	.elf -> .bin	-cflag S:3	.
nbfspack	.elf -> .bin	-cflag S:0	.
nbfspack	.elf -> .bin	-cflag S:1	.

2.4.4.3 SOMRT1061

None

2.4.4.4 MOD5441X

Executable	I/O	Flag	Description
comPCODE	.s19 -> .bin	0xC0040000 0xC1FC0000	Application address range.

2.4.4.5 NANO54415

Executable	I/O	Flag	Description
comPCODE	.s19 -> .bin	0x04000 0x800000	Application address range.

2.4.4.6 SB800EX

Executable	I/O	Flag	Description
comPCODE	.s19 -> .bin	0x04000 0x800000	Application address range.

Chapter 3

Command Line Tools

3.1 Introduction

As an alternative to NBEclipse, you can use the command line tools to build your NetBurner projects. In fact, all the example programs are built and tested internally with command line tools. You will find a makefile in each example folder, so any of the examples can be used as a demonstration of how to use command line tools. Windows, Mac and Linux are supported. The command line tools can also be used to invoke the NetBurner tools from the development environment of your choice.

3.2 Command Line Summary

Command	Description
make	Build a project using the makefile in the project directory
make -j	Make using multiple cores to speed up the process
make load	Build project and load into device
make -j load	Build project with multiple cores and load into device
make clean	Delete a project's libraries and object files

Note

The command you will use 99% of the time is: "make -j load". If you have build errors that are difficult to track down, doing a single core "make" will cause the build to stop at the first error.

3.3 Command Line Environment Variables

There are a number of environment variables that can be set to effect the command line build when you do a make. For example, you can specify the target device IP address in which to download the application with a make -j load.

On the command line, typing "set <variable>" will display the current value. Typing "set <variable>=<value>" will set the environment variable. For example, "set DEVIP" will display the current target IP address. Typing "set DEVIP=10.1.1.1" will set DEVIP to the specified IP address.

Variable	Description
DEVIP	Causes a make with the "load" parameter to download to the specified IP address
PLATFORM	Specifies the NetBurner platform to build for
NNDK_ROOT	Specifies the location of your NetBurner development tools installation
PATH	Specifies folders to search for system binaries, like <code>make</code> and other compiler tools

For example, to reference a standard NetBurner tools installation on Windows (also see "`\nburn\setenv.bat`" for an example):

```
set NNDK_ROOT=c:/nburn
set PLATFORM=MODM7AE70
set DEVIP=192.168.1.66
set PATH=C:/nburn/gcc/bin;C:/nburn/pcbins;C:/nburn/gcc/msys/1.0/bin;%path%
```

3.4 Create a New Project From an Example

The easiest way to create a new project is to copy an existing one and modify it:

- Open a command prompt at the location where you keep your projects, such as `\NetBurner\Projects`
- Create a folder for your project, lets use HelloWorld as an example
- Move to the HelloWorld folder
- Copy an example, such as "`\nburn\examples\web\SimpleHtml`"
- At this point your project structure will look like:

```
- \NetBurner\Projects
  * HelloWorld
    · html
      · index.html
    · src
      · main.cpp
    · makefile
```

- Run "`make -j`" to build the project. The "-j" options uses multiple cores for the build
- When the build completes, an obj folder is created with the object files and .bin application image file↵
: `\NetBurner\Projects\HelloWorld\obj\release\SimpleHtml.bin` (and also .s19 for SREC platforms).

```
- \NetBurner\Projects
  * HelloWorld
    · html
      · index.html
    · obj
      · release
        · SimpleHtml.bin
    · src
      · main.cpp
    · makefile
```

- To load the application into your device, use the "`make -j load`" command.

There are many files and folders under the obj folder, including the compiled libraries and object files.

Note

Each project has its own build of the libraries and system files. That way if any changes need to be made (which is rare), it can be done on a per-project basis. This will be discussed in the overload section of this document.

We named our project HelloWorld, but are running SimpleHtml at this point. To customize the project:

- Edit the makefile to change the application image file name to HelloWorld
- Edit main.cpp to change the application name to HelloWorld
- Run "make -j load" to build and load the application into the device

3.4.1 Edit the makefile

The example makefile is shown below:

```
NAME = SimpleHtml
```

```
CPP_SRC = src/main.cpp
```

```
CREATEDTARGS += src/htmldata.cpp
```

```
CPP_SRC += src/htmldata.cpp
```

```
src/htmldata.cpp : $(wildcard html/*.*)
```

```
    comphtml html -osrc/htmldata.cpp
```

```
include $(NNDK_ROOT)/make/boilerplate.mk
```

Changing the NAME from SimpleHtml to HelloWorld will create the image file as HelloWorld.bin (and .s19)

The CPP_SRC is a list of all .cpp files to build. In this case there is only one, but if there were more it would look like:

```
CPP_SRC = src/main.cpp \
        += src/file2.cpp \
        += src/file3.cpp \
        += src/file4.cpp
```

If you have .c source files you can add them with C_SRC in the same manor.

The html related lines auto-generate a cpp file from the code in the project's html directory.

The final line calls the boilerplate makefile which includes the platform specific make instructions. While you can drill down into the details, this type of makefile structure makes creating projects much easier since you only need to list the source files of your project.

3.4.2 Edit main.cpp

A fully functional application with the web server enables is actually very few lines of code:

```
#include <init.h>
#include <nbrtos.h>
#include <system.h>

const char *AppName = "Simple HTML Example";

void UserMain(void *pd)
{
    init();
    StartHttp();
    WaitForActiveNetwork();

    iprintf("Web Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());
    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

This example just initializes the system, starts the web server, prints out some information, and loops forever with a 1 second delay. Changing the AppName to HelloWorld will change the name that shows up in the find and configuration utilities.

3.5 Modifying System Files with Overload

There can be instances in which you need to modify a NetBurner system file. This is accomplished using the Overload feature. NBEclipse creates an overload folder automatically, but with command line builds it must be created manually.

One file that is frequently overridden to modify how NBRTOS works is `predef.h`. However, we suggest using `predef-overload.h` instead for compatibility with future development tools upgrades. `predef-overload.h` will be identical to `predef.h` for the build in which you overload it. The build system will include `predef-overload.h` last, so that if `predef.h` changes in a future release your application will still only overload what you intended.

Note

The overload example is located in `\nburn\examples\Overload`

To overload system files, we add an `overload` folder to our HelloWorld project. Then once you know which file you want to overload, the filename and path in the overload folder must exactly match the `NNDK_ROOT` system file path. For example, if we want to overload the `timezones.cpp` file located in the `\nburn\nbrtos\source` folder:

- `\NetBurner\Projects`
 - HelloWorld
 - * html
 - index.html
 - * obj
 - release
 - SimpleHtml.bin
 - * overload
 - nbrtos
 - source
 - timezones.cpp
 - * src
 - main.cpp
 - * makefile

Now the project's `timezones.cpp` will be used along with any changes made to it.

3.5.1 Important Overload Rules

- The first time a file is added to the overload folder, a "make clean" is required. From that point on, any modifications to that file will automatically handle building all necessary system files.

If a system include folder is overloaded, this folder should be added to your project include paths. Right click on the project and select project properties. Under C/C++ Build->Settings, select GNU C++ Compiler->Includes and add the overload include folder. If utilizing C code, then GNU C Compiler->Includes should also be added.

3.6 GNU Debugger (GDB)

To load an application and start GDB from the command line:

- Build and load a debug build of the application `make loaddebug -j`.
- Start GDB:
 - For ARM devices such as the SOMRT1061, MODM7AE70 and SBE70LC: `arm-eabi-gdb -se obj/debug/<elf.file>`
 - For MOD5441X, NANO54415, and SB800EX platforms: `m68k-elf-gdb -se obj/debug/<elf.file>`
- Connect to the target device with: `target remote <ipaddress>:2159`

To end the GDB session and leave the target running use `detach`. To end the GDB session use `quit`. The GDB command reference is located here: <http://www.gnu.org/software/gdb/documentation/>.

3.6.1 Example GDB Session

An GDB session running the SimpleHtml example on a MOD54417 is shown below. The example has been modified to add some variables that do simple counting.

```
void UserMain(void *pd)
{
    init();                                // Initialize network stack
    StartHttp();                           // Start web server, default port 80
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    iprintf("Web Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());

    uint32_t i = 0;
    uint32_t j = 0;
    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND);
        i++;
        j = j + 1;
        iprintf("i: %ld, j: %ld\r\n", i, j);
    }
}
```

Load the application. Note that the DEVIP environment variable is set to the device's IP address 10.1.1.169. The application will begin execution and wait for GDB to connect.

```
C:\NetBurner\projects\SimpleHtml>make loaddebug -j
C:\nburn\pcbin\nbupdate obj/debug/DBSimpleHtml.bin 10.1.1.169
uriReq: http://10.1.1.169:20034/appupdate.htm

urlStr: http://10.1.1.169:20034/appupdate.htm
200

C:\NetBurner\projects\SimpleHtml>
```

Start GDB:

```
C:\NetBurner\projects\SimpleHtml>m68k-elf-gdb -se obj/debug/DBSimpleHtml.elf
GNU gdb (GDB) 8.2
Copyright (C) 2018 Free Software Foundation, Inc.
License GPLv3+: GNU GPL version 3 or later <http://gnu.org/licenses/gpl.html>
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law.
Type "show copying" and "show warranty" for details.
This GDB was configured as "--host=i686-w64-mingw32 --target=m68k-unknown-elf".
Type "show configuration" for configuration details.
For bug reporting instructions, please see:
<http://www.gnu.org/software/gdb/bugs/>.
Find the GDB manual and other documentation resources online at:
<http://www.gnu.org/software/gdb/documentation/>.

For help, type "help".
Type "apropos word" to search for commands related to "word"...
Reading symbols from obj/debug/DBSimpleHtml.elf...done.
(gdb)
```

Connect to the MOD54417 target on port 2159. This will pause the application at whatever line of code it happens to be on. For simple examples that will typically be the NBRtos idle task.

```
(gdb) target remote 10.1.1.169:2159
Remote debugging using 10.1.1.169:2159
OSTaskIdle (data=0x0) at C:/nburn/arch/coldfire/source/nbrtosmain.cpp:425
425          asm ( " NOP" );
(gdb)
```

At this point you can do whatever type of GDB commands you wish. To set a break point at the `i++`; at line 29 of `main.cpp` and use the `continue` command to execute until the break point is reached:

```
(gdb) break main.cpp:29
Breakpoint 1 at 0x40009282: file src/main.cpp, line 29.
(gdb) info break
Num   Type             Disp Enb Address          What
1     breakpoint        keep y   0x40009282 in UserMain(void*) at src/main.cpp:29
(gdb) continue
Continuing.
[Switching to Thread 2]

Thread 2 hit Breakpoint 1, UserMain (pd=0x0) at src/main.cpp:29
29          i++;
(gdb)
```

The `list` command can be used to view the source code around the breakpoint:

```

Thread 2 hit Breakpoint 1, UserMain (pd=0x0) at src/main.cpp:29
29             i++;
(gdb) list
24             uint32_t i = 0;
25             uint32_t j = 0;
26             while (1)
27             {
28                 OSTimeDly(TICKS_PER_SECOND);
29                 i++;
30                 j = j + 1;
31                 iprintf("i: %ld, j: %ld\r\n", i, j);
32             }
33         }
(gdb)
\code

\latexonly \end{tcolorbox} \endlatexonly

\n
Now view the variables with print, as well as all local variables:

\latexonly \begin{tcolorbox} \endlatexonly

\code
(gdb) print i
$1 = 2
(gdb) info local
i = 2
j = 2
(gdb)

```

Use `next` to go to the next line without stepping into a function (the `step` command steps into a function). GDB commands can typically use just the first letter, in this case `n`:

```

(gdb) n
30             j = j + 1;
(gdb) info local
i = 3
j = 2
(gdb)

```

To make changes to your code use the `detach` command so that the application can resume and will be ready for your next code download:

```

(gdb) detach
Detaching from program: C:\NetBurner\projects\SimpleHtml\obj\debug\DBSimpleHtml.elf, Remote target
Ending remote debugging.
[Inferior 1 (Remote target) detached]
(gdb)

```

To exit GDB, use the `quit` command:

```

(gdb) quit

C:\NetBurner\projects\SimpleHtml>

```

3.7 Addr2line

Note

On Windows and ColdFire-based modules, you can use [WinAddr2Line](#) instead.

To get line numbers and function names from trap memory addresses, you can use `addr2line` on the command line like this:

```
addr2line -ifCe Release/YourProject.elf 00001111 11112222
```

Replace "addr2line" with the path to the appropriate program below, and replace the numbers with memory addresses you want to find.

3.7.1 ColdFire platforms

For ColdFire based platforms, use `m68k-elf-addr2line`. This is distributed in the `\nburn\gcc\bin\` folder.

3.7.2 ARM platforms

For ARM-based platforms, use `arm-unknown-eabi-addr2line`. This is distributed in the `\nburn\gcc\bin\` folder.

Chapter 4

Device Discovery and Configuration

4.1 Introduction

Device discovery and configuration can be accomplished in a number of ways, including methods that are platform independent, including Windows, macOS, Linux, tablets and mobile phones.

Note

Please refer to the [Production & Deployment](#) section of this document for methods and utilities designed to program and configure devices in a production environment.

4.1.1 Device Discovery Methods:

- If the device and computer have Internet access, open a web browser and go to 'discover.netburner.com'.
- Use the localdiscover utility located in `\nburn\pcbin\localdiscover`. This is a multi-platform utility written in Golang for Windows, macOS and Linux. The compiled version can be distributed to your customers, but not the Golang source code.
- Use the Python find utility, located in `\nburn\pctools\find`.
- Use the debug/console serial port.

4.1.2 Device Configuration methods:

- Interactively using a web browser to access the device's Configuration Server
- Sending a JSON object and a utility such as wget (See [Production & Deployment](#))
- The device's serial interface to the Configuration Server

The primary configuration method is through the device's Configuration Web Server. By utilizing a web server, a device can be configured from any platform or operating system. The underlying configuration mechanism is handled through a JavaScript Object Notation (JSON) object. This will be described in more detail later, but the important point is that it provides a simple interface that can be used by non-embedded developers (e.g. web developers) to interact and configure the device. The implementation is also designed to enable you to add any application specific information to be stored and accessed in the same manor, such as calibration values, set points, etc.

You are also able to create your own configuration web interface that will appear in place of the default interface. In this way you can organize and present data in the appropriate way for your customers, as well as add your own custom logo, images and descriptions. Examples are provided.

4.2 Configuration Procedure

- Connect your NetBurner device to a network with Internet access.
- Open a web browser on your host computer and go to `discover.netburner.com`. You will see a list of devices on your network. (If the device does not have Internet access, use the `localdiscover` utility instead).

All system and application settings can now be viewed and/or modified by navigating the tree structure.

Using `discover.netburner.com`:

Figure 4.1 Discover using `discover.netburner.com`

Using `localdiscover` utility:

Figure 4.2 LocalDiscover Utility

The "Device" link will take you to the device application web page. The "ConfigPage" link will take you to the device configuration web page, as shown below:

Figure 4.3 Configuration Web Page

4.2.1 Configuration Settings

4.2.1.1 Config

Top level configuration leaf containing System (Sys) and Application Data (AppData) configuration leafs. AppData will only be populated if an application uses the configuration system for storage/configuration of application specific items, as opposed to common system configuration settings.

Setting	Description
Version	Configuration system write counter. Increments each time new values are saved.
Reboot	Check this option to reboot the system once new values are saved

4.2.1.2 Update Application

A new application can be programmed into the device by choosing an image file and selecting the "Send File" button. Note that the Reboot checkbox should normally be checked so that the device reboots and runs the new application that was sent.

4.2.1.3 Config > Sys

System settings

Setting	Description
Application	Name of running application.
Platform	Name of hardware platform, such as MOD54415

4.2.1.4 Config > Sys > BOOT

Boot settings.

Setting	Description
Abort	Character or string to send to the boot serial port to abort the application boot process and enter the Serial Port Configuration interface. Default is 'A'.
BootBaud	Boot serial port baud rate. Default is 115200, N, 8, 1.
BootDelay	Number of seconds to delay starting the application. This is the time available to send the Abort character or string. Default is 2 seconds. DO NOT SET TO 0.
BootQuiet	At power-up the boot serial port will send the message: "Waiting 2 seconds to boot..." Enabling quiet boot will disable this message. Default is off.
BootUart	Designated boot UART number. Varies by platform, but typically default is 0.
User	Optional user name for password protection of the web page interface.
Password	Optional password to access the web page configuration interface.
SerialConfig	Boot options for the Serial Port Configuration interface: - During Boot (default) - Always Enabled - Pause after boot - Disabled

Note

The password can be reset through the Serial Port Configuration interface.

4.2.1.5 Config > Sys > NetIf

The NetIf section contains settings for all available network interfaces. For example, if the system has a single Ethernet interface, there will be a section named `Ethernet0`. If there are two Ethernet interfaces, the second will be `Ethernet1`. If a Wifi interface is available it will be listed as well.

4.2.1.6 Config > Sys > NetIf > Ethernet0

Settings for each Ethernet interface

Setting	Description
DeviceName	Interface name used for DNS and NetBIOS
DhcpDiscoverSec	Number of seconds after boot to wait before sending a DHCP Discover message. Default is 1.
DiscoveryObfuscate	Send data to Discover Server obfuscated rather than plain text for security. Default is enabled.
DiscoveryReportInterval	How often to report to Discovery Server in seconds. Default is 900.
DiscoveryReportUrl	Name of Discover Server. Default is: <code>discover.netburner.com/Device</code> ↵ <code>Post</code> .
MAC	MAC address
SupressDefault	Disable Ping and UDP Echo ports. Default is not suppressed.
VlanTag	Virtual Network tag number. Default is 0

4.2.1.7 Config > Sys > NetIf > Ethernet0 > IPv4

IPv4 network interface settings.

Setting	Description
ActiveAddr	Current IP address.
ActiveDNS1	Current DNS1 address.
ActiveDNS2	Current DNS2 address.
ActiveGate	Current Gateway address.
ActiveMask	Current IP Mask.
AutoIPAddr	Auto IP address.
AutoIPEn	Enable AutoIP feature. Default is enabled.
EnableMacmDNS	Enable device access by name in the format: <code>nburnxxxxxx.local</code> , where <code>xxxxxx</code> is the last 6 digits of the MAC address. Default is disabled.
LocalName	Specify device access by name in the <code>.local</code> format. For example: <code>mydevice.local</code> .

Setting	Description
Mode	IP Address Mode: - DHCP (default) - DHCP with fallback to static - Static - Disabled
StaticAddr	Static IP address.
StaticDNS1	Static DNS1 address.
StaticDNS2	Static DNS2 address.
StaticGate	Static Gateway address.
StaticMask	Static IP Mask.

4.2.1.7.1 DHCP With Fallback Details

After boot, the first [DHCP](#) Discover message will be sent once the network link is active. Note that if the network link is not active, such as when a network cable is not connected, [DHCP](#) will not start, and the fallback to a static address will not occur.

Once [DHCP](#) starts it will attempt to get the IP settings from a [DHCP](#) server. If not successful, it will retry 4 more times at 8, 16, 23, and 64 seconds. If not successful, then the fallback to static IP address settings will occur.

For custom applications, the retries can be modified in the [DHCP](#) Client header file (may be moved to [constants.h](#) in a future release). The defaults are shown below:

```
#define DEFAULTTIMEOUT (4)
#define DEFAULTRETRY (5)
```

4.2.1.8 Config > Sys > NetIf > Ethernet0 > IPv6

IPv6 network interface settings main leaf. Note: refer to [DHCP](#) With Fallback Details section above.

Setting	Description
Mode	IP Address Mode: - DHCP (default) - DHCP with fallback to static - Static - Disabled
StaticAddr	Static IP address.
StaticDNS1	Static DNS1 address.
StaticDNS2	Static DNS2 address.

4.2.1.8.1 Config > Sys > NetIf > Ethernet0 > IPv6 > ActiveAddr

Displays a list of active addresses. The number will depend on the network architecture. All devies should have at least a link local address with prefix fe80::. Other addresses can be assigned from a DHCPv6 server and routers on the network. The example below shows link local, DHCPv6 and a router.

```
0 fe80::203:f4ff:fe07:386b
1 2600:1700:410:190f:203:f4ff:fe07:386b
2 2600:1700:410:190f::2000
```

4.2.1.8.2 Config > Sys > NetIf > Ethernet0 > IPv6 > ActiveDNS

Displays a list of active DNS serversaddresses. The number will depend on the network architecture. All devies should have at least a link local address with prefix fe80::. Other addresses can be assigned from a DHCPv6 server and routers on the network. The example below shows link local, DHCPv6 and a router.

```
0 fe80::203:f4ff:fe07:386b
1 2600:1700:410:190f:203:f4ff:fe07:386b
2 2600:1700:410:190f::2000
```

4.2.1.8.3 Config > Sys > NetIf > Ethernet0 > IPv6 > ActiveDNS

Displays a list of active DNS servers.

4.2.1.8.4 Config > Sys > NetIf > Ethernet0 > IPv6 > Route

Displays a list of active router addresses.

4.3 The JSON Object

It is not necessary to understand the underlying JSON implementation, but for those that are interested a sample JSON object is shown below. It identifies each configuration field, which can range from a string, boolean, or a selection of values. For developers, the programmers guide and examples provide the operational details.

Warning

If you do decided to use any of the JSON configuration methods, you must first download a JSON object from your specific device. Under no circumstances should you use the example below as you actual device will likely be different in some respects.

The root of the object is Config. The next levels are AppData and Sys. AppData is available for your application to store information. Sys is used for the system configuration such as IP settings.

```
{
  "Config":{
    "AppData":{},
    "Sys":{
      "Application":"Simple HTML Example",
      "Boot":{
        "Abort":"A",
        "BootBaud":115200,
        "BootDelay":2,
        "BootQuiet":false,
        "BootUart":0,
        "Password":"",
        "SerialConfig":{
          "Choices":"DuringBoot, AlwaysEnabled, PauseAfterBoot, Disabled", "Value":"DuringBoot"
        },
        "User":""
      },
      "NetIf":{
        "Ethernet0":{
          "DeviceName":"",
          "DhcpDiscoverSec":1,
          "DiscoveryObfuscate":true,
          "DiscoveryReportInterval":900,
          "DiscoveryReportUrl":"discover.netburner.com/DevicePost",
          "IPv4":{
            "ActiveAddr":"10.1.1.73",
            "ActiveDNS1":"10.1.1.1",
            "ActiveDNS2":"0.0.0.0",
            "ActiveGate":"10.1.1.1",
            "ActiveMask":"255.255.252.0",
            "AutoIPAddr":"169.254.131.245",
            "AutoIPEn":true,
            "Mode":{
              "Choices":"DHCP,DHCP w Fallback,Static,Disabled", "Value":"DHCP"
            },
            "StaticAddr":"0.0.0.0",
            "StaticDNS1":"0.0.0.0",
            "StaticDNS2":"0.0.0.0",
            "StaticGate":"0.0.0.0",
            "StaticMask":"0.0.0.0"
          },
          "IPv6":{
            "ActiveAddr":["2602:306:b8e9:c83f::14c0","2602:306:b8e9:c83f:203:f4ff:fe0b:83f5","fe80::203:f4ff:fe0b:83f5"],
            "ActiveDNS":["2602:306:b8e9:c83f:208:a2ff:fe0c:b081","2602:306:b8e9:c83f:208:a2ff:fe0c:b081"],
            "ActiveRoute":["fe80::1:1"],
            "Mode":{
              "Choices":"DHCP,DHCP w Fallback,Static,Disabled", "Value":"DHCP"
            },
            "StaticAddr":"::",
            "StaticDNS1":"::",
            "StaticDNS2":"::"
          },
          "MAC":"00:03:F4:0B:83:F5"
        },
        "Platform":"MODM7AE70"
      },
      "Version":8,
      "Reboot":false
    }
  }
}
```

4.3.1 Developer Notes

If you were writing a web interface and need only the data under Ethernet in the tree, it can be accessed by: <http://10.1.1.71:20034/UI.html?CONFIG/SYS/NETIF/Ethernet>

To obtain just the IP address: <http://10.1.1.71:20034/UI.html?CONFIG/SYS/NETIF/Ethernet/IPv4/ActiveAddr>

Recommended Examples: The following examples are recommended to begin evaluating the platform. They are located in the \nburn\examples directory.

- ShowInterfaces
- \Configuration\Web\BasicWebConfig

4.4 Configuration Security

One of the features of NetBurner 3.0 is that each device is configured through its own configuration web interface. Data sent and received through the network interface has three options for security:

- Open: No security, plain text
- Obfuscated: Encrypted, but without TLS and a secure certificate and private key
- Secure: Encrypted with TLS and a certificate and private key

4.5 Serial Configuration Server

Network connectivity is not required to use your NetBurner device. If enabled, the Configuration Server can be accessed through the device's serial port. The configuration tree is exactly the same as what you see on the web interface and in the JSON object. For example, the Ethernet0 settings are located at `Config > Sys > NetIf > Ethernet0`.

The serial port interface is located on UART0 by default. It can be modified and enabled/disabled in the `Config > Sys > Boot` level of the Configuration Server.

Config

- AppData**
- Sys**
 - Boot**
 - Abort: A
 - BootBaud: 115200
 - BootDelay: 2
 - BootQuiet: ☐
 - BootUart: 0
 - Password:
 - SerialConfig: DuringBoot
 - User:
 - WatchdogEnabled: ☐

Figure 4.4 Config Boot Level

4.5.1 Serial Configuration

To access the serial port configuration:

- Connect a cable to the serial port selected as the BootUart
- Run a serial terminal program such as MTTTY
- Reset the device, and type a 'A' when prompted to Abort the boot sequence

Figure 4.5 Abort Boot Sequence

You are now in the serial configuration mode as indicated by the '>' character. Typing "help" will display the help menu.

Figure 4.6 Serial Help Menu

Typing the "ls" command displays the next level of the tree, which is `Config` since we are at the root level. In this example we will set the Static IP values. Note that to change from `DHCP` to static, we must also change the `Mode` option from `DHCP` to Static. To navigate to the next level you type in the name of that level. For example, to go to the `Config` level:

Figure 4.7 Config Level

The prompt will show the current location, in this case `Config>`. In the same manor to navigate to the IPv4 settings the level names are typed into the terminal. Note that tabbed auto-completion is also available.

Figure 4.8 IPv4 Level

At any level, typing a "?" will display the current values of that level and all levels beneath in the JSON object format. For example:

Figure 4.9 Display IPv4 Level

In this example we are interested in the static IP settings. There are two choices to set them: from the IPv4 level by including the name of the next level and the value, or by going down to each level individually and entering just the value. In this case we will stay at the IPv4 level and include the name of the static item we want to set. To set the StaticAddr type: StaticAddr="10.1.1.99". We will also type a "?" to see the changed value:

Figure 4.10 Set StaticAddr Value

In the same manor we will set the Mask, Gateway and DNS. To set the Mode we will need to either include the Mode level in the setting string or go to the Mode level, since the setting is a Choices selection and not a simple string like the static IP settings. To accomplish this from the IPv4 level type: `Mode.Choices="Static"`. If you navigate the to Mode level, the command would be: `Choices="Static"`. At this point the unsaved settings are:

Figure 4.11 Static Summary

Warning

From the settings display you can see that the Mode selector control has two settings: Choices and Value. The Choices are values that appear in the web page selector control and you do not want to modify them. Only modify the Value to one of the Choices values.

To store the modified values in the Configuration Record in Flash memory, type #save. This will store the values, but the IP settings will not take effect until the device is rebooted.

4.5.2 Serial App Downloads

Just as with the select file and upload feature of the web interface, applications can be uploaded to your device using the Serial Configuration Server.

The procedure is:

- Abort the boot process type typing 'A' when prompted to enter the Serial Configuration server mode. Note: the SerialConfig Server options includes an "AlwaysEnabled" setting so that the Serial Configuration Server is always active and a reboot and Abort is not required. This can be especially useful during development if you are not connecting your device to a network.
- At the '>' prompt, type "flash"
- When the download prompt appears, send the .bin file using your serial terminal program

The serial terminal output is shown below:

4.5.2.1 Start of Serial Configuration Server.

```
MAC Address = 00:03:f4:0e:21:ee
Type "A" to abort boot

Aborted to Serial Config (BOOT) to continue boot
type help for commands
>
```

4.5.2.2 Optional, type "help" to see a list of commands.

```
MAC Address = 00:03:f4:0e:21:ee
Type "A" to abort boot

Aborted to Serial Config (BOOT) to continue boot
type help for commands
>help# or <ESC> to execute command at levels other than root.
<tab> works for possible choices. <tab> ignores previously entered text
Commands are:
help          (show this)
boot          (boot to app)
reboot        (reboot system)
flash         (program app flash image)
..            (up one level in tree)
/             (up to root of tree)
ls            ( List next level of tree)
save          (save unsaved config changes)
Config        (enter Config mode)
  <configvar>? (read var)
  <configvar>=value (set var)
  Ex Config Seqs:
  > Config.Sys.Boot?
  > Config
  > Config.Sys.NetIf.Ethernet0.Ipv4.StaticAddr="10.1.0.100"

>
```

4.5.2.3 Type "flash" command

```
MAC Address = 00:03:f4:0e:21:ee
Type "A" to abort boot

Aborted to Serial Config (BOOT) to continue boot
type help for commands
>help# or <ESC> to execute command at levels other than root.
<tab> works for possible choices. <tab> ignores previously entered text
Commands are:
help          (show this)
boot          (boot to app)
reboot        (reboot system)
flash         (program app flash image)
..            (up one level in tree)
/             (up to root of tree)
ls            ( List next level of tree)
save          (save unsaved config changes)
Config        (enter Config mode)
  <configvar>? (read var)
  <configvar>=value (set var)
  Ex Config Seqs:
  > Config.Sys.Boot?
  > Config
  > Config.Sys.NetIf.Ethernet0.Ipv4.StaticAddr="10.1.0.100"

> flash
Begin Download
```

4.5.2.4 Send Application File

The device is now waiting to receive the application image file. Use your serial terminal option to send a binary file, and select the .bin file of the application you wish to send. After the file is uploaded, the device will reboot. In the display below the flash command is entered, the file is sent, and the status messages confirming the programming was complete. The device reboot information of the new application begins with "Primary network interface....".

```
> flash
Unknown command (help for help)
Begin Download

Programming complete

Primary network interface configured for DHCP
MAC Address = 00:03:f4:0e:21:ee
Type "A" to abort boot
```

4.5.3 Serial Config Settings

As mentioned previously, the Serial Configuration Server behavior has four options:

- During Boot. Must abort boot sequence by sending an 'A'.
- Always Enabled. Serial Configuration Server will always be active and process commands.
- Pause After Boot. The device will boot into the Serial Configuration Server instead of the application.
- Disabled.

The SerialConfig field is used to select the desired option. It can be done through the web page, or through the Serial Configuration Server itself. It is located in the Config > Sys > BOOT section of the tree.

Config

- AppData**
- Sys**
 - Application
 - PPS Timer Capture
 - Boot**
 - Abort: A
 - BootBaud: 115200
 - BootDelay: 2
 - BootQuiet: ☐
 - BootUart: 0
 - Password:
 - SerialConfig: DuringBoot (dropdown menu open showing: DuringBoot, AlwaysEnabled, PauseAfterBoot, Disabled)
 - User:
 - WatchdogEnabled: ☐
 - NetIf**

```

Chapter 5

Migration Guides

There are currently three NetBurner development tool branches:

- 2.7.x, IPv4 only for all products except ARM.
- 2.9.x, IPv4/IPv6 dual stack for all products except ARM. This release will continue to be fully supported for ColdFire devices.
- 3.x, Latest release including IoT enhancements. Supports 5441x (MOD5441x, NANO54415, SB800EX) and ARM (MODM7AE70) platforms.

Note

If you are updating from a 2.7.x release to a 2.9.x release, please see the IPv6 guide in the `\nburn\docs` folder.

The following sections will describe the migration path in more detail.

- [Release 2.x to 3.x Overview](#)
- [Release 2.x to 3.x Porting Guide](#)
- [Upgrade 5441x Platforms to 3.x](#)

5.1 Release 2.x to 3.x Overview

When developing NetBurner 3.x we incorporated customer requests to enable the use of the latest ARM base processors, security protocols, and IoT capabilities. For existing customers we have done our best to balance the additional capabilities with ease of migration.

5.1.1 Hardware

- Support for ARM processors, starting with the 300MHz M7.
- Support for NXP/Freescale 5441x based products: MOD54415, MOD54417, SB800EX, NANO54415. For other NetBurner platforms we will fully maintain the 2.9.x branch.
- Applications easily scale from single chip solutions to large memory platforms.

5.1.2 Configuration

A new configuration and update system has been created:

- Updates, discovery and configuration are now platform independent and do not require any computer OS specific utilities.
- Devices can be discovered by going to "discover.netburner.com" in a web browser.
- Applications can be updated from a web browser, the nbupdate utility, NBEclipse, WGET, or the serial interface.
- Configuration can now be done with a JSON object. These objects can be saved or uploaded, making configuration in a production environment much easier and faster.
- Developers can easily crease their own configuration objects.
- The IPSetup windows utility can be used to locate a device, but not configure it.

5.1.3 RTOS

The low level code of the RTOS has been modified to support new features including:

- Increased the number of tasks from 64 to a user defined value.
- OS functions are now managed as C++ objects.

5.1.4 TCP

- Increased the maximum number of sockets from 32 to a user defined value. A Maximum value over 256 may have an impact on performance.

5.1.5 Network Interfaces

- Many new interfaces supported
- Access to interfaces now requires looking at an Interface Object, rather than global variables such as ETHER-NETIP. This was needed to support additional interfaces, a larger number of interfaces, and IPv6 capability.

5.1.6 SSL/TLS

- Updated to the latest protocols and ciphers (2.9.x also has the SSL/TLS updates).
- The process for generating compiled-in certificates has been made easier, but is slightly different.
- Devices can now generate certificates.

5.1.7 System Initialization

- A new function, `init()`, is now used to initialize stack, all interfaces, and network debugging.

5.1.8 NBEclipse

- Updated to Oxygen
- Can generate makefiles that can be used on command line builds.

5.1.9 GCC

- Updated to 8.1

5.2 Release 2.x to 3.x Porting Guide

5.2.1 Device Configuration

Previously device configuration was accomplished with IPSetup, a windows based program. In 3.x there are a number of ways to configure the device that are independent of the host computer type. The primary method is through the device's own configuration web server. In this way the device can be configured by a web browser on any platform. There is also a serial interface configuration method.

- Can be configured by any web browser, and applications can be programmed into the device. *Note:* Autoupdate and IPSetup are no longer used to download applications or configure the device. However, you can still use IPSetup to discover a device's IP address.
- Devices can be found by typing `discover.netburner.com` in the web browser URL field.
- The underlying configuration mechanism is handled through a JavaScript Object Notation (JSON) object. This will be described in more detail later, but the important point is that it provides a simple interface that can be used by non-embedded developers (e.g. web developers) to interact and configure the device. The implementation is also designed to enable you to add any application specific information to be stored and accessed in the same manor, such as calibration values, set points, etc.
- You are able to create your own configuration web interface that will appear in place of the default interface. In this way you can organize and present data in the appropriate way for your customers, as well as add your own custom logo, images and descriptions. Examples are provided.

5.2.2 Configuration Procedure

- Connect your NetBurner device to a network with Internet access.
- Open a web browser on your host computer and go to `discover.netburner.com`. You will see a list of devices on your network. 
- The "Device" link will take you to the device's web page. The "ConfigPage" link will take you to the device's configuration web page as shown below: 

A sample JSON object is shown below:

```
{
  "Config":{
    "AppData":{},
    "Sys":{
      "Application":"Simple HTML Example",
      "Boot":{
        "Abort":"A",
        "BootBaud":115200,
        "BootDelay":2,
        "BootQuiet":false,
        "BootUart":0,
        "Password":"",
        "SerialConfig":{
          "Choices":"DuringBoot, AlwaysEnabled, PauseAfterBoot, Disabled", "Value":"DuringBoot"
        },
        "User":""
      },
    },
    "NetIf":{
      "Ethernet0":{
```

```

    "DeviceName": "",
    "DhcpDiscoverSec": 1,
    "DiscoveryObfuscate": true,
    "DiscoveryReportInterval": 900,
    "DiscoveryReportUrl": "discover.netburner.com/DevicePost",
    "IPv4": {
        "ActiveAddr": "10.1.1.73",
        "ActiveDNS1": "10.1.1.1",
        "ActiveDNS2": "0.0.0.0",
        "ActiveGate": "10.1.1.1",
        "ActiveMask": "255.255.252.0",
        "AutoIPAddr": "169.254.131.245",
        "AutoIPEn": true,
        "Mode": {
            "Choices": "DHCP,DHCP w Fallback,Static,Disabled", "Value": "DHCP"
        },
        "StaticAddr": "0.0.0.0",
        "StaticDNS1": "0.0.0.0",
        "StaticDNS2": "0.0.0.0",

```

If you were writing a web interface and need only the data under Ethernet in the tree, it can be accessed by:

<http://10.1.1.71:20034/UI.html?CONFIG/SYS/NETIF/Ethernet>

To obtain just the IP address: <http://10.1.1.71:20034/UI.html?CONFIG/SYS/NETIF/Ethernet/IPv4/ActiveAddr>

5.2.3 Recommended Examples

The following examples are recommended to begin evaluating the platform. They are located in the `\nburn\examples` directory.

- ShowInterfaces
- \Configuration\Web\BasicWebConfig

5.2.4 Configuration Security

One of the features of NetBurner 3.0 is that each device is configured through its own configuration web interface. Data sent and received through the network interface has three options for security:

- Open: No security, plain text
- Obfuscated: Encrypted, but without TLS and a secure certificate and private key
- Secure: Encrypted with TLS and a certificate and private key

Each NetBurner device generates a default certificate and private key, which is stored in its internal flash memory, which can be used to secure the connection as a self-signed certificate. You can also use the device's private key to create your own externally self-signed certificate, or have a certificate issued by a recognized third party. The externally signed certificate can then be installed by overwriting the device's default key.

5.2.4.1 Cautions When Using the Jumper Recover Procedure on a Device

Each device has a location to insert a shorting jumper to reset the module in the event of a catastrophic software problem, such as downloading an application image that corrupts flash memory or crashes. This recovery procedure will erase all of flash memory and download a recovery image. A new private key and certificate will then be generated. In such a case, any external self-signed or third party certificates will no longer be valid since the private key will have changed. A new certificate will have to be created from the new private key.

5.2.5 Device Application Updates

Note

The AutoUpdate utility is no longer used for download application to your device.

You will notice there is an Update Application on the web page. Application are now uploaded using the web interface. Alternatively, there is a windows executable that can be run from the command line in `\nburn\pcbin\nbupdate.exe`. Application images are now `.bin` files, they are no longer `.s19` files. If building in NBEclipse the `.bin` file will be located in your workspace project's release folder. The format using `nbupdate.exe` is as follows: `nbupdate <application .bin file> <device IP>`

5.2.6 Eclipse and Development Tools Updates

Summary of new and improved features:

- Eclipse has been updated to the Oxygen version. It also takes advantage of multiple processor cores on the host computer to greatly speed up compile times. *Note:* if using the command line to build you can use `make -j` to use multiple cores.
- GCC has been updated to version 8.1.
- Each project now has its own NetBurner library. Now any system changes you make will be specific to the project, and each project can have its own modifications.
- The makefile implementation is now identical for NBEclipse and command line builds.

5.2.7 SSL/TLS

Improvements include:

- Moving from NetBurnerSSL to wolfSSL
- Support for a much broader range of ciphers
- Support for DER encoded certificates
- Support for server-side peer verification
- Support for onboard certificate generation
- Substantial improvements to SSL stability
- Support for client side certificate authority lists
- A cleaner interface for using certificate authority lists, as well as the ability to dynamically alter them during runtime
- Faster key generation for onboard certificate generation
- Lays the groundwork for future improvements
 - TLS v1.3
 - FIPS 140 Ready
 - DTLS

5.2.8 Notes on Porting From Previous Revisions

- Big endian vs. little endian. The ColdFire processors have a big endian architecture, while ARM processors are little endian. If you have code that manipulates 16-bit or 32-bit numbers that rely on a big endian format you will need to ensure it works for both types.
- The typical startup sequence of function calls: `InitializeStack()`, `GetDhcpIfNecessary`, `EnableAutoUpdate()`, etc have been replaced with a single call: `init()` which is declared in the header file `init.h`. You will need to remove header files such as:

```
#include <startnet.h>
#include <autoupdate.h>
#include <dhcpcclient.h>
#include <NetworkDebug.h>
```
- The real-time operating system has been modified to increase performance and capabilities. The header file `ucos.h` is now `nbrtos.h`. Any RTOS function calls that had UCOS in related names have been modified to reflect this.
- `UCOS_ENTER_CRITICAL` has been replaced with `NBRTOS_ENTER_CRITICAL`.
- The `StartHTTP()` function is now `StartHttp()` and `StartHttps()`.
- Callbacks have been added to replace the `MyDoGet()` and `MyDoPost()` functions. See [HTML Processing](#) for examples on usage.
- A new function has been added to wait for an active network connection, meaning the device has link. A typical startup sequence will be:

```
init();
WaitForActiveNetwork(TICKS_PER_SECOND * 10);
StartHttp(); // or StartHttps();
```

- Types such as `WORD`, `DWORD`, etc have been replaced with `uint16_t`, `int16_t`, `uint32_t`, `int32_t`, etc.
- Registering a name with a [DHCP](#) server is no longer done by assigning a string to `extern const char pDHCPOfferName`. It is now set by assigning a name to the configuration tree JSON object element: `CONFIG:SYS:NETIF:Ethernet:DeviceName`.
- Runtime calls to the network interface such as `EthernetIP()` have been removed. Please refer to the `ShowInterfaces` example for methods to obtain runtime interface data.

5.2.9 Porting I2C From MCF52xx Based Products to MODM7AE70

Applicable Platforms:

- MOD5234
- MOD5270
- MOD5272
- MOD5282
- PK70EX
- SB70
- SB70LC
- SB72

MCF52xx platforms have a single [I2C](#) peripheral, therefore the [I2C](#) driver API knew which signal pins to use and the set of functions to send/receive data only had to consider a single peripheral. ARM based platforms have many [I2C](#) peripherals, so a different type of driver/API is required. For example, with just a single [I2C](#) peripheral, an `I2CSend()` function is all that is needed. If there are many [I2C](#) peripherals, the driver must be able to send on any of them. This applies to all [I2C](#) functions: read, write, status, error detection, etc.

The most robust and scalable implementation is to use [I2C](#) peripheral C++ objects. You do not need to be a C++ programmer to use these objects in your application, other than to understand the format to call a member function of the object instead of a global C function call. For example, if in C you had a global function named `GetI2CStatus()`, it would now be a member function of a specific [I2C](#) object/peripheral and the call would be `MyI2CObject.GetI2CStatus()`. This method enables your application to handle multiple [I2C](#) peripherals, and the status function knows which peripheral to use because it operates on the object. Note that since the status function is called as a member function of the object, it is common to take that into consideration in the member function name, so it would likely be `MyI2CObject.GetStatus()`.

In this way you can easily handle multiple [I2C](#) peripherals: `MyI2CObject1`, `MyI2CObject2`, `MyI2CObject3`, etc. Your application code does not need to manage and continuously check for which peripheral is being used, such as having a C style array of [I2C](#) peripherals.

The [I2C](#) driver for MCF52xx devices in the NNDK 2.x tools has the interface listed below. Note that there is a bit of C++ even in the old driver in terms of the function prototypes. You are likely calling some of these functions without any parameters, or with less than all the parameters listed. In C++ default parameters are specified in the function prototype with the '=' sign. So you can call `I2CInit()` with no parameters in your application, and the default parameters in the function prototype will be used.

```

void I2CInit( BYTE slave_Addr = 0x08, BYTE freqdiv = 0x3C )

BYTE I2CSend( BYTE val, DWORD ticks_to_wait = I2C_RX_TX_TIMEOUT )
BYTE I2CSendBuf( BYTE addr, PBYTE buf, int num, bool stop = true)

BYTE I2CRead( PBYTE val, DWORD ticks_to_wait = I2C_RX_TX_TIMEOUT )
BYTE I2CReadBuf( BYTE addr, PBYTE buf, int num, bool stop = true )

BYTE I2CStart( BYTE addr, bool Read_Not_Write, DWORD ticks_to_wait = I2C_RX_TX_TIMEOUT )
BYTE I2CStop( DWORD ticks_to_wait = I2C_RX_TX_TIMEOUT )
BYTE I2CRestart( BYTE addr, bool Read_Not_Write, DWORD ticks_to_wait = I2C_RX_TX_TIMEOUT )

void I2CResetPeripheral()

bool I2CRXAvail()
DWORD I2CTXAvail()
BYTE I2CGetByte()

```

The **I2C** implementation in the 3.x tools for ARM platform uses the **I2CDevice** Class. For example, on the MODM7↵AE70, an **I2C** object to select an **I2C** peripheral to interface with an EEPROM can be declared as (code taken from the **I2C** Pic Kit example):

```

#define I2C_MODULE_NUM      0          // use I2C0/TW0
#define I2C_EEPROM_ADDRESS (0xA0 > 1) // Microchip 24LC0B EEPROM, 2Kbit (256 x 8)
I2CDevice EepromDevice(i2c[I2C_MODULE_NUM], I2C_EEPROM_ADDRESS);

```

The declaration of the **I2CDevice** creates an **I2C** object for **I2C** peripheral module 0 at the specified EEPROM **I2C** address. Creating the object also handles the initialization, so the equivalent of **I2CInit()** is not needed. Once we have created the object, all we need to do is call the member functions to control it in the format: **Eeprom↵Device.<member function>**. For example, to send/write a single byte value of 0x60 to address 0x01 of the EEPROM: **EepromDevice.writeReg8(0x01, 0x60);**. Note that in ARM terms, the **I2C** addresses are referred to as registers. **writeReg8()** refers to 8-bits.

You will also note that the return values use the C++ operator ":". Whereas the 2.x driver returned an unsigned 8-bit value (BYTE), the 3.x driver returns a typed value of **Result_t**. Using typed values will result in more robust application code since the compiler can detect when a return value is used incorrectly. the "I2C::" result types are (be sure to view the latest information in the 3.x NetBurner API manual):

```

I2C_RES_ACK      Acknowledged
I2C_RES_NACK     Not acknowledged
I2C_RES_ARB_LST  Arbitration listening
I2C_RES_BUSY    Bus is busy
I2C_RES_ARG     Bad argument

```

The corresponding functions to the MCF52xx **I2CDevice** driver are below. This is the recommended driver.

```

// Constructor to create object, also initializes the I2C peripheral. The pInterface
// parameter will be i2c[0], i2c[1] or i2c[2], representing the 3 I2C peripherals.
// The optional 3rd parameter is normally left as a default. It can be used to set the
// number of register address byte to send, from 0 to 3.
// Example: I2Cdevice EepromDevice(i2c[0], address);
I2CDevice(I2C & pInterface, uint8_t deviceAddress, uint8_t numAddressBytes = 1)

```

```

Result_t writeReg8(uint32_t reg, uint8_t dat)
Result_t writeRegN(uint32_t reg, uint8_t *buf, uint32_t blen)

```

```

Result_t readReg8(uint32_t reg, uint8_t &dat)
Result_t readRegN(uint32_t reg, uint8_t *buf, uint32_t blen)

```

Start, Stop and Restart are taken care of in the **writeRegN** and **readRegN** functions. In situations in which a restart was used for sending more than 1 byte as an address, the **numAddressBytes** parameter in the **I2CDevice** constructor can be used.

```

void resetBus()
void setup(uint32_t busSpeed) // change bus speed

```

If you wish to have more manual control over the **I2C** transactions, you can create an **I2C** object instead of an **I2CDevice** object:

```

// Create an I2C peripheral object. The module parameter for the MODM7AE70 can be 0, 1 or 2.
I2C(int module)

```

```

Result_t writeReg8(uint8_t devAddr, uint32_t reg, uint8_t data)
Result_t writeRegN(uint8_t devAddr, uint32_t reg, uint8_t *buf, uint32_t blen)

```

```

Result_t readReg8(uint8_t devAddr, uint32_t reg, uint8_t &data)
Result_t readRegN(uint8_t devAddr, uint32_t reg, uint8_t *buf, uint32_t blen)

```

```

void setup(uint32_t busSpeed)

```

```

Result_t DoTransaction(I2CTxn_t *pTransaction, bool bRepeatedStart = false);

```

```

void resetBus()

```

In NNDK 3.x there is also a third option. ARM refers to the [I2C](#) as a two-wire interface, or a wire interface in general. A [WireIntf](#) class is available for even more manual control. It was written for those familiar with Arduino drivers, but can be used for more detailed control in general. Please refer to the NNDK 3.x documentation for details.

5.3 Upgrade 5441x Platforms to 3.x

5.3.1 Introduction

The ColdFire 5441x platforms were created before NetBurner 3.x, but they can be easily upgraded. The primary difference is in the device configuration. For reverse compatibility with prior tool sets, all 5441x devices are shipped with a factory application built with the 2.x release so they work with the IPSetup and AutoUpdate utilities. Once you download an application created in NetBurner 3.x, the device will then have the advantages of the 3.x features. The upgrade procedure consists of first loading a conversion application as described below. Thereafter you can load 3.x applications directly.

5.3.2 5441x Product Models Numbers

- MOD54415
- MOD54417
- NANO54415
- SB800EX

5.3.3 3.x Update Procedures

There are 3 procedures that can be used depending on the production date of your 5441x device. For reverse compatibility all 5441x devices ship from the factory running a 2.x application. All are described in more detail in the following sections.

1. For devices manufactured January 2022 or later, the 2.x factory application can process 2.x or 3.x application images, so download your 3.x application using the AutoUpdate utility.
2. For devices manufactured prior to January 2022, use the AutoUpdate utility to download a 2.x to 3.x conversion application.
3. For devices manufactured January 2022 or later, abort to the Alternate Monitor and download either a 2.x or 3.x application. Note that this procedure is also used to revert back to a 2.x compatible device.

Attention

Once a device is running a 3.x application, you will no longer use the 2.x utilities IPSetup and AutoUpdate. Instead, you will use the methods described in the Device Discovery and Configuration section of this manual.

Attention

The NetBurner development tools for 5441x platforms produce both S-Record (.s19) and binary (.bin) application images. The 2.x compatible AutoUpdate utility mentioned in the migration section only uses .s19 files. The preferred file format going forward for all 3.x applications is the .bin format.

5.3.3.1 Procedure For a New 5441x Device Running The NetBurner Factory App

New devices from the factory are programmed with a 2.x factory application to be compatible with older designs. The application can process both 2.x and 3.x applications. The procedure is to identify the device and download a 3.x application.

- Connect the NetBurner device to the network and verify you can see the device's IP address with the Auto↔ Update utility.
- Select your 3.x application and update.

5.3.3.2 Procedure Using the 2.x to 3.x Conversion Application: xxxx-3p0-Update_APP.s19

This procedure can be used for a 5441x device that is currently running any 2.x application. The procedure is to identify the device, download a 2.x to 3.x conversion application, then download any 3.x application.

- Connect the NetBurner device to the network and verify you can see the device's IP address with the Auto↔ Update utility.
- Use the Autoupdate utility to download the appropriate conversion application image for your particular platform, located in the folder: `\nburn\platform\<platform name>\original\`. For example, a MOD5441x application name would be: "MOD5441X-3p0-Update_APP.s19".
- You will now be able to create and download 3.x applications on the device.

5.3.3.3 Procedure Using Alternate Boot Monitor

As of April 2021, the Alternate Boot Monitor has the ability to process a 3.x image file (older revisions must use the previous procedure by loading the conversion application). Alternate Boot Monitor revisions must be the revision shown below or later:

Platform	Revision
MOD5441x	1.11
NANO54415	1.05
SB800EX	1.05

- Connect to the debug/console port of the device with a serial terminal such as MTTTY
- Reset or power cycle the device (or use the recovery jumper)
- Press the 'A' key to abort when prompted (or use the recovery jumper)
- Use the AutoUpdate utility to download your 3.x application image

Note

If you have a device with an earlier Alternate Boot Monitor revision and wish to update it (the Alternate Boot Monitor), please contact NetBurner Support at <https://support.netburner.com>.

5.3.4 Procedure to Revert Back to 2.x

If you wish to revert back to 2.x, there are two methods to abort the boot sequence and enter the Alternate Boot Monitor:

1. Using the serial port interface
2. Using the hardware reset jumper

5.3.4.1 Serial Port Procedure

- Connect to the RS-232 debug/console port of the device with a serial terminal such as MTTTY
- Reset or power cycle the device
- Press the 'A' key to abort when prompted to abort to the Alternate Boot Monitor
- Use the AutoUpdate utility to download your 2.x application image

5.3.4.2 Hardware Reset Jumper Procedure

- Insert the hardware reset jumper
- Reset or power cycle the device to abort to the Alternate Boot Monitor
- Use the AutoUpdate utility to download your 2.x application image

5.3.5 Note on IPSetup utility and 3.x Devices

The windows IPSetup utility will still identify the IP address of a 3.x device. However, it cannot configure the device. The IPSetup device window designates these devices with a prefix of NEWCONFIG.

Figure 5.1 IPSetup with 3.x Application

Chapter 6

NBEclipse

There are three different ways to develop with the NetBurner Tools:

1. Install NBEclipse, which provides project management, a make system, and an editing environment.
2. From the command line using the make utility. Each example in the `\nburn\examples` folder provides an example makefile.
3. Use your own editing environment, and have that environment call the makefile for the project.

The documents in this section will describe how to use the NBEclipse environment and command line.

[Getting Started Guide](#)

[Add a Library to a Project](#)

[Change The IP Targeted By A Project](#)

[Change CompCode Settings for EDFS](#)

6.1 Getting Started Guide

6.1.1 Introduction

6.1.1.1 How to Use This Guide

The goal of the NetBurner Eclipse Getting Started Guide is to familiarize new users with the NetBurner Eclipse (NBEclipse) interface and basic operation. NBEclipse is based on the standard Eclipse release with additional features to support development with NetBurner hardware, such as the ability to locate your NetBurner device on the network, and download an application to the device's flash memory. Topics include:

- How to create a new project
- Import, compile, and execute example programs
- Debug an example program
- Use the application wizard to create a new program
- Various tips on useful features of the NBEclipse environment

6.1.1.2 Source Code for Example Programs

Source code for the examples in this document are located in the `\nburn\examples` directory of your NetBurner tools installation.

6.1.1.3 Hardware Setup

This document assumes you have a working hardware platform on which you can run the examples. Your NetBurner development kit hardware is pre-programmed with an example application at the factory. Before executing the examples in this document, it would be a good idea to connect your NetBurner device to your computer and verify you have serial and network communication with the device as described in the NNDK Quick Start Guide.

6.1.1.4 Software Installation

NetBurner software tools run on Microsoft Windows and OSX. When you receive your development kit there will be a bright red card with a keycode. Register this keycode at <https://support.netburner.com> to download the development tools.

6.1.1.5 Upgrading From a Previous Installation

Do not install over an existing version when upgrading from a previous version of the NetBurner tools. The upgrade requires that you either rename or uninstall the existing installation directory. The recommended procedure is as follows:

1. Backup any existing projects you want to save, especially if they are in the NetBurner tools installation directory.
2. Rename the existing tools installation folder. For example, if upgrading from revision 2.8.8, rename `\nburn` to `\nburn2p8p8`, then install the new version to `\nburn`. This way you can always get back to the previous installation and environment by renaming `\nburn2p8p8` to `\nburn`.

6.1.1.6 Java Installation

Newer versions of NBEclipse (3.3.3 and higher) bundle Java internally and so no separate installation is required.

Older versions of NBEclipse (3.3.2 and lower) require the 64-bit Java Runtime Environment (JRE) revision 1.8 or higher. Direct links to recommended versions are provided on the NNDK Download page. Download either the Java SE (Standard Edition) Development Kit (JDK) or Runtime Environment and follow the installation prompts. You may need to restart your computer after installation is complete.

Note

NBEclipse tools version prior to 3.0 require the 32-bit JRE.

6.1.1.7 Debug Port

Throughout this guide, we will refer to the "serial debug port". The serial debug port is one of the RS-232 ports that can be used to interact with your NetBurner device in the example programs. Stdout, stdin, and stderr are mapped to the debug port by default, so when you use functions like printf(), scanf(), gets(), they read and write to the serial debug port. Mapping of the stdio is configurable, as you can disable the serial debug port and use it as a general purpose UART, or reassign the stdio file descriptors to use other serial or network interfaces. Debugging in NBEclipse on network-enabled platforms will occur through the Ethernet connection, while debugging on non-network platforms will use the serial port.

6.1.2 Platform Overview

6.1.2.1 NetBurner Development Platform Choices

Your NetBurner Network Development Kit provides two options for development:

1. NBEclipse Integrated Development Environment (IDE)
2. Command line tools using the GNU make utility.

The choice of what platform you wish to use depends on personal preferences. The command line tools use makefiles, which are included for every example program and can be used as a starting point for your own makefiles. The make utility can also be invoked from within other IDEs and code editors such as Microsoft Visual Studio.

6.1.3 Project Management

The following points are useful to users who have not used a similar type of project manager. There are three primary methods to maintain and build a project:

1. Use NBEclipse to manage the project with the project files located in the NBEclipse workspace. This is the recommended method.
2. Use NBEclipse to manage the project with the project files located in an existing directory outside the NBEclipse workspace.
3. Configure NBEclipse to use an external makefile that you maintain.

6.1.3.1 NBEclipse Key Points

1. NBEclipse uses a "workspace" in which projects are created and source files are copied.
2. All source code files must reside in the project's "src" folder.
3. If using the web server, all HTML and associated files must reside in the project's "html" folder.
4. All recognized files in a project directory will be compiled. Recognized files have extensions of .c, .cpp, and .s (.s is an assembly language file).
5. The Project Explorer tab on the left side of the NBEclipse IDE is a navigation window like a file browser, it is not a file project manager. All recognized files will be built as part of the application. If you have non-project related files in your project directory and wish to see only the project files in the tab, you can select a filter to display only source code files.
6. To download an application to your NetBurner device, select "Run as NetBurner Application" from the project's Build Targets folder.
7. Application build output files such as .o, .elf, .map, .bin and .s19, and .bin will be written to project sub-directories named "Release" and "Debug" that correspond to the type of build executed. The .bin and .s19 files are the application image files.
8. The keyboard shortcut `<ctrl> b` will build the active project.
9. The keyboard combination of `<ctrl> <space>` invokes function auto-complete.

6.1.4 Creating Projects and Importing Files

This is the most common type of project creation. It will be used to build and run example programs, and is a good starting point for your own projects. By "empty project" we are referring to creating a project without running the Application Wizard to auto-generate a minimal application. After we create the project we will use the project import feature to import source code files from an example into the project.

1. Create an empty project.
2. Import source files by right-clicking on the project name and using the Import feature from the drop down menu.
3. Build the application and download to your NetBurner device.

6.1.4.1 Create a New Project

From the main menu, select **File->New->Project**:

Figure 6.1 Create a New Project

6.1.4.2 Select the NetBurner Project Type

Select the NetBurner project type, then select Next:

Figure 6.2 Select Product Type

6.1.4.3 Specify Project Name and Executable Option

Enter your project name in the Project Name field (it is best not to use spaces with gcc tool chains). In this example we entered "SimplHtml", since that is the example we will import. Make sure the Executable is set to: "NetBurner C++ Project".

Warning

Be sure to select NetBurner Device Executable, do not select the C/C++ option.

Note

You can create a project in a directory outside of your workspace by unchecking the Use Default Location checkbox, and using the Browse button to select the directory containing the source files.

Figure 6.3 Select NetBurner Device Executable

6.1.4.4 Project Configurations

The default options for the project configurations are both Release and Debug. Leave the defaults and select Next.

Figure 6.4 Project Configurations

6.1.4.5 Select Your NetBurner Target Device

There are two ways to select your target NetBurner device:

1. Click on the Search button to bring up a list of NetBurner devices on your network (device must be operational).
2. Manually: Click on the Target Platform drop down box to select your platform, then type in the IP address.

Figure 6.5 Search for devices

When using the Search feature, select the device in the list that corresponds to the MAC address printed on the label of your NetBurner device. In the image below we can see the device type, MODM7AE70, it's MAC address, and it's IP address. It will then fill in the platform and IP address for you. When done select Next.

Figure 6.6 Successful search entry

6.1.4.6 Application Wizard

Since we are creating an empty project and will be importing our own source files we do not want to select any items here. However, if you wish to generate a minimal application using the Application Wizard, select both Standard Initialization and Web Server. This will generate a main.cpp source file to use as a starting point for your application.

Select Finish to complete the project creation.

Figure 6.7 Skip Application Wizard code generation

6.1.4.7 New Project Created

You will now see your new project in the Project Explorer pane. At this point we have a project, but still need to import our source files (if you did not use the Application Wizard).

Figure 6.8 A new project has been created

6.1.4.8 Import Example Source Files to the Project SRC Folder

The next step is to import the source files of an example. NBEclipse uses a make utility to manage projects, and will attempt to build all source files in your project directory. Do not import non-source code files, such as .o, .elf, .map, .mk, auto-generated htмлdata.cpp files, etc. NBEclipse will store all output files similar to these in project subdirectories named "Release" and "Debug" corresponding to the build type performed.

For this demonstration we will use "`\\nburn\\examples\\Web\\SimpleHtml`". The first step is to right-click on your project in the NBEclipse Project Explorer pane:

Figure 6.9 Select Import

Next select the General->File System, then select Next:

Figure 6.10 Select File System

Select the Browse button to bring up a file selection window, navigate to `\nburn\examples\Web\SimpleHtml`, and select the OK button:

Figure 6.11 Select the Simple HTML Example

Once back at the File System dialog box, click on the ">" symbol next to the SimpleHtml name to open the tree structure. You can see that there is a folder named src and a folder named html. We want the files in both folders, so select the checkbox next to the name "SimpleHtml", which will select all folders underneath it. Note: the makefile you see is only used for command line builds, but it does no harm to import it as well.

Figure 6.12 Select all SimpleHtml files for import

Select Finish, which will import the files and automatically build the project. You can view the status of the build process in the console window, located in the lower right corner of your screen. In the Project Explorer, click on the ">" symbol next to SimpleHtml. Some important items of note:

- Build Targets has two functions: downloading code to your device, and rebuilding the system libraries if needed.
- The src folder contains all your source code files, such as main.cpp.
- The html folder contains all your web based code.
- The overload directory is used to override any system library files. See the example in \nburn\examples\OverloadDirectory for more details.

Figure 6.13 Import complete

6.1.4.9 Open your main.cpp source file

Clicking on the ">" symbol next to the src folder, you can open main.cpp in the editor

Figure 6.14 Open main.cpp

6.1.4.10 Project Import Complete

At this point you have a project complete with source code files. You can use the editor to modify both src and html files. If you wish to open a html file in text mode to do things like add dynamic content tags such as CPPCALL, VARIABLE, etc, right-click on the html file and use the Open With option to select the text editor:

Figure 6.15 Open HTML files in text mode

By default, any time you modify and save a source file, the system will automatically build the application. If you prefer to turn off the auto-build option, to build the project: from the main menu select Project->Build Project, or use the `<ctrl> b` keyboard shortcut.

Figure 6.16 Build the Project

6.1.4.11 Download the Application to Your Device

Now that an application image has been built, the next step is to download the binary image to your NetBurner device. NBEclipse can simultaneously handle multiple NetBurner hardware platforms of the same or different types. For example, multiple MODM7AE70 core modules, or a mix with some MOD54415 modules. Targeting a project to a specific hardware device, is accomplished by creating a Run Configuration for release mode project builds, or a Debug Configuration for project debug builds. An important part of such a configuration is associating the device's IP address with the project so NBEclipse knows where to download the project's binary image.

When you create a new project and select the download option for the first time, NBEclipse will create a Run Configuration for you (Run and Debug Configurations can also be created manually). First select your project by left clicking on it in the Project Window:

Figure 6.17 Select Project

Then click on the Run button in the upper right corner of NBEclipse:

Figure 6.18 Select Run Button

The Run As dialog box will appear. Select NetBurner Application, which will run the application on the remote system: When you click the OK button, NBEclipse will download the binary image to the remote device and reboot it.

**Figure 6.19 Select Run Application**

The application should now be running on the device. If you do not remember the IP address of the device, you can find it using the "Find" window in the lower left of NBEclipse. In the screenshot below there are 3 devices. The device running SimpleHtml has IP address 10.1.1.196.

**Figure 6.20 Find Device IP**

6.1.4.12 View the Device Web Page

Opening a web browser and typing 10.1.1.196 in the URL field:

Figure 6.21 HTML Page

If you now look at the upper left side of NBEclipse, you will see the configuration set to Run, and the project set to SimpleHtml for the configuration.

Figure 6.22 Run Configuration

6.1.4.13 View Serial Port Status Messages with MTTTY

All NetBurner examples make use of the debug/console serial port to provide status messages. You will need to have a serial connection to your device either through USB or the DB9 on the development board, depending on your hardware configuration. You can then use the MTTTY serial terminal application to view the serial output. To open MTTTY:

Figure 6.23 Open MTTTY

When the device boots the SimpleHtml application you will see:

Figure 6.24 MTTTY Output

6.1.5 Debugger

In the previous section we created and ran a project in release mode. To use a debugger, the application must be built in debug mode. All debuggers require the code be built in a different manor than a release build:

- Code optimization is disabled
 - If the platform uses external SDRAM with the internal SRAM acceleration for stacks, buffers and variables, it is disabled
- NBEclipse uses a network debugger. This means that an application must be able to at least boot through network initialization so the NBEclipse agent can connect to the GDB stub on the target device.

6.1.5.1 Starting a Debug Session

We will pick up right where we left off for the SimpleHtml example project in the previous section. First, lets open main.cpp and add a variable. UserMain() is shown below:

```
void UserMain(void *pd)
{
    init();                      // Initialize network stack
    StartHttp();                 // Start web server, default port 80
    WaitForActiveNetwork();

    iprintf("Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());

    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

Add two lines of code to create an integer and increment it:

int i = 0; and i++;

So UserMain() becomes:

```
void UserMain(void *pd)
{
    init();                      // Initialize network stack
    StartHttp();                 // Start web server, default port 80
    WaitForActiveNetwork();

    iprintf("Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());

    int i = 0;                    // <--- Declare variable
    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND);
        i++;                     // <--- Increment variable
    }
}
```

Previously for the Run Configuration and download we clicked on the green play button in the upper right corner of NBEclipse. This time we will click on the debug button, which is next to it on the left:

Figure 6.25 Select Debug Configuration

It will take a few seconds for the debugger to connect, and the NBEclipse Perspective will change from the NetBurner perspective to the Debug perspective:

Figure 6.26 Debug Perspective

At this point the code is running. To set a breakpoint on our new variable, double click to the left of the line of code. In this example it is just to the left of line 29:

Figure 6.27 Set Breakpoint

The screen shot below shows the program stopped at line 29. The Variables window in the upper right shows the variable 'i', which has incremented 7 times so far.

Figure 6.28 Stopped at Breakpoint

The debugger operations are controlled with the tool bar at the top of the screen. If you hover the cursor over the icon the tool tip will describe what it does. Common features are:

- Resume: Available when stopped at a breakpoint. Selecting it will resume the application and stop at the next breakpoint.
- Terminate: Disconnects the debugger from the target device. The device will resume execution without any breakpoints.

- Disconnect: Identical to Terminate.
 - Step Into: Single step into a function call.
 - Step Over: Single step to the next line of code in the current function.
 - Step Return: Execute until current function returns.
- Notes on debugging:
- You can switch between the Debug perspective and NetBurner perspective using the NetBurner and Debug icons in the upper right corner of the screen.
 - You can edit and build your application from either perspective.
 - Hovering the cursor over variables, macros and functions in the source code window will display information on that item.
 - The upper left window displays the RTOS task stack.
 - It is recommended to terminate a debug session before starting a new one.
 - The three icons at the top left of the screen: build, debug and stop, are not used by either perspective.

6.1.6 Rebuilding Projects & Libraries

6.1.6.1 Rebuild Project Source Files

A project "clean" will rebuild all of the project's source code files. It does not affect the library system files associated with the project. From the Project Explorer pane, right-click on your project, then select Clean Project:

Figure 6.29 Rebuild project files

6.1.6.2 Rebuild Library Files

This is normally not necessary, but there are cases in which the user may want to rebuild the NetBurner system library files. For example, if the user made changes to system source files or added a system source file to a project's overload directory. In these cases, it's recommended to rebuild the NetBurner system library files followed by "cleaning" the project's source files.

To force a rebuild of the NetBurner library files associated with a project, double-click on Clean Project Library in the Build Targets tree:

Figure 6.30 Rebuild a project library

6.1.7 Overload Directory

The overload directory, located inside a project, is used to override any system file by including local copies of system source or header files. This allows the user to isolate system files changes to a specific project. The overload directory provides an alternative to modifying the original system files, which would affect all projects.

One file that is frequently overridden to modify how NBRTOS works is `predef.h`, however we suggest using `predef-overload.h` instead for portability.

Figure 6.31 Project's Overload Directory

To use this feature, the file to be overloaded should be placed in the overload directory under a directory structure that matches the file's location relative to the NNDK install directory.

To demonstrate the usage and configuration of the overload directory, we will show an example. Let's say the user wants to overload the system's timezone structure so that they can change the name of a timezone. Perhaps the user is deploying their device in a non-English speaking country and would like to change the language used for timezone names. The timezone names are defined in a system file located in the following directory:

```
/nburn/nbrtos/source/timezones.cpp
```

Therefore, the directory structure is replicated inside the overload directory with the following structure:

```
<project root>/overload/nbrtos/source/timezones.cpp
```

The directory structure can be created by right-clicking the overload directory and selecting New->Folder. The overload directory must have a matching directory structure to the path of the system file to be overloaded. For this example, the overload directory should look like the following:

Figure 6.32 Project's Overload Directory Structure

Next, the modified source file must be placed in the correct path in the overload directory. The file can be drag and dropped in place. Alternatively, the file can be imported into the overload directory by right-clicking the overload directory and navigating to Import->General->File System and navigating to the source file. After adding timezone.cpp, our overload example would look like the following:

Figure 6.33 Overload Source File Added

Next, the project properties must be configured so that the C++ compiler knows to include the path to the overloaded source file. This can be done by right-clicking the project and selecting "Properties" as shown in the image below.

Figure 6.34 Project Properties

Navigate to C/C++ Build->Settings, select GNU C++ Compiler->Includes.

Figure 6.35 Overload Include Paths

Add the overload directory path to the "Include Paths" list by selecting the "+" logo. If utilizing C code, then the path to the overload directory should be added to GNU C Compiler->Includes as well.

Figure 6.36 Overload Include Path Selection

After adding the overload directory path to the list of "Include Paths," the list should look like the following↵
:

Figure 6.37 Overload Directory Path Added to Include Paths List

Confirm that the new overload directory path has been added to the "Include paths" list above the paths that begin with "\$NNDK_ROOT)/" as shown in the image above. If not, use the up-arrow button to move the overload directory path higher in the list.

Select "Apply and Close" to apply the modifications.

Last, we need to rebuild the NetBurner system library files then clean the project files (the order of operations matters). For instructions on doing so, see [Rebuilding Projects & Libraries](#). From this point on, modifying the overloaded source file, `timezone.cpp`, will automatically re-build the necessary files in the NetBurner system files when the project builds.

6.2 Add a Library to a Project

NBEclipse includes the most common libraries by default. However, there are times you will need to tell the build system to include additional libraries, such as if your application uses the Embedded Flash File System (EFFS) for flash memory cards, in which case you need to add the FatFile library.

Note: If you are building a project that uses EFFS functions, and have not added the FatFile library, you will see many link errors for functions that start with `f_` and `fm_`.

To add a library:

- In NBEclipse, right-click on your project, and select "Properties".

- Select "C/C++ Builds -> Settings" on the left-hand side.
- Select "GNU C/C++ Linker -> Libraries" under the "Tool Settings".
- In the "Libraries" list box, add "FatFile" by using the add icon in top-right corner of the list.
- In the "Libraries Search Path" list box, add the path to the library. For example, for MOD5441x device, the path is: `\nburn\platform\MOD5441X\original\lib`. Note: the naming convention for gcc is as follows: the name of the library is actually `libFatFile.a`, but in the Libraries entry box you only use what comes after "lib" and do not use the `.a` suffix. In this case, we just use "FatFile".

Note

The other common library to add is the EDFS-STD library: `StdFile`. EDFS-FAT is a FAT32 library for flash memory cards. EDFS-STD is used to create a file system in the flash memory chip on the device.

6.3 Change The IP Targeted By A Project

If the IP of your device changes (for example, if you unplug it and it is assigned a different IP when you plug it back in), you will need to tell the build system to target a different IP.

To change the targeted IP:

- In NBEclipse, click on "Project" from the top menu, then click "Properties".
- In the left-hand panel of the Properties menu, click "NetBurner Options".
- Change the targeted IP address in the right-hand side of the panel.

6.4 Change CompCode Settings for EDFS

The CompCode utility is used in the final stage of a build to compress an application image. The COMPCODE memory address range defines the amount of space available as application space so programming an application in flash memory does not overwrite any of the space allocated for the EDFS-STD file system. Documentation on the memory map for your particular device can be found in the Platform Reference section of this document.

To change the CompCode memory address range for the application in NBEclipse:

1. Right-click on your project, and select "Properties".
2. Select "C/C++ Builds > Settings" on the left-hand side.

3. Select "NB Compcode". In the All Options section the current value of the application memory range is displayed. In this example it is a NANO54415 platform. To make the next step easier, highlight and copy the memory address range.

Figure 6.38 Compcode default values

4. Select the NB Compcode > General tab. If the current value is the factory default, you will see the macro `$(COMPCODEFLAGS)` displayed. This is the value that is read from the factory default file.

Figure 6.39 Compcode default values

5. Delete `${COMPCODEFLAGS}` and paste the memory range you copied in the previous step, then edit it to specify the desired memory range. In this example we will change `0x800000` to `0x700000`. So you end up with: `0x04000 0x700000`. This would be used to allocate `0x100000` bytes to the EFFS-STD file system space. When you are finished editing, click on Apply or Apply and Close.

Figure 6.40 Compcode default values

Chapter 7

PC Tools and Utilities

This guide describes the PC tools and utilities that run as stand-alone programs, as well as automatically as part of the NetBurner development tools suite. The executable version of the tools are located in `\nburn\pcbin`, and the source code is located in `\nburn\pctools`.

7.1 Multi-threaded TTY Serial Terminal (MTTTY)

Multi-Threaded TTY (MTTTY) is a serial terminal utility that you can use to communicate with the RS-232 serial ports on your NetBurner device or development kit. It is multi-threaded in that you can run multiple instances of MTTTY for each serial port.

MTTTY is commonly used for:

- Displaying status messages sent from the NetBurner device, such as when using `iprintf()`
- As a serial interface to any application

MTTTY can be started from:

- Inside NBEclipse by clicking on the MTTTY icon
- From the Windows NetBurner program group
- From a command line. The path is: `\nburn\pcbin\mttty.exe`

7.1.1 MTTY FAQ

- The default serial port used for stdio for NetBurner devices is UART0.
- The DB9 connector pinout on NetBurner development boards will have the RS-232 rx and tx signals reversed, so that a null-modem adapter is not required and you can use a straight-through serial cable.
- The DB9 connector pinout on NetBurner Serial-To-Ethernet devices, such as the SB700EX and SB800EX, will be identical to a standard PC type pinout, so a null-modem adapter will be required. (The serial cable that comes with the NetBurner development kits for these specific devices is a null-modem cable)

7.2 Wget

Primary method to program an application into a NetBurner device by posting the application file to the device's config server. It is used automatically by both NBEclipse and the Makefile command line tools. The default flags to call wget are as follows: `wget -nv -O- --progress=dot:micro --post-file=<file name> <Device IP>:20034/appupdate.htm`

Wget also supports loading code onto a device that has been protected by username/password authentication. On the command line, the device username and password are configured by setting the environment flags NBUSER and NBPASSWORD. For example, in a make load, set the username and password as follows: `make load NBUSER=foo NBPASSWORD=bar`. In NBEclipse, username and password are set via the project options. Right click on a project and select Properties. Username and password text input boxes can be found under NetBurner Options. Finally, if manually utilizing wget, use the following wget flags to set a username and password: `--user=foo --password=bar`.

7.3 NBUpdate

Alternative method used to program an application into a NetBurner device by posting the application file to the device's config server. It is invoked as part of the make system for NetBurner development kit NBEclipse and command line builds. It can be replaced with WGET. The format is `nbupdate <file name> <device IP>`

7.4 Smart Traps

While smart traps is not a specific PC application, the interface is accomplished by running the MTTTY serial terminal. During software development it is possible for a software developer to download an application with a coding error severe enough to cause an application to crash. Common causes of a system crash are: task stack overflow, indexing an array out of bounds and bad pointer assignments. When a system crash occurs a device will usually recover by a reboot of the system. The purpose of the SmartTrap utility is to provide more information about the system when the crash occurred to assist with debugging the problem. Smart traps are automatically enabled by the `init()` function. Note that smart traps are disabled when building an application in debug mode.

- SmartTraps are commonly used for debugging an application crash
- SmartTraps are used in conjunction with the MTTTY serial terminal program. The SmartTraps information will be displayed on the debug serial port

Figure 7.1 Example Smart Traps Output

The output has four sections. It is beyond the scope of this document to go into detail on each of the processor registers, please refer to the processor manual for more information, located in the `\nburn\docs` directory of your development tools installation.

7.4.1 Trap Information

This section displays the processor status and error registers. The most significant is the Faulted PC, with is the Program Counter register indicating the area where the fault occurred. In this example the program counter value at the time a trap was detected is 0x02000152.

7.4.2 Register Information

This section displays the processor's Address and Data registers.

7.4.3 RTOS Information

Identifies the RTOS Task Control Block and the current running task. The priority number is in hexadecimal. Traps caused by stack overflows may corrupt this section of the report.

7.4.4 Task Information

This is a very useful section of the report. It identifies each task, as well as its current state, wait time, and call stack. If you look at the Main task, you can see 6 entries with 0x02000152 (the faulted pc) at the left, and 0 at the right. The value of 0 is the start of the call stack. Each hexadecimal address between those two numbers represents each function that was called.

Each address can be related to the corresponding line number in the source code by using the WinAddr2Line utility. By selecting the .elf file location and each address in the call stack you can determine the calling sequence starting from 0 on the right and moving to the left. The last line signifies the end of the SmartTrap output. Since the boot monitor is configured to "boot to application", the device reboots after the trap occurs.

7.5 Task Scan

TaskScan is a network connected debugging tool that can be used to view the RTOS tasks and status of your running NetBurner application. This tool is unique in that it is active in the release build of your code, rather than the debug build which is compiled without optimization. It is very useful to determine such things as why a specific task is not running the way you had anticipated, if it is waiting on other tasks, and its call stack. TaskScan is only active when the PC program generates a request, so it will not impact your release code execution speed otherwise.

The `init()` function will automatically include `taskmon.h` and call `EnableTaskMonitor()`. TaskScan requires that you have the Executable and Linking Format (ELF) file for the specific application that is running on your NetBurner device. The .elf file is created by the compiler each time you build your application. It contains information TaskScan needs to link the application executable to the source code and task information. For example, if you have a project named MyProject, a file named MyProject.elf will be created.

TaskScan is commonly used for:

- Determining which tasks are running, their state and call stack.
- Looking for blocked tasks.

TaskScan can be started from:

- From the Windows NetBurner program group
- From a command line. The path is: `\nburn\pcbin\taskscan.exe`

7.5.1 TaskScan FAQ

- You must have a valid IP address and mask that can communicate with your PC that is running TaskScan
- TaskScan essentially takes a snapshot picture of what your application is doing at the time you press the Scan button. It does not otherwise impact the application
- You must have the exact .elf file used to create the application that is running on your NetBurner device to get valid information

After starting the Task Scan application use the Browse button to locate your project's elf file, and the Find button to locate the IP address.

Figure 7.2 Starting Task Scan

Then select the Scan button:

Figure 7.3 Scan Results

Icon	Description
	Green OK
	Green Running Man
	Red Hour Glass
	Red Hand

Figure 7.4 Task Scan Icons

7.6 WinAddr2Line

WinAddr2Line only works for ColdFire-based platforms. For ARM, see [Addr2line](#)

Utility to determine the source code location for a specified memory address and .elf file. This application is typically used in conjunction with the SmartTraps utility when debugging an application that is crashing.

WinAddr2Line is commonly used for:

- Determining the source code address using a faulted program counter memory address from SmartTraps.
- If the cause of a crash is severe memory corruption due to bad pointers, it is possible for the Faulted Program Counter to be pointing to an address in which not code exists. In this case WinAddr2Line will not be able to provide a source code reference because no source code exists at that location.

WinAddr2Line can be started from:

- NBEclipse main tool bar
- The Windows NetBurner program group.
- The command line. The path is: \nburn\pcbin\winaddr2line.exe.

7.6.1 Using WinAddr2Line

- Use the Browse button to select the .elf file for your application and type in the hexadecimal memory address, usually obtained by SmartTraps as the Faulted PC.
- Click on the Decode button.

Figure 7.5 Select file and enter address in hexadecimal

7.7 IPSetup

The Windows IPSetup utility was used for network configuration in releases prior to 3.x. Network configuration is now down through the network configuration server on the NetBurner device. See [Device Discovery and Configuration](#) and [Config Server Programming Guide](#) for documentation on the 3.x network configuration system.

7.8 AutoUpdate

Autoupdate was used for loading applications to a device in releases prior to 3.x. Updating code is now done through the configuration server, nbupdate utility, or WGET.

7.9 Virtual Comm Port

The virtual comm port driver for Windows creates a virtual serial port and associates it with a network IP address and port number. It is typically used for legacy Windows applications without the ability to communicate over a network.

7.10 CompHtml

This utility is used by the NetBurner make system. It takes the contents of a project's html directory, implements the NetBurner dynamic web content scheme, callbacks, variables, access priorities, and mime types, and creates a file named `htmldata.cpp`.

7.11 CompCode

This utility is used by the NetBurner make system for 5441x platforms. It processes a `.s19` file into a compressed binary with checksum and header.

7.12 flashpack

This utility is used by the NetBurner make system for ARM platforms. It processes the `application.elf` file into a compressed binary with checksum and header.

Chapter 8

Platform References

This section provides the hardware reference information for your NetBurner platform, including memory maps, boot monitor and module recovery procedures in the event you download an application that is crashing the device.

- [MODM7AE70 Platform Reference](#)
- [MOD54415, MOD54417 Platform Reference](#)
- [NANO54415 Platform Reference](#)
- [SB800EX Platform Reference](#)
- [SBE70LC Platform Reference](#)
- [SOMRT1061 Platform Reference](#)
- [Recovery: MODM7AE70, SBE70LC](#)
- [Recovery: MOD5441x, NANO54415, SB800EX](#)
- [Recovery: SOMRT1061](#)
- [ARM Cache Management](#)

8.1 MODM7AE70 Platform Reference

8.1.1 Introduction

This document provides the memory map and locations of reference materials for those who wish to add additional hardware to their NetBurner device.

8.1.2 Processor Information

The MODM7AE70 uses the Microchip ARM SAME70 microprocessor. The reference manual and datasheet provide in-depth information on the processor, including register settings, bus configuration and timing information. It is located in the `<nburn_install>\docs\Arm` directory of your NetBurner installation.

8.1.2.1 Definitions

Definitions for the SAME70 can be found at [arch/cortex-m7/cpu/SAME70/include/same70q21.h](#)

8.1.3 Datasheet

The datasheet for the MODM7AE70 module includes information on connectors, signal names, and operational parameters. It is located on the MODM7AE70 product page under Documents and Downloads: [MODM7AE70 Datasheet](#).

8.1.4 Development Board Schematic

The MOD-DEV-70CR development board schematic is located in the `<nburn_install>\docs\NetBurner\platform\Schematics` directory. This schematic can be used for design ideas in your own hardware implementation for power, RS-232, RS-485, and SD Flash card implementation.

8.1.5 Memory Operation

The MODM7AE70 uses 3 types of memory:

- 2MB Flash memory for non-volatile system configuration storage, user application storage, the application in a compressed format, and the optional EFFS-STD file system (note this is different from the EFFS-FAT flash card file system).
- 8MB SDRAM containing the uncompressed application as well as any application data.
- 384KB on-chip SRAM located in the SAME70 microprocessor.

At power-up the application is decompressed from Flash memory to SDRAM and execution begins. If the application is continuously trapping the device can be recovered using the jumper recovery method as described in the Recover section, or if you have serial communication enabled the boot sequence can be aborted by sending the appropriate serial command when prompted after a power cycle.

8.1.6 Memory Map

Region	Size	Address Range	Description
Boot Loader	6k	0x00400000 to 0x004017FF	Initial boot and application extraction
Config Record	10k	0x00401800 to 0x00403FFF	System and User Configuration Data Flash
Cert. Storage	8k	0x00404000 to 0x00405FFF	Optional Security certificate storage
User Flash	8k	0x00406000 to 0x00407FFF	Unstructured binary User Flash Storage
App Flash	1.97M	0x00408000 to 0x005FFFFF	Compressed Application and opt file system
Vector Table	-	0x20400000 to 0x2040013F	SRAM - Interrupt Vector Table
Fast App RAM	384k	0x20400180 to 0x2045FFFF	SRAM - Fast Application RAM
Backup RAM	1k	0x40074000 to 0x400743FF	Low power backup RAM
External Bus	-	0x60000000 to 0x60FFFFFF	Chip Select 0
External Bus	16M	0x61000000 to 0x61FFFFFF	Chip Select 1
External Bus	16M	0x62000000 to 0x62FFFFFF	Chip Select 2
External Bus	16M	0x63000000 to 0x63FFFFFF	Chip Select 3
App RAM	8M	0x70000000 to 0x707FFFFFFF	SDRAM - Standard Application RAM where code is decompressed and variables are allocated
QSPI XIP	-	0x80000000 to 0x80FFFFFF	QSPI (User add-on) - For utilizing memory Mapped Quad SPI memories

8.1.7 External Bus Interface

The MODM7AE70 provides 17 address lines (A0-A16) and a 16-bit data bus line (D0-D15). The data and address lines shared with the SDRAM are buffered to the module's P1 header pins. Please refer to the MODM7AE70 schematic and datasheet for connector and signal locations. The Microchip SAME70 datasheet, section 33 on External Bus Interface (EBI) and section 34 on Static Memory Controller (SMC), provide details on peripheral functionality and configuration.

8.2 MOD54415, MOD54417 Platform Reference

8.2.1 Introduction

This document provides the memory map and locations of reference materials for those who wish to add additional hardware to their NetBurner device. The MOD54415 and MOD54417 are very similar. The difference is the MOD54417 provides two hardware network interfaces. The designation MOD5441x in this document applies to both modules.

8.2.2 Processor Information

The MOD54415 uses the NXP MCF54415 microprocessor, and the MOD54417 uses the MCF54417 microprocessor. The NXP MCF5441x reference manual and datasheet provide in-depth information on both processors and is located in the `<nburn_install>\docs\NXP` directory of your NetBurner Network Development Kit installation.

8.2.2.1 Definitions

Definitions for the MCF5441X can be found at [arch/coldfire/cpu/MCF5441X/include/sim5441x.h](http://arch.coldfire/cpu/MCF5441X/include/sim5441x.h)

8.2.3 Datasheet

The datasheet for the MOD5441x module can be found on the MOD54415/MOD54417 product page under Documents and Downloads: [MOD5441x Datasheet](#). The datasheet is the primary control document for connector pin-outs and signal functions.

8.2.4 Development Board Schematic

The MOD-DEV-70CR development board schematic is located in the `<nburn_install>\docs\NetBurner\platform\Schematics` directory. This schematic can be used for design ideas in your own hardware implementation for power, RS-232, RS-485, and SD Flash card implementation.

8.2.5 Memory Operation

The MOD5441x uses 4 types of memory:

- A 4MB write protected serial SPI Flash chip containing the Boot Monitor and Alternate Boot monitor. This provides a recovery method should events such as a bad application that causes continuous traps, or application Flash memory corruption.
- A 32MB parallel Flash chip containing non-volatile system configuration storage, user application storage, the application in a compressed format, and the optional EDFS-STD file system (note this is different from the EDFS-FAT flash card file system).
- A 64MB DDR2 Memory chip that contains the uncompressed application as well as any application data.
- 64KB on-chip SRAM located on the MCF5441x microprocessor.

Note

The reference to "2.x" is there for customers migrating from the NetBurner 2.x development tools. 2.x System Configuration is not used when running 3.x applications.

4MB SPI Boot Flash	32MB Parallel Flash	64MB DDR2 RAM
Boot Monitor	2.x System Configuration	Application (decompressed)
Alternate Boot Monitor	User Parameters	System Stack
	Application (compressed)	

3.x System Configuration

The Boot Monitor executes at power-up and attempts to decompress the application into DDR2 RAM and begin execution. If the application is corrupted or does not exist, it will attempt to run the Alternate Boot Monitor. If the Alternate Boot Monitor cannot be run, the system will remain in the Boot Monitor. The Alternate Boot Monitor provides network communication to enable an application download, and is the normal recovery method should unrecoverable application errors occur. The Boot Monitor only provides serial communication.

8.2.6 Memory Map

The MOD5441x provides 16 address lines (A0-A15) and a 16-bit data bus (D16-D31) running in mode 2. An address bus latch is included on the MOD5441x so external latch is not required for this mode. If you are adding peripherals to your NetBurner device's address/data bus, you can choose unused memory locations from the table below. Once a range has been selected, you will need to configure the appropriate chip select address and option registers in the MCF5451x processor. Please refer to the chip select sections of the NXP MCF5441x processor manual for details on the register configuration. Unlike many ColdFire processors, you are not free to use any unused address for chip selects. The range is restricted. In this table we have used "undefined" for restricted ranges and "unused" for ranges that are valid for additional chip selects. Please see the MCF5441x Manual Section 20.3.1 and the Note above Figure 20-1 for additional details.

Memory Region	Address Range	Description
Undefined	0x00000000 to 0x01FFFFFF	Undefined area to catch null pointers
Unused	0x02000000 to 0x3FFFFFFF	Available to applications
DDR2 RAM	0x40000000 to 0x43FFFFFF	64MB of DDR2 RAM
VBR	0x40000000 to 0x400003FF	1kB processor vector base register
RAMBAR	0x80000000 to 0x8000FFFF	64kB Processor internal SRAM
Parallel Flash	0xC0000000 to 0xC1FFFFFF	32MB parallel flash memory
System Config	0xC0000000 to 0xC001FFFF	128kB system configuration flash sector
2.x Config Rec	0xC0000000 to 0xC0000400	1kB 2.x configuration storage
3.x Certificate	0xC0000400 to 0xC0002400	8kB 3.x certificate storage
3.x System Config.	0xC0002400 to 0xC001FFFF	119kB 3.x system configuration
User Params	0xC0020000 to 0xC003FFFF	128kB user parameter storage
Application Code	0xC0040000 to 0xC1FFFFFF	Compressed application code
Unused	0xC2000000 to 0xDFFFFFFF	Available to applications
IPSBAR	0xE0000000 to 0xFFFFFFFF	Processor internal device registers - accessible using the SIM structure defined in sim5441x.h

8.3 NANO54415 Platform Reference

8.3.1 Introduction

This document provides the memory map and locations of reference materials for those who wish to add additional hardware to their NetBurner device.

8.3.2 Processor Information

The NANO54415 uses the NXP MCF54415 microprocessor. The reference manual and datasheet provide in-depth information on the microprocessor, including register settings, bus configuration and timing information. It is located

in the <nburn_install>\docs\NXP directory of your NetBurner installation.

8.3.2.1 Definitions

Definitions for the MCF5441X can be found at arch/coldfire/cpu/MCF5441X/include/sim5441x.h

8.3.3 Datasheet

The datasheet for the NANO54415 module includes information on connectors, signal names, and operational parameters. It is located on the NANO54415 product page under Documents and Downloads:

[NANO54415 Datasheet](#).

8.3.4 Development Board Schematic

The NANO54415 development board schematic is located in the <nburn_install>\docs\NetBurner\Platform\Schematics directory. This schematic can be used for design ideas in your own hardware implementation for power, RS-232, RS-485, and SD Flash card implementation.

8.3.5 Memory Operation

The NANO54415 uses 4 types of memory:

- A 4MB write protected serial SPI Flash chip containing the Boot Monitor and Alternate Boot monitor. This provides a recovery method should events such as a bad application that causes continuous traps, or application Flash memory corruption.
- A 8MB serial SPI Flash chip containing non-volatile system configuration storage, user application storage, the application in a compressed format, and the optional EFFS-STD file system (note this is different from the EFFS-FAT flash card file system).
- A 64MB DDR2 memory chip that contains the uncompressed application as well as any application data.
- 64KB on-chip SRAM located on the MCF54415 microprocessor.

The Boot Monitor executes at power-up and attempts to decompress the application into DDR2 RAM and begin execution. If the application is corrupted or does not exist, it will attempt to run the Alternate Boot Monitor. If the Alternate Boot Monitor cannot be run, the system will remain in the Boot Monitor. The Alternate Boot Monitor provides network communication to enable an application download, and is the normal recovery method should unrecoverable application errors occur. The Boot Monitor only provides serial communication.

Note

The reference to "2.x" is there for customers migrating from the NetBurner 2.x development tools. 2.x System Configuration is not used when running 3.x applications.

4MB SPI Boot Flash	8MB SPI Flash	64MB DDR2 RAM
Boot Monitor	2.x System Configuration	Application (decompressed)
Alternate Boot Monitor	User Parameters	System Stack
	Application (compressed)	
	3.x System Configuration	

8.3.6 Processor Runtime Memory Map

The runtime memory map for the location of the microprocessors onboard SRAM and DDR2 RAM is shown below:

Memory Region	Address Range	Description
Undefined	0x00000000 to 0x01FFFFFF	Undefined area to detect null pointers
DDR2 RAM	0x40000000 to 0x43FFFFFF	64MB of DDR2 RAM
VBR	0x40000000 to 0x400003FF	1kB Processor Vector Base Register
RAMBAR	0x80000000 to 0x8000FFFF	64kB Processor internal SRAM
IPSBAR	0xE0000000 to 0xFFFFFFFF	Processor internal device registers

8.3.7 Application SPI Flash Memory

There is a total of 8MB SPI Flash memory used to store the compressed application and non-volatile parameters. Read/write operations are only accessible through system API functions. The memory does not appear in the microprocessor's address map.

SPI Address	Description
0x000000	8kB 2.x System Configuration Record storage
0x002000	8kB User Parameter Storage
0x004000	7.9MB Compressed Application Code
0x7EE000	8kB 3.x Reserved System Configuration Storage
0x7F0000	64kB 3.x System Configuration

8.4 SB800EX Platform Reference

8.4.1 Introduction

This document provides the memory map and locations of reference materials for those who wish to add additional hardware to their NetBurner device.

8.4.2 Processor Information

The SB800EX uses the NXP MCF54415 microprocessor. The reference manual and datasheet provide in-depth information on the microprocessor, including register settings, bus configuration and timing information. It is located in the <nburn_install>\docs\NXP directory of your NetBurner installation.

8.4.2.1 Definitions

Definitions for the MCF5441X can be found at arch/coldfire/cpu/MCF5441X/include/sim5441x.h

8.4.3 Datasheet

The datasheet for the SB800EX module includes information on connectors, signal names, and operational parameters. It is located on the SB800EX product page under Documents and Downloads: [SB800EX Datasheet](#).

8.4.4 Memory Operation

The SB800EX uses 4 types of memory:

- A 4MB write protected serial SPI Flash chip containing the Boot Monitor and Alternate Boot monitor. This provides a recovery method should events such as a bad application that causes continuous traps, or application Flash memory corruption.

- An 8MB serial SPI Flash chip containing non-volatile system configuration storage, user application storage, the application in a compressed format, and the optional EDFS-STD file system (note this is different from the EDFS-FAT flash card file system).
- A 64MB DDR2 memory chip that contains the uncompressed application as well as any application data.
- 64K on-chip SRAM located on the MCF54415 microprocessor.

The Boot Monitor executes at power-up and attempts to decompress the application into DDR2 RAM and begin execution. If the application is corrupted or does not exist, it will attempt to run the Alternate Boot Monitor. If the Alternate Boot Monitor cannot be run, the system will remain in the Boot Monitor. The Alternate Boot Monitor provides network communication to enable an application download, and is the normal recovery method should unrecoverable application errors occur. The Boot Monitor only provides serial communication.

Note

The reference to "2.x" is there for customers migrating from the NetBurner 2.x development tools. 2.x System Configuration is not used when running 3.x applications.

4MB SPI Boot Flash	8MB SPI Flash	64MB DDR2 RAM
Boot Monitor	2.x System Configuration	Application (decompressed)
Alternate Boot Monitor	User Parameters	System Stack
	Application (compressed)	
	3.x System Configuration	

8.4.5 Processor Runtime Memory Map

The runtime memory map for the location of the microprocessors onboard SRAM and DDR2 RAM is shown below:

Memory Region	Address Range	Description
Undefined	0x00000000 to 0x01FFFFFF	Undefined area to detect null pointers
DDR2 RAM	0x40000000 to 0x43FFFFFF	64MB of DDR2 RAM
VBR	0x40000000 to 0x400003FF	1kB Processor Vector Base Register
RAMBAR	0x80000000 to 0x8000FFFF	64kB Processor internal SRAM
IPSBAR	0xE0000000 to 0xFFFFFFFF	Processor internal device registers

8.4.6 Application SPI Flash Memory

There is a total of 8MB SPI Flash memory used to store the compressed application and non-volatile parameters. Read/write operations are only accessible through system API functions. The memory does not appear in the microprocessor's address map.

SPI Address	Description
0x000000	8kB 2.x System Configuration Record storage
0x002000	8kB User Parameter Storage
0x004000	7.9MB Compressed Application Code

0x7EE000	8kB 3.x Reserved System Configuration Storage
0x7F0000	64kB 3.x System Configuration

8.5 SBE70LC Platform Reference

8.5.1 Introduction

This document provides the memory map and locations of reference materials for those who wish to add additional hardware to their NetBurner device.

8.5.2 Processor Information

The SBE70LC uses the Microchip ARM SAME70 microprocessor. The reference manual and datasheet provide in-depth information on the processor, including register settings, bus configuration and timing information. It is located in the `<nburn_install>\docs\Arm` directory of your NetBurner installation.

8.5.2.1 Definitions

Definitions for the SAME70 can be found at arch/cortex-m7/cpu/SAME70/include/same70q21.h

8.5.3 Datasheet

The datasheet for the SBE70LC module includes information on connectors, signal names, and operational parameters. It is located on the SBE70LC product page under Documents and Downloads: [SBE70LC Datasheet](#).

8.5.4 Development Board Schematic

The SB70LC-ADPT-100 development board schematic is located in the `<nburn_install>\docs\NetBurner\platform\Schematics` directory. This schematic can be used for design ideas in your own hardware implementation for power, RS-232, RS-485, and SD Flash card implementation.

8.5.5 Memory Operation

The SBE70LC uses 3 types of memory:

- 2MB Flash memory for non-volatile system configuration storage, user application storage, the application in a compressed format, and the optional EDFS-STD file system (note this is different from the EDFS-FAT flash card file system).
- 8MB SDRAM containing the uncompressed application as well as any application data.
- 384KB on-chip SRAM located in the SAME70 microprocessor.

At power-up the application is decompressed from Flash memory to SDRAM and execution begins. If the application is continuously trapping the device can be recovered using the jumper recovery method as described in the Recover section, or if you have serial communication enabled the boot sequence can be aborted by sending the appropriate serial command when prompted after a power cycle.

8.5.6 Memory Map

Region	Size	Address Range	Description
Boot Loader	6k	0x00400000 to 0x004017FF	Initial boot and application extraction
Config Record	10k	0x00401800 to 0x00403FFF	System and User Configuration Data Flash

Region	Size	Address Range	Description
Cert. Storage	8k	0x00404000 to 0x00405FFF	Optional Security certificate storage
User Flash	8k	0x00406000 to 0x00407FFF	Unstructured binary User Flash Storage
App Flash	1.97M	0x00408000 to 0x005FFFFFFF	Compressed Application and opt file system
Vector Table	-	0x20400000 to 0x2040013F	SRAM - Interrupt Vector Table
Fast App RAM	384k	0x20400180 to 0x2045FFFF	SRAM - Fast Application RAM
Backup RAM	1k	0x40074000 to 0x400743FF	Low power backup RAM
External Bus	-	0x60000000 to 0x60FFFFFFF	Chip Select 0
External Bus	16M	0x61000000 to 0x61FFFFFFF	Chip Select 1
External Bus	16M	0x62000000 to 0x62FFFFFFF	Chip Select 2
External Bus	16M	0x63000000 to 0x63FFFFFFF	Chip Select 3
App RAM	8M	0x70000000 to 0x707FFFFFFF	SDRAM - Standard Application RAM where code is decompressed and variables are allocated
QSPI XIP	-	0x80000000 to 0x80FFFFFFF	QSPI (User add-on) - For utilizing memory Mapped Quad SPI memories

8.6 SOMRT1061 Platform Reference

8.6.1 Introduction

This document provides the memory map and locations of reference materials for those who wish to add additional hardware to their NetBurner device.

8.6.2 Processor Information

The SOMRT1061 uses the NXP i.MX RT1061 microprocessor. The reference manual and datasheet provide in-depth information on the microprocessor, including register settings, bus configuration and timing information. It is located in the `<nburn_install>\docs\NXP` directory of your NetBurner installation.

8.6.2.1 Definitions

Definitions for the MIMXRT1061 can be found at <arch/cortex-m7/cpu/MIMXRT10xx/include/MIMXRT1061.h>

8.6.3 Datasheet and Pins

The datasheet for the SOMRT1061 module includes information on connectors, signal names, and operational parameters. It is located on the [SOMRT1061 product page](#) under Documents and Downloads.

An Excel spreadsheet of pin assignments is also available under the same Datasheet link.

Finally, NetBurner has created an interactive [Pin Configurator tool which is available online](#) as well as in your NNDK installation under `<nburn_install>\docs\NetBurner\Platform\PinConfigurator`

You may also find `pinconstant.h` to be a useful reference.

8.6.4 Development Board Schematic

The DEV-SOMRT1061 development board schematic is located in the `<nburn_install>\docs\NetBurner\platform\Schematics` directory. This schematic can be used for design ideas in your own hardware implementation for power, RS-232, RS-485, and SD Flash card implementation.

8.6.5 SOMRT1061 Platform General Information

The SOMRT1061 uses the NXP i.MX RT1061 microcontroller. The reference manual and datasheet provide in-depth information on the processor, including register settings, bus configuration and timing information. The reference manual is located in the <nburn_install>\docs\NXP directory of your NetBurner installation.

- i.MX RT1061 running at 528MHz (ind temp)
- 8MB SPI Flash (stores compressed application image)
- 32MB PSRAM
- 1MB onboard SRAM:
 - 128k ITCM single cycle instruction fetch memory,
 - 128K DTCM single cycle data fetch memory
 - 768k general purpose fast SRAM

8.6.5.1 The 8MB of Flash uses a Flash File System and is used for all storage purposes:

- Sectors are 8k
- The standard NetBurner configuration, certificate and user flash operate transparently through the file system.
- First sector reserved for file partition table. Note: If you need direct flash access, please contact NetBurner support.
- You can add a secondary Flash File System as demonstrated in the EDFS-STD examples. Multiple partitions are supported. Please refer to the documentation and examples, such as the EDFS-STD multiple partition (multi-part) example.
- Application space varies by use case, but is typically 7.5MB for the compressed application. Items that can reduce the 8MB total space include: file system overhead, certificates, configuration data, secondary file system.

8.6.5.2 External Memory Bus

- Chip selects configurable anywhere in the external bus range

8.6.6 Boot Sequence

At power-up or reset, the application is decompressed from Flash memory to PSRAM, verified by checksum, and execution begins. If the checksum fails or the application crashes, the device will reboot to the Configuration Server to facilitate a recovery by downloading a new application.

If the application causes an issue in which continuous traps occur, or the state of the system is such the Configuration Server cannot run, a recovery hardware jumper procedure can be used to reset the device.

Note

It is always a good idea to have a serial port terminal connected to the boot/debug serial port to view status messages, or use the 'A' to abort the boot sequence command when prompted to abort application execution and boot to the Configuration Server.

8.6.7 UART Signals and Port Number Mapping

There can be a maximum of 7 serial port configured on the device. Note that each signal pin on the microprocessor can be configured for up to 5 different functions, so to achieve the maximum number of serial ports some peripheral functions will be unavailable.

Please refer to the Open All Serial Ports example for hardware and software port mapping: [Open All UARTs](#). Port number mapping for software API calls is defined in [SOMRT1061/include/serial_platdefs.h](#) in the `<nburn_install>\platform` folder.

8.7 Recovery: MODM7AE70, SBE70LC

8.7.1 Introduction

Applicable Hardware Platforms: MODM7AE70 and SBE70LC.

Device recovery in the event of an errant application running on the device is an important part of the development process. This document describes recovery procedures for a device stuck in a repeating trap/reset condition, or a totally unresponsive device.

8.7.2 Repeating Traps or Resets

The easiest method of recovery is to abort the user application boot process and run only the Configuration Server. The Configuration server will enable a new application to be downloaded using:

- The Configuration Server web page at `<device IP>:20034`
- The nbupdate utility
- The wget utility
- The device serial port

8.7.2.1 Step 1: Abort to the Configuration Server

1. Run a serial terminal such as MTTTY and connect to the device serial port.
2. Power cycle the module.
3. Press "A" when the message, `Type "A" to Abort boot` is displayed. Note that "A" is the default abort command, but the command is configurable in the Configuration Server settings. If the abort command is different, use that command instead of "A".
4. Wait for the `>` prompt to display.

The Configuration Server is now active on both network and the device serial port.

8.7.2.2 Step 2: Download a New Application

At this point a new application can be downloaded through the device web page, nbupdate or serial port.

8.7.2.2.1 Web Page

1. Locate the device using [discover.netburner.com](#), the `localdiscover` utility, or open a web browser and type the device address in the URL field: `<device IP>:20034`. For example, `192.168.1.10:20034`.
2. In the Update Application section, select the new .bin file to download and select the Send File button.

8.7.2.2.2 NBUpdate

1. Open a command prompt.
2. Type `nbupdate <file name> <device IP>`

8.7.2.2.3 Serial Port

Note

MTTTY is a serial terminal program. You should be able to use any serial terminal program of your choice. When starting the download the binary file must be sent as text or raw data.

Warning

The .bin file is a binary file. You must have serial software flow control disabled. If using MTTY, from the main menu select `TTY > Flow Control` and uncheck both `Xon/Xoff Input Control` and `Xon/Xoff Input Control`. Otherwise the data stream will be corrupted.

1. At the `>` prompt, type `fla` into the serial prompt and then hit enter.
2. At the message 'Begin Download', start the file download (if using MTTY, type the `F5` key).
3. When the file window opens, navigate to the .bin application file that you want to load.
4. Hit 'Open', and the application will start the load process.

8.7.3 Unresponsive Device or No Serial Port Access

In a situation in which the device is completely unresponsive and aborting to the Configuration Server is not possible, or if there is no access to the device serial port, shorting two hole locations on the device PCB (also called "jumper recovery") will reset it to a factory default state. The PCB hole locations are 0.1 inches apart so that a shorting jumper can be used. This procedure will erase flash memory including the configuration and application. The device will then be ready to receive a new application using any of the procedures described in the download a New Application section.

1. Power off the device.
2. Short the jumper recovery PCB locations with a shorting jumper or wire.
3. Power on the device.
4. Wait for the device to finish erasing the flash and loading the default application. Progress is indicated by the two blinking LEDs on the device (D1 and D2). When the LEDs stop blinking the reset is complete. For the SBE70LC, the jumper should be removed after 2 seconds. If it is left inserted for 30 seconds or more, it will continually reset.
5. Remove the short jumper or wire.

8.7.3.1 Recovery Jumper Locations

8.7.3.1.1 MODM7AE70

The reset jumper location is labeled "Recovery", located on the end of the board opposite the RJ-45 connector.

Figure 8.1 MODM7AE70 Recovery Jumper Location

8.7.3.1.2 SBE70LC

The reset jumper location is labeled "JP6", located on the end of the board opposite the RJ-45 connector.

Figure 8.2 SBE70LC Recovery Jumper Location

8.8 Recovery: MOD5441x, NANO54415, SB800EX

NetBurner 5441x based devices include: MOD54415, MOD54417, NANO54415 and the SB800EX. These devices have a Recovery Jumper. This is a 2 hole pin location on the circuit board. When shorted during the boot process, the device will boot to the Alternate Boot Monitor rather than the application. If the configuration section of flash has been corrupted, it will also use a safe default version instead of what is in flash memory.

8.8.1 Step 1: Abort to the Alternate Boot Monitor

There is the primary boot monitor, accessible by entering the 'A' (0x41) character immediately on boot. This should allow you to recover the module normally. If for some reason that fails, or you cannot enter the 'A' character, the

have a secondary boot monitor to allow the user to recover from (virtually) all software or configuration faults. The procedure is:

1. Power off the module.
2. Short the 2 pins at the alternate boot jumper location (see below).
3. Power on the module.
4. Wait for the module to finish boot and enter the monitor.
5. Remove the short on the alternate boot jumper location.

8.8.2 Recovery Jumper Locations

8.8.2.1 NANO54415

The boot jumper is a pair of circular pads located near the middle line of the board near the connector.

Figure 8.3 NANO54415 Recovery Jumper Location

8.8.2.2 MOD5441x

The boot jumper is the unpopulated header 'TP1', located near the Ethernet jack.

Figure 8.4 MOD5441x Recovery Jumper Location

8.8.2.3 SB800EX

The boot jumper is the unpopulated header 'JP1', located near the center of the board.

Figure 8.5 SB800EX Recovery Jumper Location

8.8.3 Step 2: Download a New Application

Once the Alternate Boot Monitor is running you should be able to locate your device using:

8.8.3.1 Network

The 5441x devices predate the NetBurner 3.x Development Tools and network recovery requires the use of the AutoUpdate utility. Run the AutoUpdate utility and select the device and new application to download. Autoupdate requires `_APP.s19` file format. The original, factory application is a safe application to load on to a device that needs to be recovered. It can be found in the `platform\<PLATFORM>\original` directory.

8.8.3.2 Serial Port

Note

MTTTY is a serial terminal program. You should be able to use any serial terminal program of your choice. When starting the download the binary file must be sent as text or raw data.

Warning

The `.bin` file is a binary file. You must have serial software flow control disabled. If using MTTY, from the main menu select `TTY > Flow Control` and uncheck both `Xon/Xoff Input Control` and `Xon/Xoff Input Control`. Otherwise the data stream will be corrupted.

1. At the `NB>` prompt type `fla` then hit enter.
2. At the message 'Begin Download', start the file download (if using MTTY, type the `F5` key).
3. When the file window opens, navigate to the `.bin` application file that you want to load.
4. Hit 'Open', and the application will start the load process.

Once the download is complete the device will reboot and run the new application.

8.9 Recovery: SOMRT1061

8.9.1 Introduction

Applicable Hardware Platforms: SOMRT1061

Device recovery in the event of an errant application running on the device is an important part of the development process. This document describes recovery procedures for a device stuck in a repeating trap/reset condition, or a totally unresponsive device.

8.9.2 Boot Components and Features Overview

An overview of the key components and features of the boot process are listed below. The remainder of this article will provide further details and usage on each.

- **Boot Monitor.** Executes at power-up or reset. Decompresses Application, performs system verification and jumps to application to begin execution.
- **Application.** Your custom program/application that runs when things are working properly.
- **Configuration Server.** Runs as part of the Application. For recovery, the boot sequence can be aborted in the initialization process (the `init()` function in `UserMain()` will not return), enabling you to change configuration parameters or upload a new application. Note that the application must be able to boot and run to the `init()` function to use this feature. The Configuration Server can be accessed through the web server interface or the serial console port. A new application can be uploaded to the device through any of the following:
 - Configuration Server web page at `<device IP>:20034`
 - `nbupdate` utility
 - `wget` utility
 - serial console interface
- **Alternate Boot Monitor.** Used as part of a recovery method when aborting to the Configuration Server is not possible. There are two use cases:
 - If you can abort to the Configuration Monitor but are unable to load a new application for some reason, you can issue the command "ABOOT" through the serial console and the device will reboot to the Alternate Boot Monitor without having to use the jumper recovery procedure. You can then issue the "Erase All" command to erase Flash memory.
 - If there is no application programmed into the device, it will boot to the Alternate Boot Monitor.
 - If the application is crashing before `UserMain()` starts, such as a crashing global constructor, you will need to boot to the Alternate Boot Monitor with the recovery jumper procedure described later in this article.

8.9.3 Boot Sequence Overview

8.9.3.1 Normal Boot

For a properly running application. Boot Monitor starts, decompresses application to RAM, performs system checks, then jumps to the start of the application.

8.9.3.2 Incorrect Network Settings

Symptom:** The application boots and runs, but the network IP settings are such that the device cannot communicate. Resolution:** Abort to the **Configuration Server** and modify network settings with serial console interface.

8.9.3.3 Application Starts, But Traps After Application Initialization

Symptom:** The application boots and can run to the point of initialization (the `init()` function in `UserMain()`), but traps afterwards.

Resolution:** Abort to the **Configuration Server** and upload corrected application.

8.9.3.4 Application Starts, But Traps Before Application Initialization

Symptom:** The application traps immediately upon boot. The Configuration Server is not accessible.

Resolution:** Abort to the **Alternate Boot Monitor** and upload corrected application. Access through the serial console interface or telnet.

8.9.4 Procedure to Abort to the Configuration Server

Abort the boot sequence and run the Configuration Server, accessible on the web interface and serial console interface.

- Run a serial terminal such as MTTY and connect to the device serial console interface.
- Reset or power cycle the module.
- Press the "A" key when the message: `Type "A" to Abort` is displayed. Note that "A" is the default abort command, but the command is configurable in the Configuration Server settings. If the abort command is different, use that command instead of "A".
- At the `>` prompt you can now type serial console commands, or use the web interface if you have network connectivity.
- A new application can be uploaded as described in the Uploading a New Application section.

8.9.5 Uploading a New Application

The following application update methods can be used from the Configuration Server or Alternate Boot Monitor.

8.9.5.1 Web Page Upload

- Locate the device using `discover.netburner.com`, the `localdiscover` utility, or open a web browser and type the device address in the URL field: `<device IP>:20034`. For example, `192.168.1.10:20034`.
- In the Update Application section, select the new .bin file to download and select the Send File button.

8.9.5.2 NBUpdate

- Open a command prompt.
- Type `nbupdate <file name> <device IP>`

8.9.5.3 Serial Console Interface

Note

MTTY is a serial terminal program. You should be able to use any serial terminal program of your choice. When starting the download the binary file must be sent as text or raw data.

Warning

The .bin file is a binary file. You must have serial software flow control disabled. If using MTTTY, from the main menu select `TTY > Flow Control` and uncheck both `Xon/Xoff Input Control` and `Xon/Xoff Input Control`. Otherwise the data stream will be corrupted.

- At the `>` prompt, type `fla` into the serial prompt and then hit enter.
- At the message 'Begin Download', start the file download (if using MTTTY, type the `F5` key).
- When the file window opens, navigate to the .bin application file that you want to load.
- Hit 'Open', and the application will start the load process.

8.9.6 Procedures to Abort to the Alternate Boot Monitor

There are three instances in which the Alternate Boot Monitor is needed for device recovery. A new application can be uploaded as described in the Uploading a New Application section.

8.9.6.1 No Valid Application

If no application had been programmed into the device, or the checksum verification fails when an application is decompressed from Flash to RAM, the Boot Monitor will automatically jump to the Alternate Boot Monitor.

8.9.6.2 Configuration Server Access Operational

If the Configuration Server can run but code updates are not working correctly, the "ABOOT" command can be used on the Serial Console Interface to invoke the Alternate Boot Monitor without having to perform the jumper recovery procedure.

8.9.6.3 Application Traps Before UserMain() Starts

If the application is crashing before `UserMain()` starts, such as a crashing global constructor, access to the Configuration Server is not possible as it is part of the application. Your only choice will be to access the Alternate Boot monitor with the recovery jumper. Please see the recovery jumper procedure section.

8.9.7 Hardware Jumper Recovery

In a situation in which the device is completely unresponsive, continually trapping prior to the "Type A to Abort" prompt, or if there is no access to the device's serial console interface, shorting the recovery pad to ground on the device (referred to as "jumper recovery") can be used to abort the boot process and run the Alternate Boot Monitor. The device will then be ready to receive a new application using any of the procedures described in the download a New Application section.

8.9.7.1 Recovery Jumper Operation

The recovery pad can be shorted with a jumper in two ways:

- **Short Hold:** Boot to Configuration Server. Loads existing configuration and mount file system. Remove shorting jumper right after reset or power-on. The device should now be running the Configuration Server which can be accessed via the serial console interface or web interface.

- **Long Hold:** Boot to Alternate Boot Monitor. Do not load existing configuration or mount file system. Hold shorting jumper in place throughout the entire boot process until the Alternate Boot Monitor command prompt appears in the serial console interface or the network LEDs on the RJ-45 jack become active. Application Flash is not accessible except for the `Erase All` command in the Alternate Boot Monitor. After erasing Flash memory, the next time the device boots it will reset to factory defaults.

Note

A Long Hold will initialize the device to factory default settings, such as network configuration set to [DHCP](#), AutoIP enabled and Local Discovery enabled.

8.9.7.2 Procedure

- Power off the device.
- Short the jumper recovery pad to the nearby ground pad or some other accessible ground location with a shorting jumper or wire.
- Reset or power on the device.
- Hold shorting jumper in place for either a Short Hold or Long Hold.
- Remove the jumper or wire.

8.9.7.3 Recovery Jumper Location

The recovery pad and ground pad are located on the corner of the module between P2 and P3. Using a pair of tweezers may be easiest for shorting the two pads. Alternatively, the recovery pad can be shorted to any ground pin to achieve the same result, which may be easier, especially if using the DEV-SOMRT1061 development board.

Figure 8.6 SOMRT1061 Recovery Jumper Location

8.10 ARM Cache Management

When using some features like DMA or otherwise experiencing cache coherency issues and instability, you may want to disable memory caching.

8.10.1 Details

What happens if memory changes a region AND there is a delayed write to the same region? Who wins? Is this an issue for things like ethernet where both CPU and DMA hardware can both change an area? Whoever writes to RAM later wins: For example if the CPU has the address in the cache and writes to it, and then the Hardware writes to it, then the CPU evicts the cache line and flushes, the CPU wins. If the CPU writes to the RAM first, then the Hardware writes to it, the Hardware wins. Either way, this will be a poorly defined system that will fail in real operations.

Whenever DMA is expected to write to memory, the CPU shall not write to that region. Whenever the CPU needs to read data that DMA has written, unless the region is known to be non-cached, the code shall issue a cache invalidation for the region in question.

Whenever the CPU writes to a region that is cached and needs DMA to read a coherent state of the memory, the software shall issue a cache cleaning for the region in question.

8.10.2 Instructions

8.10.2.1 Turning cache on/off

- `SCB_EnableDCache();`
- `SCB_DisableDCache();`
- `SCB_EnableICache();`
- `SCB_DisableICache();`

8.10.2.2 Declaring static objects non cacheable

Non cacheable objects only live in On Chip FlexRAM which is SRAM. PSRAM is all cached.

To declare a variable as non-cached, use the variable tag `DO_NOT_CACHE`, akin to `FAST_USER_VAR: uint32_t foo DO_NOT_CACHE;`

Note

You cannot assign a static value to non-cached objects.

8.10.2.3 Cleaning Cache

(Making sure all cache -> memory transactions are complete)

- For whole cache:

```
asm("dsb");
SCB_CleanDCache();
```
- For a defined region of memory:

```
asm("dsb");
SCB_CleanDCache_by_Addr(<start address>, <buffer size>);
```

8.10.2.4 Invalidating Cache

(Making sure memory changes make it to cache)

- For whole cache.

```
asm("dsb");
SCB_InvalidateDCache();
```
- For a defined region of memory:

```
asm("dsb");
SCB_InvalidateDCache_by_Addr(<start address>, <buffer size>);
```

Chapter 9

Production & Deployment

9.1 Production Releases and Customer Deployment

Once product development is complete, there are a number of choices for device location and configuration:

- How to find the device on a network
- How to program the application into devices in production
- How to configure devices in production
- How Customers can change configuration settings

Note

Utility source code is located in `\nburn\pctools`, and built versions are in `\nburn\pbin`. You may modify or rebrand these utilities and distribute to your end customers, so long as they are only run with NetBurner target hardware.

9.2 Finding a Device on a Network

A device can be located the following ways:

- If the device and computer have Internet access, open a web browser and go to discover.netburner.com
- Use the `localdiscover` utility. This is a multi-platform utility written in Golang for Windows, macOS and Linux. The compiled version can be distributed to your customers, but not the Golang source code.
- The Python `find` utility, located in `\nburn\pctools\find`.
- Use the debug/console serial port

9.3 Application Programming

Applications are programmed into flash memory by sending an application image to the device's configuration server, located at its IP address on port 20034. This can be done in a number of ways, all of which are multi-platform (Windows, macOS, and Linux):

- A web browser from the device's configuration server web page
- The nbupdate command-line utility
- The WGET command-line utility
- A serial port using the serial command processor

9.3.1 Configuration Web Page

To send a file from a web browser, enter the URL of your device. The URL format is "<ip address>:<port number>", such as: "10.1.1.100:20034". Once at the web page, browse for the application image file and select "Update".

9.3.2 nbupdate Utility

nbupdate is a multi-platform command-line utility written by NetBurner. The format is: `nbupdate <filename> <ip address>`. For example, `nbupdate myApp.bin 10.1.1.196`, or `nbupdate myApp.s19 10.1.1.196`.

If the environment variable DEVIP is set the IP address parameter is not required. For example, `SET DEVIP=10.1.1.196`. Now you can call nbupdate with only the application file name. To determine the current setting of DEVIP, type "SET DEVIP".

9.3.3 wget Utility

WGET is an industry standard utility that allows you to download files over TCP/IP protocols FTP, HTTP and HTTPS. If you are using macOS or Linux, WGET is usually already installed (or can using your package manager). Windows users will need to install it, please refer to <https://www.gnu.org/software/wget/>.

The WGET utility can be used for a number of things:

- Updating the device application image
 - Retrieving device configuration information in JASON
 - Updating device configuration information in JASON
- In the examples below we use an example device IP address of 10.1.1.60, and an application name of myApplication.bin.

9.3.3.1 Program an Application

To program a new application into the device:

```
wget --post-file=myApplication.bin 10.1.1.60:20034/appupdate.html
```

All updates are processed by the Configuration Server running on the device. The `--post-file` specifies a POST operation is to be performed. The IP address and configuration port number are next, along with the server post destination that will always be appupdate.html.

If using authentication with a username of "user", and password of "pass":

```
wget --auth-no-challenge --user=user --password=pass --post-file=myApplication.↵
bin 10.1.1.60:20034/appupdate.html
```

9.3.3.2 Read The Configuration

Read the current configuration into a file named config.txt: `wget 10.1.1.60:20034/Config`.

In this case the destination is Config, rather than appupdate.html.

If you would like to specify a directory to store the file, use the `-P` option: `wget 10.1.1.60:20034/Config -P \myDir`

9.3.3.3 Program New Configuration Settings

The easiest way to do this is to first read the configuration and save to a file so you have a template to work with, then edit the settings you need. Then post the configuration file to each new device:

```
wget --post-file=newconfig 10.1.1.60:20034/Config
```

9.4 NetBurner SSL Certificate Upload Commands

9.4.1 Overview

NetBurner devices provide a web interface for uploading SSL/TLS certificates and private keys. The web form submits to the `/httpsform` endpoint using HTTP POST with `multipart/form-data` encoding, expecting two file fields:

- `certificateFile` - The SSL certificate file (*.crt)
- `keyFile` - The private key file (*.key)

9.4.2 Requirements

- RSA key sizes must be at least 512 and no more than 4096 bits in OpenSSH/OpenSSL format
- ECDSA key sizes must be at least 192 and no larger than 256 bits
- Files should be in standard certificate (*.crt) and key (*.key) formats

9.4.3 Linux/Unix Commands

9.4.3.1 Using curl (Recommended)

```
curl -X POST \
  -F "certificateFile=@certificate.crt" \
  -F "keyFile=@private.key" \
  http://YOUR_DEVICE_IP/httpsform
```

9.4.3.2 Using wget (Simple approach)

```
# Create the multipart body in a temporary file
cat > /tmp/ssl_upload.txt « 'EOF'
-----WebKitFormBoundary7MA4YWxkTrZu0gW
Content-Disposition: form-data; name="certificateFile"; filename="certificate.crt"
Content-Type: application/x-x509-ca-cert

EOF

cat certificate.crt » /tmp/ssl_upload.txt

cat » /tmp/ssl_upload.txt « 'EOF'

-----WebKitFormBoundary7MA4YWxkTrZu0gW
Content-Disposition: form-data; name="keyFile"; filename="private.key"
Content-Type: application/x-pem-file

EOF

cat private.key » /tmp/ssl_upload.txt

echo "-----WebKitFormBoundary7MA4YWxkTrZu0gW--" » /tmp/ssl_upload.txt

# Submit with wget
wget --post-file=/tmp/ssl_upload.txt \
```

```
--header="Content-Type: multipart/form-data; boundary=---WebKitFormBoundary7MA4YWxkTrZu0gW" \
http://YOUR_DEVICE_IP/httpsform

# Clean up
rm /tmp/ssl_upload.txt
```

9.4.4 Windows PowerShell Commands

9.4.4.1 Method 1: Using Invoke-RestMethod (Recommended)

```
$deviceIP = "YOUR_DEVICE_IP"
$certFile = "certificate.crt"
$keyFile = "private.key"

$form = @{
    certificateFile = Get-Item -Path $certFile
    keyFile = Get-Item -Path $keyFile
}

Invoke-RestMethod -Uri "http://$deviceIP/httpsform" -Method Post -Form $form
```

9.4.4.2 Method 2: Using Invoke-WebRequest

```
$deviceIP = "YOUR_DEVICE_IP"
$certFile = "certificate.crt"
$keyFile = "private.key"

$form = @{
    certificateFile = Get-Item -Path $certFile
    keyFile = Get-Item -Path $keyFile
}

Invoke-WebRequest -Uri "http://$deviceIP/httpsform" -Method Post -Form $form
```

9.4.4.3 Method 3: Manual multipart construction

```
$deviceIP = "YOUR_DEVICE_IP"
$certFile = "certificate.crt"
$keyFile = "private.key"
$boundary = "---WebKitFormBoundary7MA4YWxkTrZu0gW"

# Read file contents
$certContent = Get-Content -Path $certFile -Raw
$keyContent = Get-Content -Path $keyFile -Raw

# Build multipart body
$body = @"
--$boundary
Content-Disposition: form-data; name="certificateFile"; filename="certificate.crt"
Content-Type: application/x-x509-ca-cert

$certContent
--$boundary
Content-Disposition: form-data; name="keyFile"; filename="private.key"
Content-Type: application/x-pem-file

$keyContent
--$boundary--
"@

# Convert to bytes
$bodyBytes = [System.Text.Encoding]::UTF8.GetBytes($body)

# Set headers
$headers = @{
    "Content-Type" = "multipart/form-data; boundary=$boundary"
}

# Send request
Invoke-RestMethod -Uri "http://$deviceIP/httpsform" -Method Post -Body $bodyBytes -Headers $headers
```

9.4.5 Windows Command Prompt

9.4.5.1 Method 1: Using curl (Windows 10/11)

```
curl -X POST -F "certificateFile=@certificate.crt" -F "keyFile=@private.key" http://YOUR_DEVICE_IP/httpsform
```

9.4.5.2 Method 2: PowerShell one-liner from Command Prompt

```
powershell -Command "Invoke-RestMethod -Uri 'http://YOUR_DEVICE_IP/httpsform' -Method Post -Form
@{certificateFile = Get-Item -Path 'certificate.crt'; keyFile = Get-Item -Path 'private.key'}"
```

9.4.5.3 Method 3: Batch file approach

Create upload_ssl.bat:

```
@echo off
set DEVICE_IP=YOUR_DEVICE_IP
set CERT_FILE=certificate.crt
set KEY_FILE=private.key
set BOUNDARY=----WebKitFormBoundary7MA4YWxkTrZu0gW

echo Creating multipart data...

(
echo --%BOUNDARY%
echo Content-Disposition: form-data; name="certificateFile"; filename="%CERT_FILE%"
echo Content-Type: application/x-x509-ca-cert
echo.
type "%CERT_FILE%"
echo.
echo --%BOUNDARY%
echo Content-Disposition: form-data; name="keyFile"; filename="%KEY_FILE%"
echo Content-Type: application/x-pem-file
echo.
type "%KEY_FILE%"
echo.
echo --%BOUNDARY%--
) > temp_upload.txt

powershell -Command "$body = Get-Content -Path 'temp_upload.txt' -Raw; $headers = @{'Content-Type' =
'multipart/form-data; boundary=%BOUNDARY%'}; Invoke-RestMethod -Uri 'http://%DEVICE_IP%/httpsform'
-Method Post -Body ([System.Text.Encoding]::UTF8.GetBytes($body)) -Headers $headers"

del temp_upload.txt
echo Upload complete!

Then run:
upload_ssl.bat
```

9.4.6 Usage Notes

1. **Replace placeholders:** Change YOUR_DEVICE_IP to your actual NetBurner device IP address
2. **File paths:** Adjust certificate and key file names/paths as needed
3. **File location:** Ensure certificate and key files are accessible from the command execution directory
4. **Network access:** The NetBurner device must be reachable on your network
5. **File formats:** Use standard OpenSSL/OpenSSH certificate and key formats

9.4.7 Recommended Approaches

- **Linux/Unix:** Use curl for simplicity and reliability
- **Windows PowerShell:** Use Invoke-RestMethod with -Form parameter
- **Windows Command Prompt:** Use curl if available, otherwise PowerShell one-liner

9.4.8 Troubleshooting

- Verify the device IP address is correct and reachable
- Ensure certificate and key files are in the correct format
- Check that files exist in the specified paths
- Confirm the NetBurner device web interface is accessible
- Verify RSA key size requirements (512-4096 bits) or ECDSA (192-256 bits)

9.4.9 Security Considerations

- Use secure connections when possible
- Protect private key files with appropriate file permissions
- Consider using HTTPS if the NetBurner device supports it
- Store certificates and keys securely

9.5 Customer Configuration

Once deployed, your customers can modify the configuration by:

- Using the interactive web interface at 10.1.1.60:20034. Note that you can create your own web interface to override the default NetBurner interface, and use your custom brand.
- If connected to the Internet, a web browser at: discover.netburner.com, which provides a link to the device configuration page and also the device's main web page on port 80.
- The NetBurner localdiscover utility, which provides a link to the device configuration page, and also the device's main web page on port 80.
- Using WGET
- Your application can provide the means to change configuration

Chapter 10

Programmers Guide

10.1 Overview

This guide provides comprehensive information on fundamental concepts in the NetBurner development system. The documents cover both introductory material and advanced topics to support embedded network application development.

10.2 Table of Contents

- [About This Guide](#)
- [Introduction](#)
- [Config Server Programming Guide](#)
- [Custom Branding](#)
- [IPv4/IPv6 Dual Stack Guide](#)
- [EFS Programming Guide](#)
- [File Descriptors](#)
- [HTML Processing](#)
- [Interrupt Handling](#)
- [JSON Lexer](#)

10.3 About This Guide

10.3.1 Guide Navigation

10.3.1.1 Quick Start Path

For developers new to NetBurner, follow this learning path:

[Start Here](#)

10.3.1.2 By Use Case

10.3.1.2.1 Web Application Development

- Introduction to NetBurner Programming
- Web Server Programming
- HTML Processing Techniques
- Configuration Server

10.3.1.2.2 Real-Time Systems

- NetBurner RTOS
- Interrupt Handling
- File Descriptors

10.3.1.2.3 Network Programming

- Network Protocols Guide
- IPv4-IPv6 Dual Stack
- SSL/TLS Security
- SSH Protocol

10.3.1.2.4 Data Management

- JSON Lexer
- EDFS File System
- Configuration Server

10.3.1.2.5 Product Deployment

- Custom Branding Options
- Configuration Management
- Security Implementation

10.3.2 Document Descriptions

10.3.2.1 Introduction to NetBurner Programming

Focus:** Getting started with NetBurner development Key Topics:**

- Development environment setup
- First application creation
- Template application structure
- System initialization
- Core functions and constants

When to Read:** Start here if you are new to NetBurner

Architecture Overview:**

10.3.2.2 Configuration Server

Focus:** Device configuration and settings management Key Topics:**

- Configuration system architecture
- Web-based configuration interface
- Serial configuration access
- AppData structure usage
- System settings management

When to Read:** When you need persistent device settings

Configuration Hierarchy:**

10.3.2.3 Custom Branding

Focus:** OEM customization and white-label solutions Key Topics:**

- Logo replacement options
- Custom web interfaces
- Physical device labeling
- Discovery utility customization

- Cloud infrastructure replacement

When to Read:** When deploying products with your brand

Branding Layers:**

Your Brand Identity
Custom Web Interface
Device Labels
Network Discovery
NetBurner Platform

10.3.2.4 IPv4-IPv6 Dual Stack

Focus:** Dual-stack networking implementation Key Topics:**

- IPADDR object changes
- IPv6 address assignment
- DNS resolution strategies
- Migration from IPv4-only code
- Platform-specific considerations

When to Read:** When supporting both IPv4 and IPv6

IP Address Evolution:**

IPv4 Only (Pre-2.8.0)	Dual Stack (2.8.0+)

10.3.2.5 EFFS File System

Focus:** Embedded Flash File System operations Key Topics:**

- File system initialization
- File operations (open, read, write, close)
- Directory management
- Flash memory considerations
- Performance optimization

When to Read:** When using file storage in your application

File System Stack:**

Application File I/O
POSIX-like API
EFFS Implementation
Flash Memory Hardware

10.3.2.6 File Descriptors

Focus:** Unified I/O abstraction layer Key Topics:**

- File descriptor architecture
- Standard I/O operations
- TCP socket integration
- Serial port access
- Custom I/O driver creation

When to Read:** When implementing I/O operations or custom drivers

File Descriptor Map:**

FD Range Purpose

0-2	>	Standard I/O
3-4	>	Serial Ports
5-128	>	TCP Sockets
129-250	>	Custom Drivers

10.3.2.7 HTML Processing

Focus:** Dynamic web content generation Key Topics:**

- CPPCALL tag usage
- VARIABLE tag implementation
- INCLUDE tag for linking
- Custom data type display
- Web server integration

When to Read:** When creating dynamic web interfaces

Dynamic Content Flow:**

HTML File

C++ Code

10.3.2.8 Interrupt Handling

Focus:** Hardware interrupt processing Key Topics:**

- Preemptive interrupt architecture
- ISR implementation patterns
- Platform-specific setup
- Interrupt priorities
- Safe ISR practices

When to Read:** When handling hardware events and interrupts

Interrupt Flow:**

10.3.2.9 JSON Lexer

Focus:** JSON parsing and data access Key Topics:**

- [ParsedJsonDataSet](#) usage
- [JsonRef](#) navigation
- Type conversion
- Validation functions
- Performance optimization

When to Read:** When parsing JSON data from web APIs or files

JSON Access Pattern:**

10.3.2.10 NetBurner RTOS

Focus:** Real-Time Operating System concepts Key Topics:**

- Task creation and management
- Priority-based scheduling
- Inter-task communication
- Synchronization primitives
- System configuration

When to Read:** When implementing multi-tasking applications

RTOS Components:**

User Tasks
- Semaphores - Mailboxes - Queues - Flags
Task Scheduler
Hardware Platform

10.3.2.11 Network Protocols

Focus:** TCP/IP stack and protocol implementation Key Topics:**

- TCP socket programming
- UDP communication
- [MQTT](#) client usage
- Protocol best practices
- Network debugging

When to Read:** When implementing network communication

Network Stack:**

Application Protocols (HTTP, MQTT , Custom)
Transport Layer (TCP, UDP)
Network Layer (IPv4, IPv6)
Link Layer (Ethernet, WiFi)

10.3.2.12 SSL-TLS Security

Focus:** Secure communication implementation Key Topics:**

- SSL/TLS configuration
- Certificate management
- Secure server setup
- Client authentication
- Security best practices

When to Read:** When implementing secure communications

Security Layers:**

Application Data
SSL/TLS Encryption
TCP Transport
IP Network

10.3.2.13 SSH Protocol

Focus:** Secure Shell implementation Key Topics:**

- SSH server configuration
- Key management
- Secure remote access
- Authentication methods

- Session management

When to Read:** When providing secure remote access

SSH Architecture:**

10.3.2.14 Web Server

Focus:** Embedded HTTP server programming Key Topics:**

- Web server architecture
- Static content serving
- Dynamic content generation
- Form processing
- Resource management

When to Read:** When building web-based interfaces

Web Server Architecture:**

10.3.3 Development Workflow

10.3.3.1 Typical Application Development Process

1. Requirements Analysis

2. Architecture Design

3. Implementation

4. Integration

10.3.4 Common Implementation Patterns

10.3.4.1 Pattern 1: Web-Based Device Control

Components Used:**

- Introduction (basics)
- Web Server (interface)
- RTOS (task management)
- Configuration Server (settings)

Architecture:**

10.3.4.2 Pattern 2: Network Data Logger

Components Used:**

- Network Protocols (communication)
- EDFS (data storage)
- JSON Lexer (data format)
- Configuration (settings)

Architecture:**

10.3.4.3 Pattern 3: Secure Remote Monitoring

Components Used:**

- SSL/TLS (security)
- SSH (remote access)
- Web Server (interface)
- Interrupt Handling (events)

Architecture:**

Secure Connection

10.3.5 Cross-Reference Guide

10.3.5.1 By Task

10.3.5.1.1 Setting Up Network Communication

1. Introduction - Basic network initialization
2. Network Protocols - Protocol implementation
3. IPv4-IPv6 Dual Stack - IP version support
4. File Descriptors - Socket I/O

10.3.5.1.2 Creating User Interfaces

1. Web Server - HTTP server basics
2. HTML Processing - Dynamic content
3. Configuration Server - Built-in UI
4. Custom Branding - UI customization

10.3.5.1.3 Managing Data

1. JSON Lexer - Data parsing
2. EDFS File System - Storage
3. Configuration Server - Settings persistence
4. File Descriptors - I/O operations

10.3.5.1.4 Implementing Real-Time Features

1. NetBurner RTOS - Task management
2. Interrupt Handling - Hardware events
3. File Descriptors - Device I/O
4. Network Protocols - Communication

10.3.5.1.5 Securing Your Application

1. SSL/TLS Security - Encrypted communication
 2. SSH Protocol - Secure access
 3. Configuration Server - Access control
 4. Custom Branding - Security customization
-

10.3.6 Quick Start Checklist

10.3.6.1 Essential Reading for New Developers

- [] 1. Read Introduction
 - Understand UserMain()
 - Learn `init()` function
 - Study example code
- [] 2. Review RTOS Basics
 - Task creation
 - Basic synchronization
 - System timing
- [] 3. Explore Web Server
 - Static content
 - Dynamic tags
 - Basic callbacks
- [] 4. Study Configuration
 - System settings
 - Application data
 - Web interface
- [] 5. Understand File Descriptors
 - I/O abstraction
 - Network sockets
 - Serial ports

10.3.6.2 Advanced Topics Preparation

- [] Master RTOS features
 - All synchronization types
 - Task priorities
 - System configuration
- [] Network programming
 - TCP/UDP sockets
 - Protocol implementation
 - IPv4/IPv6 support
- [] Security implementation
 - SSL/TLS setup
 - SSH configuration

```

- Certificate management
[ ] Custom development
  - Interrupt handlers
  - Custom drivers
  - Branding options

```

10.3.7 Document Conventions

10.3.7.1 Code Examples

Throughout this guide, code examples use the following conventions:

```

// Full working examples are marked
void ExampleFunction() {
    // Code here...
}
// Tested
// Conceptual examples show patterns
void ConceptualExample() {
    // Pseudocode or simplified logic
}

```

10.3.7.2 Platform References

Platform-specific information is clearly marked:

- **All Platforms** - Universal features
 - **MCF5441x** - ColdFire specific
 - **SAME70** - Cortex-M7 specific
 - **SOMRT1061** - i.MX RT specific
-

10.3.8 Getting Help

10.3.8.1 Documentation Resources

10.3.9 Version Information

This Programmer's Guide is maintained alongside the NetBurner Network Development Kit (NNDK). Always refer to the documentation version matching your NNDK release.

Document Organization:**

- Each major topic has a dedicated section
 - Cross-references guide related topics
 - Examples demonstrate practical implementation
-

10.3.10 Next Steps

After reviewing this main guide:

1. **Begin with Introduction** for fundamental concepts
2. **Choose topic areas** based on your application needs
3. **Study example projects** in the SDK
4. **Implement incrementally** building on working examples
5. **Refer to API documentation** for detailed function references

10.4 Introduction

10.4.1 Intro to NetBurner Programming

10.4.2 Overview

The NetBurner Programming Guide provides a comprehensive overview of the features and capabilities of the NetBurner Network Development Kit (NNDK). This guide focuses on practical implementation of network applications using NetBurner hardware, software, and development tools through a hands-on, example-driven approach.

10.4.3 Prerequisites

Before beginning this guide, ensure you have:

- **Installed** the NetBurner Network Development Kit
- **Configured** a running NetBurner device on your network
- **Familiarity** with either:
 - NBEclipse development environment (see NBEclipse Getting Started Guide), or
 - Command-line tools and your preferred development environment
- **Knowledge** of your target device's network configuration
- **Successfully** created and deployed a test project to your target device

10.4.4 Learning Approach

This guide employs a **learn-by-example** methodology. Each example builds upon a foundational template application that serves as a starting point for most NetBurner projects. Progressive examples demonstrate increasingly complex networking capabilities.

Development Flow

10.4.5 Source Code Location

All example programs referenced in this guide are located in the following directory:

<NNDK_ROOT>/examples/

Where <NNDK_ROOT> is your NetBurner tools installation directory.

10.4.6 Creating Your First Application

10.4.6.1 Using the NBEclipse Application Wizard

The quickest way to start is with the NBEclipse Application Wizard:

1. Launch NBEclipse and create a new project
2. Select the following wizard options:
 - **Standard Initialization**
 - **Web Server**
3. Complete the wizard to generate your project

If you're unfamiliar with NBEclipse, consult the NBEclipse Getting Started Guide before proceeding.

10.4.6.2 Template Application Structure

The Application Wizard generates a `main.cpp` file with the following structure:

```
#include <predef.h>           // System level options and definitions
#include <init.h>             // Initialization functions
#include <stdio.h>            // Standard I/O functions
#include <nbrtos.h>           // NetBurner Real Time Operating System (RTOS)
#include <http.h>             // HTTP functions

const char * AppName = "AppWizard";    // Application name for discovery

void UserMain(void * pd)
{
    init();                          // Initialize system
    WaitForActiveNetwork(TICKS_PER_SECOND * 5); // Wait up to 5 seconds
    StartHttp();                     // Start web server

    printf("Application %s started\n", AppName);

    while (1)                        // Main application loop
    {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

10.4.6.3 Application Execution Flow

10.4.7 Key System Functions

10.4.7.1 init()

The `init()` function performs critical system initialization:

- **stdio Configuration:** Initializes standard I/O to the debug/console port
- **Configuration Processing:** Reads system settings including:
 - Network interface parameters
 - Serial port configuration
 - Boot options
- **Network Stack:** Initializes the TCP/IP stack
- **Task Priority:** Sets `UserMain()` priority to `MAIN_PRIO`
- **Task Monitor:** Enables task monitoring utilities
- **Debug Support:** Activates GDB debugger in debug builds

10.4.7.2 WaitForActiveNetwork()

Blocks execution until a network link is established or timeout occurs.

Parameters:**

- Timeout value in system ticks
- Use `TICKS_PER_SECOND` constant for time calculations

Example:**

```
WaitForActiveNetwork(TICKS_PER_SECOND * 5); // Wait up to 5 seconds
```

10.4.7.3 StartHttp()

Launches the HTTP web server.

Default Configuration:**

- Port: 80 (standard HTTP)
 - Can specify alternate port: `StartHttp(8080)`
- Secure Alternative:**
- Use `StartHttps()` for SSL/TLS support

10.4.8 Output Functions

10.4.8.1 printf() vs printf()

NetBurner supports both standard output functions:

Function	Description	Use Case
<code>printf()</code>	Full formatting support including floating-point	General purpose output
<code>printf()</code>	Integer-only formatting	Resource-constrained applications

Recommendation:** Use `printf()` when floating-point output is not required to conserve system resources.

Example:**

```
printf("Application %s started\n", AppName);
printf("Network IP: %d.%d.%d.%d\n", ip[0], ip[1], ip[2], ip[3]);
```

10.4.9 Application Design Principles

10.4.9.1 The Main Loop

Your application **must never return** from `UserMain()`. The standard pattern uses an infinite loop:

```
while (1)
{
    OSTimeDly(TICKS_PER_SECOND); // Yield CPU periodically
}
```

10.4.9.2 Timing Considerations

Always use `TICKS_PER_SECOND` for time-based calculations:

```
// Correct: Portable timing
OSTimeDly(TICKS_PER_SECOND * 2); // Delay 2 seconds

// Avoid: Hard-coded tick values
OSTimeDly(200); // Not portable!
```

Why? The `TICKS_PER_SECOND` constant ensures code portability if system tick rates change across platforms or configurations.

10.4.9.3 Resource Management

Application Resource Flow

10.4.10 Next Steps

With this foundation, you're ready to explore:

1. **Network Communication** - TCP/IP, UDP protocols
2. **Web Server Development** - Dynamic content, forms, APIs
3. **Serial Communications** - UART configuration and protocols
4. **Real-Time Features** - Task management, interrupts
5. **Advanced Topics** - SSL/TLS, [MQTT](#), custom protocols

Each subsequent section builds upon this template application, adding functionality progressively.

10.4.11 Quick Reference

10.4.11.1 Critical Constants

```
TICKS_PER_SECOND // System tick rate
MAIN_PRIO        // UserMain task priority
```

10.4.11.2 Core Functions

```
init() // System initialization
WaitForActiveNetwork(ticks) // Network wait
StartHttp() // HTTP server
StartHttps() // HTTPS server
OSTimeDly(ticks) // Task delay
printf(format, ...) // Stdout printf
```

10.4.12 Architecture Overview

NetBurner Application Stack

10.5 Config Server Programming Guide

10.5.1 Configuration Server Programming Guide

10.5.2 Introduction

The NetBurner Configuration System provides a comprehensive solution for managing system and application settings stored in flash memory. This system enables configuration through multiple interfaces while maintaining data persistence across power cycles.

10.5.2.1 Configuration System Overview

10.5.2.2 Access Methods

The configuration data can be accessed and modified through multiple interfaces:

1. **System Configuration Web Server** - Port 20034
2. **Application Code** - Direct programmatic access
3. **Custom Web Interface** - Your own web pages
4. **Serial Config Server** - Command-line interface via UART

10.5.2.3 Key Features

- **Persistent Storage** - All settings saved to flash memory
- **JSON Format** - Configuration stored as JSON blobs
- **Hierarchical Structure** - Tree-based organization with leaves
- **Flexible Access** - Modify entire JSON or individual components

- **Version Control** - Automatic version tracking on updates
- **Application Upload** - Built-in firmware update capability

10.5.3 Configuration Structure

The configuration system uses a hierarchical tree structure with distinct branches for system and application data.

10.5.3.1 Configuration Tree Hierarchy

10.5.3.2 Root Level: Config

The top-level Config object contains:

Field	Type	Description
Version	Integer	Automatically updated when settings saved
Reboot	Boolean	Forces module reboot when configuration updated
AppData	Object	User application data container
Sys	Object	System settings container

Example Structure:**

```

{
  "Config": {
    "Version": 15,
    "Reboot": false,
    "AppData": { ... },
    "Sys": { ... }
  }
}

```

10.5.4 Config.AppData

The AppData leaf is dedicated to user application data, providing a designated space for custom settings and parameters.

10.5.4.1 Purpose and Usage

10.5.4.2 Available Configuration Objects

The system provides various typed configuration objects:

- **config_string** - Text values
- **config_int** - Integer values
- **config_bool** - Boolean values
- **config_chooser** - Selection lists/dropdowns
- **Custom Objects** - User-defined structures

10.5.4.3 Example: Application Settings

```
// Define application configuration
namespace AppConfig
{
    config_string deviceName("DeviceName", "Device-001",
                             "Display name for this device");

    config_int sampleRate("SampleRate", 1000,
                          "Sensor sampling rate (Hz)");

    config_bool enableLogging("EnableLogging", true,
                              "Enable data logging");

    config_chooser mode("Mode",
                       {"Normal", "Debug", "Production"},
                       0, "Operating mode");
}
```

10.5.4.4 Configuration Object Hierarchy

For detailed examples**, see:

- BasicConfigVariable example
- \examples\Configuration\BasicConfigVariable

10.5.5 Config.Sys - System Settings

The Sys leaf contains all device system settings including boot parameters and network configuration.

10.5.5.1 System Configuration Tree

10.5.6 Config.Sys.Boot - Boot Settings

Boot settings control system startup behavior, security, and serial configuration access.

10.5.6.1 Boot Configuration Parameters

Parameter	Type	Description
Abort	String	Key sequence to interrupt boot (default: "A")
BootBaud	Integer	Baud rate for boot UART
BootDelay	Integer	Wait time for abort sequence (seconds)
BootQuiet	Boolean	Suppress boot output messages
BootUart	Integer	UART number for boot output
Password	String	Configuration/upload password
User	String	Configuration/upload username
SerialConfig	Enum	Serial config server mode

10.5.6.2 Boot Process Flow

10.5.6.3 Serial Config Server Modes

The `SerialConfig` parameter offers four operational modes:

10.5.6.3.1 Mode Descriptions

DuringBoot (Recommended)**

- Serial config available only during boot
 - Use abort character sequence to enter
 - Safe for production use
- AlwaysEnabled (Use with Caution)**
- Serial config always accessible via BootUart

- May interfere with application serial I/O
- Risk of accidental config corruption
PauseAfterBoot**
- Boot pauses after `init()` called
- Serial config enabled automatically
- Type `boot` to resume application
Disabled**
- Serial config completely disabled
- No boot interruption possible
- Maximum security, no serial access

10.5.6.4 Security Configuration

When both User and Password are set:

- Required for configuration changes
- Required for application uploads
- Protects against unauthorized access

10.5.7 Config.Sys.NetIf - Network Interfaces

The `NetIf` section contains settings for all network interfaces including Ethernet and WiFi.

10.5.7.1 Network Interface Tree

10.5.7.2 Common Interface Parameters

Parameter	Description
DeviceName	Interface name for DDNS/NetBIOS registration
DhcpDiscoverSec	Delay before DHCP Discover (seconds)
DiscoveryReportInterval	Device discovery report frequency
DiscoveryReportUrl	Discovery server URL
MAC	Interface MAC address

10.5.7.3 Discovery Configuration

Device Discovery

Discovery Options:**

- **Default:** Reports to NetBurner's discovery server
- **Custom:** Set your own discovery server URL
- **Disabled:** Leave URL blank to disable reporting

10.5.8 Config.Sys.NetIf.Ethernet0.IPv4

IPv4 configuration settings for Ethernet interfaces.

10.5.8.1 IPv4 Settings Overview

10.5.8.2 IPv4 Parameters

10.5.8.2.1 Active Settings (Read-Only)

Parameter	Description
ActiveAddr	Current IPv4 address in use
ActiveDNS1	Current primary DNS server
ActiveDNS2	Current secondary DNS server
ActiveGate	Current gateway address
ActiveMask	Current subnet mask
AutoIPAddr	Auto-assigned IP (if applicable)
AutoIPEn	Auto-IP enabled status

10.5.8.2.2 Static Settings (User Configurable)

Parameter	Description
StaticAddr	Manually configured IP address
StaticDNS1	Manually configured primary DNS
StaticDNS2	Manually configured secondary DNS
StaticGate	Manually configured gateway

StaticMask	Manually configured subnet mask

10.5.8.3 IPv4 Mode Selection

The Mode parameter determines how IPv4 settings are obtained:

10.5.8.3.1 Mode Descriptions

DHCP**

- Obtain all settings from **DHCP** server
- If **DHCP** fails, no network connectivity
- **DHCP with Fallback****
- Try **DHCP** first
- Fall back to static values if **DHCP** unavailable
- Recommended for most applications

Static**

- Use manually configured static values
- No **DHCP** attempts

Disabled**

- Interface completely disabled
- No network activity

10.5.9 Config.Sys.NetIf.Ethernet0.IPv6

IPv6 configuration settings for Ethernet interfaces.

10.5.9.1 IPv6 Settings Overview

10.5.9.2 IPv6 Parameters

10.5.9.2.1 Active Settings (Read-Only)

Parameter	Description
ActiveAddr	Array of active IPv6 addresses
ActiveDNS	Array of active IPv6 DNS servers
ActiveRoutes	Array of active IPv6 routes

10.5.9.2.2 Static Settings (User Configurable)

Parameter	Description
StaticAddr	Manually configured IPv6 address
StaticDNS1	Manually configured primary IPv6 DNS
StaticDNS2	Manually configured secondary IPv6 DNS

10.5.9.3 IPv6 Mode Selection

Similar to IPv4, the Mode parameter offers:

- **DHCP** - DHCPv6/SLAAC automatic configuration
- **DHCP w/Fallback** - Try auto-config, fall back to static
- **Static** - Use manually configured values
- **Disabled** - Disable IPv6 on interface

10.5.10 Configuration Web Interface

The configuration web server runs on **port 20034** and provides a full-featured interface for viewing and modifying settings.

10.5.10.1 Accessing the Web Interface

Example URL**: <http://10.1.1.100:20034>

10.5.10.2 Web Interface Features

10.5.10.2.1 Navigation Controls

10.5.10.2.2 Action Buttons

Button	Function	Action
Expand All	Expand entire tree	Shows all configuration branches
Collapse All	Collapse entire tree	Hides all sub-branches
Update Record	Save changes	Writes current values to flash
Download Config	Export configuration	Downloads JSON file
Restore Config	Import configuration	Uploads JSON file
Raw Config Page	View raw interface	Shows unformatted JSON editor
NB Discover	NetBurner discovery	Opens discover.netburner.com
Discover Local	Local network scan	Finds devices without internet

10.5.10.3 Application Update Feature

Application Update Process

Update Steps:**

1. Click "Choose File" button
2. Select compiled .bin file
3. Click "Send File" to upload
4. Wait for verification and programming
5. Device automatically reboots with new application

10.5.11 Serial Configuration Interface

The serial configuration interface provides command-line access to the configuration system via UART.

10.5.11.1 Accessing Serial Config

10.5.11.2 Serial Config Prompt

When successfully entered, you'll see:

```
>
```

As you navigate, the prompt shows your location:

```

>                                     # Root level
Config.Sys>                         # In Sys branch
Config.Sys.Boot>                   # In Boot settings

```

10.5.11.3 Navigation Model

The serial config operates like a file system:

10.5.11.4 Serial Config Commands

Command	Syntax	Description
help	help	Display all available commands
boot	boot	Exit config server and boot application
reboot	reboot	Restart the module
flash	flash	Upload new application via serial
ls	ls	List current level contents
..	..	Move up one level in tree
<var>?	Config?	Display variable contents
<var>=<val>	Boot.Abort="B"	Set variable value
save	save	Save changes to flash

10.5.11.5 Command Examples

10.5.11.5.1 Viewing Configuration

```

> Config?
{
  "Version": 15,
  "Reboot": false,

```

```

    "AppData": {...},
    "Sys": {...}
}

> Config.Sys.Boot?
{
  "Abort": "A",
  "BootBaud": 115200,
  "BootDelay": 3,
  ...
}

```

10.5.11.5.2 Modifying Settings

```

> Config.Sys.Boot
Config.Sys.Boot> Abort="B"
Config.Sys.Boot> BootDelay=5
Config.Sys.Boot> save
Configuration saved.
Config.Sys.Boot> ..
Config.Sys> boot
Continuing boot...

```

10.5.11.5.3 Navigation Example

```

> Config
Config> Sys
Config.Sys> NetIf
Config.Sys.NetIf> Ethernet0
Config.Sys.NetIf.Ethernet0> IPv4
Config.Sys.NetIf.Ethernet0.IPv4> ls
ActiveAddr
ActiveDNS1
ActiveDNS2
Mode
StaticAddr
...
Config.Sys.NetIf.Ethernet0.IPv4> ..
Config.Sys.NetIf.Ethernet0> ..
Config.Sys.NetIf> ..
Config.Sys> ..
Config> ..
>

```

10.5.11.6 Uploading Application via Serial

Serial Flash Process

Steps:**

1. Enter serial config mode
2. Type `flash` and press Enter
3. In MTTTY: Press F5 to open file dialog
4. Select your `.bin` file
5. Wait for transfer and programming
6. Device reboots automatically

10.5.12 Creating a Custom Web Interface

The configuration web interface can be completely customized with your own design, branding, and functionality.

10.5.12.1 Customization Workflow

10.5.12.2 Steps to Customize

10.5.12.2.1 Option 1: Replace System Interface

1. **Locate system file:**
`<NNDK Install Directory>\nbrtos\source\ROOT.html`
2. **Create your custom ROOT.html**
3. **Rebuild system libraries:**
 - Follow NBEclipse Getting Started Guide
 - Rebuild system libraries section

10.5.12.2.2 Option 2: Replace Logo Only

1. **Locate logo file:**
`<NNDK Install Directory>\nbrtos\source\LOGO.gif`
2. **Replace with your logo image**
3. **Rebuild system libraries**

10.5.12.3 Custom Interface Example

A complete example demonstrating the current config web interface structure is available:

Location:**

`<NNDK Install Directory>\examples\Configuration\BasicWebConfig`

This example shows:

- HTML structure
- JavaScript interaction
- CSS styling
- Configuration API usage

10.5.13 Configuration API Examples

NetBurner provides comprehensive examples demonstrating various aspects of the configuration system.

10.5.13.1 Example Projects Overview

10.5.13.2 Available Examples

10.5.13.2.1 1. BasicConfigVariable

Location:** <NNDK>\examples\Configuration\BasicConfigVariable
Demonstrates:**

- Basic config object usage
- Creating config variables
- Reading and writing values
- Saving to flash

Key Concepts:**

```

// String configuration
config_string deviceName("Name", "Device-001", "Device identifier");

// Integer configuration
config_int sampleRate("Rate", 1000, "Sample rate in Hz");

// Boolean configuration
config_bool enabled("Enabled", true, "Feature enabled");

// Reading values
const char* name = deviceName.c_str();
int rate = sampleRate;
bool isEnabled = enabled;

// Writing values
deviceName = "Device-002";
sampleRate = 2000;
enabled = false;

// Save to flash
SaveConfigToStorage();
  
```

10.5.13.2.2 2. BasicWebConfig

Location:** <NNDK>\examples\Configuration\BasicWebConfig
Demonstrates:**

- Config system web interface basics
- Dynamic web page generation
- Real-time value updates
- Form handling

Architecture:**

10.5.13.2.3 3. CustomWebConfig

Location:** <NNDK>\examples\Configuration\CustomWebConfig

Demonstrates:**

- Advanced web interface design
- Bootstrap framework integration
- jQuery for dynamic updates
- Professional UI/UX

Features:**

- Responsive design
- Interactive controls
- Real-time validation
- Modern web technologies

10.5.13.2.4 4. CustomRangeLimit

Location:** <NNDK>\examples\Configuration\CustomRangeLimit

Demonstrates:**

- Extending config objects
- Custom validation logic
- Min/max range checking
- Input constraints

Example:**

```
// Custom range-limited integer
class config_int_limit : public config_int
{
public:
    config_int_limit(const char* name, int defaultVal,
                    int minVal, int maxVal, const char* desc)
        : config_int(name, defaultVal, desc),
          min(minVal), max(maxVal) {}

    bool SetValue(int val) override
    {
        if (val < min || val > max)
            return false; // Reject out-of-range
        return config_int::SetValue(val);
    }

private:
    int min, max;
};

// Usage
config_int_limit temperature("Temp", 25, 0, 100,
                             "Temperature (0-100C)");
```

10.5.13.3 Example Selection Guide

10.5.14 Best Practices

10.5.14.1 Configuration Design Principles

10.5.14.1.1 1. Organization Strategy

Guidelines:**

- Keep application data in `Config.AppData`
- Don't modify `Config.Sys` unless necessary
- Group related settings together
- Use descriptive names
- Add helpful descriptions

10.5.14.1.2 2. Variable Naming

Good Variable Names:

<code>deviceName</code>	Clear purpose
<code>sampleRateHz</code>	Includes units
<code>enableDataLogging</code>	Boolean prefix
<code>motorSpeedRPM</code>	Descriptive + units

Poor Variable Names:

<code>var1</code>	Meaningless
<code>x</code>	Too short
<code>temp</code>	Ambiguous
<code>d</code>	No context

10.5.14.1.3 3. Security Considerations

Recommendations:**

- Always set User and Password for production
- Use strong passwords (8+ characters, mixed case, numbers)
- Disable serial config in deployed systems
- Limit web interface access by network
- Consider custom web interface with authentication

10.5.14.1.4 4. Performance Optimization

**Tips:****

- Cache frequently accessed values
- Update cache when config changes
- Minimize flash writes
- Batch configuration updates

10.5.14.1.5 5. Validation and Error Handling**Implementation:****

- Always validate user input
- Use custom config classes for complex validation
- Provide clear error messages
- Log configuration changes

10.5.15 Troubleshooting**10.5.15.1 Common Issues and Solutions****10.5.15.1.1 Issue: Cannot Access Web Interface**

Symptom: Browser cannot connect to port 20034

**Solutions:****

1. Verify device IP address is correct
2. Ensure using port 20034: <http://ip:20034>
3. Check firewall allows port 20034
4. Verify config web server is enabled in code

10.5.15.1.2 Issue: Serial Config Not Accessible

Symptom: Abort sequence doesn't work

Solutions:**

1. Verify Abort key is correct (default: "A")
2. Send abort key during BootDelay window
3. Ensure using correct UART port
4. Check SerialConfig not set to "Disabled"

10.5.15.1.3 Issue: Configuration Changes Not Saved

Symptom: Settings revert after reboot

Solutions:**

1. Web Interface: Click "Update Record" button
2. Serial: Execute save command
3. Code: Call `SaveConfigToStorage()`
4. Check flash memory not full/corrupted

10.5.15.1.4 Issue: Custom Config Variables Not Appearing

Symptom: Variables not visible in interface

Solutions:**

1. Ensure config object created globally
2. Check object registered to Config.AppData
3. Verify namespace/path is correct
4. Rebuild project completely

10.5.15.2 Debug Checklist

Configuration Debug Process

```

Verify Network Settings
    |
    v
Test with Examples
    |
    v
Review System Logs
    |
    v
Check Flash Memory

```

Debug Steps:**

1. Enable serial debug output with `printf()`
2. Monitor boot messages on UART
3. Verify network connectivity
4. Test with provided examples first
5. Check system logs for errors
6. Verify flash memory health

10.5.16 Advanced Topics

10.5.16.1 Custom Configuration Objects

You can create custom configuration types by extending base classes:

```

// Custom enum configuration
class config_enum : public config_chooser
{
public:
    enum MyEnum { OPTION_A, OPTION_B, OPTION_C };

    config_enum(const char* name, MyEnum defaultVal, const char* desc)
        : config_chooser(name, {"A", "B", "C"},
                          (int)defaultVal, desc) {}

    MyEnum GetValue() const {
        return (MyEnum)GetSelection();
    }
};

```

10.5.16.2 Configuration Callbacks

Implement change notifications:

```

class config_int_notify : public config_int
{
public:
    using NotifyCallback = void (*)(int oldVal, int newVal);

    config_int_notify(const char* name, int defaultVal,
                     const char* desc, NotifyCallback cb)
        : config_int(name, defaultVal, desc), callback(cb) {}

    bool SetValue(int val) override {
        int oldVal = GetValue();
        if (config_int::SetValue(val)) {
            if (callback) callback(oldVal, val);
            return true;
        }
        return false;
    }

private:
    NotifyCallback callback;
};

// Usage
void onSpeedChanged(int oldVal, int newVal) {
    printf("Speed changed from %d to %d\n", oldVal, newVal);
    UpdateMotorSpeed(newVal);
}

config_int_notify motorSpeed("Speed", 1000, "Motor speed",
                             onSpeedChanged);

```

10.5.16.3 Configuration Persistence

10.5.17 API Quick Reference

10.5.17.1 Core Configuration Functions

```

// Initialize configuration system
void InitConfigSystem();

// Save configuration to flash
bool SaveConfigToStorage();

// Load configuration from flash
bool LoadConfigFromStorage();

// Reset to factory defaults
void ResetConfigToDefaults();

// Get configuration as JSON
std::string GetConfigJSON();

// Set configuration from JSON
bool SetConfigJSON(const char* json);

```

10.5.17.2 Configuration Object Types

```

// String configuration
config_string myString("name", "default", "description");

// Integer configuration
config_int myInt("name", 0, "description");

// Boolean configuration
config_bool myBool("name", false, "description");

// Chooser/dropdown configuration
config_chooser myChoice("name", {"opt1", "opt2"}, 0, "description");

```

10.5.17.3 Accessing Values

```

// Reading
const char* str = myString.c_str();
int value = myInt;
bool flag = myBool;
int selection = myChoice.GetSelection();

// Writing
myString = "new value";
myInt = 42;
myBool = true;
myChoice.SetSelection(1);

// Save to flash
SaveConfigToStorage();

```

10.5.18 Summary

The NetBurner Configuration System provides a powerful, flexible solution for managing device settings:

10.5.18.1 Key Features Recap

10.5.18.2 Access Methods Summary

Interface	Port/Method	Use Case
Web UI	Port 20034	User-friendly configuration
Serial Config	Boot UART	Command-line access
Application API	Direct code	Programmatic control
Custom Web	Your design	Branded interface

10.5.18.3 Configuration Hierarchy

```

Config (Root)
├── Version (auto-updated)
├── Reboot (force reboot flag)
├── AppData (your application data)
│   ├── Custom variables
│   ├── Settings
│   └── Parameters
├── Sys (system settings)
│   ├── Boot (boot configuration)
│   │   ├── Abort key
│   │   ├── Serial config
│   │   └── Security
│   └── NetIf (network interfaces)
│       ├── Ethernet0
│       │   ├── IPv4
│       │   └── IPv6
│       └── [Other interfaces]
  
```

10.5.18.4 Best Practices Checklist

- Organize application data in Config.AppData
- Use descriptive variable names with units
- Set User and Password for production
- Validate all user input
- Cache frequently accessed values
- Provide helpful descriptions
- Test with provided examples
- Implement error handling
- Document custom configurations
- Use version control for config schemas

10.5.18.5 Getting Started

1. Learn the Basics

- Review `BasicConfigVariable` example
- Understand config object types
- Practice reading/writing values

2. Web Integration

- Study `BasicWebConfig` example
- Create simple web interface
- Test configuration updates

3. Advanced Features

- Explore `CustomWebConfig` for UI
- Implement validation with `CustomRangeLimit`
- Create custom config objects

4. Production Deployment

- Set security credentials
- Disable unnecessary interfaces
- Implement change logging
- Test recovery procedures

The NetBurner Configuration System simplifies device management while providing the flexibility needed for complex embedded applications.

10.6 Custom Branding

10.6.1 Custom Branding

10.6.2 Overview

NetBurner is an OEM (Original Equipment Manufacturer) that enables complete customization of our products to align with your brand identity. Whether you need simple logo changes or comprehensive white-label solutions, NetBurner provides the flexibility to present your brand to your customers seamlessly.

10.6.3 Branding Capabilities Options

Custom branding options include:

- Configuration Server web page logo
- Custom web page user interface
- Physical label customization using NetBurner label template
- NetBurner application utilities branding
- Private cloud server to replace `discover.netburner.com`

10.6.4 Customization Options

10.6.4.1 1. Configuration Server Logo Replacement

Replace the NetBurner logo on configuration screens with your company branding.

Default Configuration Page

Custom Branded Page

Implementation:**

- Reference the CustomWebConfigSystem example
- Replace logo image file
- Update HTML references
- Rebuild and deploy

Location:** See example in NNDK examples directory

10.6.4.2 2. Custom Configuration Interface

Create a fully branded configuration interface integrated into your application.

Application Architecture

Key Points:**

- The default configuration server is **optional**
- Your application has **full access** to all configuration settings
- Settings can be modified via:
 - Custom web interface
 - Application code directly
 - REST APIs
 - Command protocols

Example Location:**

<NNDK_ROOT>/examples/web/

Typically /nburn/examples/web/

Capabilities:**

- Display current settings
- Modify any configuration parameter
- Save changes to persistent storage
- Apply changes at runtime

10.6.4.3 3. Physical Device Labeling

Order NetBurner hardware without NetBurner branding.

Standard Label

Custom Label

Options:**

1. **No Label:** Order devices without any NetBurner label
2. **Custom Label:** Use NetBurner-provided templates to create labels with:
 - Your company logo
 - Your part numbers
 - Your branding elements
 - Required regulatory markings

Process:**

1. Contact NetBurner sales for label templates
2. Design your custom label
3. Submit for approval
4. Order devices with custom labels

10.6.4.4 4. Discovery Utility Customization

Rebrand NetBurner PC utilities to match your company identity.

Discovery Tool Workflow

Available Tools:**

Utility	Function	Customization Level
localdiscover	Find devices on local network	Full source available
find	Device discovery tool	Full source available
Additional tools	Various utilities	Source provided

Source Location:**

<NNDK_ROOT>/pctools/

Customization Capabilities:**

- Change application name and branding
- Modify user interface

- Add custom functionality
- Integrate with your systems
- Deploy with your software packages

Build Process:**

1. Locate source in `pctools` directory
2. Modify branding elements
3. Update strings and resources
4. Compile for target platform
5. Distribute with your product

10.6.4.5 5. Custom Cloud Server Infrastructure

Difficulty:** Expert

Replace `discover.netburner.com` with your own cloud infrastructure.

Default Architecture

Custom Architecture

Requirements:**

Infrastructure:**

- Cloud hosting platform (AWS, Azure, GCP, etc.)
- SSL/TLS certificates
- Domain name and DNS configuration
- Load balancing (for production)
- Database for device registry
- API endpoints for device communication

Protocol Implementation:**

- Device discovery protocol
- Secure authentication
- Registration and management
- Status monitoring
- Firmware update distribution
- Client application APIs

Architecture Components:**

Cloud Server Stack

Security Considerations:**

- Device authentication tokens
- Encrypted communications
- Access control and permissions
- Audit logging
- Compliance requirements

Warning:** This is an advanced customization requiring:

- Strong backend development skills
- Cloud infrastructure expertise
- Security best practices knowledge
- DevOps capabilities
- Ongoing maintenance commitment

10.6.5 Implementation Strategy

10.6.5.1 Planning Your Customization

Step 1: Assess Requirements

Step 2: Choose Approach

10.6.5.2 Recommended Path

Phase 1 - Quick Wins (Week 1)**

1. Change configuration server logo
2. Order devices with custom labels
3. Update application name and strings

Phase 2 - Custom Interface (Week 2-3)**

1. Design custom web UI
2. Implement configuration interface
3. Add your branding elements
4. Test thoroughly

Phase 3 - Utilities (Week 4)**

1. Customize discovery tools
2. Update PC utilities
3. Rebrand documentation
4. Package for distribution

Phase 4 - Advanced (Month 2+)**

1. Plan cloud infrastructure (if needed)
2. Implement custom services
3. Migrate devices
4. Monitor and maintain

10.6.6 Best Practices

10.6.6.1 Visual Consistency

Ensure brand consistency across all touchpoints:

Brand Touchpoints

10.6.6.2 Configuration Access Patterns

10.6.6.3 Testing Checklist

- ☐ Logo displays correctly on all screens
 - ☐ All text reflects your branding
 - ☐ Custom utilities function properly
 - ☐ Configuration changes persist across reboots
 - ☐ Discovery tools find your devices
 - ☐ Documentation references your brand
 - ☐ Physical labels are accurate
 - ☐ Cloud services (if applicable) are operational
-

10.6.7 Resources and Support

10.6.7.1 Example Code Locations

Customization Type	Location	Description
Configuration Logo	CustomWebConfigSystem	Logo replacement example
Custom Web Interface	<NNDK_ROOT>/examples/web/	Web-based configuration
PC Utilities Source	<NNDK_ROOT>/pctools/	Discovery and management tools

10.6.7.2 Getting Started

For Simple Customizations:**

1. Review the CustomWebConfigSystem example
2. Prepare your logo files (PNG, SVG formats)
3. Follow example documentation
4. Test on development device

For Complex Customizations:**

1. Contact NetBurner technical support
2. Discuss your requirements
3. Review available options
4. Plan implementation timeline

10.6.7.3 Support Channels

- **Technical Documentation:** NetBurner NNDK documentation
 - **Example Code:** Examples directory in NNDK
 - **Technical Support:** NetBurner support team
 - **Community Forums:** NetBurner developer community
-

10.6.8 Security Considerations

When implementing custom branding, maintain security:

Security Layers

Your Branded Interface	< Authentication
Configuration Access	< Authorization
Device Communication	< Encryption
Cloud Services (if any)	< Secure Channels

Key Principles:**

- Maintain authentication mechanisms
- Preserve encryption protocols
- Don't expose sensitive configuration
- Validate all user inputs
- Log security-relevant events
- Keep firmware update security intact

Quick Decision Matrix:**

Your Needs	Recommended Approach
Simple logo change	> Configuration logo replacement
Custom look and feel	> Custom web interface
Complete white label	> All customization options
Enterprise deployment	> Custom cloud infrastructure
Time-to-market priority	> Start with logo, iterate
Full control requirement	> Complete customization path

Start with simple customizations and expand as your product evolves and requirements grow.

10.7 IPv4/IPv6 Dual Stack Guide

10.7.1 Overview

NetBurner release 2.8.0 introduced a fundamental change to IP address handling. The `IPADDR` type evolved from a simple 32-bit integer to a C++ object capable of representing both IPv4 and IPv6 addresses. This guide covers the migration path and best practices for dual-stack networking.

10.7.1.1 Key Changes in 2.8.0+

Before (IPv4 only):**

`IPADDR` = 32-bit unsigned integer

After (Dual Stack):**

`IPADDR` = C++ object (32-bit for IPv4, 128-bit for IPv6)

10.7.2 IPv6 Address Assignment

Unlike IPv4's typical single-address-per-interface model, IPv6 interfaces inherently support multiple addresses simultaneously. Understanding how these addresses are assigned is crucial for dual-stack development.

10.7.2.1 Address Assignment Flow

10.7.2.2 Link-Local Addresses

Every IPv6 interface automatically generates a link-local address (fe80::/64 prefix) derived from its MAC address.

Address Generation:**

```

MAC Address:      00:03:f4:01:23:47
                   |
                   v
Link-Local:       fe80::203:f4ff:fe01:2347
  
```

Characteristics:**

- Non-routable (local network segment only)
- Used for network negotiation and neighbor discovery
- Always present on IPv6-enabled interfaces
- Deterministic (same for a given MAC address)

10.7.2.3 Router Auto-Configuration (SLAAC)

Routers advertise network prefixes that devices use to auto-configure global IPv6 addresses.

Address Construction:**

IPv6 Address (128 bits)	
Router Prefix (64 bits) From Router Advertisement	Host Portion (64 bits) From MAC (EUI-64)

Example:

```

Router Prefix:    2001:db8:1:2::
MAC-based Suffix: 203:f4ff:fe01:2347
                   |
                   v
Full Address:     2001:db8:1:2:203:f4ff:fe01:2347
  
```

Multiple Router Scenario:**

```

Device Interface
|
|-- Router A Prefix > Address A
|-- Router B Prefix > Address B
|-- Router C Prefix > Address C
+-- Link-Local      > fe80::...
  
```

10.7.2.4 DHCPv6 Configuration

DHCPv6 servers provide address assignment and network configuration, similar to DHCPv4 but with enhanced capabilities.

DHCPv6 Types:**

Automatic DHCPv6 Activation:**

- Router advertisements can signal DHCPv6 server presence
- NetBurner automatically initiates DHCPv6 client when signaled
- Manual DHCPv6 client start available for networks without routers

10.7.2.5 Static IP Addresses

Manual address assignment remains available when automatic methods are insufficient or undesired.

10.7.2.6 Complete Address Assignment Hierarchy

10.7.3 IPADDR Class Migration

10.7.3.1 Storage Considerations

Critical Change:** When compiled for IPv6, IPADDR grows from 32 bits to 128 bits.

Impact on Persistent Storage:**

Existing applications storing IPADDR in:

- UserParams structures
- File systems
- Flash memory
- Configuration files

Will encounter deserialization issues when upgrading to IPv6-enabled firmware.

Migration Strategy - Storage Key Pattern:**

```

struct Config {
    uint32_t storageKey;    // Version identifier
    IPADDR serverAddress;
    // ... other fields
};

const uint32_t CURRENT_KEY = 2; // Increment on structure changes

void LoadConfig(Config& cfg) {
    // Read from persistent storage
    ReadFromFlash(&cfg, sizeof(cfg));

    if (cfg.storageKey != CURRENT_KEY) {
        // Key mismatch - initialize with defaults
        InitializeDefaults(cfg);
        cfg.storageKey = CURRENT_KEY;
        SaveConfig(cfg);
    }
}
  
```

10.7.3.2 Null Value Checking

Old IPv4 Pattern (No Longer Valid):**

```
if (EthernetIP == 0) {
    // Configure DHCP
}
```

New Dual-Stack Pattern:**

```
if (EthernetIP.IsNull()) {
    // Configure DHCP
}
```

10.7.3.3 Null IP in Function Parameters

Old IPv4 Pattern:**

```
DNSResult = GetHostByName(serverName, &serverIp, 0, TICKS_PER_SECOND * 20);
```

New Dual-Stack Patterns:**

```
// Option 1: Using NullIP() static method
DNSResult = GetHostByName(serverName, &serverIp, IPADDR::NullIP(), TICKS_PER_SECOND * 20);
```

```
// Option 2: Using INADDR_ANY constant
```

```
DNSResult = GetHostByName(serverName, &serverIp, INADDR_ANY, TICKS_PER_SECOND * 20);
```

Note: INADDR_ANY is defined as `IPADDR::NullIP()` in system headers.

10.7.4 IPADDR Member Functions

The IPADDR class uses object-oriented syntax with member functions accessed via dot notation.

10.7.4.1 Function Types

```
IPADDR Object
|
+-- Member Functions (instance.function())
|   |
|   +-- Setting values
|   +-- Checking values
|   +-- Output functions
|
+-- Static Functions (IPADDR::function())
    |
    +-- Factory methods
    +-- Utility functions
```

10.7.4.2 Setting IP Address Values

Member Functions (Instance Methods):**

```
IPADDR myIpObject;

// Set to null
myIpObject.SetNull();

// Set from string
myIpObject.SetFromAscii("192.168.1.100");
myIpObject.SetFromAscii("2001:db8::1");

// Set from IPv4 address
IPADDR4 ipv4Addr = 0xC0A80164; // 192.168.1.100
myIpObject.SetFromIP4(ipv4Addr);
```

Static Functions (Class Methods):**

```
// Create null IP address
IPADDR nullAddr = IPADDR::NullIP();

// Create from ASCII string
IPADDR serverAddr = IPADDR::AsciiToIp("192.168.1.1");
IPADDR ipv6Addr = IPADDR::AsciiToIp("2001:db8::8a2e:370:7334");
```

10.7.4.3 Reading and Checking IP Address Values

Boolean Checks:**

```
IPADDR addr;

if (addr.IsNull()) { /* Address is null */ }
if (addr.IsLoopBack()) { /* Is loopback (127.0.0.1 or ::1) */ }
if (addr.IsMultiCast()) { /* Is multicast address */ }
if (addr.IsLinkLocal()) { /* Is IPv6 link-local (fe80::/10) */ }
if (addr.IsEmbeddedIPv4()) { /* Is IPv4-mapped IPv6 (::FFFF:x.x.x.x) */ }
```

Address Type Detection:**

**Multicast MAC Conversion:****

```

IPADDR mcastAddr = IPADDR::AsciiToIp("ff02::1");
if (mcastAddr.IsMultiCast()) {
    MACADDR mac = mcastAddr.McastMac();
    // Use MAC address for multicast operations
}

```

10.7.4.4 Output Functions**Console Output:****

```
IPADDR addr = IPADDR::AsciiToIp("192.168.1.100");
```

```

// Print to stdout (debug serial port)
addr.printf();
// Output: 192.168.1.100

```

File Descriptor Output:**

```
int tcpSocket = /* ... established TCP connection ... */;
```

```

// Print to TCP socket
serverAddr.fprintf(tcpSocket);

```

String Buffer Output:**

```

char buffer[128];
int written = addr.sprintf(buffer, sizeof(buffer));
printf("Address: %s (%d chars)\n", buffer, written);

```

Output Method Comparison:****10.7.5 Domain Name Service (DNS)**

DNS function signatures vary between IPv4 and IPv6 modes, but can be written to work identically in both.

10.7.5.1 DNS Function Variants

IPv6 mode: `GetHostByName6()`

10.7.5.2 Universal DNS Code Pattern

Works in both IPv4 and IPv6 modes:**

```
IPADDR resultIP;
int result = GetHostByName(
    "thename.com",           // Hostname to resolve
    &resultIP,               // Result storage
    IPADDR::NullIP(),       // Use system DNS server
    10 * TICKS_PER_SECOND   // Timeout
);

if (result == DNS_OK) {
    printf("Resolved to: ");
    resultIP.printf();
    printf("\n");
}
```

10.7.5.3 DNS Record Types

DNS Query
|
v

Record Type Selection	
DNS_A	- IPv4 address (A record)
DNS_AAAA	- IPv6 address (AAAA)
DNS_CNAME	- Canonical name
DNS_MX	- Mail exchange
DNS_MB	- Mailbox resource
DNS_MG	- Mail group resource

10.7.5.4 IPv6 DNS Priority Control

GetHostByName6 () supports dual-stack resolution with configurable priority:

```
int GetHostByName(
    const char *name,           // Name to resolve
    IPADDR *pResultIP,         // Result storage
    const IPADDR &dnsServerIP, // DNS server (or NullIP)
    WORD timeout,              // Timeout in ticks
    WORD TYPE1 = DNS_A,        // Primary type (default: IPv4)
    WORD TYPE2 = DNS_AAAA       // Secondary type (default: IPv6)
);
```

Resolution Flow:**

```

graph TD
    A[DNS Query: "example.com"] --> B[v]
    B --> C[Try TYPE1]
    C --> D[v]
    C --> E[v]
    D --> F[Success]
    E --> G[Failure]
    G --> H[v]
    H --> I[Try TYPE2]
    I --> J[v]
    I --> K[v]
    J --> L[Success]
    K --> M[Failure]
    L --> N[+]
    M --> O[v]
    N --> P[Return Result]
    O --> Q[Return Error]

```

Default Behavior (IPv4 first):**

```
// Tries IPv4 (DNS_A), falls back to IPv6 (DNS_AAAA)
GetHostByName("example.com", &result, IPADDR::NullIP(), 10 * TICKS_PER_SECOND);
```

IPv6-First Resolution:**

```
// Tries IPv6 first, falls back to IPv4
```

```
GetHostByName(
    "example.com",
    &result,
    IPADDR::NullIP(),
    10 * TICKS_PER_SECOND,
    DNS_AAAA, // Try IPv6 first
    DNS_A      // Fall back to IPv4
);
```

Replace with: - <code>IsNull()</code> - Key versioning

Replace with: - <code>NullIP()</code> - <code>INADDR_ANY</code>

10.7.7.2 Storage Migration

Step 1: Add Version Key

<pre>uint32_t version; IPADDR addresses...</pre>

|
v

Step 2: Check on Load

<pre>if (version != cur) Initialize()</pre>

|
v

Step 3: Save with Key

<pre>config.version = cur SaveToFlash(config)</pre>

10.7.7.3 Testing Strategy

Dual-Stack Testing Matrix:**

10.7.8 Best Practices

10.7.8.1 Portable Code Patterns

Use `GetHostByName()` without version suffix:**

```
// Portable across IPv4/IPv6
GetHostByName(hostname, &result, IPADDR::NullIP(), timeout);
```

Always use `IsNull()` for comparisons:**

```
// Portable null checking
if (addr.IsNull()) {
    // Configure or error
}
```

Use `IPADDR::NullIP()` for null parameters:**

```
// Portable null parameter
Connect(host, port, IPADDR::NullIP());
```

10.7.8.2 Storage Design

Version-aware configuration structures:**

```
struct NetworkConfig {
    uint32_t configVersion; // First field
    IPADDR staticIP;
    IPADDR gateway;
    IPADDR dnsServer;
    // ... other fields
};
```

Always validate on load:**

```
void LoadConfig(NetworkConfig& cfg) {
    ReadFromStorage(&cfg, sizeof(cfg));

    if (cfg.configVersion != CURRENT_CONFIG_VERSION) {
        InitDefaults(cfg);
        SaveConfig(cfg);
    }
}
```

10.7.8.3 DNS Resolution

Prefer IPv6 when available:**

```
// IPv6-first resolution with IPv4 fallback
GetHostByName(
    hostname,
    &result,
    IPADDR::NullIP(),
    timeout,
    DNS_AAAA, // Try IPv6 first
    DNS_A     // IPv4 fallback
);
Specify timeout appropriately:**
// Allow time for both TYPE1 and TYPE2 queries
WORD timeout = 20 * TICKS_PER_SECOND; // Not 10 seconds
```

10.7.9 Summary

10.7.9.1 Key Takeaways

IPADDR is now an object, not a 32-bit integer
Use IsNull() instead of == 0
Use NullIP() instead of 0 in parameters
IPv6 interfaces have multiple addresses
Storage size changes: 32-bit > 128-bit
Use version keys for persistent storage
DNS supports dual-stack with priority control
Link-local addresses need scope ID on BSD/macOS

10.7.9.2 Migration Path

```
Current IPv4 Code
|
v
Audit for patterns
|
v
Update null checks
|
v
Add storage versioning
|
v
Test in IPv4 mode
|
v
Test in IPv6 mode
|
v
Test dual-stack
|
v
Deploy gradually
```

For detailed API documentation, consult the [IPADDR6](#) class reference in the NetBurner API documentation.

10.8 EFFS Programming Guide

10.8.1 NetBurner EFFS Programming Guide

10.8.2 Overview

This guide covers the NetBurner implementation of the HCC Embedded Flash File System (EFFS) and NetBurner flash card hardware interface. EFFS provides file system capabilities for both external flash cards (EFFS-FAT) and on-chip flash memory (EFFS-STD).

10.8.2.1 Topics Covered

- Example programs and supported platforms
- EFFS-FAT file system for external flash cards
- EFFS-STD file system for on-chip flash memory
- Hardware interface design for external flash cards
- Debug port configuration

10.8.3 System Architecture

10.8.4 Supported Platforms

10.8.4.1 Platform Capabilities Matrix

Platform	External Flash Card	On-board Flash Card
MODM7AE70	SPI	N/A
MOD54415	SPI	SPI
MOD54417	SPI	SPI
SB800EX	SDIO	-
NANO54415	SPI	SDIO

Note: All platforms support EFFS-STD on-chip flash file system

10.8.4.2 Interface Types

SPI Mode**: Serial Peripheral Interface

- Single data channel operation
 - Lower data transfer rates
 - Simpler hardware implementation
- SDIO Mode**: Secure Digital Input/Output
- Four parallel data channels
 - Higher data transfer rates
 - More complex hardware design

10.8.5 Example Programs

10.8.5.1 EFFS-FAT Examples

Located at: `\nburn\examples\EFFS\Fat`

Available examples demonstrate:

- Simple file storage operations
- FTP server integration
- HTTP server with file system
- HTTP with variable tags
- Multi-task file system access
- RAM drive implementation
- Application updates from flash

10.8.5.2 EFFS-FAT Security Examples

Advanced security implementations:

`HttpsDualCert**`

- Dual certificate support (compiled-in and SD card-based)
- Dynamic certificate loading from EFFS-FAT
- Web server SSL/TLS configuration
`SSL_pop3**`
- Secure email retrieval via SSL
- Email storage to SD/MMC flash card
- POP3 protocol implementation
`SendMailAttach**`
- File attachment from EFFS-FAT
- Secure email transmission with SSL/TLS
- SMTP integration

10.8.5.3 EFFS-STD Examples

Located at: `\nburn\examples\EFFS\Std`

`HTTP Example**`

- Web page serving from STD file system
- Application-level page serving
- File system override capability
`Security Examples** (\nburn\examples\SSL)`
`HttpsUploadCert**`
- Certificate and key upload via web interface
- SSL/TLS credential storage in EFFS-STD
`SslVerifyPeerEfs**`
- CA List upload and storage
- Peer verification support
- Certificate authority management

10.8.6 Flash Card Hardware Interface

10.8.6.1 SD/MMC Hardware Connection Diagram

10.8.6.2 Signal Connection Table

SD/MMC Pin	Signal Name	NetBurner Connection
1	/CS (Chip Select)	J2-35 (10k pull-up)
2	DI (Data In)	J2-28 (QSPI DOUT)
3	GND	Ground
4	VCC	VCC 3.3V
5	CLK	J2-J5 (QSPI CLK)
6	GND	Ground
7	DO (Data Out)	J2-J7 (QSPI DIN)
8	NC	No Connection
9	NC	No Connection
D	CD (Card Detect)	J2-47 (10k pull-up)
W	WP (Write Protect)	J2-40 (10k pull-up)
Com	Common	Ground

Note: GPIO pins (CS, CD, WP) are configurable in mmc_m7.cpp or mmc_mcf.cpp depending on platform

10.8.6.3 Hardware Specifications

SD/MMC Connector**: Mouser Electronics Part # 688-SCDA1A0901

Card Compatibility**:

- Must support native SPI mode transfers
- Standard SD/MMC: Up to 2GB

- SDHC: Up to 32GB

SPI Interface Requirements**:

- EFFS normally requires exclusive use of SPI interface
- Sharing SPI with other peripherals is not officially supported

- Exclusive use recommended for optimal performance

10.8.6.4 GPIO Pin Configuration

Configure interface control pins in platform-specific files:

MODM7AE70**: \nburn\platform\<platform>\mmc_m7.cpp Other Platforms**: \nburn\platform\<platform>\mmc_mcf.cpp

Key functions to modify:

```
void MMC_BaseInit(int CurrentDrive) // Configure SD/MMC interface pins
int get_cd(int currentDrive) // Get Card Detect state
int get_wp(void) // Get Write Protect state
void spi_cs_lo(void) // Set SPI chip select low
void spi_cs_hi(void) // Set SPI chip select high
```

10.8.6.5 Interrupt-Driven SPI (ColdFire Platforms Only)

For MOD5441X, SB800EX, and NANO54415 platforms:

Enable interrupt-driven SPI for improved system performance at the cost of slightly lower SD/MMC performance.

This is beneficial when network or user tasks need priority during file system access.

Configuration**: Uncomment in \nburn\platform\<platform>\mmc_mcf.cpp:

```
#define SD_IRQ_SPI
```

Then rebuild the platform system directory.

10.8.7 EFFS-FAT File System Operation

10.8.7.1 Typical Operation Flow

10.8.7.2 Common EFFS-FAT Function Calls

10.8.7.2.1 Working Directory Management

```
int f_enterFS(void);           // Create working directory for current task
void f_releaseFS(void);       // Release working directory
```

10.8.7.2.2 Mount/Dismount Operations

```
int f_mountfat(MMC_DRV_NUM, mmc_initfunc, F_MMC_DRIVE0); // Mount flash card
int f_delvolume(int drivenum);                          // Dismount flash card
```

10.8.7.2.3 File Operations

```
F_FILE *f_open(const char *filename, const char *mode); // Open file
int f_close(F_FILE *filehandle);                       // Close file
```

10.8.7.2.4 Read/Write Operations

```
int f_getfreespace(int drivenum, F_SPACE *pspace);
long f_write(const void *buf, long size, long size_st, F_FILE *filehandle);
long f_read(void *buf, long size, long size_st, F_FILE *filehandle);
long f_seek(F_FILE *filehandle, long offset, long whence);
int f_eof(F_FILE *filehandle);
int f_rewind(F_FILE *filehandle);
int f_delete(const char *filename);
```

10.8.7.2.5 Directory Operations

```
int f_findfirst(const char *filename, F_FIND *find);
int f_findnext(F_FIND *find);
int f_chdir(const char *dirname);
int f_mkdir(const char *dirname);
```

10.8.7.2.6 Time/Date Functions

```
int f_settime(const char *filename, unsigned short ctime, unsigned short cdate);
int f_gettime(const char *filename, unsigned short *ptime, unsigned short *pdate);
```

10.8.7.3 File Time and Date Stamps

EFFS supports file time and date stamps obtained through:

- Network Time Protocol (NTP) server
- Real-Time Clock (RTC)
- Manual configuration

Note**: If no time/date is set, files will be stamped with January 1, 1980.

10.8.7.4 File System Utilities

All NetBurner EFFS examples include `FileSystemUtils.cpp` providing:

- Easy-to-use initialization interface
- Status checking functions
- Testing utilities
- Read/write helpers

Location**:

- FAT utilities: `<nburn_install>\examples\_common\EFFS\FAT`
- STD utilities: `<nburn_install>\examples\_common\EFFS\STD`

Card Type Selection**: Edit `cardtype.h` to select between CF or SD/MMC cards.

10.8.8 EFFS-FAT Project Configuration

10.8.8.1 NBEclipse Project Setup

10.8.8.1.1 Step 1: Add EFFS-FAT Library

1. Right-click project in Project Explorer
2. Navigate to: C/C++ Build > Settings > GNU C/C++ Linker > Libraries
3. Add "FatFile" to Libraries (-l) list

10.8.8.1.2 Step 2: Import Source Files

Import files from: <nburn_install>\examples_common\EFFS\FAT

10.8.8.2 Makefile Configuration

Add the following lines to your project makefile:

```
XTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libFatFFile.a
include $(NNDK_ROOT)/examples/_common/EFFS/FAT/common.mak
```

10.8.9 EFFS-STD File System (On-Chip Flash)

10.8.9.1 EFFS-FAT vs EFFS-STD Comparison

Feature	EFFS-FAT	EFFS-STD
Storage	External Flash Card (SD/MMC)	On-chip Flash Memory
Format	FAT32	Custom
Size	Up to 32GB	Platform Dependent
Functions	f_* prefix (e.g., f_open())	fs_* prefix (e.g., fs_open())
Library	libFatFile.a	libStdFFile.a
Removable	Yes	No

10.8.9.2 Flash Memory Layout

Flash Memory Map

10.8.9.3 Memory Allocation Considerations

When using EFFS-STD, you must:

1. Determine application code size (use compressed size from build output)
2. Allocate flash sectors for file system
3. Ensure sufficient room for application growth
4. Configure COMPCODE flags to define memory boundaries

Flash memory is divided into sectors (typically 4KB or 64KB). The EFFS-STD file system requires allocation of specific sectors. Consult your platform's flash memory datasheet for architecture details.

10.8.10 EFFS-STD Project Configuration

10.8.10.1 NBEclipse Configuration

10.8.10.1.1 Step 1: Import Source Files

Import from: `<nburn_install>\examples\_common\EFFS\STD`

10.8.10.1.2 Step 2: Add EFFS-STD Library

1. Right-click project
2. Navigate to: `C/C++ Build > Settings > GNU C/C++ Linker > Libraries`
3. Add "StdFFFile" to Libraries section (no .a extension)

10.8.10.1.3 Step 3: Platform-Specific Configuration

10.8.10.1.3.1 MODM7AE70, SBE70LC Platforms

Enable "Locate Application at Fixed Address in Flash":

1. Right-click project > Properties
2. Navigate to: `C/C++ Build > Settings > NB Flashpack > General`
3. Check "Locate Application at Fixed Address in Flash"

Purpose**: Disables background flash erase to preserve file system sectors

10.8.10.1.3.2 NANO54415, SB800EX Platforms

Modify CompCode flags to reserve file system space:

1. Right-click project
2. Navigate to: `C/C++ Build > Settings > NBCompCode > General`
3. Change memory address range:

Original: `COMPCODEFLAGS = 0x04000 0x800000`
 Modified: `COMPCODEFLAGS = 0x04000 0x700000`

Parameters**:

- First address: Application start
- Second address: File system start

10.8.10.1.3.3 MOD54415, MOD54417 Platforms

Modify CompCode flags:

1. Right-click project
2. Navigate to: `C/C++ Build > Settings > NBCompCode > General`
3. Change memory address range:

Original: `COMPCODEFLAGS = 0xC0040000 0xC2000000`
 Modified: `COMPCODEFLAGS = 0xC0040000 0xC1F00000`

10.8.11 EFFS-STD Makefile Configuration

10.8.11.1 Step 1: Add EFFS-STD Library

```
XTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libStdFFile.a
DBXTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libStdFFile.a
```

10.8.11.2 Step 2: Platform-Specific Configuration

10.8.11.2.1 MODM7AE70, SBE70LC

Enable fixed application address:

```
EXTRAPACKARGS += -cflag C:3
```

10.8.11.2.2 NANO54415, SB800EX

Modify memory address range:

```
# Original
COMPCODEFLAGS = 0x04000 0x800000
```

```
# Modified for file system
COMPCODEFLAGS = 0x04000 0x700000
```

10.8.11.2.3 MOD54415, MOD54417

Modify memory address range:

```
# Original
COMPCODEFLAGS = 0xC0040000 0xC2000000
```

```
# Modified for file system
COMPCODEFLAGS = 0xC0040000 0xC1F00000
```

10.8.12 Flash Memory Address Configuration

10.8.12.1 Platform Memory Map

Platform	Total Size	Start Address	End Address	Configuration Example
MODM7AE70	2MB	0x00400000	0x005FFFFF	512K Flash File System: Application: 0x00406004 File System: 0x005A0000 COMPCODEFLAGS = 0x00406004 0x005A0000 #define FLASH_SIZE (2*1024*1024) #define FS_SIZE (256*512)

10.8.12.2 Memory Region Diagram

MODM7AE70 Flash Memory (2MB Total)

10.8.12.3 Configuration File Reference

For SAME70Q21 platform configuration details, refer to: [\nburn\examples_common\EFFS\STD\src\flash←Chip\SAME70Q21.h](#)

10.8.13 Debug Port Configuration

10.8.13.1 Overview

The debug port is an RS-232 serial port used for interactive communication with your NetBurner device during development and testing.

10.8.13.2 Default Configuration

By default, the debug port has the following mappings:

Standard I/O Mappings	
stdout	> Debug Port (console output)
stdin	> Debug Port (console input)
stderr	> Debug Port (error output)

10.8.13.3 Supported Functions

Standard C/C++ I/O functions work with the debug port:

```
printf()    // Formatted output to debug port
scanf()     // Formatted input from debug port
gets()      // Read string from debug port
puts()      // Write string to debug port
getchar()   // Read single character
putchar()   // Write single character
```

10.8.13.4 Custom Configuration

The debug port is fully configurable:

Option 1*: Disable and use as general-purpose UART

- Frees port for custom communication protocols
- Suitable for production deployments
- Option 2*: Reassign stdio descriptors
- Route stdout/stdin/stderr to network interfaces
- Use telnet or SSH for remote debugging
- Implement custom logging mechanisms
- Option 3*: Multiple debug interfaces
- Combine serial and network debug output
- Create redundant logging paths
- Support simultaneous local and remote debugging

10.8.14 API Reference Documentation

10.8.14.1 EFFS-FAT API Reference

Complete function documentation located at: `\nburn\docs\NetBurner\EFFS`

10.8.14.2 EFFS-STD API Reference

Detailed function documentation available in NetBurner documentation under `@ref groupEFFSSTD`

10.8.14.3 Key Function Mapping

EFFS-FAT (External)	EFFS-STD (On-chip)
<code>f_enterFS()</code> <code>f_releaseFS()</code> <code>f_open()</code> <code>f_close()</code> <code>f_read()</code> <code>f_write()</code> <code>f_seek()</code> <code>f_delete()</code> <code>f_chdir()</code> <code>f_mkdir()</code>	<code>fs_enterFS()</code> <code>fs_releaseFS()</code> <code>fs_open()</code> <code>fs_close()</code> <code>fs_read()</code> <code>fs_write()</code> <code>fs_seek()</code> <code>fs_delete()</code> <code>fs_chdir()</code> <code>fs_mkdir()</code>

10.8.15 Best Practices

10.8.15.1 General Guidelines

1. **Always check return values** from file system functions
2. **Close files properly** to prevent data loss
3. **Handle card removal gracefully** in EFFS-FAT applications
4. **Reserve adequate flash space** for EFFS-STD file systems
5. **Test with actual hardware** before production deployment

10.8.15.2 EFFS-FAT Specific

- Verify card is inserted before mounting
- Implement card detect monitoring in applications
- Handle write-protect status appropriately
- Use proper file modes for read/write operations
- Dismount volumes before card removal when possible

10.8.15.3 EFFS-STD Specific

- Calculate application size carefully
- Leave room for application growth
- Understand flash sector architecture
- Consider wear leveling implications
- Don't exceed allocated file system space

10.8.15.4 Performance Optimization

- Use interrupt-driven SPI when system responsiveness is critical
- Batch file operations when possible
- Minimize file open/close cycles
- Use appropriate buffer sizes for read/write operations
- Consider RAM drive for frequently accessed temporary files

10.8.16 Troubleshooting

10.8.16.1 Common EFFS-FAT Issues

Card Not Detected**

- Check physical connections
- Verify power supply (3.3V)
- Confirm card detect pin configuration
- Test with known-good card

Mount Failures**

- Ensure card is formatted FAT32
- Verify card capacity limits (2GB for standard, 32GB for SDHC)
- Check SPI interface configuration
- Confirm correct initialization sequence

Read/Write Errors**

- Check write-protect status
- Verify sufficient free space
- Ensure proper file handles
- Confirm correct file modes

10.8.16.2 Common EFFS-STD Issues

Insufficient Space**

- Recalculate application size
- Adjust COMPCODE flags
- Reduce file system allocation if needed
- Verify compressed vs uncompressed size

Flash Erase Conflicts**

- Ensure fixed address mode enabled (MODM7AE70/SBE70LC)
- Check memory map configuration
- Verify sector boundaries
- Confirm no overlap with application space

File System Corruption**

- Avoid power interruption during writes
- Implement proper shutdown sequences
- Check flash wear level
- Verify sector allocation

10.8.17 Additional Resources

10.8.17.1 Documentation References

- **EFFS API Reference:** `\nburn\docs\NetBurner\EFFS`
- **Platform Data Sheets:** Consult for flash memory specifications
- **Hardware Schematics:** Development board design references
- **Example Applications:** `\nburn\examples\EFFS`

10.8.17.2 Support Files

- `FileSystemUtils.cpp`: Common utilities for all examples
- `cardtype.h`: Flash card type selection
- Platform-specific `mmc_*.cpp`: Hardware interface configuration
- Flash chip headers: Platform memory configuration

10.8.17.3 Example Locations

```

10.8.18 Summary

The NetBurner EFFS provides robust file system capabilities for embedded applications:

- **EFFS-FAT:** External flash card storage with FAT32 compatibility
- **EFFS-STD:** On-chip flash storage with custom format
- **Easy Integration:** Well-documented APIs and extensive examples
- **Flexible Hardware:** Multiple platform support with various interfaces
- **Security Ready:** Integration with NetBurner security libraries

Choose EFFS-FAT for removable storage and large capacity requirements. Choose EFFS-STD for integrated, non-volatile storage in resource-constrained applications.

Both file systems provide reliable, production-ready storage solutions for NetBurner embedded systems.

10.9 File Descriptors

10.9.1 File Descriptors

10.9.2 Overview

The NetBurner environment provides a unified I/O abstraction layer through file descriptors (FDs), seamlessly integrating the RTOS, TCP/IP stack, and hardware peripherals into a standard POSIX-like interface. A file descriptor serves as a handle to various I/O resources including network sockets, serial ports, system peripherals, and custom I/O devices.

This unified approach enables consistent I/O operations across different resource types using standard functions like `read()`, `write()`, `select()`, and `close()`.

10.9.3 File Descriptor Architecture

Application Layer

10.9.4 File Descriptor Allocation

NetBurner provides a maximum of **255 file descriptors** (0-254), organized into specific ranges:

10.9.4.1 Allocation Map

File Descriptor Space			
0-2	3-4	5-128	129-250
Standard I/O	Serial Ports	TCP Sockets	Expansion Pool
3 FDs	2 FDs	124 FDs	122 FDs
Fixed System	Fixed UART 0-1	32 TCP Connections	Available for Custom Use

10.9.4.2 Detailed Breakdown

Range	Count	Purpose	Description
0-2	3	Standard I/O	stdin (0), stdout (1), stderr (2)
3-4	2	Serial Ports	UART 0 (fd=3), UART 1 (fd=4)
5-128	124	TCP Sockets	Network connections (32 sockets)
129-250	122	Expansion	Custom drivers, additional UARTs, buffers

10.9.4.3 Expansion Pool Usage

The expansion range (129-250) can accommodate:

Expansion File Descriptors (129-250)

External UARTs SPI-to-Serial	Additional TCP Sockets Beyond the 32 default	Custom Buffers Ring Buffers
I2C Devices I2C bus access	Custom Protocols Proprietary interfaces	Virtual Devices Memory streams

10.9.5 Creating Custom I/O Drivers

10.9.5.1 Driver Architecture

Custom file descriptors enable integration of any I/O device into the standard file descriptor framework.

Custom Driver Implementation Flow

10.9.5.2 Core Header File

```
#include <iointernal.h> // Located in: <NNDK_ROOT>/include/
```

10.9.5.3 State Management Functions

Functions to control the state of your file descriptor:

State Control Functions

Purpose:** These functions update the state of your file descriptor for use with I/O functions such as `select()`, `read()`, and `write()`.

10.9.6 IoExpandStruct Definition

The core structure for custom file descriptor implementation:

```

struct IoExpandStruct
{
    int (*read)(int fd, char *buf, int nbytes); // Read function
    int (*write)(int fd, const char *buf, int nbytes); // Write function
    int (*close)(int fd); // Close function
    void *extra; // Custom data pointer
};

```

10.9.6.1 Structure Members

Member	Type	Purpose
read	Function pointer	Implements read operations for your device
write	Function pointer	Implements write operations for your device
close	Function pointer	Cleanup and release resources
extra	void*	Optional pointer to device-specific data

10.9.6.2 Data Flow

10.9.7 File Descriptor Management API

10.9.7.1 Core Functions

```

// Allocate a new file descriptor
int GetExtraFD(void *extra_data, struct IoExpandStruct *pFuncs);

// Retrieve custom data associated with a file descriptor
void* GetExtraData(int fd);

// Release a file descriptor back to the pool
void FreeExtraFD(int fd);

```

10.9.7.2 Function Details

10.9.7.2.1 GetExtraFD()

Purpose:** Allocate a file descriptor for your custom I/O device.

Parameters:**

- `extra_data`: Optional pointer to device-specific data
- `pFuncs`: Pointer to `IoExpandStruct` containing your function implementations

Returns:** File descriptor handle (int), or -1 on failure

Usage Example:**

```

IoExpandStruct myDeviceFuncs = {
    .read = myReadFunction,
    .write = myWriteFunction,
    .close = myCloseFunction,
    .extra = &myDeviceData
};

int fd = GetExtraFD(&myDeviceData, &myDeviceFuncs);
if (fd < 0) {
    printf("Failed to allocate file descriptor\n");
}

```

10.9.7.2.2 GetExtraData()

Purpose:** Retrieve the custom data pointer associated with a file descriptor.

Parameters:**

- fd: File descriptor handle

Returns:** Pointer to extra data (void*), or NULL if not set

Usage:**

```
MyDeviceStruct *device = (MyDeviceStruct*)GetExtraData(fd);
if (device != NULL) {
    // Access device-specific data
    device->status = READY;
}
```

10.9.7.2.3 FreeExtraFd()

Purpose:** Release a file descriptor back to the available pool.

Parameters:**

- fd: File descriptor to release

Important:** Always call this when your device is closed to prevent descriptor leaks.

```
void myCloseFunction(int fd) {
    // Cleanup device resources
    MyDeviceStruct *device = (MyDeviceStruct*)GetExtraData(fd);
    if (device) {
        // Device-specific cleanup
        device->shutdown();
    }

    // Release the file descriptor
    FreeExtraFd(fd);
}
```

10.9.8 TCP Socket Notifications

10.9.8.1 Callback System

NetBurner provides a callback mechanism for TCP socket events:

TCP Event Flow

10.9.8.2 Callback Definition

```
// Callback function type
typedef void (tcp_read_notify_handler)(int tcp_fd);

// Registration function
void RegisterTCPReadNotify(int tcp_fd, tcp_read_notify_handler *newhandler);
```

10.9.8.3 Callback Parameters

When your callback is invoked:

Condition	tcp_fd Value	Meaning
Data available	fd >= 0	Socket has new data to read
Error state	fd < 0	TCP connection has entered error state

10.9.8.4 Implementation Example

```
// Your callback handler
void myTcpNotifyHandler(int tcp_fd) {
    if (tcp_fd >= 0) {
        // New data available
        char buffer[256];
        int bytesRead = read(tcp_fd, buffer, sizeof(buffer));
        if (bytesRead > 0) {
            // Process received data
            processIncomingData(buffer, bytesRead);
        }
    } else {
        // Error condition
        printf("TCP socket error detected\n");
        handleTcpError();
    }
}

// Register the callback
void setupTcpSocket(int tcp_fd) {
    RegisterTCPReadNotify(tcp_fd, myTcpNotifyHandler);
}
```

10.9.9 Using select() with File Descriptors

10.9.9.1 Multiplexing Multiple I/O Sources

One of the most powerful features of the file descriptor system is the ability to wait on multiple I/O sources simultaneously using `select()`.

`select()` Multiplexing

10.9.9.2 select() Usage Pattern

```
#include <iosys.h>

void monitorMultipleSources() {
    int serial_fd = 3;      // UART 0
    int tcp_fd = 5;         // TCP socket
    int custom_fd = 129;    // Custom device

    fd_set readfds;

    while (1) {
        // Initialize the set
        FD_ZERO(&readfds);
        FD_SET(serial_fd, &readfds);
        FD_SET(tcp_fd, &readfds);
        FD_SET(custom_fd, &readfds);

        // Find the highest fd number
        int max_fd = custom_fd;

        // Wait for activity on any descriptor
    }
}
```

```

int result = select(max_fd + 1, &readfds, NULL, NULL, NULL);

if (result > 0) {
    // Check which descriptor has activity
    if (FD_ISSET(serial_fd, &readfds)) {
        handleSerialData(serial_fd);
    }

    if (FD_ISSET(tcp_fd, &readfds)) {
        handleTcpData(tcp_fd);
    }

    if (FD_ISSET(custom_fd, &readfds)) {
        handleCustomDevice(custom_fd);
    }
}
}
}

```

10.9.9.3 Mixing Device Types

You can combine any file descriptor types in a single `select()` call:

Mixed Device Selection

10.9.10 Complete Implementation Example

10.9.10.1 Custom Ring Buffer Device

Here's a complete example of implementing a ring buffer as a file descriptor:

```

#include <iointernal.h>
#include <nbrtos.h>

// Device-specific data structure
typedef struct {
    char buffer[1024];
    int read_pos;
    int write_pos;
    int count;
    OS_CRIT critical_section;
} RingBufferDevice;

// Read function implementation
int ringBufferRead(int fd, char *buf, int nbytes) {
    RingBufferDevice *dev = (RingBufferDevice*)GetExtraData(fd);
    if (!dev) return -1;

    OSCritEnter(&dev->critical_section, CRIT_FLAG_NONE);

    int bytes_to_read = (nbytes < dev->count) ? nbytes : dev->count;
    int bytes_read = 0;

    for (int i = 0; i < bytes_to_read; i++) {
        buf[i] = dev->buffer[dev->read_pos];
        dev->read_pos = (dev->read_pos + 1) % 1024;
        dev->count--;
        bytes_read++;
    }
}

```

```

    if (dev->count == 0) {
        ClrDataAvail(fd); // No more data available
    }

    OSCritLeave(&dev->critical_section);
    return bytes_read;
}

// Write function implementation
int ringBufferWrite(int fd, const char *buf, int nbytes) {
    RingBufferDevice *dev = (RingBufferDevice*)GetExtraData(fd);
    if (!dev) return -1;

    OSCritEnter(&dev->critical_section, CRIT_FLAG_NONE);

    int space_available = 1024 - dev->count;
    int bytes_to_write = (nbytes < space_available) ? nbytes : space_available;
    int bytes_written = 0;

    for (int i = 0; i < bytes_to_write; i++) {
        dev->buffer[dev->write_pos] = buf[i];
        dev->write_pos = (dev->write_pos + 1) % 1024;
        dev->count++;
        bytes_written++;
    }

    if (dev->count > 0) {
        SetDataAvail(fd); // Data available for reading
    }

    if (dev->count < 1024) {
        SetWriteAvail(fd); // Space available for writing
    } else {
        ClrWriteAvail(fd); // Buffer full
    }

    OSCritLeave(&dev->critical_section);
    return bytes_written;
}

// Close function implementation
int ringBufferClose(int fd) {
    RingBufferDevice *dev = (RingBufferDevice*)GetExtraData(fd);
    if (dev) {
        // Clean up resources
        delete dev;
    }
    FreeExtraFd(fd);
    return 0;
}

// Create ring buffer file descriptor
int createRingBufferFd() {
    RingBufferDevice *device = new RingBufferDevice;
    device->read_pos = 0;
    device->write_pos = 0;
    device->count = 0;
    OSCritInit(&device->critical_section);

    IoExpandStruct funcs = {
        .read = ringBufferRead,
        .write = ringBufferWrite,
        .close = ringBufferClose,
        .extra = device
    };

    int fd = GetExtraFD(device, &funcs);
    if (fd >= 0) {
        SetWriteAvail(fd); // Initially ready for write
    }

    return fd;
}

```

10.9.10.2 Usage of Custom Device

```

void useCustomRingBuffer() {
    // Create the custom file descriptor
    int ring_fd = createRingBufferFd();

    if (ring_fd < 0) {
        printf("Failed to create ring buffer\n");
        return;
    }
}

```

```

// Write data
const char *message = "Hello, Ring Buffer!";
write(ring_fd, message, strlen(message));

// Read data
char readBuffer[256];
int bytesRead = read(ring_fd, readBuffer, sizeof(readBuffer));
readBuffer[bytesRead] = '\0';

printf("Read from ring buffer: %s\n", readBuffer);

// Close when done
close(ring_fd);
}

```

10.9.11 Best Practices

10.9.11.1 Resource Management

File Descriptor Lifecycle

10.9.11.2 Guidelines

1. Always Release File Descriptors

- Call `FreeExtraFd()` in your close function
- Prevent descriptor exhaustion

2. Thread Safety

- Use critical sections for shared data
- Protect state changes with `OSCritEnter/Leave`

3. State Management

- Update availability flags appropriately
- Use `SetDataAvail()` when data arrives
- Use `ClrDataAvail()` when buffer empties

4. Error Handling

- Return appropriate error codes
- Use `SetHaveError()` for error conditions
- Check return values from all functions

5. Resource Initialization

- Initialize all structure members
- Verify allocations succeed
- Set initial state flags correctly

Problem	Cause	Solution

10.9.12 Troubleshooting

10.9.12.1 Common Issues

Problem	Cause	Solution
<code>select()</code> never returns	State flags not set	Call <code>SetDataAvail()</code> when data ready
File descriptor allocation fails	Pool exhausted	Release unused FDs with <code>FreeExtraFd()</code>
Data corruption	Missing critical sections	Protect shared data with <code>OSCritEnter/Leave</code>
Memory leaks	Not freeing resources	Implement proper cleanup in close function

10.9.12.2 Debugging Tips

Debug Flow

10.9.13 Summary

10.9.13.1 Key Concepts

File Descriptor System:**

- Unified I/O abstraction for all device types
- POSIX-like interface for consistent access

- 255 total descriptors with defined ranges

Custom Driver Implementation:**

- Define `read()`, `write()`, and `close()` functions
- Use `IoExpandStruct` to register functions
- Manage state with `Set/Clr` functions

Multiplexing:**

- Use `select()` to wait on multiple sources
- Mix network, serial, and custom devices
- Efficient event-driven programming

Best Practices:**

- Always release file descriptors
- Implement thread-safe operations
- Update state flags correctly
- Handle errors gracefully

10.9.13.2 Quick Reference

```
// Essential includes
#include <iointernal.h>

// Core functions
int fd = GetExtraFD(extra_data, &funcs);
void *data = GetExtraData(fd);
FreeExtraFd(fd);

// State management
SetDataAvail(fd);    ClrDataAvail(fd);
SetWriteAvail(fd);   ClrWriteAvail(fd);
SetHaveError(fd);    ClrHaveError(fd);

// TCP callbacks
RegisterTCPReadNotify(tcp_fd, handler);
```

The file descriptor system provides a powerful and flexible foundation for integrating diverse I/O resources into your NetBurner applications.

10.10 HTML Processing

10.10.1 HTML Processing

10.10.2 Introduction

The NetBurner Web Server automatically processes all content in your project's `html/` folder. Whether you're using HTML examples, the application wizard, or creating a project from scratch, the web server provides powerful tools for serving both static and dynamic content.

10.10.2.1 Quick Start

1. Create an `html/` folder in your project (if it doesn't exist)
2. Add your web content (HTML, CSS, JavaScript, images, etc.)
3. Call `StartHttp()` or `StartHttps()` in your application
4. Build your project - content is automatically compiled and linked

The NetBurner build system automatically compiles web content into your application image, eliminating the need for external file storage (though file system delivery is also supported).

10.10.2.2 Web Server Initialization

```
StartHttp();           // Default port 80
StartHttp(2000);        // Custom HTTP port
StartHttps();           // Default port 443 (HTTPS only)
StartHttps(527);        // Custom HTTPS port
StartHttps(443, 80);    // Both HTTPS and HTTP on standard ports
```

10.10.2.3 Content Sources

Web content can be delivered from multiple sources:

10.10.3 Dynamic Content Overview

Dynamic content is generated at runtime on your NetBurner device, enabling real-time updates, interactive controls, and data visualization.

10.10.3.1 Dynamic Content Methods

Available methods:

1. **HTML Tags** - Embed dynamic content directly in HTML
2. **Function Callbacks** - Execute C/C++ functions during page rendering
3. **Variable Tags** - Insert application variable values in real-time
4. **JavaScript** - Client-side dynamic behavior
5. **GET Handlers** - Intercept and customize page requests
6. **POST Handlers** - Process form submissions
7. **WebSockets** - Two-way real-time communication

10.10.4 HTML Tags

HTML tags enable real-time dynamic content by embedding directives in your HTML source code. When the web server streams content to the browser, it processes these tags and takes appropriate action.

10.10.4.1 Tag Overview

Tag	Purpose	Use Case
CPPCALL	Execute C++ function without parameters	Display computed data, trigger actions
VARIABLE ()	Execute C++ function with parameters	Parameterized callbacks, complex operations
VARIABLE	Insert application variable value	Display sensor readings, system state
CONFIGVALUE	Display configuration variable	Show system settings
CONFIGINPUT	Create input field with config value	Edit system configuration
CONFIGTABLE	Generate configuration table	Display hierarchical settings

10.10.4.2 Tag Syntax

Tags are embedded within HTML comments to avoid interfering with standard HTML processing:

```

<!--CPPCALL functionName -->
<!--VARIABLE expression -->
<!--VARIABLE functionName(fd, parameters) -->

```

Important*: Spacing matters!

- No space between <!-- and tag name
- Space required before -->

```

Correct: <!--CPPCALL myFunction -->
Incorrect: <!-- CPPCALL myFunction-->
Incorrect: <!--CPPCALL myFunction-->

```

10.10.5 The CPPCALL Tag

The CPPCALL tag executes a C++ function when encountered during page rendering. The function receives the socket file descriptor and URL, giving it full control over response generation.

10.10.5.1 Function Flow

10.10.5.2 Function Signature

```

void YourFunctionName(int sock, PCSTR url)
{
    // Your code here
    // Write to sock to send data to browser
}
  
```

10.10.5.3 Example: Display Client Information

HTML Code:**

```

<html>
<body>
    <h1>Connection Information</h1>
    Client Address: <!--CPPCALL webShowClientInfo -->
</body>
</html>
  
```

C++ Implementation:**

```

void webShowClientInfo(int sock, PCSTR url)
{
    IPADDR localIP = GetSocketLocalAddr(sock);
    uint32_t remotePort = GetSocketRemotePort(sock);

    localIP.fprintf(sock); // Write IP address
    fprintf(sock, ":%d<br>\r\n", remotePort); // Write port number
}
  
```

Result:**

```
Client Address: 192.168.1.100:54321
```

10.10.6 The VARIABLE Tag

The VARIABLE tag has two distinct uses:

1. **Direct Variable Display** - Insert variable or expression value
2. **Parameterized Function Call** - Execute function with custom parameters

10.10.6.1 Use Case 1: Display Variables

Simple Variable Display:**

```
<!-- Display system uptime in ticks -->
```

```
System Ticks: <!--VARIABLE TimeTick -->

<!-- Display uptime in seconds using expression -->
Uptime: <!--VARIABLE TimeTick/TICKS_PER_SECOND --> seconds
```

10.10.6.2 Supported Variable Types

The following types are automatically supported (defined in [htmlfiles.h](#)):

```
void WriteHtmlVariable(int fd, char c);
void WriteHtmlVariable(int fd, int i);
void WriteHtmlVariable(int fd, short i);
void WriteHtmlVariable(int fd, long i);
void WriteHtmlVariable(int fd, uint8_t b);
void WriteHtmlVariable(int fd, uint16_t w);
void WriteHtmlVariable(int fd, unsigned long dw);
void WriteHtmlVariable(int fd, const char *);
void WriteHtmlVariable(int fd, MACADDR ma);
void WriteHtmlVariable(int fd, IPADDR ip);
```

10.10.6.3 Use Case 2: Parameterized Function Calls

When you need to pass parameters to a function (beyond the fixed CPPCALL signature), use `VARIABLE()`:

```
HTML: <!--VARIABLE MyFunc(fd, param1, param2) -->
      |
      v
Converted To: WriteHtmlVariable(fd, MyFunc(fd, param1, param2));
      |
      v
      MyFunc Executes and Returns Result
      |
      v
      Result Written to Browser
```

Header Declaration:**

```
const char* DisplaySensorData(int fd, int sensorId);
```

HTML Usage:**

```
Sensor 1: <!--VARIABLE DisplaySensorData(fd, 1) --><br>
Sensor 2: <!--VARIABLE DisplaySensorData(fd, 2) --><br>
```

Implementation:**

```
const char* DisplaySensorData(int fd, int sensorId)
{
    int reading = ReadSensor(sensorId);
    fdprintf(fd, "Sensor %d: %d units", sensorId, reading);
    return ""; // Empty string - output already written to fd
}
```

10.10.7 The INCLUDE Tag and htmlvar.h

For the build system to resolve variable and function references in HTML tags, it needs access to appropriate headers.

10.10.7.1 Two Methods for Include Resolution

10.10.7.2 Method 1: INCLUDE Tag in HTML

Place the include directive directly in your HTML file:

```
<html>
<body>
<!--INCLUDE myIncludeFile.h -->
Value = <!--VARIABLE MyVar --><br>
</body>
</html>
```

10.10.7.3 Method 2: htmlvar.h Header File

Create a file named `htmlvar.h` in your project. The build system automatically searches for this file:

```
#ifndef HTMLVARS_H_
#define HTMLVARS_H_

#include <nbrtos.h>      // For TimeTick, TICKS_PER_SECOND

extern int  gIntVal;
extern char gStrVal[];

// Function with parameters for VARIABLE() tag
const char* DisplayWithParam(int fd, int value);

#endif
```

10.10.7.4 Include Resolution Flow

10.10.8 Extending VARIABLE Tag Support

You can extend the `VARIABLE` tag to support custom types by overloading `WriteHtmlVariable()`.

10.10.8.1 Custom Type Example

Define Custom Structure:**

```
struct SensorData {
    int temperature;
    int humidity;
    char location[80];
    uint32_t timestamp;
};
```

SensorData sensor1;

Add to `htmlvar.h`:**

```
void WriteHtmlVariable(int fd, SensorData data);
```

Use in HTML:**

```
Sensor Status: <!--VARIABLE sensor1 -->
```

Implement the Function:**

```
void WriteHtmlVariable(int fd, SensorData data)
{
    fprintf(fd, "<div class='sensor'>");
    fprintf(fd, "  Location: %s<br>", data.location);
    fprintf(fd, "  Temperature: %dC<br>", data.temperature);
    fprintf(fd, "  Humidity: %d%%<br>", data.humidity);
    fprintf(fd, "  Timestamp: %lu", data.timestamp);
    fprintf(fd, "</div>");
}
```

10.10.8.2 System Example: MAC Address Display

Here's how the system implements MAC address display:

```
void WriteHtmlVariable(int fd, MACADDR ma)
{
    PBYTE lpb = (PBYTE)&ma;
    for (int i = 0; i < 5; i++)
    {
        fd_writehex(fd, lpb[i]);
        write(fd, ":", 1);
    }
    fd_writehex(fd, lpb[5]);
}
```

10.10.9 Configuration System Tags

The CONFIG tags simplify displaying and modifying system configuration and application variables from the Configuration Record.

10.10.9.1 Configuration Tag Types

Tag	Function	Creates
CONFIGVALUE	Display value	Read-only text
CONFIGINPUT	Display + edit	HTML input field
CONFIGTABLE	Display hierarchy	HTML table

10.10.9.2 Configuration Tree Structure

10.10.9.3 Example: Display Configuration Values

```

<!-- Display system hostname -->
Hostname: <!--CONFIGVALUE Sys/Application/HostName -->

<!-- Create editable input for application variable -->
Device Name: <!--CONFIGINPUT AppData/DeviceName -->

<!-- Display entire configuration section as table -->
<!--CONFIGTABLE Sys/NetIf -->
  
```

10.10.9.4 Configuration Access Flow

10.10.10 HTTP GET Request Handler

GET handlers intercept browser requests before normal file serving, enabling URL encoding, custom processing, and dynamic routing.

10.10.10.1 When to Use GET Handlers

- URL-encoded parameters: `http://device/status?sensor=1`
- Dynamic page generation based on request
- Stateful applications (session management via URL)

- API endpoints
- Custom routing logic

10.10.10.2 GET Handler Flow

10.10.10.3 Creating a GET Handler

Step 1: Define Callback Function**

```

int callbackGetOddEven(int sock, HTTP_Request &request)
{
    // Send HTML header
    SendHTMLHeader(sock);

    // Custom processing
    printf("GET request from: %I\r\n", request.client_IPaddr);

    // Conditional response based on system time
    if ((Secs % 2) == 0)
        SendFileFragment("even.html", sock);
    else
        SendFileFragment("odd.html", sock);

    return 1; // Indicates request was handled
}
  
```

Step 2: Register Handler**

```

CallBackFunctionPageHandler getHandler(
    "OddEven.html",      // URL to intercept
    callbackGetOddEven,  // Callback function
    tGet,                // Request type
    0,                  // Access group (0 = no password)
    true                 // beforeFiles: true = always called
);
  
```

10.10.10.4 CallBackFunctionPageHandler Parameters

Parameter	Description	Example
pURL	URL mask to match (supports wildcards)	"status.html", "api/*"
pFunction	Pointer to callback function	myCallback
reqType	Request type (tGet, tPost, etc.)	tGet
accessGroup	Security group (0 = no restriction)	0
beforeFiles	When to call: true = always, false = only if file not found	true

10.10.10.5 URL Encoding Example

```
// Handler for: http://device/sensor?id=5&type=temp
int sensorHandler(int sock, HTTP_Request &request)
{
    SendHTMLHeader(sock);

    // Parse URL parameters
    const char* id = GetRequestParameter(request, "id");
    const char* type = GetRequestParameter(request, "type");

    fprintf(sock, "<html><body>");
    fprintf(sock, "Sensor ID: %s<br>", id);
    fprintf(sock, "Type: %s<br>", type);

    // Read and display sensor
    int value = ReadSensor(atoi(id));
    fprintf(sock, "Value: %d</body></html>", value);

    return 1;
}

CallbackFunctionPageHandler sensorGet("sensor*", sensorHandler, tGet, 0, true);
```

10.10.11 HTTP Form POST Handler

POST handlers process form submissions, enabling user input, configuration updates, and interactive web applications.

10.10.11.1 Creating a POST Handler

```
HTML Form Creation
    |
    v
POST Handler Callback
    |
    v
Handler Declaration
    |
    v
Processing Complete
```

10.10.11.2 Step 1: Create HTML Form

```
<html>
<title>Configuration Form</title>
<body>
    <h1>Device Configuration</h1>

    <form action="updateconfig" method="post">
        Device Name: <input type="text" name="DeviceName" value="Default"><br>
        IP Address:  <input type="text" name="IPAddress" value="192.168.1.100"><br>
        Port:       <input type="text" name="Port" value="80"><br>
        Enable:     <input type="checkbox" name="Enable" checked><br>
        <br>
        <input type="submit" value="Update Configuration">
    </form>
</body>
</html>
```

10.10.11.3 Step 2: Create Callback Function

```
void configPostCallback(int sock, PostEvents event,
                        const char* pName, const char* pValue)
{
    static char deviceName[80];
    static char ipAddress[20];
    static int port;
    static bool enabled;
    static bool error = false;

    switch(event)
    {
        case eStartingPost:
            // Initialize before processing variables
            deviceName[0] = '\0';
            ipAddress[0] = '\0';
            port = 0;
            enabled = false;
            error = false;
    }
```

```

        break;

    case eVariable:
        // Process each form variable
        if (strcmp("DeviceName", pName) == 0)
        {
            strncpy(deviceName, pValue, 79);
            printf("Device Name: %s\r\n", deviceName);
        }
        else if (strcmp("IPAddress", pName) == 0)
        {
            strncpy(ipAddress, pValue, 19);
            printf("IP Address: %s\r\n", ipAddress);
        }
        else if (strcmp("Port", pName) == 0)
        {
            port = atoi(pValue);
            printf("Port: %d\r\n", port);
        }
        else if (strcmp("Enable", pName) == 0)
        {
            enabled = (strcmp(pValue, "on") == 0);
            printf("Enabled: %s\r\n", enabled ? "true" : "false");
        }
        else
        {
            printf("Unknown variable: %s\r\n", pName);
            error = true;
        }
        break;

    case eFile:
        // Handle file upload (if applicable)
        break;

    case eEndOfPost:
        // Processing complete - send response
        if (error)
        {
            RedirectResponse(sock, "error.html");
        }
        else
        {
            // Apply configuration
            ApplyConfiguration(deviceName, ipAddress, port, enabled);
            RedirectResponse(sock, "success.html");
        }
        break;
}
}

```

10.10.11.4 Step 3: Register Handler

```

HtmlPostVariableListCallback postHandler(
    "updateconfig*",          // URL mask to match
    configPostCallback        // Callback function
);

```

10.10.11.5 POST Event Flow

10.10.11.6 POST Events

Event	When Called	Purpose
eStartingPost	Once at start	Initialize variables, clear state
eVariable	Once per form field	Process each input value
eFile	If file uploaded	Handle file data
eEndOfPost	Once at end	Finalize, validate, send response

10.10.11.7 Multiple Form Handling

You can use wildcards to handle multiple forms with one callback:

```
void multiFormHandler(int sock, PostEvents event,
                     const char* pName, const char* pValue)
{
    switch(event)
    {
        case eStartingPost:
            // Determine which form based on URL
            break;

            // ... handle events
    }
}

// Handles form1.html, form2.html, form3.html, etc.
HtmlPostVariableListCallback multiPost("form*", multiFormHandler);
```

10.10.12 Complete Examples

10.10.12.1 Example 1: System Status Page with Mixed Tags

```
<!DOCTYPE html>
<html>
<head>
    <title>System Status</title>
    <!--INCLUDE htmlvar.h -->
</head>
<body>
    <h1>NetBurner System Status</h1>

    <h2>System Information</h2>
    <table border="1">
        <tr>
            <td>Uptime (seconds):</td>
            <td><!--VARIABLE Secs --></td>
        </tr>
        <tr>
            <td>Uptime (ticks):</td>
            <td><!--VARIABLE TimeTick --></td>
        </tr>
        <tr>
            <td>MAC Address:</td>
            <td><!--VARIABLE GetMacAddress() --></td>
        </tr>
        <tr>
            <td>Client Info:</td>
            <td><!--CPPCALL webShowClientInfo --></td>
        </tr>
    </table>

    <h2>Configuration</h2>
    Hostname: <!--CONFIGVALUE Sys/Application/HostName --><br>

    <h2>Sensor Readings</h2>
    Temperature: <!--VARIABLE ReadTemperature(fd) -->C<br>
    Pressure: <!--VARIABLE ReadPressure(fd) --> kPa<br>
</body>
</html>
```

10.10.12.2 Example 2: Interactive Control Panel

HTML Form:**

```
<html>
<head><title>Control Panel</title></head>
<body>
    <h1>Device Control Panel</h1>

    <form action="control" method="post">
```

```

<h2>Output Control</h2>
Output 1: <input type="checkbox" name="Out1"><br>
Output 2: <input type="checkbox" name="Out2"><br>
Output 3: <input type="checkbox" name="Out3"><br>

<h2>PWM Settings</h2>
Duty Cycle: <input type="range" name="Duty" min="0" max="100" value="50">
<span id="duty-value">50</span><br>

<br>
<input type="submit" value="Apply Settings">
</form>

<script>
// Update duty cycle display
document.querySelector('input[name="Duty"]').oninput = function() {
    document.getElementById('duty-value').textContent = this.value;
};
</script>
</body>
</html>

```

POST Handler:**

```

void controlPostCallback(int sock, PostEvents event,
                        const char* pName, const char* pValue)
{
    static bool out1 = false, out2 = false, out3 = false;
    static int dutyCycle = 0;

    switch(event)
    {
        case eStartingPost:
            out1 = out2 = out3 = false;
            dutyCycle = 0;
            break;

        case eVariable:
            if (strcmp("Out1", pName) == 0)
                out1 = (strcmp(pValue, "on") == 0);
            else if (strcmp("Out2", pName) == 0)
                out2 = (strcmp(pValue, "on") == 0);
            else if (strcmp("Out3", pName) == 0)
                out3 = (strcmp(pValue, "on") == 0);
            else if (strcmp("Duty", pName) == 0)
                dutyCycle = atoi(pValue);
            break;

        case eEndOfPost:
            // Apply settings to hardware
            SetOutput(1, out1);
            SetOutput(2, out2);
            SetOutput(3, out3);
            SetPWMDutyCycle(dutyCycle);

            printf("Outputs: %d %d %d, Duty: %d%\r\n",
                out1, out2, out3, dutyCycle);

            RedirectResponse(sock, "control.html");
            break;
    }
}

```

```
HtmlPostVariableListCallback controlPost("control*", controlPostCallback);
```

10.10.13 Best Practices

10.10.13.1 Tag Usage Guidelines

Use VARIABLE when:**

- Displaying simple variable values
- Showing calculated expressions

- Output is straightforward text/numbers
Use `VARIABLE()` when:**
- Need to pass parameters to function
- Require conditional formatting
- Complex data processing needed
Use `CPPCALL` when:**
- Need full control over output
- Complex HTML generation
- Multiple operations required
Use `CONFIG` tags when:**
- Working with Configuration Record
- Simplifying configuration UI
- Displaying system settings

10.10.13.2 Performance Considerations

1. **Minimize Function Calls:** Each tag invokes processing overhead
2. **Buffer Output:** Use efficient I/O operations
3. **Cache Values:** Don't recalculate on every request
4. **Use Appropriate Tags:** `CONFIG` tags are optimized for configuration data

10.10.13.3 Security Guidelines

1. **Validate Input:** Always validate POST data
2. **Sanitize Output:** Prevent injection attacks
3. **Use Access Groups:** Restrict sensitive pages
4. **Implement Timeouts:** Prevent resource exhaustion

10.10.13.4 Code Organization

Recommended:**

- Keep HTML files in `html/` folder
- Centralize handlers in dedicated source files
- Use `htmlvar.h` for all HTML-exposed declarations
- Document callback functions clearly
- Group related handlers together

10.10.14 Troubleshooting

10.10.14.1 Common Issues and Solutions

Issue: CPPCALL function not found**

Symptom: Linker error or runtime error

Solution: Verify function signature exactly matches:
`void FunctionName(int sock, PCSTR url)`

Issue: VARIABLE not displaying**

Symptom: Blank output where variable should appear

Solution:

1. Check `htmlvar.h` includes proper headers
2. Verify variable is `extern` declared
3. Ensure `WriteHtmlVariable()` overload exists for type

Issue: POST variables not received**

Symptom: `eVariable` not called for form fields

Solution:

1. Verify form action matches handler URL mask
2. Check `method="post"` in form tag
3. Ensure input fields have name attributes

Issue: Spacing in tags**

Symptom: Tag not processed, appears as comment

Solution: Verify spacing:

Correct: `<!--CPPCALL func -->`
 Incorrect: `<!-- CPPCALL func -->`
 Incorrect: `<!--CPPCALL func-->`

10.10.14.2 Debug Checklist

1. Enable serial console debugging with `printf()`
2. Check web browser developer console for errors
3. Verify HTML is syntactically correct
4. Test with minimal examples first
5. Use `RedirectResponse()` for POST debugging
6. Monitor socket operations with diagnostic output

10.10.15 Additional Resources

10.10.15.1 Related Documentation

- **Web Server Examples:** `\nburn\examples\web`
- **Configuration System:** NetBurner Configuration Guide
- **WebSockets:** WebSocket Programming Guide
- **Security:** Authentication and Access Control

10.10.15.2 Key Header Files

```
#include <http.h>           // HTTP server functions
#include <htmlfiles.h>      // WriteHtmlVariable() overloads
#include <nbrtos.h>         // Timing, system functions
#include <netinterface.h>   // Network interface utilities
```

10.10.15.3 Quick Reference

Tag Syntax:**

```
<!--CPPCALL functionName -->
<!--VARIABLE expression -->
<!--VARIABLE function(fd, params) -->
<!--CONFIGVALUE path/to/variable -->
<!--CONFIGINPUT path/to/variable -->
```

Function Signatures:**

```
// CPPCALL
void FunctionName(int sock, PCSTR url);

// VARIABLE()
const char* FunctionName(int fd, int param);

// GET Handler
int HandlerName(int sock, HTTP_Request &request);

// POST Handler
void HandlerName(int sock, PostEvents event,
                 const char* pName, const char* pValue);
```

Declaration Templates:**

```
// GET Handler
CallbackFunctionPageHandler name("url", callback, tGet, 0, true);

// POST Handler
HtmlPostVariableListCallback name("url*", callback);
```

10.10.16 Summary

NetBurner's HTML processing system provides a comprehensive toolkit for building dynamic web applications on embedded devices:

Core Capabilities:**

- Seamless integration of C/C++ code with HTML
- Real-time variable display and function execution
- Form processing and user input handling
- Custom request routing and URL encoding
- Configuration system integration

Development Workflow:**

```
Design HTML Interface
    |
    v
Add Dynamic Tags
    |
    v
Implement Callbacks
    |
    v
Register Handlers
    |
    v
Build and Deploy
    |
    v
Test and Iterate
```

Key Takeaways:**

- Start with simple VARIABLE and CPPCALL tags
- Progress to GET/POST handlers for complex interactions
- Use CONFIG tags for configuration management
- Follow best practices for security and performance

- Leverage examples and documentation

The NetBurner HTML processing system eliminates the complexity of traditional CGI or server-side scripting while providing powerful dynamic content capabilities optimized for embedded systems.

10.11 Interrupt Handling

10.11.1 interrupt_handling Interrupt Handling in NetBurner Applications

10.11.2 interrupt_overview Overview

An **interrupt** is a hardware or software signal that temporarily suspends normal program execution to handle a time-critical event. When an interrupt occurs, the processor:

1. Saves the current execution context
2. Executes the Interrupt Service Routine (ISR)
3. Restores the context and resumes normal execution

10.11.2.1 interrupt_sources Common Interrupt Sources

NetBurner devices handle interrupts from various sources:

- **Hardware Timers** - Periodic or one-shot timing events
- **Serial Ports** - UART data reception/transmission
- **Ethernet Controllers** - Network packet events
- **GPIO Pins** - External hardware signals
- **Software Traps** - Programmatically triggered interrupts

10.11.2.2 interrupt_platform_variations Platform Variations

Interrupt handling implementation varies by processor architecture:

Platform	Complexity	Key Characteristics
ARM (Cortex-M7)	Simple	Direct function calls, minimal setup
ColdFire (MCF5441x)	Complex	Requires entry/exit macros, controller setup

NetBurner provides abstraction layers to simplify interrupt configuration across all platforms.

10.11.3 core_interrupt_functions Core Interrupt Functions

The following functions work across **all NetBurner platforms** and provide a consistent interface for interrupt management.

10.11.3.1 interrupt_header_requirements Header Requirements

```
#include <pins.h>           // For PinIO objects
#include <system.h>         // For interrupt functions
```

10.11.3.2 interrupt_function_overview Function Overview

Interrupt Configuration Workflow

10.11.3.3 interrupt_setpinirq SetPinIrq() - Configure Interrupt Pin

Function Signature:**

```
bool SetPinIrq(PinIO pin, int polarity, PinIrq_t func);
```

Parameters:**

Parameter	Type	Description
pin	PinIO	Pin object to configure as interrupt source
polarity	int	Trigger condition (see polarity table below)
func	PinIrq_t	Function pointer to the ISR

Polarity Values:**

Signal Polarity Configuration

Value	Trigger Type	Signal Diagram
2	High Level	
1	Rising Edge (Pos)	
0	Any Edge (Both)	
-1	Falling Edge (Neg)	

Returns:** true if configuration successful, false otherwise.

Example:**

```
// ISR function
void MyButtonISR() {
    // Handle button press
    printf("Button pressed!\r\n");
}

// Configure pin 23 for falling edge interrupt
PinIO buttonPin(23);
buttonPin.function(PINMODE_GPIO);
SetPinIrq(buttonPin, -1, MyButtonISR);
```

10.11.3.4 interrupt_enableirq EnableIrq() - Activate Interrupt

Function Signature:**

```
void EnableIrq(PinIO pin);
```

Enables interrupt processing for the specified pin.

Example:**

```
EnableIrq(buttonPin); // Start receiving interrupts
```

10.11.3.5 interrupt_disableirq DisableIrq() - Deactivate Interrupt

Function Signature:**

```
void DisableIrq(PinIO pin);
```

Disables interrupt processing for the specified pin.

Example:**

```
DisableIrq(buttonPin); // Stop receiving interrupts
```

10.11.4 isr_restrictions ISR Restrictions

10.11.4.1 isr_critical_constraints Critical Constraints

The code within an ISR executes in an **interrupt context**, which has strict limitations. The following operations are **PROHIBITED** in an ISR:

ISR Execution Context

10.11.4.2 isr_prohibited_rtos Prohibited RTOS Functions

All blocking/waiting functions are forbidden:**

```
// NEVER call these in an ISR:
OSMboxPend() // Mailbox wait
OSSemPend() // Semaphore wait
OSQPend() // Queue wait
OSCritEnter() // Critical section entry
OSChangePrio() // Priority change
OSTaskDelete() // Task deletion
OSLock() // Scheduler lock
OSUnlock() // Scheduler unlock
OSTaskCreate() // Task creation
OSTimeDly() // Time delay
```

Allowed RTOS operations (non-blocking only):**

```
// Safe to call in ISR:
OSMboxPendNoWait() // Non-blocking mailbox check
OSSemPendNoWait() // Non-blocking semaphore check
```

```

OSQPendNoWait()    // Non-blocking queue check
OSMboxPost()       // Post to mailbox
OSSemPost()        // Post to semaphore
OSQPost()          // Post to queue

```

10.11.4.3 isr_prohibited_io Prohibited I/O Functions

All I/O operations that may block are forbidden:**

```

// NEVER call these in an ISR:
write()           // File/socket write
writeall()        // Complete write
read()            // File/socket read
printf()          // Formatted output
fprintf()         // File formatted output
fdprintf()        // Descriptor formatted output
printf()          // Integer formatted output
scanf()           // Formatted input
gets()            // Line input
puts()            // String output

```

10.11.4.4 isr_prohibited_memory Prohibited Memory Functions

Dynamic memory operations are forbidden:**

```

// NEVER call these in an ISR:
malloc()          // Allocate memory
free()            // Free memory
new               // C++ allocation
delete            // C++ deallocation

```

10.11.4.5 isr_recommended_pattern Recommended ISR Pattern

```

// Correct ISR Implementation
volatile bool eventFlag = false;
volatile uint32_t eventData = 0;

// ISR: Minimal processing, set flag
void MyISR() {
    // Read hardware register
    eventData = ReadHardwareRegister();

    // Set flag for main loop
    eventFlag = true;

    // Optional: Signal task via semaphore
    OSSemPost(&processingTask);
}

// Main task: Handle event
void ProcessingTask(void* pd) {
    while (1) {
        OSSemPend(&processingTask, 0);

        if (eventFlag) {
            eventFlag = false;

            // Now safe to use all functions
            ProcessEvent(eventData);
            printf("Event processed: %lu\r\n", eventData);
        }
    }
}

```

10.11.5 platform_specific_implementations Platform-Specific Implementations

Different processor architectures require different interrupt setup procedures.

Platform Interrupt Architecture

 v	 v
Simple Config	Complex Config
- Direct ISR	- INTERRUPT macro
- Port priority	- SetIntc() setup
- PinIO based	- Vector tables

10.11.6 same70_platforms SAME70 Platforms (MODM7AE70 and SBE70LC)

10.11.6.1 same70_architecture Architecture Overview

The SAME70 (Cortex-M7) features:

- **Any GPIO pin** can be used as an interrupt source
- **Port-based priority** - all pins on same port share priority
- **7 Priority Levels** - 1 (highest) to 7 (lowest)

SAME70 Interrupt Structure

10.11.6.2 same70_port_priority Port Priority Configuration

10.11.6.2.1 SetPortIrqPriority() - By PinIO Object

Function Signature:**

```
bool SetPortIrqPriority(PinIO pin, int priority);
```

Parameters:**

Parameter	Type	Description
pin	PinIO	Any pin on the target port
priority	int	Priority level: 1 (highest) to 7 (lowest)

Important:** Setting priority for any pin affects the **entire port**.

Returns:** true if successful, false otherwise.

Example:**

```
PinIO myPin(23); // Pin on PIOB
SetPortIrqPriority(myPin, 3); // All PIOB interrupts now priority 3
```

10.11.6.2.2 SetPortIrqPriority() - By Port Number

Function Signature:**

```
bool SetPortIrqPriority(int portNum, int priority);
```

Parameters:**

Parameter	Type	Description
portNum	int	Port number: PIOA=0, PIOB=1, PIOC=2, PIOD=3, PIOE=4
priority	int	Priority level: 1 (highest) to 7 (lowest)

Example:**

```
SetPortIrqPriority(1, 3); // Set PIOB to priority 3
```

10.11.6.3 same70_port_mapping Port Priority Mapping

SAME70 Port Assignments

Port Number	Port Name	Example Usage
0	PIOA	High priority sensors
1	PIOB	Medium priority inputs
2	PIOC	Communication signals
3	PIOD	General I/O
4	PIOE	Low priority monitoring

10.11.6.4 same70_workflow Configuration Workflow

Critical:** Always set port priority **before** configuring pin interrupts.

SAME70 Interrupt Setup Sequence

10.11.6.5 same70_example Complete SAME70 Example

```
#include <pins.h>
#include <system.h>
#include <nbrtos.h>

// ISR for external sensor
void SensorISR() {
    // Minimal processing in ISR
    OSemPost(&sensorEvent);
}

void ConfigureSensorInterrupt() {
    // Pin 42 is on PIOB (port 1)
    PinIO sensorPin(42);
    sensorPin.function(PINMODE_GPIO);

    // Step 1: Set port priority (all PIOB pins)
    SetPortIrqPriority(1, 2); // High priority (2)

    // Step 2: Configure pin interrupt
    SetPinIrq(sensorPin, 1, SensorISR); // Rising edge trigger

    // Step 3: Enable interrupt
    EnableIrq(sensorPin);

    printf("Sensor interrupt configured on pin 42\r\n");
}
```

10.11.7 mcf5441x_platforms MCF5441x Platforms (MOD54415, MOD54417, NANO54415 and SB800EX)

10.11.7.1 mcf5441x_architecture Architecture Overview

The MCF5441x (ColdFire) processor requires more complex setup:

- **INTERRUPT() macro** - Handles ISR entry/exit code
- **SetIntc() function** - Configures interrupt controller hardware

- **7 Priority Levels** - 1 to 7, with 7 being highest (unmaskable)

ColdFire Interrupt Flow

10.11.7.2 mcf5441x_interrupt_macro INTERRUPT() Macro

The INTERRUPT() macro simplifies ISR implementation by handling:

- Saving processor registers
- Setting status register
- RTOS notification
- Restoring registers on exit

10.11.7.2.1 Header Requirements

```
#include <nbrtos.h>      // RTOS functions
#include <cfinter.h>     // ColdFire interrupt support
```

10.11.7.2.2 Macro Syntax

```
INTERRUPT(FunctionName, SR_Value)
{
    // ISR code here
}
```

10.11.7.2.3 Parameters

Parameter	Description
FunctionName	ISR function name (used with SetIntc())
SR_Value	Status Register value - controls interrupt masking

10.11.7.2.4 Status Register Values

The Status Register (SR) controls which interrupts can preempt the current ISR:

ColdFire Status Register Interrupt Masking

SR Value	Mask Level	Allows Interrupts At Level	Blocks
0x2000	0	All (1-7)	None
0x2100	1	2 and above	Level 1
0x2200	2	3 and above	Levels 1-2
0x2300	3	4 and above	Levels 1-3
0x2400	4	5 and above	Levels 1-4
0x2500	5	6 and above	Levels 1-5
0x2600	6	7 only	Levels 1-6
0x2700	7	None (masks all maskable)	All < 7

Note: Level 7 interrupts are unmaskable - they always execute
 Bit 29 is supervisor bit (always set = 0x2000 base)

10.11.7.2.5 Interrupt Priority Hierarchy

Interrupt Priority Levels

Level 7	—————	Highest (Unmaskable) Critical system events Can interrupt anything
^		
Level 6	—————	Very High Priority Time-critical operations
^		
Level 5	—————	High Priority Important peripherals
^		
Level 4	—————	Medium-High Priority Communication interfaces
^		
Level 3	—————	Medium Priority General peripherals
^		
Level 2	—————	Low-Medium Priority Non-critical I/O
^		
Level 1	—————	Low Priority Background tasks
^		
Level 0	—————	Disabled

10.11.7.2.6 Level 7 Warning

CRITICAL:** Level 7 interrupts are **unmaskable** and can interrupt themselves!

Level 7 Interrupt Danger

Mitigation Strategy:**

```

// Ensure ISR completes before next Level 7 can occur
__interrupt(CriticalISR, 0x2700)
{
    // 1. Acknowledge interrupt source immediately
    ClearInterruptFlag();

    // 2. Minimal processing only
    volatile uint32_t data = ReadHardwareRegister();

    // 3. Set flag for main loop processing
    criticalEventFlag = true;

    // Exit quickly - no delays!
}
  
```

10.11.7.3 mcf5441x_setintc SetIntc() Function

Configures the interrupt controller to route hardware interrupts to ISR functions.

10.11.7.3.1 Function Declaration

Important:** SetIntc() is defined in platform HAL files and must be declared as extern:

```
extern void SetIntc(int intcnum, long func, int vector, int level);
```

Location:** \nburn\platform\MOD5441x\hal.cpp

10.11.7.3.2 Parameters

Parameter	Type	Description
intcnum	int	Interrupt controller number (0 or 1 for MCF5441x)

Parameter	Type	Description
func	long	Pointer to ISR function (from INTERRUPT macro)
vector	int	Interrupt vector number (0-255, device-specific)
level	int	Interrupt priority level (0=disabled, 1-7)

10.11.7.3.3 Vector Numbers

The MCF5441x has 256 exception vectors:

- **0-63:** Core exceptions (reserved)
- **64-255:** Peripheral interrupt sources (192 device-specific vectors)

Common MCF5441x Interrupt Sources

Source	Vector	Typical Use
UART 0	26	Serial communication
UART 1	27	Serial communication
PIT Timer 2	15	Periodic timer
1-Wire	63	1-Wire bus interface
Ethernet	varies	Network events

Reference:** See Chapter 17, Table 17.2.9.1 in NXP MCF5441x Reference Manual

10.11.7.3.4 Interrupt Controller Selection

MCF5441x Interrupt Controllers

Controller 0 (intcnum = 0)	Controller 1 (intcnum = 1)
- UART 0 (Vector 26) - PIT Timers - Ethernet 1-Wire (Vector 63) - Core peripherals	- Additional peripherals - Extended I/O - Communication interfaces - Platform-specific devices

10.11.7.4 mcf5441x_example Complete MCF5441x Example: 1-Wire Interface

```
#include <nbrtos.h>
#include <cfinter.h>
#include <sim5441x.h>

// Declare external SetIntc function
extern void SetIntc(int intc, long func, int vector, int level);

// State tracking
volatile enum { OK, BUSY, ERROR } ow_state = OK;

// Actual ISR implementation
void OWMasterIsr()
{
    // Read 1-Wire status
    uint8_t status = siml.ow.sr;

    // Clear interrupt flag
    siml.ow.sr = status;

    // Update state
    if (status & OW_SR_RBF) {
        // Receive buffer full
        ow_state = OK;
    }
}

// INTERRUPT macro wrapper - sets SR to mask interrupts below level 6
INTERRUPT(ow_master_int_routine, 0x2600)
{
    OWMasterIsr();
}

// Initialization function
void OWInit()
{
    // Configure 1-Wire hardware registers
    siml.ow.cr = 0;           // Control register
    siml.ow.div = 0x7C;       // Divide peripheral clock to 1 MHz
}
```

```

siml.ow.cmd = 0;           // Command register
siml.ow.ier = OW_IER_ERBF; // Enable receive buffer full interrupt

// Configure interrupt controller
// Controller 0, ISR function, Vector 63, Level 3
SetIntc(0, (long)&ow_master_int_routine, 63, 3);

// Initialize state
ow_state = OK;

printf("1-Wire interrupt configured: Vector 63, Level 3\r\n");
}

// Usage in UserMain()
void UserMain(void *pd)
{
    init();

    // Initialize 1-Wire with interrupt support
    OWInit();

    while (1) {
        // Application code
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

10.11.7.5 mcf5441x_workflow MCF5441x Configuration Workflow

ColdFire Interrupt Setup Process

Step 1: Implement ISR Logic

```

void MyIsr() {
    // Handle interrupt
}

```

|
v

Step 2: Wrap with INTERRUPT Macro

```

INTERRUPT(my_isr, 0x2500) {
    MyIsr();
}

```

|
v

Step 3: Configure Hardware

```

// Set registers
peripheral.control = ...;
peripheral.enable = ...;

```

|
v

Step 4: Configure Controller

```

SetIntc(0,
(long)&my_isr,
vector_num,
priority_level);

```

|
v

Step 5: Interrupt Active

```

ISR Called on Events

```

10.11.7.6 mcf5441x_best_practices Best Practices for MCF5441x

1. **Always use INTERRUPT() macro** - Never write bare ISR functions
2. **Match SR value to needs** - Don't block higher priority interrupts unnecessarily
3. **Initialize hardware first** - Set up peripheral registers before SetIntc()
4. **Use correct vector numbers** - Consult reference manual for device-specific vectors
5. **Avoid Level 7 unless critical** - Use lower levels when possible

10.11.8 somrt1061_platform SOMRT1061 Platform

10.11.8.1 somrt1061_overview Overview

The SOMRT1061 platform uses the i.MX RT1061 processor (ARM Cortex-M7). Interrupt configuration follows the standard NetBurner approach with some platform-specific considerations.

i.MX RT1061 Interrupt Architecture

10.11.8.2 somrt1061_configuration Configuration Approach

The SOMRT1061 uses the **standard NetBurner interrupt functions**:

```
#include <pins.h>
#include <system.h>

// ISR function
void MyRT1061ISR() {
    // Handle interrupt
}

// Configuration
void ConfigureInterrupt() {
    PinIO myPin(23);
    myPin.function(PINMODE_GPIO);

    // Standard functions work directly
    SetPinIrq(myPin, 1, MyRT1061ISR); // Rising edge
    EnableIrq(myPin);
}
```

10.11.8.3 somrt1061_notes Platform-Specific Notes

1. **No port-based priority** - Each GPIO can have individual priority
2. **Direct ISR calls** - No INTERRUPT() macro needed
3. **Fast interrupt response** - Cortex-M7 architecture provides low latency
4. **Standard PinIO support** - All GPIO pins accessible via PinIO objects

10.11.8.4 somrt1061_example SOMRT1061 Example

```
#include <init.h>
#include <nbrtos.h>
#include <pins.h>
#include <system.h>

const char *AppName = "RT1061 Interrupt Example";

// Semaphore for signaling
OS_SEM buttonSem;

// Simple ISR - post semaphore
void ButtonPressISR() {
    OSSemPost(&buttonSem);
}

// Processing task
void ButtonTask(void *pd) {
    while (1) {
        OSSemPend(&buttonSem, 0);
        printf("Button pressed at %lu seconds\r\n", Secs);
    }
}
```

```

}

void UserMain(void *pd) {
    init();

    // Initialize semaphore
    OSemInit(&buttonSem, 0);

    // Configure button on pin 23
    PinIO buttonPin(23);
    buttonPin.function(PINMODE_GPIO);

    // Setup interrupt for falling edge (button press)
    SetPinIrq(buttonPin, -1, ButtonPressISR);
    EnableIrq(buttonPin);

    // Create processing task
    OSTaskCreate(ButtonTask,
        NULL,
        (void *)&ButtonTaskStack[USER_TASK_STK_SIZE],
        (void *)&ButtonTaskStack,
        MAIN_PRIO - 1);

    printf("%s: Interrupt configured on pin 23\r\n", AppName);

    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

10.11.9 interrupt_summary Summary and Best Practices

10.11.9.1 interrupt_cross_platform Cross-Platform Compatibility

For maximum portability across NetBurner platforms:

```

// Always use these standard functions:
SetPinIrq(pin, polarity, isr_func);    // Configure
EnableIrq(pin);                       // Enable
DisableIrq(pin);                      // Disable

```

10.11.9.2 interrupt_platform_selection Platform Selection Guide

Choose Your Approach Based on Platform

Platform	Complexity	Key Functions
SAME70 (MODM7AE70)	Simple	SetPinIrq() SetPortIrqPriority() EnableIrq() / DisableIrq()
MCF5441x (MOD54415, etc)	Complex	INTERRUPT() macro SetIntc() Manual register setup
SOMRT1061 (i.MX RT1061)	Simple	SetPinIrq() EnableIrq() / DisableIrq()

10.11.9.3 interrupt_general_best_practices General Best Practices

1. **Keep ISRs short** - Minimal processing, set flags, post semaphores
2. **Use volatile for shared variables** - Prevent compiler optimization issues
3. **Never block in ISRs** - No waiting, no delays, no blocking I/O
4. **Signal tasks for processing** - Use semaphores/mailboxes to defer work
5. **Test interrupt rates** - Ensure ISR completes before next interrupt
6. **Document vector/priority choices** - Make interrupt configuration clear
7. **Initialize hardware before interrupts** - Configure peripherals, then enable IRQ

10.11.9.4 interrupt_debugging Debugging Interrupts

Interrupt Debugging Checklist

10.11.9.5 interrupt_error_prevention Error Prevention

```
// WRONG - Blocking in ISR
void BadISR() {
    OSTimeDly(TICKS_PER_SECOND); // NEVER!
    printf("Interrupt!\r\n");      // NEVER!
}

// CORRECT - Signal and exit
void GoodISR() {
    interruptFlag = true;
    OSSemPost(&processSem);      // Non-blocking post
}
```

10.11.10 interrupt_resources Additional Resources

10.12 JSON Lexer

10.12.1 JSON Lexer Programming Guide

10.12.2 Overview

The JSON Lexer provides a powerful interface for parsing and accessing JSON data in NetBurner applications. This guide covers version 3.3.9 and later, which includes significant improvements over earlier versions.

10.12.2.1 Core Components

The JSON Lexer interface is defined in `json_lexer.h` and provides two primary object types:

10.12.2.1.1 ParsedJsonDataSet

Represents a complete JSON object that has been parsed and stored internally. This object contains the entire tokenized JSON structure in an optimized format using NetBurner poolBuffers.

10.12.2.1.2 JsonRef

A reference object that acts as a pointer to a location within a [ParsedJsonDataSet](#). It simplifies navigation through complex JSON hierarchies by providing a clean, intuitive interface for accessing nested data.

10.12.2.2 Version Notes

The interface introduced in version 3.3.9 supersedes the previous API. While legacy code continues to work, all new development should use the JsonRef-based interface described in this guide for improved clarity and ease of use.

10.12.3 Loading JSON Data

There are three primary methods to populate a [ParsedJsonDataSet](#) object:

10.12.3.1 Method 1: From Text Blob

Load JSON directly from a text string or character array.

```
// Example from: \nburn\examples\JsonLexer\ParseTest
const char* jdata = "{\"key\": \"value\"}";
size_t jlen = strlen(jdata);
ParsedJsonDataSet pjd((const char *)jdata, jlen, true);
```

10.12.3.2 Method 2: From Web Server

Retrieve JSON from an external HTTP endpoint.

```
// Examples in:
// \nburn\examples\JSON\GetJsonFromServer
// \nburn\examples\JSON\PostAndGetJsonExternalServer
// \nburn\examples\WebClient\EarthQuake

ParsedJsonDataSet pjds;
// Use web client functions to fetch data into pjds
```

10.12.3.3 Method 3: From File Descriptor

Read JSON from any file descriptor source (web socket, serial port, etc.).

```
ParsedJsonDataSet pjds;           // Declare the object
pjds.ReadFrom(int fd);           // Read from file descriptor
```

10.12.4 Data Flow Diagram

10.12.5 Accessing JSON Data

10.12.5.1 Example JSON Structure

Consider the following JSON data:

```
{
  "Anumber": 1234,
  "AString": "ImaString",
  "AnObject": {
    "Item1": 1,
    "Item2": "TheItem2"
  },
  "AnArray": [1, 2, 3, 4]
}
```

10.12.5.2 Basic Access Patterns

10.12.5.2.1 Simple Values

```
// Extract integer
int i = pjds("Anumber");

// Extract strings (two methods)
NBString s = pjds("AString");           // NBString object
const char* pStr = pjds("AString");     // Raw pointer (valid until dataset destroyed)
```

10.12.5.2.2 Nested Objects

Use [JsonRef](#) to simplify access to nested structures:

```
// Create a reference to the nested object
JsonRef jr = pjds("AnObject");

// Access nested values through the reference
int i1 = jr("Item1");
NBString s2 = jr("Item2");
```

10.12.5.2.3 Array Access

Use array indexing to access elements:

```
// Iterate through array elements
for(int i = 0; i < 4; i++) {
    printf("Item[%d] = %d\n", i, pjds("AnArray")[i]);
}
```

10.12.6 Access Operator Summary

The [ParsedJsonDataSet](#) and [JsonRef](#) objects use the following notation:

- ("name") - Find element by name
- [index] - Access array element by index

10.12.6.1 Navigation Example

```
pjds
├── ("Anumber") → int value
├── ("AString") → string value
├── ("AnObject") → JsonRef
│   ├── ("Item1") → int value
│   └── ("Item2") → string value
└── ("AnArray")
    ├── [0] → value
    ├── [1] → value
    ├── [2] → value
    └── [3] → value
```

10.12.7 Type Conversion Operators

The [ParsedJsonDataSet](#) supports automatic type conversion through operator overloading:

```
operator bool()      const { return PermissiveCurrentBool(); }
operator float()     const { return (float)CurrentNumber(); }
operator double()    const { return CurrentNumber(); }
operator uint8_t()   const { return (uint8_t)CurrentNumber(); }
operator int()       const { return (int)CurrentNumber(); }
operator uint16_t()  const { return (uint16_t)CurrentNumber(); }
operator uint32_t()  const { return (uint32_t)CurrentNumber(); }
operator int8_t()    const { return (int8_t)CurrentNumber(); }
operator int16_t()   const { return (int16_t)CurrentNumber(); }
operator int32_t()   const { return (uint32_t)CurrentNumber(); }
operator time_t()    const { return (time_t)CurrentNumber(); }
operator const char*() const { return CurrentString(); }
operator NBString()  const { return (NBString)CurrentString(); }
```

10.12.8 Validation Functions

10.12.8.1 IsValid() Method

Verify that a [JsonRef](#) points to valid data:

```
pjds("AnArray")[3].IsValid(); // returns true (valid element)
pjds("AnArray")[4].IsValid(); // returns false (out of bounds)
```

10.12.8.2 Type Checking Functions

Determine the type of JSON data:

```
IsNumber() // Check if element is a number
IsObject() // Check if element is an object
IsString() // Check if element is a string
IsBool()   // Check if element is boolean
IsNull()   // Check if element is null
IsArray()  // Check if element is an array
```

10.12.8.3 Validation Flow

10.12.9 Example References

Complete working examples demonstrating these concepts:

- **Basic Parsing:** `\nburn\examples\JsonLexer\ParseTest`
- **Complex Parsing:** `\nburn\examples\webclient\Earthquake`

The Earthquake example demonstrates parsing a large, complex JSON structure from a live web service and extracting specific fields efficiently.

10.12.9.1 Earthquake Example Application

10.12.9.1.1 Overview

This example retrieves earthquake data from the USGS API and parses the complex JSON response to display recent seismic activity.

10.12.9.2 Source Code

```
#include <init.h>
#include <stdio.h>
#include <ctype.h>
#include <buffers.h>
#include <json_lexer.h>
#include <webclient/http_funcs.h>
#include <nbttime.h>

const char* url = "https://earthquake.usgs.gov/earthquakes/feed/v1.0/summary/4.5_day.geojson";
const char* AppName = "EarthQuake";

void UserMain(void* pd)
{
    init(); // Initialize network stack
    EnableSystemDiagnostics(); // Enable diagnostics
    WaitForActiveNetwork(TICKS_PER_SECOND * 5); // Wait for DHCP address

    printf("Application started\n");

    bool bTimeSet = SetTimeNTPFromPool();

    if(bTimeSet) {
        printf("Time Set\r\n");
    }

    ParsedJsonDataSet JsonResult;
    bool result = DoGet(url, JsonResult);

    if (result)
    {
        // Get earthquake count from metadata
        int32_t nQuakes = JsonResult("metadata")("count");
        printf("In the last Day we have had %ld Earthquakes > 4.5\r\n", nQuakes);

        // Iterate through earthquake events
        for (int i = 0; i < nQuakes; i++)
        {
            // Create a reference to properties for this earthquake
            JsonRef OneQuakeProperties = JsonResult("features")[i]("properties");

            if (OneQuakeProperties.Valid())
            {
                double magnitude = OneQuakeProperties("mag");
                NBString place_name = OneQuakeProperties("place");
                printf("Magnitude :%2.1f at %s", magnitude, place_name.c_str());

                if (bTimeSet)
                {
                    time_t when = OneQuakeProperties("time");
                    when /= 1000;
                    time_t now = time(NULL);
                    time_t delta = (now - when);
                    int sec = delta % 60;
                    int mins = (delta / 60) % 60;
                    int hour = (delta / 3600);
                    printf(" %02d:%02d:%02d ago", hour, mins, sec);
                }
                printf("\r\n");
            }
            else
            {
                printf("Parse error failed to find array element %d\r\n", i);
            }
        }
    }
    else
    {
        printf("Failed to contact server\r\n");
    }

    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND * 1);
    }
}
```

10.12.9.3 JSON Structure Navigation

The earthquake data follows this hierarchy:

```
root
├── ("metadata")
│   └── ("count") → number of earthquakes
```

```

└─> ("features") ──> array
    └─> [i] ──> array element
        └─> ("properties")
            └─> ("mag") ──> magnitude
            └─> ("place") ──> location string
            └─> ("time") ──> timestamp

```

10.12.9.4 Data Extraction Flow

```

DoGet(url)
  |
  v
ParsedJsonDataSet
└─> metadata
    └─> count ──────────> Loop Control
└─> features[i]
    └─> properties
        └─> mag ─────────> Display
        └─> place ──────> Display
        └─> time ───────> Calculate & Display

```

10.12.9.5 Example Output

```

Application started
Time Set
In the last Day we have had 17 Earthquakes > 4.5
Magnitude :4.5 at Fiji region 01:44:12 ago
Magnitude :4.6 at 128 km W of San Juan, Peru 10:06:35 ago
Magnitude :4.5 at 7 km NW of Papayal, Peru 10:32:50 ago
Magnitude :4.9 at 56 km SSE of Sand Point, Alaska 10:47:22 ago
Magnitude :4.9 at 22 km SSE of Padong, Philippines 11:05:28 ago
Magnitude :5.1 at 70 km WNW of San Antonio de los Cobres, Argentina 12:25:58 ago
Magnitude :5.3 at 116 km SSE of Kushiro, Japan 13:12:09 ago
Magnitude :4.6 at 112 km SSE of Kushiro, Japan 13:13:00 ago
Magnitude :4.8 at 129 km WNW of Pangai, Tonga 13:49:43 ago
Magnitude :4.9 at 256 km ESE of Ust'-Kamchatsk Staryy, Russia 20:15:25 ago
Magnitude :4.6 at 120 km NNE of Tobelo, Indonesia 20:23:53 ago
Magnitude :4.9 at 57 km ESE of Koseda, Japan 21:28:56 ago
Magnitude :4.8 at 24 km NE of La Paz, Philippines 22:38:44 ago
Magnitude :4.5 at northern Qinghai, China 23:10:02 ago
Magnitude :4.6 at 8 km S of Padong, Philippines 23:13:24 ago
Magnitude :4.5 at Fiji region 23:19:04 ago
Magnitude :5.1 at 108 km SSE of Hihifo, Tonga 23:39:10 ago

```

10.12.10 USGS JSON Response Structure

10.12.10.1 Response Schema

The USGS earthquake API returns data in GeoJSON format with the following structure:

```

{
  "type": "FeatureCollection",
  "metadata": { ... },
  "features": [ ... ],
  "bbox": [ ... ]
}

```

10.12.10.2 Metadata Section

```

"metadata": {
  "generated": <timestamp>,
  "url": <string>,
  "title": <string>,
  "status": <number>,
  "api": <version>,
  "count": <number>
}

```

10.12.10.3 Features Array

Each earthquake event is represented as a feature:

```

"features": [
  {
    "type": "Feature",
    "properties": {

```

```

        "mag": <number>,
        "place": <string>,
        "time": <timestamp>,
        "updated": <timestamp>,
        "url": <string>,
        "status": <string>,
        "tsunami": <0|1>,
        ...
    },
    "geometry": {
        "type": "Point",
        "coordinates": [<lon>, <lat>, <depth>]
    },
    "id": <string>
},
...
]

```

10.12.10.4 Parsing Strategy

10.12.11 Complete JSON Sample

The following shows a condensed version of the actual JSON returned by the USGS API. To view the complete response structure when running the example, uncomment this line in the source code:

```
// JsonResult.PrintObject(true);
```

10.12.11.1 Sample Structure

```

{
  "type": "FeatureCollection",
  "metadata": {
    "generated": 1666815488000,
    "url": "https://earthquake.usgs.gov/earthquakes/feed/v1.0/summary/4.5_day.geojson",
    "title": "USGS Magnitude 4.5+ Earthquakes, Past Day",
    "status": 200,
    "api": "1.10.3",
    "count": 17
  },
  "features": [
    {
      "type": "Feature",
      "properties": {
        "mag": 4.5,
        "place": "Fiji region",
        "time": 1666809240464,
        "updated": 1666814388040,
        "url": "https://earthquake.usgs.gov/earthquakes/eventpage/us7000ikie",
        "status": "reviewed",
        "tsunami": 0,
        "type": "earthquake"
      },
      "geometry": {
        "type": "Point",
        "coordinates": [-178.3577, -20.3848, 551.981]
      },
      "id": "us7000ikie"
    },
    ...
  ],
  "bbox": [-178.3577, -24.0942, 10, 166.3788, 55.5213, 590.211]
}

```

10.12.12 Best Practices

10.12.12.1 Memory Management

- [JsonRef](#) objects are lightweight references, not copies
- `const char*` strings are valid only while the [ParsedJsonDataSet](#) exists
- Use [NBString](#) for persistent storage

10.12.12.2 Error Handling

Always validate before accessing data:

```
JsonRef element = pjds("SomeKey");
if (element.IsValid()) {
    // Safe to access
    int value = element;
} else {
    // Handle missing or invalid data
}
```

10.12.12.3 Performance Considerations

Best Practice: Cache [JsonRef](#) Objects

Good:

```
JsonRef props = pjds("features")[i]("properties");
double mag = props("mag");
NBString place = props("place");
```

Avoid:

```
double mag = pjds("features")[i]("properties")("mag");
NBString place = pjds("features")[i]("properties")("place");
```

10.12.12.4 Type Safety

Use type checking before conversion:

```
if (element.IsNumber()) {
    double value = element;
}
if (element.IsString()) {
    NBString text = element;
}
```

10.12.13 Advanced Usage

10.12.13.1 Nested Array Navigation

```
// Access deeply nested structures
JsonRef deepElement = pjds("level1")("level2")[index]("level3");
```

10.12.13.2 Dynamic Key Access

```
// Build key names at runtime
NBString keyName = "dynamic_" + NBString(i);
int value = pjds(keyName.c_str());
```

10.12.13.3 Array Iteration Patterns

```
// Safe iteration with validation
JsonRef array = pjds("myArray");
if (array.IsArray()) {
    for (int i = 0; array[i].IsValid(); i++) {
        // Process array[i]
    }
}
```

10.12.14 Summary

The JSON Lexer provides a powerful, intuitive interface for working with JSON data in NetBurner applications:

- [ParsedJsonDataSet](#) handles parsing and storage
- [JsonRef](#) simplifies navigation of complex structures
- Automatic type conversion reduces boilerplate code
- Validation functions ensure safe data access
- Performance optimizations through internal poolBuffer management

For complete working examples, refer to the NetBurner example applications in the `\nburn\examples` directory.

10.13 NetBurner RTOS

10.13.1 Introduction

The NetBurner Real-Time Operating System (NBRTOS) is a full-featured preemptive multitasking RTOS supporting:

- Multiple tasks with 255 priority levels
- Semaphores for resource protection
- Mailboxes for message passing
- FIFOs for flexible queuing
- Message queues for structured communication
- Critical sections for mutual exclusion

The RTOS comes pre-configured as part of the NetBurner development package. Your application begins execution in the `UserMain()` task.

10.13.2 Priority Levels

To conserve system resources, the default number of tasks is 64, with 64 being the Idle task that will run when all other higher priority tasks are blocked. You can increase the number of tasks up to 255. There are a number of system tasks running at priorities defined in [constants.h](#). The recommended `UserMain()` priority is `MAIN_PRIO`, which is a value of 50. When creating additional tasks:

- Add or subtract from `MAIN_PRIO` for readability. For example, `MAIN_PRIO-1` is a higher priority task, which `MAIN_PRIO+1` is a lower priority task.

- Use the helper task function: `OSGetNextPrio()` to choose. For example, `OSGetNextPrio(← OSNextPrio::Above)`

```
enum class OSNextPrio {
    Maximum = -2, // Highest priority currently unused, 0->OS_LO_PRIO
    Above = -1, // Lowest priority that is higher than the current task, OSTaskID()->0
    Below = 0, // Highest priority that is lower than the current task,
    OSTaskID()->OS_LO_PRIO
    Next = Below, // Highest priority that is lower than the current task,
    OSTaskID()->OS_LO_PRIO
    Minimum = 1 // Lowest priority currently unused, OS_LO_PRIO->0
};
```

Task Priority Range:

Priority Range: 1 - 255 (Default maximum is 64).

Lower Number = Higher Priority 1 <--- Highest Priority 2 .

```

.   Application Tasks
.
64 <--- Lowest Priority (Idle)
.   (Default Maximum)
.
.
.
.
254
255 <--- Lowest Priority

```

Important**: Each priority level can only be used by ONE task at a time. Always check return values when creating tasks or changing priorities.

10.13.3 What is a Preemptive RTOS?

10.13.4 Core Principle

The highest priority task ready to run will ALWAYS run.**

This is fundamentally different from time-sliced operating systems like Windows or Unix. In NBRRTOS:

- No round-robin scheduling
- No time slices
- Priority-based execution only

10.13.5 Task Execution Flow

10.13.6 Blocking Scenarios

A higher priority task MUST block for lower priority tasks to execute:

10.13.7 Function Categories

10.13.7.1 RTOS Blocking Functions

Functions that pend on resources or create time delays:

- `OSTimeDly()` - Time delay
- `OSSemPend()` - Semaphore wait
- `OSMboxPend()` - Mailbox wait
- `OSQPend()` - Queue wait
- `OSFlagPendAny()` - Flag wait (any)
- `OSFlagPendAll()` - Flag wait (all)

10.13.7.2 I/O Functions That Block

Functions that perform read operations or pend on file descriptors:

- `select()` - Wait for I/O readiness
- `read()` - Read data (blocks until data available)
- `write()` - Write data (blocks until space available)
- `gets()` - Get string from input
- `getchar()` - Get character
- `fgets()` - Get string from file

10.13.7.3 Network Functions That Block

Functions that wait for connections or data:

- `accept()` - Wait for incoming connection
- `UDPPacket()` - Wait to receive UDP packet (when configured for receive)

10.13.7.4 Functions That Unblock Tasks

Functions that post to pending resources:

- `OSMboxPost()` - Post message to mailbox
- `OSQPost()` - Post message to queue
- `OSSemPost()` - Post to semaphore

10.13.8 System Task Priorities

System tasks use predefined priority levels defined in `nbrtos/include/constants.h`. The exact tasks depend on:

- Your platform (MOD5441X, SOMRT1061, etc.)
- Enabled system features (HTTP server, network stack, etc.)

Example*: Calling `StartHTTP()` creates a system task for web server request handling.

10.13.9 Task Creation

10.13.10 Entry Point: UserMain()

Every NetBurner application begins in the `UserMain()` task, which is created automatically by the system.

10.13.11 Task Creation Methods

10.13.11.1 Method 1: OSTaskCreatewName() - Full Control

Provides complete control over all task parameters with status return value.

Parameters**:

1. Task function name
2. Optional parameter to pass (NULL if unused)
3. Top of task stack
4. Bottom of task stack

5. Task priority
6. Task name (string)

Returns**: Status code (OS_NO_ERR on success)

10.13.11.2 Method 2: OSSimpleTaskCreatewName() - Simplified

Automatically allocates stack space, requires only:

1. Task function name
2. Task priority
3. Task name (string)

Note**: Does not return status code

10.13.12 Priority Selection Helper

Use `OSGetNextPrio()` to automatically find an available priority, but ensure:

- Not higher than critical system tasks (e.g., `ETHER_TASK_PRIO`)
- Not too low for your real-time requirements
- Refer to [constants.h](#) for system priority definitions

10.13.13 Complete Example

```

/*
    Task Creation Example
    Demonstrates both OSTaskCreateName() and OSSimpleTaskCreateName()
*/
#include <init.h>
#include <stdlib.h>
#include <nbrtos.h>
#include <system.h>
#include <utils.h>

const char *AppName = "Task Creation Example";

// Stack allocation for full task creation method
uint32_t TaskAllParamsStack[USER_TASK_STK_SIZE];

/*
    Task created with OSTaskCreateName()
    Demonstrates passing parameters and full control
*/
void TaskAllParams(void *pd)
{
    uint32_t loopCount = 0;
    uint32_t delayTime = (uint32_t)pd; // Cast parameter

    printf("TaskAllParams delay: %ld seconds\r\n", delayTime);

    while (1)
    {
        printf("TaskAllParams iteration: %ld\r\n", loopCount);
        loopCount++;
        OSTimeDly(TICKS_PER_SECOND * delayTime);
    }
}

/*
    Task created with OSSimpleTaskCreateName()
    Simplified creation with automatic stack allocation
*/
void TaskSimple(void *pd)
{
    uint32_t loopCount = 0;
    uint32_t delayTime = 6;

    printf("TaskSimple delay: %ld seconds\r\n", delayTime);

    while (1)
    {
        printf("TaskSimple iteration: %ld\r\n", loopCount);
        loopCount++;
        OSTimeDly(TICKS_PER_SECOND * delayTime);
    }
}

/*
    Main entry point
*/
void UserMain(void *pd)
{
    uint32_t delayTime = 3;
    int returnCode;

    init(); // Initialize network stack
    WaitForActiveNetwork(TICKS_PER_SECOND * 5); // Wait for DHCP

    // Create task with full parameter control
    printf("Creating TaskAllParams...\n");
    returnCode = OSTaskCreateName(
        TaskAllParams, // Task function
        (void *)delayTime, // Parameter to pass
        &TaskAllParamsStack[USER_TASK_STK_SIZE], // Stack top
        TaskAllParamsStack, // Stack bottom
        MAIN_PRIO - 1, // Priority
        "TaskAllParams" // Name
    );

    if (returnCode == OS_NO_ERR)
        printf("Success\r\n");
    else
        printf("*** Error: %d\r\n", returnCode);

    // Create task with simplified method
    printf("Creating TaskSimple\r\n");
    OSSimpleTaskCreateName(TaskSimple, MAIN_PRIO - 2, "TaskSimple");

    while (1)

```

```

{
    OSTimeDly(TICKS_PER_SECOND);
}

```

10.13.14 Protecting Shared Data

10.13.15 Mechanism Selection Guide

Choose the appropriate protection mechanism based on your needs:

10.13.16 Protection Mechanisms (Ordered by System Impact)

10.13.17 Detailed Mechanism Comparison

Mechanism	Purpose	Blocks	IRQ Impact	Best For
OSSemPend()/Post()	Signal/protect resource	Task only	None	Event signaling, simple resource protection
OSMboxPend()/Post()	Pass pointer message	Task only	None	Passing single message/pointer between tasks
OSQPend()/Post()	Message queue (FIFO)	Task only	None	Multiple messages, bounded queue
OSFifoPend()/Post()	Linked list queue	Task only	None	Unbounded message passing, complex structures
OSCritEnter()/Exit()	Counted mutex	Task only	None	Multi-task resource protection

Mechanism	Purpose	Blocks	IRQ Impact	Best For
OSLock()/Unlock()	Disable task switch	All tasks	None	Short critical sections
USER_ENTER/EXIT↔ _CRITICAL()	Disable all	Tasks + IRQs	All disabled	Absolute protection (use sparingly)

10.13.18 Important Considerations

10.13.18.1 Queue vs. FIFO

Queue**:

- Fixed size (declared at compile time)
- Bounded memory usage
- Predictable behavior
- Good for embedded systems

FIFO**:

- Dynamic size (linked list)
- Memory allocated by application
- Flexible but requires memory management
- Avoid dynamic allocation in embedded systems

Recommendation**: Use static memory pools for FIFO structures to avoid fragmentation.

10.13.19 Semaphores

10.13.20 Concept

A semaphore is a protected counter used for:

- Controlling access to shared resources
- Signaling event occurrence
- Task synchronization

10.13.21 Operation Flow

10.13.22 Usage Pattern

```

// 1. Declare semaphore
OS_SEM MySemaphore;

// 2. Initialize semaphore (typically in UserMain)
OS_SemInit(&MySemaphore, 0); // Initial value: 0

// 3. Post to semaphore (signal/release)
  
```

```

OSSemPost (&MySemaphore);

// 4. Pend on semaphore (wait/acquire)
OSSemPend(&MySemaphore, 0); // 0 = wait forever

// 5. Pend with timeout
OSSemPend(&MySemaphore, TICKS_PER_SECOND * 5); // Wait 5 seconds

```

10.13.23 Timeout Specification

Timeout Parameter:

0	= Wait forever
TICKS_PER_SECOND	= 1 second
TICKS_PER_SECOND * 5	= 5 seconds
TICKS_PER_SECOND / 2	= 500 milliseconds

10.13.24 Resource Protection Example

```

OS_SEM SerialPortSem;

void UserMain(void *pd) {
    init();
    OSSemInit(&SerialPortSem, 1); // Initial count: 1 (available)

    // Create tasks that share serial port...
}

void TaskA(void *pd) {
    while (1) {
        OSSemPend(&SerialPortSem, 0); // Acquire

        // Protected: exclusive access to serial port
        SerialPort.Write("Task A\r\n");

        OSSemPost (&SerialPortSem); // Release

        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

10.13.25 Message Queues

10.13.26 Concept

Message queues enable tasks and ISRs to send and receive pointer-sized messages. The pointers typically reference structures or objects containing actual data.

10.13.27 Queue Structure

10.13.28 Message Flow

10.13.29 Usage Example

```

// Define message structure
typedef struct {
    uint32_t sensorId;
    float temperature;
    uint32_t timestamp;
} SensorReading;

// Declare queue
OS_Q SensorQueue;
void *SensorQueueStorage[10]; // Storage for 10 messages

void UserMain(void *pd) {
    init();

    // Initialize queue with 10 entries
    OSQInit(&SensorQueue, SensorQueueStorage, 10);

    // Create producer and consumer tasks...
}

void SensorTask(void *pd) {
    SensorReading reading;

    while (1) {
        // Read sensor
        reading.sensorId = 1;
        reading.temperature = ReadSensor();
        reading.timestamp = Secs;

        // Post to queue
        OSQPost(&SensorQueue, (void *)&reading);

        OSTimeDly(TICKS_PER_SECOND);
    }
}

void ProcessingTask(void *pd) {
    while (1) {
        // Wait for message
        SensorReading *msg = (SensorReading *)OSQPend(&SensorQueue, 0);

        // Process message
        printf("Sensor %lu: %.2fC at %lu\r\n",
            msg->sensorId, msg->temperature, msg->timestamp);
    }
}

```

10.13.30 FIFOs

10.13.31 Concept

FIFOs are similar to queues but specifically designed for linked-list-based message passing. Unlike queues with fixed size, FIFOs grow dynamically within available memory.

10.13.32 Structure Requirements

The first element of any FIFO structure MUST be a `void *` pointer for OS internal linking:

```

typedef struct MyFifoStruct {
    void *next; // REQUIRED: Must be first element
    uint32_t data1; // Your data
    float data2; // Your data
    char message[64]; // Your data
} MyFifoStruct;

```

10.13.33 FIFO Architecture

10.13.34 Memory Management Strategies

10.13.34.1 Strategy 1: Static Pool (Recommended)

```

#define FIFO_POOL_SIZE 20

// Create static pool of FIFO structures
MyFifoStruct fifoPool[FIFO_POOL_SIZE];
bool poolInUse[FIFO_POOL_SIZE] = {false};

// Allocate from pool
MyFifoStruct* AllocateFifoStruct() {
    for (int i = 0; i < FIFO_POOL_SIZE; i++) {
        if (!poolInUse[i]) {
            poolInUse[i] = true;
            return &fifoPool[i];
        }
    }
    return NULL; // Pool exhausted
}

// Return to pool
void FreeFifoStruct(MyFifoStruct *ptr) {
    int index = ptr - fifoPool;
    if (index >= 0 && index < FIFO_POOL_SIZE) {
        poolInUse[index] = false;
    }
}

```

10.13.34.2 Strategy 2: Dynamic Allocation (Not Recommended)

```

// Avoid in embedded systems due to fragmentation risk
MyFifoStruct *ptr = (MyFifoStruct *)malloc(sizeof(MyFifoStruct));
// ... use ...
free(ptr);

```

10.13.35 Queue vs. FIFO Decision

Choose Queue When:

```

Fixed message count
Predictable memory
Simple data types
Bounded behavior

```

Choose FIFO When:

```

Variable msg count
Complex structures
Need flexibility
Can manage memory

```

10.13.36 FIFO Functions

- OSFifoInit() - Initialize FIFO
- OSFifoPost() - Add to end of FIFO
- OSFifoPostFirst() - Add to front of FIFO (priority)
- OSFifoPend() - Wait for and remove first item
- OSFifoPendNoWait() - Check and remove without waiting

10.13.37 Critical Sections

10.13.38 OSCrit - Counted Critical Section

A counting mutex that restricts resource access to one task at a time.

10.13.39 Operation Flow

10.13.40 Counting Behavior

Critical Section Counter:

```

OSCritEnter()  -> Count++
OSCritExit()   -> Count--

When Count reaches 0:
-> Resource released
-> Next task can enter
  
```

10.13.41 Usage Examples

10.13.41.1 Manual Enter/Exit

```

OSCritObj linkedListGuard;

void TaskA(void *pd) {
    while (1) {
        OSCritEnter(&linkedListGuard, 0); // Enter critical section

        // Protected: manipulate linked list
        linkedList.Add(data);

        OSCritExit(&linkedListGuard);      // Exit critical section

        OSTimeDly(TICKS_PER_SECOND);
    }
}
  
```

10.13.41.2 C++ Scoped Object (Recommended)

```

OSCritObj linkedListGuard;

void TaskB(void *pd) {
    while (1) {
        {
            // Automatic enter on construction
            OSCritObj lock(&linkedListGuard);

            // Protected: manipulate linked list
            linkedList.Remove(data);

        } // Automatic exit on destruction (scope end)

        OSTimeDly(TICKS_PER_SECOND);
    }
}
  
```

10.13.42 OSCrit vs. OSLock

OSCrit vs OSLock
OSCrit (Resource Mutex): - Blocks only tasks accessing same resource - Other tasks can still run - IRQs not affected - Good for: Protecting shared data OSLock (Task Switch Disable): - Blocks ALL task switching - No tasks can preempt - IRQs still run - Good for: Brief critical operations

10.13.43 OSLock Usage Pattern

```
void QuickOperation() {
    OSLock(); // Disable task switching

    // Very brief critical operation
    // (keep this SHORT!)
    globalCounter++;

    OSUnlock(); // Enable task switching
}

// C++ scoped version
void QuickOperationCpp() {
    {
        OSLockObj lock; // Auto OSLock() on creation

        // Brief critical operation
        globalCounter++;

    } // Auto OSUnlock() on destruction
}
```

Warning:** Keep OSLock sections as short as possible to maintain system responsiveness.

10.13.44 OS Flags

10.13.45 Concept

OSFlags enable monitoring multiple events simultaneously using a 32-bit bitmap where each bit represents a distinct flag or event.

10.13.46 Flag Bitmap Structure

32-bit Flag Register:

10.13.47 Flag Operations

Flag Manipulation:

```
OSFlagSet(flags, 0x0001)
[Bit 0 = 1]

OSFlagSet(flags, 0x0004)
[Bit 0 = 1, Bit 2 = 1]

OSFlagClear(flags, 0x0001)
```

```
[Bit 2 = 1]
```

10.13.48 Pending Modes

Wait **for** ANY flag (OR):

```
Mask: 0x0007 (bits 0, 1, 2)

OSFlagPendAny(flags, 0x0007, ...)

Unblocks when:
Bit 0 = 1 OR
Bit 1 = 1 OR
Bit 2 = 1
```

Wait for ALL flags (AND):

```
Mask: 0x0007 (bits 0, 1, 2)

OSFlagPendAll(flags, 0x0007, ...)

Unblocks when:
Bit 0 = 1 AND
Bit 1 = 1 AND
Bit 2 = 1
```

10.13.49 Flag Functions Summary

Function	Description
OSFlagCreate()	Create flag object
OSFlagSet()	Set specified bits
OSFlagClear()	Clear specified bits
OSFlagState()	Read current flag value
OSFlagPendAll()	Wait until ALL specified flags set
OSFlagPendAny()	Wait until ANY specified flag set
OSFlagPendNoWait()	Check ALL flags without waiting
OSFlagPendAnyNoWait()	Check ANY flag without waiting

10.13.50 Usage Example

```
OS_FLAGS systemFlags;

// Define flag bits
#define FLAG_SENSOR_READY 0x0001 // Bit 0
#define FLAG_NETWORK_UP 0x0002 // Bit 1
#define FLAG_DATA_AVAILABLE 0x0004 // Bit 2
#define FLAG_ERROR 0x0008 // Bit 3

void UserMain(void *pd) {
    init();
    OSFlagCreate(&systemFlags);

    // Create tasks...
}

void SensorTask(void *pd) {
    while (1) {
        // Read sensor
        if (SensorValid()) {
            OSFlagSet(&systemFlags, FLAG_SENSOR_READY);
        }
        OSTimeDly(TICKS_PER_SECOND);
    }
}

void ProcessingTask(void *pd) {
    while (1) {
        // Wait for sensor AND network
        uint32_t flags = OSFlagPendAll(
            &systemFlags,
```

```

        FLAG_SENSOR_READY | FLAG_NETWORK_UP,
        TICKS_PER_SECOND * 10
    );

    if (flags) {
        // Both conditions met, process data
        ProcessSensorData();

        // Clear flags
        OSFlagClear(&systemFlags, FLAG_SENSOR_READY);
    }
}

void MonitorTask(void *pd) {
    while (1) {
        // Check for any error condition (non-blocking)
        uint32_t flags = OSFlagPendAnyNoWait(
            &systemFlags,
            FLAG_ERROR
        );

        if (flags & FLAG_ERROR) {
            printf("Error detected!\r\n");
            OSFlagClear(&systemFlags, FLAG_ERROR);
        }

        OSTimeDly(TICKS_PER_SECOND / 10);
    }
}

```

10.13.51 System Configuration

10.13.52 Predef.h and Predef-overload.h

The NetBurner system uses `predef.h` for base-level system configuration through `#define` statements.

10.13.53 Configuration Architecture

System Configuration Hierarchy:

10.13.54 Why Use Predef-overload.h?

Problems with modifying `predef.h` directly**:

1. File changes frequently between NNDK releases
2. Difficult to track your custom changes
3. Merge conflicts during updates
4. Confusing compilation errors after upgrades

Benefits of `predef-overload.h`**:

1. Only contains YOUR changes
2. Survives NNDK updates cleanly
3. Easy to review and maintain
4. No merge conflicts

10.13.55 Setup Methods

10.13.55.1 NBEclipse Setup

Refer to NBEclipse Getting Started Guide - Overload Directory section

10.13.55.2 Command Line Tools Setup

Refer to Command Line Tools - Overload section

10.13.56 Predef-overload.h Best Practices

```
/*
    predef-overload.h
    Custom system configuration overrides
*/

// Best practice: #undef before #define
// Prevents duplicate definition warnings

// Example 1: Disable IPv6
#undef IPV6
#undef IPV4ONLY
#define IPV4ONLY (1)

// Example 2: Custom buffer sizes
#undef TCP_BUFFER_SIZE
#define TCP_BUFFER_SIZE (8192)

// Example 3: Enable debug features
#undef DEBUG_LEVEL
#define DEBUG_LEVEL (2)

// Example 4: Stack sizes
#undef USER_TASK_STK_SIZE
#define USER_TASK_STK_SIZE (4096)
```

10.13.57 Configuration Workflow

Development Process:

10.13.58 Common Configuration Overrides

```
// Network Configuration
#undef IPV4ONLY
#define IPV4ONLY (1)           // IPv4-only mode

#undef DEFAULT_NET_TIMEOUT
```

```

#define DEFAULT_NET_TIMEOUT (30)           // 30 second timeout

// Task Configuration
#undef USER_TASK_STK_SIZE
#define USER_TASK_STK_SIZE (8192)         // 8KB stack per task

#undef MAX_USER_TASKS
#define MAX_USER_TASKS (20)                // Support 20 user tasks

// System Resources
#undef NUM_OS_FIFOS
#define NUM_OS_FIFOS (32)                  // 32 FIFO objects

#undef NUM_OS_SEMS
#define NUM_OS_SEMS (64)                   // 64 semaphores

// Debug Configuration
#undef DEBUG_BUILD
#define DEBUG_BUILD (1)                    // Enable debug features

#undef ENABLE_REMOTE_CONSOLE
#define ENABLE_REMOTE_CONSOLE (1)          // Enable remote console

```

10.13.59 Verification After Changes

```

# Clean build to ensure all changes applied
make clean

# Rebuild with new configuration
make

# Verify settings at runtime
# Check console output or use system diagnostics

```

10.13.60 Summary

10.13.61 Key Takeaways

1. RTOS Fundamentals

- Highest priority ready task always runs
- Tasks must block for lower priority tasks to execute
- 255 priority levels (1 = highest, 255 = lowest)

2. Task Creation

- Entry point: `UserMain()`
- Full control: `OSTaskCreateName()`
- Simplified: `OSSimpleTaskCreateName()`

3. Data Protection Hierarchy

Semaphore < Mailbox < Queue < FIFO < OSCrit < OSLock < Critical Section
(Least impact) —————> (Most impact)

4. Best Practices

- Use `predef-overload.h` for configuration
- Prefer static memory over dynamic allocation
- Keep critical sections short
- Check return values from task creation
- Match enter/exit calls for counted resources

5. Configuration Management

- Never modify `predef.h` directly
- Use `predef-overload.h` for customization
- Always `#undef` before `#define`
- Clean rebuild after configuration changes

10.13.62 Quick Reference

Common RTOS Calls:

```

├── Timing
│   └── OSTimeDly(TICKS_PER_SECOND)
├── Semaphores
│   ├── OSSemInit(&sem, 0)
│   ├── OSSemPend(&sem, timeout)
│   └── OSSemPost(&sem)
├── Queues
│   ├── OSQInit(&queue, storage, size)
│   ├── OSQPend(&queue, timeout)
│   └── OSQPost(&queue, msg)
├── Flags
│   ├── OSFlagCreate(&flags)
│   ├── OSFlagSet(&flags, bits)
│   ├── OSFlagPendAny(&flags, mask, timeout)
│   └── OSFlagPendAll(&flags, mask, timeout)
└── Critical Sections
    ├── OSCritEnter(&crit, timeout)
    ├── OSCritExit(&crit)
    ├── OSLock()
    └── OSUnlock()

```

10.14 Network Protocols TCP and UDP

10.14.1 TCP vs UDP Comparison

This guide covers TCP and UDP network protocols in NetBurner applications, including practical implementation patterns and complete working examples. The first section is an overview and comparison of TCP vs UDP, followed by detailed discussions of each:

- [TCP Protocol](#)
- [UDP Protocol](#)

When designing network applications, choosing between TCP (Transmission Control Protocol) and UDP (User Datagram Protocol) is a critical architectural decision. Each protocol serves different use cases based on reliability requirements, overhead tolerance, and application characteristics.

10.14.1.1 Protocol Characteristics

10.14.1.1.1 TCP (Transmission Control Protocol)

- **Connection-oriented:** Point-to-point stream-based protocol
- **Reliable delivery:** Guarantees packet delivery with acknowledgments
- **Ordered transmission:** Data arrives in the same sequence it was sent
- **Error detection:** Built-in error checking and retransmission
- **Stream-based:** Continuous data flow without message boundaries

10.14.1.1.2 UDP (User Datagram Protocol)

- **Connectionless:** Fire-and-forget datagram protocol
- **Best-effort delivery:** No delivery guarantees
- **Unordered:** Packets may arrive out of sequence
- **Lightweight:** Minimal overhead, no connection establishment
- **Message-based:** Each send operation creates one discrete datagram

10.14.1.2 Protocol Comparison Diagram

10.14.1.3 Real-World Analogies

TCP*: Like a telephone call

- Establish connection (dial and answer)
- Two-way conversation with confirmation ("Hello?" "Yes, I hear you")
- Orderly exchange of information
- Explicit termination ("Goodbye")

UDP*: Like sending postcards

- Write and send without confirmation
- No guarantee of delivery
- No confirmation the recipient received it
- Messages may arrive out of order

10.14.1.4 Decision Factors

10.14.1.4.1 Choose TCP When:

- **Reliability is critical:** Financial transactions, control commands, configuration data
- **Order matters:** Sequential data like file transfers or protocol messages
- **Connection state is useful:** Authentication, session management
- **Data integrity is paramount:** Critical system operations

10.14.1.4.2 Choose UDP When:

- **Speed is essential:** Real-time applications, gaming, video streaming
- **Overhead is prohibitive:** High-frequency sensor data, telemetry
- **Application handles reliability:** Custom retry logic at application layer
- **Broadcast/multicast needed:** Network discovery, status updates
- **Occasional loss is acceptable:** Streaming media, periodic updates

10.14.1.5 Common Protocol Usage

10.14.1.5.1 Applications Using TCP:

- HTTP/HTTPS - Web traffic
- FTP - File transfers
- Telnet - Remote terminal
- SMTP - Email transmission
- SSH - Secure remote access

10.14.1.5.2 Applications Using UDP:

- **DHCP** - Network configuration
- BOOTP - Bootstrap protocol
- SNMP - Network monitoring
- DNS - Name resolution
- NTP - Time synchronization
- VoIP - Voice communications

10.14.1.6 Performance Considerations

TCP Overhead Example**:

Sending 10 A/D readings **using** TCP (single connection):

```
9827312932342498273129323424982731293234 <- Stream of digits
```

Problem: Cannot identify individual readings without delimiters

UDP Datagram Example**:

Sending 10 A/D readings **using** UDP:

```
9827 3129 3234 2498 ...
```

Advantage: Each reading is a discrete packet

10.14.1.7 Key Takeaways

1. **TCP** provides reliability at the cost of overhead and connection management
2. **UDP** provides speed and simplicity at the cost of reliability
3. **SNMP** uses UDP to avoid connection overhead when monitoring many devices
4. **Custom protocols** may choose UDP and implement their own reliability layer
5. **Connection parameters:** TCP requires 4-tuple (source IP, source port, dest IP, dest port)

10.14.1.8 Additional Resources

10.14.1.8.1 NetBurner Tools

- **UDP Terminal** (Windows): Test UDP communication from PC
- **TcpServerWin.exe**: Simple TCP server for testing
- **MTTTY**: Serial terminal for debug output
- **nbdiscovery**: Network device discovery

10.14.1.9 Quick Reference

10.14.1.9.1 TCP Functions

Function	Description
listen()	Create listening socket
accept()	Accept incoming connection
connect()	Initiate outbound connection
read()	Receive data
write()	Send data
close()	Close connection
select()	Multiplex multiple connections
fdprintf()	Formatted output to socket
writestring()	Send string to socket

10.14.1.9.2 UDP Class Methods

Function	Description
RegisterUDPFifo()	Register FIFO for port
UDPPacket()	Constructor (receives packet)
Validate()	Check packet validity
GetDataBuffer()	Get packet data pointer
GetDataSize()	Get data length
GetSourceAddress()	Get sender IP

Function	Description
SetSourcePort()	Set source port
SetDestinationPort()	Set destination port
AddData()	Add data to packet
Send()	Transmit packet

10.14.1.9.3 UDP Socket Functions

Function	Description
RegisterUDPFifo()	Register FIFO for port
UDPPacket()	Constructor (receives packet)
Validate()	Check packet validity
GetDataBuffer()	Get packet data pointer
GetDataSize()	Get data length
GetSourceAddress()	Get sender IP
SetSourcePort()	Set source port
SetDestinationPort()	Set destination port
AddData()	Add data to packet
Send()	Transmit packet
CreateRxUdpSocket()	Create receive socket
CreateTxUdpSocket()	Create transmit socket
recvfrom()	Receive datagram
sendto()	Send datagram

10.14.2 TCP Protocol

10.14.2.1 TCP Protocol

TCP establishes a reliable byte-stream connection between two network hosts. The listening host is the **server**, and the connecting host is the **client**. Unlike UDP, TCP transmits data as a continuous stream without automatic message boundaries.

10.14.2.2 TCP Stream Behavior

Data Transmission Without Delimiters:

```
Sender: "9827" "3129" "3234" "2498"
        [send] [send] [send] [send]
```

↓
v TCP Stream

```
Receiver sees: "98273129323424498..."
Problem: Where does one message end?
```

Solution: Application must add delimiters/framing

10.14.2.3 TCP Connection Requirements

Every TCP connection requires four parameters:

- Source IP address
- Source port number
- Destination IP address
- Destination port number

10.14.2.4 Well-Known Port Numbers

Protocol	Port	Description
FTP	21	File Transfer
Telnet	23	Remote Terminal
SMTP	25	Email Sending
DNS	53	Name Resolution
TFTP	69	Trivial FTP
HTTP	80	Web Traffic
POP3	110	Email Retrieval
NTP	123	Time Sync

10.14.2.5 TCP Server Implementation

A TCP server listens for incoming connections on a specified port, accepts connection requests, and communicates with connected clients.

10.14.2.5.1 TCP Server Flow

Server Lifecycle:

10.14.2.5.2 TCP Server Functions

Core functions for TCP server implementation:

- `listen()` - Open a listening socket on a specific port
- `accept()` - Accept incoming connection requests (blocking)
- I/O functions - `read()`, `write()`, `fdprintf()`, `writestring()`
- `close()` - Close network socket

10.14.2.5.3 Basic TCP Server Example

A NetBurner embedded TCP server application that creates a listening socket on port 23 (Telnet) and accepts client connections for communication. Location*: \nburn\examples\TCP

10.14.2.5.3.1 Overview

This application demonstrates how to implement a basic TCP server on NetBurner hardware. The server listens for incoming connections and provides a simple echo-style communication interface where it receives data from clients and displays it locally.

10.14.2.5.3.2 Features

- **TCP Server:** Creates a listening socket on port 23 (standard Telnet port)
- **Client Connection Handling:** Accepts incoming TCP connections from clients
- **Data Reception:** Reads data from connected clients using a simple `read()` function

- **Connection Management:** Handles client disconnections gracefully
- **Multi-tasking:** Uses RTOS tasks for concurrent operation

10.14.2.5.3.3 Technical Details

Configuration

- **Listen Port:** 23 (Telnet)
- **Receive Buffer Size:** 4096 bytes
- **Maximum Pending Connections:** 5
- **Task Priority:** MAIN_PRIO - 1 (higher than UserMain)

10.14.2.5.3.4 Key Components

TcpServerTask

The main server task that:

1. Creates a listening socket bound to INADDR_ANY on the specified port
2. Waits for client connections using `accept ()`
3. Sends welcome messages to connected clients
4. Continuously reads data from clients until disconnection
5. Closes connections and waits for new ones

Buffer Management

- Uses a global receive buffer (`RXBuffer`) of 4096 bytes
- Null-terminates received data for string processing
- Displays received data length and content via `printf()`

10.14.2.5.3.5 Usage

Testing with Telnet

To test the TCP server, use a Telnet client from any system on the same network:

```
telnet <netburner_ip_address>
```

Where `<netburner_ip_address>` is the IP address of your NetBurner device.

Expected Behavior

1. The server displays "Waiting for connection on port 23..."
2. When a client connects, it shows the client's IP address
3. The client receives welcome messages:
 - "Welcome to the NetBurner TCP Server"
 - Connection details with server IP and port
4. Any data sent by the client is echoed to the server console
5. When the client disconnects, the server closes the connection and waits for new ones

10.14.2.5.3.6 Implementation Notes

Connection Lifecycle

- The server uses a blocking `accept()` call to wait for connections
- Each client connection is handled sequentially (single client at a time)
- The `read()` function blocks until data is received or connection closes
- Connection closure is detected when `read()` returns 0 or negative value

Limitations

- **Single Client:** This example handles one client connection at a time
- **Sequential Processing:** New connections must wait until the current client disconnects
- **No Timeout:** Connections remain open indefinitely until client closes

For Multiple Clients

This example uses a simple `read()` approach for single client connections. For handling multiple simultaneous client connections, refer to the "TCP Multi Socket Server" example.

```
#include <init.h>
#include <tcp.h>
#include <iosys.h>
#include <fdprintf.h>

const char *AppName = "Simple TCP Server Example";

#define TCP_LISTEN_PORT 23 // Telnet port number
#define RX_BUFSIZE (4096)

char RXBuffer[RX_BUFSIZE];

// Allocate task stack for TCP listen task
uint32_t TcpServerTaskStack[USER_TASK_STK_SIZE];

/*-----
   TCP Server Task
   -----*/
void TcpServerTask(void *pd)
{
    int listenPort = (int)pd;

    // Set up the listening TCP socket
    int fdListen = listen(INADDR_ANY, listenPort, 5);

    if (fdListen > 0)
    {
        IPADDR clientAddress;
        uint16_t clientPort;

        while (1)
        {
            /* The accept() function will block the current task until a TCP client
               requests a connection. Once a client connection is accepting, the
               file descriptor fdAccept is used to read/write to it.
            */
            printf("Waiting for connection on port %d...\n", listenPort);
            int fdAccept = accept(fdListen, &clientAddress, &clientPort, 0);
            printf("Connected to: %I\r\n", GetSocketRemoteAddr(fdAccept));

            writestring(fdAccept, "Welcome to the NetBurner TCP Server\r\n");
            fdprintf(fdAccept, "You are connected to IP Address %I:%d\r\n", GetSocketRemoteAddr(fdAccept),
                GetSocketRemotePort(fdAccept));

            while (fdAccept > 0)
            {
                /* Loop while connection is valid. The read() function will return 0 or a negative number if
                   the client closes the connection, so we test the return value in the loop. Note: you can also
                   use ReadWithTimeout() in place of read to enable the connection to terminate after a period of
                   inactivity.
                */
                int n = 0;
                do
                {

```

```

        n = read(fdAccept, RXBuffer, RX_BUFSIZE);
        RXBuffer[n] = '\0';
        printf("Read %d bytes: %s\n", n, RXBuffer);
    } while (n > 0);

    printf("Closing client connection: %I\r\n", GetSocketRemoteAddr(fdAccept));
    close(fdAccept);
    fdAccept = 0;
}
} // while(1)
} // while listen
}

/*-----
User Main
-----*/
void UserMain(void *pd)
{
    init();
    //Enable system diagnostics. Probably should remove for production code.
    EnableSystemDiagnostics();
    WaitForActiveNetwork(TICKS_PER_SECOND*5);

    // Create TCP Server task
    OSTaskCreateWName(TcpServerTask,
        (void *)TCP_LISTEN_PORT,
        &TcpServerTaskStack[USER_TASK_STK_SIZE],
        TcpServerTaskStack,
        MAIN_PRIO - 1, /* higher priority than UserMain */
        "TCP Server");

    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND * 5);
    }
}

```

10.14.2.5.3.7 Basic Server Limitations

This simple example demonstrates core TCP server concepts but has limitations:

- Listens on only one port
- Handles only one connection at a time
- No graceful connection termination from server side
- Client must close connection

10.14.2.5.4 Multi-Connection Server Example

For production applications, use `select()` to handle multiple simultaneous connections efficiently.

10.14.2.5.4.1 Overview

This application demonstrates a TCP server implementation that can handle multiple simultaneous client connections using the NetBurner embedded platform. The server uses the `select()` function to efficiently manage multiple TCP connections concurrently without blocking.

10.14.2.5.4.2 Features

- **Multi-client support:** Handles up to 10 simultaneous TCP connections
- **Non-blocking I/O:** Uses `select()` to efficiently manage multiple file descriptors
- **Connection management:** Automatically accepts new connections and manages client disconnections
- **Simple protocol:** Clients can send 'Q' to quit their connection
- **Debug output:** Status messages displayed on debug serial port

10.14.2.5.4.3 Configuration

The application uses the following configurable parameters:

- **Listen Port:** 23 (Telnet port)
- **Maximum Connections:** 10 simultaneous clients
- **Read Buffer Size:** 1024 bytes per connection

These values can be modified by changing the corresponding `#define` statements in `main.cpp`.

10.14.2.5.4.4 How It Works

Multi-Connection Architecture

Select () Multiplexing Pattern:

Server Initialization

1. Initializes the NetBurner system and waits for network connectivity
2. Creates a listening socket on port 23
3. Displays the device's IP addresses for client connection reference

Connection Management

The server uses a file descriptor array (`fdArray`) to track active client connections. The main loop:

1. **Sets up file descriptor sets** for `select()` monitoring
2. **Calls `select()`** to block until activity occurs on any socket
3. **Processes new connections** when clients connect to the listening port
4. **Handles client data** when existing connections have data to read
5. **Manages errors** by closing problematic connections

Client Interaction

- **Welcome message:** New clients receive a greeting upon connection
- **Quit command:** Clients can send 'Q' to cleanly disconnect
- **Echo behavior:** The server reads client data and logs it to the debug port
- **Connection limits:** If the server is full (10 connections), new clients are rejected with an error message

10.14.2.5.4.5 Testing the Application

Using Telnet

The easiest way to test this application is using multiple Telnet sessions:

```
telnet <netburner_ip_address> 23
```

You can open up to 10 simultaneous Telnet connections to test the multi-client functionality.

Expected Behavior

1. **Successful connection:** You'll see "Welcome to the NetBurner Multi-Socket TCP Server! 'Q' to quit."
2. **Server full:** If you try to connect when 10 clients are already connected, you'll see "I am sorry, but the server is full"
3. **Quit command:** Type 'Q' to cleanly disconnect
4. **Debug output:** Connection status, received data, and errors are logged to the serial debug port

10.14.2.5.4.6 Code Structure

Key Functions

- `**UserMain()` **: Main application entry point and event loop
- `**select()` **: Monitors multiple file descriptors for activity
- `**accept()` **: Accepts new client connections
- `**read()` **: Reads data from client connections
- `**close()` **: Closes file descriptors and cleans up connections

File Descriptor Management

The application maintains an array of file descriptors (`fdArray`) where:

- Index 0-9: Active client connections (0 = unused slot)
- Separate `fdListen`: The listening socket for new connections

Error Handling

- **Connection errors:** Automatically detected and connections are closed
- **Read errors:** Treated as connection problems and handled gracefully
- **Listen socket errors:** The listening socket is closed and reopened

10.14.2.5.4.7 Troubleshooting

- **Cannot connect:** Verify the NetBurner device has network connectivity and check IP address
- **Connection refused:** Ensure no other service is using port 23
- **Unexpected disconnections:** Check debug serial output for error messages
- **Server appears full:** Existing connections may not have closed properly; restart the application

10.14.2.5.4.8 Source Code

```

#include <init.h>
#include <iosys.h>
#include <tcp.h>
#include <ipshow.h>

const char *AppName = "TCP Multisocket Server";

#define listenPort (23)          // TCP port number to listen on
#define maxConnections (10)      // Max number of file descriptors/connections
#define readBufferSize (1024)   // Connection read buffer size

int fdArray[maxConnections];    // Array of TCP file descriptors

/*-----
  User Main
  -----*/
void UserMain(void *pd)
{
    init();
    //Enable system diagnostics. Probably should remove for production code.
    EnableSystemDiagnostics();
    WaitForActiveNetwork(TICKS_PER_SECOND * 10);
    showIpAddresses();

    // Listen for incoming TCP connections. You only need to call listen() one time.
    // Any incoming IP address is allowed, queue up to 5 connection requests at one time
    int32_t fdListen = listen(INADDR_ANY, listenPort, 5);
    printf("Listening for incoming connections on port %d\r\n", listenPort);

    while (1)
    {
        // Declare file descriptor sets for select()
        fd_set readFds;
        fd_set errorFds;

        // Init the fd sets
        FD_ZERO(&readFds);
        FD_ZERO(&errorFds);

        // Configure the fd sets so select() knows what to process. In this case any fd data to be read, or
        // an error
        for (int32_t i = 0; i < maxConnections; i++)
        {
            if (fdArray[i])    // The fd in the array will be > 0 if open and valid, so reset the file
                descriptor sets
            {
                FD_SET(fdArray[i], &readFds);
                FD_SET(fdArray[i], &errorFds);
            }
        }

        // select() should also process the listen fd
        FD_SET(fdListen, &readFds);
        FD_SET(fdListen, &errorFds);

        /* select() will block until any fd has data to be read, or has an error. When select() returns,
           readFds and/or errorFds variables will have been modified to reflect the events.
        */
        select(FD_SETSIZE, &readFds, (fd_set *)0, &errorFds, 0);

        // If the listen fd has a connection request, accept it.
        if (FD_ISSET(fdListen, &readFds))
        {
            IPADDR clientIp;
            uint16_t clientPort;

            int fdAccept = accept(fdListen, &clientIp, &clientPort, 0);

            // If accept() returned, find an open fd array slot
            if (fdAccept > 0)
            {
                for (int i = 0; i < maxConnections; i++)
                {
                    if (fdArray[i] == 0)
                    {
                        fdArray[i] = fdAccept;
                        writestring(fdAccept, "Welcome to the NetBurner Multi-Socket TCP Server! 'Q' to
quit.");
                        printf("Added connection on fd[%d] = %d, Client IP: %I:%d\r\n", i, fdAccept,
                            GetSocketRemoteAddr(fdAccept), GetSocketRemotePort(fdAccept));
                        fdAccept = 0;
                        break;
                    }
                }
            }
        }
    }
}

```

```

    }

    // If no array positions are open, close the connection
    if (fdAccept)
    {
        writestring(fdAccept, "I am sorry, but the server is full\r\n");
        printf("Server Full\r\n");
        close(fdAccept);
    }
}

// If the listen fd has an error, close it and reopen
if (FD_ISSET(fdListen, &errorFds))
{
    close(fdListen);
    fdListen = listen(INADDR_ANY, listenPort, 5);
}

// Process each fd array element and check it against readFds and errorFds.
for (int i = 0; i < maxConnections; i++)
{
    if (fdArray[i])
    {
        // Check for data to be read
        if (FD_ISSET(fdArray[i], &readFds))
        {
            char buffer[readBufferSize];
            int rv = read(fdArray[i], buffer, readBufferSize);
            if (rv > 0)
            {
                buffer[rv] = 0;
                if (buffer[0] == 'Q')
                {
                    printf("Closing connection fd[%d]\r\n", i);
                    writestring(fdArray[i], "Bye\r\n");
                    close(fdArray[i]);
                    fdArray[i] = 0;
                }
                else
                {
                    printf("Read \"%s\" from fd[%d]\r\n", buffer, i);
                    // snprintf( buffer, readBufferSize, "Server read %d byte(s)\r\n", rv );
                    // writestring( fdArray[i], buffer );
                }
            }
            else
            {
                printf("Read Error on fd[%d]\r\n", fdArray[i]);
                FD_SET(fdArray[i], &errorFds);
            }
        } // data available to read

        // Check for errors
        if (FD_ISSET(fdArray[i], &errorFds))
        {
            printf("Error on fd[%d], closing connection\r\n", i);
            close(fdArray[i]);
            fdArray[i] = 0;
        }
    } // if fd is valid
} // process each connection in the array
} // while (1)
} // UserMain

```

10.14.2.6 TCP Client Implementation

A TCP client initiates connections to TCP servers using the `connect()` function. This section demonstrates a web-based TCP client interface.

This is a simple TCP client application built for NetBurner hardware that demonstrates how to create and use a TCP client connection. The application provides a web-based interface that allows users to send messages to any TCP server by specifying the destination IP address, port number, and message content.

10.14.2.6.1 Features

- **Web-based Interface:** Complete interaction through a web page interface
- **Configurable Connection:** Set destination IP address and port number
- **Message Transmission:** Send custom messages to TCP servers
- **Auto-fill Functionality:** Automatically fills in the requesting client's IP address as default destination

- **Error Handling:** Comprehensive error reporting and logging
- **Real-time Feedback:** Connection status and transmission results displayed

10.14.2.6.2 User Main (main.cpp)

```
#include <init.h>
#include <nbrtos.h>
#include <ipshow.h>

const char *AppName = "Simple TCP Client Example";

/*-----
User Main
-----*/
void UserMain(void *pd)
{
    init();
    //Enable system diagnostics. Probably should remove for production code.
    EnableSystemDiagnostics();
    StartHttp();
    WaitForActiveNetwork(TICKS_PER_SECOND * 10);
    showIpAddresses();

    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

10.14.2.6.3 Client Web Page User Interface to Connect (clientweb.cpp)

```
/*NB_REVISION*/

/*NB_COPYRIGHT*/

/*-----
This code implements the web page entries for the message,
destination IP address and destination port number. When the
web page first loads it will automatically fill in the IP
address from the source requesting the web page, because in
most cases it will also be the address of the TCP Server.
The web page is a form, and when a user presses the submit
button the SendMsg() function will open a TCP connection to
the server, send the message, and close the connection.
Any error messages will be sent to stdout and can be viewed
with MTTY.

A TCP server program must already be listening at the specified
IP address and port number for the message to be sent. A simple
TCP Server called TcpServerWin.exe is located in the
\ncburn\pctools directory of your NetBurner installation.

        case eStartingPost: // Called at the beginning of the post before any data is sent
            break;

        case eVariable: // Called once for each variable in the form
            processPostVariables(pName, pValue);
            break;

        // Called back with a file handle if the post had a file
        case eFile:
            break; // No file type here so we do nothing

        // Called back when the post is complete. You should send your response here.
        case eEndOfPost:
        {
            printf("\r\n\r\n"); // just some new lines for easier console reading
            RedirectResponse(sock, "INDEX.HTML"); // Our response is to redirect to the index page
        }
    }
}

```

```

    }
    break;
} // Switch

return 0;
}

// Create a global static post handling object that responds to the specified html page.
// A separate post handler can be created for each form in your application.
HtmlPostVariableListCallback poster("index.html", PostCallBack);

```

10.14.2.7 TCP Error Handling

Status codes and error values returned by TCP socket operations. These error codes are returned by TCP socket functions such as `listen()`, `accept()`, `connect()`, `read()`, `write()`, and other socket operations. Understanding these codes is essential for proper error handling and debugging network issues.

10.14.2.7.1 Return Value Convention

TCP socket functions follow this convention:

- **Positive values:** Valid file descriptor (socket successfully created/connected)
- **Zero:** Success for non-FD operations (e.g., `TCP_ERR_NORMAL`)
- **Negative values:** Error condition (use these constants to identify the error)

10.14.2.7.2 Error Handling Pattern

```

int sock = connect("example.com", 80, TICKS_PER_SECOND * 10);
if (sock < 0) {
    // Error occurred - check which one
    switch (sock) {
        case TCP_ERR_TIMEOUT:
            printf("Connection timed out\r\n");
            break;
        case TCP_ERR_NONE_AVAIL:
            printf("No sockets available\r\n");
            break;
        default:
            printf("Connection error: %d\r\n", sock);
            break;
    }
} else {
    // Success - sock is a valid file descriptor
    printf("Connected on socket %d\r\n", sock);
}

```

10.14.2.7.3 Common Usage Scenarios

10.14.2.7.3.1 Client Connections

- `TCP_ERR_TIMEOUT`: Server unreachable or not responding
- `TCP_ERR_NONE_AVAIL`: Too many open connections
- `TCP_ERR_CON_RESET`: Server rejected connection

10.14.2.7.3.2 Server Operations

- `TCP_ERR_TIMEOUT`: `accept()` timeout (not necessarily an error)
- `TCP_ERR_NONE_AVAIL`: Socket pool exhausted

10.14.2.7.3.3 Data Transfer

- `TCP_ERR_NOCON`: Connection closed before operation
- `TCP_ERR_CLOSING`: Connection in teardown state
- `TCP_ERR_CON_RESET`: Remote host reset connection

Expand for Example Usage

Examples

Example 1: Basic Error Handling in Client Connection

```
int ConnectToServer(const char *host, uint16_t port) {
    printf("Connecting to %s:%d...\r\n", host, port);

    int sock = connect(host, port, TICKS_PER_SECOND * 10);

    if (sock == TCP_ERR_TIMEOUT) {
        printf("ERROR: Connection timed out\r\n");
        return -1;
    } else if (sock == TCP_ERR_NONE_AVAIL) {
        printf("ERROR: No sockets available\r\n");
        return -1;
    } else if (sock < 0) {
        printf("ERROR: Connection failed with code %d\r\n", sock);
        return -1;
    }

    printf("Successfully connected (socket %d)\r\n", sock);
    return sock;
}
```

Example 2: Server Accept with Timeout Handling

```
void ServerAcceptLoop(int listenSock) {
    while (1) {
        // Accept with 5 second timeout
        int clientSock = accept(listenSock, NULL, NULL, TICKS_PER_SECOND * 5);

        if (clientSock == TCP_ERR_TIMEOUT) {
            // Timeout is normal - just loop again
            continue;
        } else if (clientSock == TCP_ERR_NONE_AVAIL) {
            printf("WARNING: No sockets available for new connection\r\n");
            OSTimeDly(TICKS_PER_SECOND); // Wait before retry
            continue;
        } else if (clientSock < 0) {
            printf("ERROR: Accept failed with code %d\r\n", clientSock);
            break;
        }

        // Valid connection
        printf("New client connected on socket %d\r\n", clientSock);
        HandleClient(clientSock);
    }
}
```

Example 3: Comprehensive Error Reporting

```
const char* GetTCPErrString(int errorCode) {
    switch (errorCode) {
        case TCP_ERR_NORMAL:
            return "Success";
        case TCP_ERR_TIMEOUT:
            return "Operation timed out";
        case TCP_ERR_NOCON:
            return "No active connection";
        case TCP_ERR_CLOSING:
            return "Socket is closing";
        case TCP_ERR_NOSUCH_SOCKET:
            return "Socket does not exist";
        case TCP_ERR_NONE_AVAIL:
            return "No sockets available";
        case TCP_ERR_CON_RESET:
            return "Connection reset by peer";
        case TCP_ERR_CON_ABORT:
            return "Connection aborted";
        default:
            return "Unknown error";
    }
}

void ReportConnectionError(int errorCode, const char *operation) {
    printf("TCP Error during %s: %s (code: %d)\r\n",
        operation, GetTCPErrString(errorCode), errorCode);
}

// Usage
int sock = connect("server.com", 80, TICKS_PER_SECOND * 10);
if (sock < 0) {
    ReportConnectionError(sock, "connect");
}
```

Example 4: Read with Connection Error Detection

```

int ReadWithErrorHandling(int sock, char *buffer, int bufSize) {
    int bytesRead = read(sock, buffer, bufSize);

    if (bytesRead > 0) {
        // Data received successfully
        return bytesRead;
    } else if (bytesRead == 0) {
        // Connection closed gracefully
        printf("Connection closed by remote host\r\n");
        return 0;
    } else {
        // Error occurred
        if (bytesRead == TCP_ERR_NOCON) {
            printf("ERROR: No active connection\r\n");
        } else if (bytesRead == TCP_ERR_CLOSING) {
            printf("ERROR: Socket is closing\r\n");
        } else if (bytesRead == TCP_ERR_CON_RESET) {
            printf("ERROR: Connection reset by peer\r\n");
        } else if (bytesRead == TCP_ERR_TIMEOUT) {
            printf("ERROR: Read timeout\r\n");
        } else {
            printf("ERROR: Read failed with code %d\r\n", bytesRead);
        }
        return -1;
    }
}

```

Example 5: Socket Pool Management

```

#define MAX_RETRY_ATTEMPTS 3
int ConnectWithRetry(const char *host, uint16_t port) {
    for (int attempt = 1; attempt <= MAX_RETRY_ATTEMPTS; attempt++) {
        printf("Connection attempt %d/%d...\r\n", attempt, MAX_RETRY_ATTEMPTS);

        int sock = connect(host, port, TICKS_PER_SECOND * 5);

        if (sock >= 0) {
            // Success
            return sock;
        }

        if (sock == TCP_ERR_NONE_AVAIL) {
            printf("No sockets available, waiting for one to free up...\r\n");
            OSTimeDly(TICKS_PER_SECOND * 2); // Wait for sockets to free
        } else if (sock == TCP_ERR_TIMEOUT) {
            printf("Timeout, retrying...\r\n");
            OSTimeDly(TICKS_PER_SECOND); // Brief delay before retry
        } else {
            // Other error - don't retry
            printf("Fatal error %d, aborting\r\n", sock);
            return sock;
        }
    }

    printf("Failed to connect after %d attempts\r\n", MAX_RETRY_ATTEMPTS);
    return TCP_ERR_TIMEOUT;
}

```

Example 6: Connection State Monitoring

```

typedef struct {
    int sock;
    bool isConnected;
    uint32_t lastActivity;
    int lastError;
} ConnectionState;

void UpdateConnectionState(ConnectionState *conn) {
    // Try a zero-length read to check connection status
    char dummy;
    int result = read(conn->sock, &dummy, 0);

    if (result == TCP_ERR_NOCON || result == TCP_ERR_CON_RESET ||
        result == TCP_ERR_CON_ABORT) {
        if (conn->isConnected) {
            printf("Connection lost: %s\r\n", GetTCPErrString(result));
            conn->isConnected = false;
            conn->lastError = result;
        }
    } else if (result == TCP_ERR_CLOSING) {
        printf("Connection closing...\r\n");
        conn->isConnected = false;
        conn->lastError = result;
    } else {

```

```

        // Connection still active
        conn->lastActivity = Secs;
    }
}

```

Example 7: Graceful Shutdown on Error

```

void CloseConnectionGracefully(int sock) {
    if (sock < 0) {
        return; // Invalid socket
    }

    // Try to shutdown gracefully
    printf("Closing socket %d...\r\n", sock);

    // Attempt to send any pending data with timeout
    OSTimeDly(TICKS_PER_SECOND / 10); // 100ms grace period

    close(sock);
    printf("Socket closed\r\n");
}

void HandleConnectionError(int sock, int errorCode) {
    printf("Handling error: %s\r\n", GetTCPErrorString(errorCode));

    switch (errorCode) {
        case TCP_ERR_CON_RESET:
        case TCP_ERR_CON_ABORT:
            // Connection already gone, just close FD
            close(sock);
            break;

        case TCP_ERR_CLOSING:
            // Wait briefly for close to complete
            OSTimeDly(TICKS_PER_SECOND / 2);
            close(sock);
            break;

        default:
            CloseConnectionGracefully(sock);
            break;
    }
}

```

Example 8: Diagnostic Logging

```

void LogSocketOperation(const char *operation, int result) {
    if (result >= 0) {
        printf("[OK] %s: fd=%d\r\n", operation, result);
    } else {
        printf("[ERROR] %s: %s (code=%d)\r\n",
            operation, GetTCPErrorString(result), result);
    }
}

// Usage
int sock = connect("example.com", 80, TICKS_PER_SECOND * 10);
LogSocketOperation("connect", sock);
if (sock >= 0) {
    int bytes = write(sock, "GET /", 5);
    LogSocketOperation("write", bytes);
}

```

10.14.2.7.4 Functions that return TCP Status Codes:

Function	Description
connect()	Establish TCP client connection
listen()	Create listening TCP socket
accept()	Accept incoming TCP connection
read()	Read data from TCP socket
write()	Write data to TCP socket
close()	Close TCP socket

10.14.2.7.5 TCP Return Codes

TCP Socket Status and Error Codes are defined here: [TCP Socket Status](#). A summary is provided below and the following sections detail each error code as well as possible causes and corrective measures.

```
#define TCP_ERR_NORMAL      (0)    // Operation completed successfully with no errors
#define TCP_ERR_TIMEOUT    (-1)   // Operation timed out before completion
#define TCP_ERR_NOCON      (-2)   // No active connection exists on this socket
#define TCP_ERR_CLOSING    (-3)   // Socket is currently in the closing state
#define TCP_ERR_NOSUCH_SOCKET (-4) // The specified socket does not exist
#define TCP_ERR_NONE_AVAIL (-5)   // No sockets available in the system pool
#define TCP_ERR_CON_RESET  (-6)   // Connection was reset by remote host
#define TCP_ERR_CON_ABORT  (-7)   // Connection was aborted
```

10.14.2.7.5.1 Operation completed successfully with no errors

```
#define TCP_ERR_NORMAL (0)
```

Indicates that a socket operation completed without any error conditions. This is the expected return value for successful non-FD operations.

10.14.2.7.5.2 Operation timed out before completion

```
#define TCP_ERR_TIMEOUT (-1)
```

The socket operation did not complete within the specified timeout period. Common causes:

- Remote host unreachable or not responding
- Network congestion or packet loss
- Timeout value too short for operation
- Firewall blocking connection

For [accept\(\)](#) with timeout, this is not necessarily an error - it just means no connection arrived within the timeout period.

Note

When this occurs during [connect\(\)](#), the remote host is likely down or unreachable

For [read\(\)](#) operations, this may indicate the peer stopped sending data

10.14.2.7.5.3 No active connection exists on this socket

```
#define TCP_ERR_NOCON (-2)
```

Attempted to perform an operation on a socket that has no active connection. Common causes:

- Trying to read/write on a socket that was never connected
- Connection was closed by remote peer
- Connection attempt failed but socket was still used
- Using a socket after [close\(\)](#) was called

Note

Always check connection establishment before attempting I/O operations

This error indicates the socket exists but has no connection

10.14.2.7.5.4 Socket is currently in the closing state

```
#define TCP_ERR_CLOSING (-3)
```

The socket is in the process of closing and cannot accept new operations. This is a transitional state during connection teardown.

Common causes:

- [close\(\)](#) was called and TCP is performing graceful shutdown
 - FIN packet sent but waiting for acknowledgment
 - TCP TIME_WAIT or CLOSE_WAIT state
-

Note

Wait briefly and the socket will complete closing
Do not attempt further I/O on this socket

10.14.2.7.5.5 The specified socket does not exist

```
#define TCP_ERR_NOSUCH_SOCKET (-4)
```

The file descriptor does not correspond to a valid socket in the system. Common causes:

- Using an invalid file descriptor number
- Socket was already closed
- File descriptor number was never allocated
- Corruption of the socket handle

Note

This indicates a programming error - verify FD validity before use
Check that socket creation succeeded before using the FD

10.14.2.7.5.6 No sockets available in the system pool

```
#define TCP_ERR_NONE_AVAIL (-5)
```

The system has exhausted its pool of available socket resources and cannot create new connections. This is a resource limitation error.

Common causes:

- Too many simultaneous connections open
- Sockets not being closed properly (resource leak)
- Application exceeding design limits
- System configuration limits too low

Solutions:

- Close unused sockets promptly
- Implement connection pooling or limiting
- Increase system socket pool size if possible
- Check for socket leaks in application code

Warning

This error indicates a serious resource constraint

Note

Monitor socket usage to prevent this condition

10.14.2.7.5.7 Connection was reset by remote host

```
#define TCP_ERR_CON_RESET (-6)
```

The remote peer forcibly closed the connection, typically by sending a TCP RST (reset) packet. This indicates an abnormal connection termination.

Common causes:

- Remote application crashed
- Remote host rebooted
- Firewall or security device terminated connection
- Protocol violation or invalid data sent
- Remote application explicitly reset the socket

Note

This is different from a graceful close (FIN packet)

Data may have been lost when this occurs

Warning

Connection cannot be recovered - must establish new connection

10.14.2.7.5.8 Connection was aborted

```
#define TCP_ERR_CON_ABORT (-7)
```

The connection was terminated abnormally, typically due to a local or network error condition. This is a general abort condition.

Common causes:

- Local TCP stack detected fatal error
- Network path broken
- Excessive retransmission failures
- Local application requested abort
- System resources exhausted during transfer

Note

Similar to TCP_ERR_CON_RESET but indicates local-side abort

Warning

Connection cannot be recovered - must establish new connection

10.14.3 UDP Protocol**10.14.3.1 UDP Protocol**

The NetBurner API provides two methods to implement UDP: a C++ class interface and traditional socket functions. Both methods offer equivalent performance; choose based on your coding preference.

10.14.3.2 UDP Implementation Comparison

Class Interface

```
UDPPacket
.Send()
.Validate()
```

vs

Socket Interface

```
recvfrom()
sendto()
select()
```

Object-oriented

Function-based

10.14.3.3 UDP Class Interface

The `UDPPacket` class provides an object-oriented approach to UDP communication.

10.14.3.3.1 Receiving UDP Packets (Class Method)

Setup Process**:

1. Create an `OS_FIFO` to hold incoming packets
2. Register the FIFO with `RegisterUDPFifo()` for specific port(s)
3. Construct `UDPPacket` object to receive packets (blocking)
4. Validate packet with `Validate()` member function
5. Extract data with `GetDataBuffer()` member function

Multi-Port Listening**:

- Use separate `OS_FIFO` for each port, OR
- Use single `OS_FIFO` for multiple ports by calling `RegisterUDPFifo()` multiple times

10.14.3.3.2 Sending UDP Packets (Class Method)

Transmission Process**:

1. Declare `UDPPacket` instance
2. Set source and destination ports
3. Add data using member functions
4. Call `Send()` to transmit packet

10.14.3.3.3 UDP Class Example

This example demonstrates bidirectional UDP communication using the `UDPPacket` class.

```
/*
   UDP Send/Receive Example using UDPPacket Class

   Features:
   - Receives UDP packets and displays on serial port
   - Sends user-typed messages as UDP packets
   - Uses OS_FIFO for packet buffering
   - Demonstrates task-based architecture

   Testing:
   - Use NetBurner UDP Terminal on Windows
   - Configure matching IP addresses and ports
   - Messages sent from terminal appear in MTTY
   - Messages typed in MTTY sent via UDP
*/

#include <init.h>
#include <stdlib.h>
#include <system.h>
#include <udp.h>
#include <utils.h>

const char *AppName = "UDP Send/Receive Example";

// Allocate stack space for the listen task
uint32_t UdpReceiveTaskStack[USER_TASK_STK_SIZE];

/*
   UDP Receive Task
   Waits for incoming packets on specified port
*/
void UdpReceiveTask(void *pd)
{
    static OS_FIFO fifo;    // FIFO for incoming packets
```

```

int listenPort = (int)pd;

printf("Listening on UDP port: %d\r\n", listenPort);

// Register FIFO to receive packets on this port
RegisterUDPFifo(listenPort, &fifo);

while (1)
{
    // Construct UDP packet object (blocks until packet received)
    // Second parameter is timeout (0 = wait forever)
    UDPPacket upkt(&fifo, 0 * TICKS_PER_SECOND);

    // Check if valid packet received
    if (upkt.Validate())
    {
        uint16_t len = upkt.GetDataSize();
        printf("Received UDP packet with %d bytes from: %I\r\n",
            (int)len, upkt.GetSourceAddress());
        ShowData(upkt.GetDataBuffer(), len); // Hex dump
        printf("\r\n");
    }
}

/*
User Main
*/
void UserMain(void *pd)
{
    int portNumber;
    IPADDR destIpAddress;
    char buffer[80];

    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    printf("Application: %s\r\nNDK Revision: %s\r\n",
        AppName, GetReleaseTag());

    printf("Enter the UDP port number (send & receive): ");
    gets(buffer);
    portNumber = atoi(buffer);

    printf("\r\nEnter the destination IP Address: ");
    gets(buffer);
    destIpAddress = AsciiToIp(buffer);

    printf("Listening/Sending on UDP Port %d, Sending to: %I\r\n",
        portNumber, destIpAddress);

    // Create UDP receive task
    OSTaskCreateName(UdpReceiveTask,
        (void *)portNumber,
        &UdpReceiveTaskStack[USER_TASK_STK_SIZE],
        UdpReceiveTaskStack,
        MAIN_PRIO - 1, // Higher priority than UserMain
        "UDP Receive");

    // Main loop: send user input as UDP packets
    printf("Enter data and hit return to send.\r\n");
    while (1)
    {
        gets(buffer);

        UDPPacket pkt;
        pkt.SetSourcePort(portNumber);
        pkt.SetDestinationPort(portNumber);
        pkt.AddData(buffer);
        pkt.AddDataByte(0);
        pkt.Send(destIpAddress);
        printf("\r\n");

        printf("Sent \"%s\" to %I:%d\r\n", buffer, destIpAddress, portNumber);
    }
}

```

10.14.3.3.4 UDP Class Architecture

Task Architecture:

```

3. Loop:
    -> Read user input
    -> Create UDPPacket
    -> Set ports
    -> Add data
    -> Send()

```

UdpReceiveTask (Higher Priority)

```

1. Create OS_FIFO
2. RegisterUDPFifo(port, &fifo)
3. Loop:
    -> UDPPacket upkt(&fifo, timeout)
       [BLOCKS until packet received]
    -> Validate()
    -> GetDataBuffer()
    -> Display data

```

10.14.3.3.5 Key Class Methods

Sending**:

```

UDPPacket pkt;
pkt.SetSourcePort(localPort);
pkt.SetDestinationPort(remotePort);
pkt.AddData(dataBuffer);
pkt.Send(destinationIP);

```

Receiving**:

```

OS_FIFO fifo;
RegisterUDPFifo(port, &fifo);
UDPPacket upkt(&fifo, timeout);
if (upkt.Validate()) {
    uint8_t *data = upkt.GetDataBuffer();
    uint16_t len = upkt.GetDataSize();
    IPADDR source = upkt.GetSourceAddress();
}

```

10.14.3.4 UDP Sockets Interface

The socket-based UDP interface provides a traditional function-based approach to UDP communication.

10.14.3.4.1 Receiving UDP Packets (Socket Method)

Setup Process**:

1. Call `CreateRxUdpSocket()` to open listening socket (returns file descriptor)
2. Call `recvfrom()` to receive packets (blocks by default)
3. Optionally wrap `recvfrom()` in `select()` for timeout control

10.14.3.4.2 Sending UDP Packets (Socket Method)

Transmission Process**:

1. Call `CreateTxUdpSocket()` to open socket (returns file descriptor)
2. Call `sendto()` to transmit packets

10.14.3.4.3 UDP Socket Error Processing

These negative values are returned by UDP socket creation and operation functions to indicate specific error conditions. All successful operations return non-negative values (valid file descriptors ≥ 0 or byte counts ≥ 0).

```

#define UDP_ERR_NOSUCH_SOCKET    (-1)
#define UDP_ERR_NOTOPEN_TO_WRITE (-2)
#define UDP_ERR_NOTOPEN_TO_READ  (-3)

```

10.14.3.4.3.1 UDP_ERR_NOSUCH_SOCKET

Socket does not exist or operation failed

```
#define UDP_ERR_NOSUCH_SOCKET (-1)
```

Returned when:

- Socket creation fails (port conflict, resource exhaustion)
- Invalid socket descriptor used in operation
- Socket was closed but still being referenced
- System cannot allocate required resources

Common Scenarios:

Scenario 1: Port Already in Use

```
int sock1 = CreateRxUdpSocket(8080); // Success: sock1 = valid descriptor
int sock2 = CreateRxUdpSocket(8080); // Failure: returns UDP_ERR_NOSUCH_SOCKET
// Solution: Use different port or close sock1 first
```

Scenario 2: Using Closed Socket

```
int sock = CreateRxUdpSocket(5000);
close(sock);
int result = sendto(sock, data, len, ip, port); // Returns UDP_ERR_NOSUCH_SOCKET
// Solution: Don't use socket after closing
```

Scenario 3: Resource Exhaustion

```
// Creating too many sockets
for (int i = 0; i < 100; i++) {
    int sock = CreateRxUdpSocket(5000 + i);
    if (sock < 0) {
        printf("Failed at socket %d: UDP_ERR_NOSUCH_SOCKET\r\n", i);
        // Solution: Close unused sockets, reduce simultaneous socket count
        break;
    }
}
```

10.14.3.4.3.2 UDP_ERR_NOTOPEN_TO_WRITE

Socket not configured for sending operations

```
UDP_ERR_NOTOPEN_TO_WRITE (-2)
```

Returned when attempting to send data through a socket that was created in receive-only mode (using `CreateRxUdpSocket()`). The socket can only receive packets, not send them.

Common Scenarios:

Scenario 1: Sending on Receive-Only Socket

```
// Wrong: Create receive-only socket, then try to send
int sock = CreateRxUdpSocket(5000); // Receive-only!
uint8_t data[] = "Hello";
int result = sendto(sock, data, sizeof(data), destIP, 8080);
// Returns UDP_ERR_NOTOPEN_TO_WRITE

// Correct: Use transmit or bidirectional socket
int sock = CreateTxUdpSocket(destIP, 8080, 0); // Can send
int result = sendto(sock, data, sizeof(data), destIP, 8080); // Success
```

Scenario 2: Echo Server Without Bidirectional Socket

```
// Wrong: Echo server needs to send responses
int sock = CreateRxUdpSocket(5000); // Can only receive
uint8_t buf[512];
IPADDR clientIP;
uint16_t lp, rp;

int n = recvfrom(sock, buf, sizeof(buf), &clientIP, &lp, &rp); // OK
sendto(sock, buf, n, clientIP, rp); // Fails: UDP_ERR_NOTOPEN_TO_WRITE

// Correct: Use bidirectional socket
int sock = CreateRxTxUdpSocket(clientIP, rp, 5000); // Can send & receive
int n = recvfrom(sock, buf, sizeof(buf), &clientIP, &lp, &rp); // OK
sendto(sock, buf, n, clientIP, rp); // OK
```

Solution Patterns:

Pattern 1: Use Correct Socket Type

- For **servers that only listen**: `CreateRxUdpSocket()` is correct
- For **clients that only send**: `CreateTxUdpSocket()`
- For **request/response**: `CreateRxTxUdpSocket()`
- For **echo servers**: `CreateRxTxUdpSocket()` or use separate sockets

Pattern 2: Separate Sockets for Send/Receive

```
// Alternative: Use two separate sockets
int rxSock = CreateRxUdpSocket(5000); // For receiving
int txSock = CreateTxUdpSocket(destIP, destPort, 0); // For sending

// Receive on one socket
recvfrom(rxSock, buf, len, &srcIP, &lp, &rp);

// Send on different socket
sendto(txSock, data, dataLen, destIP, destPort);
```

Warning

This error does NOT mean the socket descriptor is invalid. The socket exists and may be used for receiving, just not sending.

10.14.3.4.3.3 UDP_ERR_NOTOPEN_TO_READ

Socket not configured for receiving operations

```
#define UDP_ERR_NOTOPEN_TO_READ (-3)
```

Returned when attempting to receive data from a socket that was created in transmit-only mode (using [CreateTxUdpSocket\(\)](#)). The socket can only send packets, not receive them.

Common Scenarios:**

Scenario 1: Receiving on Transmit-Only Socket**

```
// Wrong: Create transmit-only socket, then try to receive
IPADDR serverIP = AsciiToIp("192.168.1.100");
int sock = CreateTxUdpSocket(serverIP, 8080, 0); // Transmit-only!

uint8_t buffer[512];
IPADDR srcIP;
uint16_t lp, rp;
int n = recvfrom(sock, buffer, sizeof(buffer), &srcIP, &lp, &rp);
// Returns UDP_ERR_NOTOPEN_TO_READ

// Correct: Use receive or bidirectional socket
int sock = CreateRxUdpSocket(localPort); // Can receive
int n = recvfrom(sock, buffer, sizeof(buffer), &srcIP, &lp, &rp); // Success
```

Scenario 2: Request/Response Without Bidirectional Socket**

```
// Wrong: Client expecting response but using transmit-only socket
IPADDR serverIP = AsciiToIp("10.0.1.50");
int sock = CreateTxUdpSocket(serverIP, 6000, 0); // Transmit-only

// Send request
uint8_t request[] = "GET /data";
sendto(sock, request, sizeof(request), serverIP, 6000); // OK

// Try to receive response
uint8_t response[512];
IPADDR respIP;
uint16_t lp, rp;
int n = recvfrom(sock, response, sizeof(response), &respIP, &lp, &rp);
// Fails: UDP_ERR_NOTOPEN_TO_READ

// Correct: Use bidirectional socket for request/response
int sock = CreateRxTxUdpSocket(serverIP, 6000, 0); // Can send & receive
sendto(sock, request, sizeof(request), serverIP, 6000); // OK
int n = recvfrom(sock, response, sizeof(response), &respIP, &lp, &rp); // OK
```

Scenario 3: DNS Query (Typical Request/Response)**

```
// Wrong approach
IPADDR dnsServer = AsciiToIp("8.8.8.8");
int sock = CreateTxUdpSocket(dnsServer, 53, 0); // Can't receive response!

// Correct approach
int sock = CreateRxTxUdpSocket(dnsServer, 53, 0); // Full duplex

// Send DNS query
uint8_t query[512];
int qlen = BuildDnsQuery(query, "example.com");
sendto(sock, query, qlen, dnsServer, 53);

// Receive DNS response
uint8_t response[512];
IPADDR srcIP;
uint16_t lp, rp;
int rlen = recvfrom(sock, response, sizeof(response), &srcIP, &lp, &rp);
```

Solution Patterns:**

Pattern 1: Choose Appropriate Socket Type**

- One-way transmission: [CreateTxUdpSocket\(\)](#) is correct

- **One-way reception:** [CreateRxUdpSocket\(\)](#) is correct
- **Request/Response:** [CreateRxTxUdpSocket\(\)](#) required
- **Client expecting replies:** [CreateRxTxUdpSocket\(\)](#) required

Pattern 2: Evaluate Communication Pattern**

```
// Ask: "Does this need to receive?"

// NO (logging, notifications, broadcast) -> CreateTxUdpSocket()
int logSock = CreateTxUdpSocket(logServer, 514, 0);
sendto(logSock, logMsg, len, logServer, 514);

// YES (queries, RPC, protocols with ACK) -> CreateRxTxUdpSocket()
int rpcSock = CreateRxTxUdpSocket(server, 8080, 0);
sendto(rpcSock, request, reqLen, server, 8080);
recvfrom(rpcSock, response, respLen, &srcIP, &lp, &rp);
```

Warning

This error does NOT mean the socket descriptor is invalid. The socket exists and may be used for sending, just not receiving.

Note

If you need truly one-way fire-and-forget communication, [CreateTxUdpSocket\(\)](#) is more efficient than [CreateRxTxUdpSocket\(\)](#) because it doesn't allocate receive buffers. However, most protocols benefit from at least basic acknowledgment, making bidirectional sockets the better choice.

See also

[CreateRxUdpSocket\(\)](#) - For sockets that can receive
[CreateRxTxUdpSocket\(\)](#) - For bidirectional communication
[recvfrom\(\)](#) - Function that may return this error

10.14.3.4.3.4 Error Handling Pattern

Always check return values from UDP socket functions:

```
int sock = CreateRxUdpSocket(5000);
if (sock < 0) {
    switch (sock) {
        case UDP_ERR_NOSUCH_SOCKET:
            printf("Socket does not exist or creation failed\r\n");
            break;
        case UDP_ERR_NOTOPEN_TO_WRITE:
            printf("Socket not configured for sending\r\n");
            break;
        case UDP_ERR_NOTOPEN_TO_READ:
            printf("Socket not configured for receiving\r\n");
            break;
        default:
            printf("Unknown error: %d\r\n", sock);
            break;
    }
    return; // Don't proceed with invalid socket
}

// Safe to use socket
uint8_t buffer[1024];
IPADDR srcIP;
uint16_t lp, rp;
int bytesReceived = recvfrom(sock, buffer, sizeof(buffer), &srcIP, &lp, &rp);
```

10.14.3.4.3.5 Common Causes and Solutions

UDP_ERR_NOSUCH_SOCKET

Causes:

- Port already in use by another socket
- System resource exhaustion (too many sockets)

- Invalid socket descriptor passed to function
- Socket was closed but still being referenced

Solutions:

- Check that port is not already bound
- Close unused sockets to free resources
- Verify socket is valid before operations
- Use different port numbers for different sockets

```
// BAD: Port conflict
int sock1 = CreateRxUdpSocket(8080);
int sock2 = CreateRxUdpSocket(8080); // Returns UDP_ERR_NOSUCH_SOCKET

// GOOD: Different ports or close first socket
int sock1 = CreateRxUdpSocket(8080);
// ... use sock1 ...
close(sock1);
int sock2 = CreateRxUdpSocket(8080); // Now succeeds
```

UDP_ERR_NOTOPEN_TO_WRITE

Causes

- Attempting `sendto()` on receive-only socket (`CreateRxUdpSocket`)
- Socket was created for receiving but not transmitting
- Socket configuration flags incorrect

Solutions:**

- Use `CreateTxUdpSocket()` or `CreateRxTxUdpSocket()` for sending
- Create separate sockets for different operations
- Verify socket type matches intended operation

```
// BAD: Using receive-only socket for sending
int rxSock = CreateRxUdpSocket(5000);
sendto(rxSock, data, len, destIP, destPort); // Returns UDP_ERR_NOTOPEN_TO_WRITE

// GOOD: Use appropriate socket type
int txSock = CreateTxUdpSocket(destIP, destPort, 0);
sendto(txSock, data, len, destIP, destPort); // Succeeds

// OR: Use bidirectional socket
int rxtxSock = CreateRxTxUdpSocket(destIP, destPort, 5000);
sendto(rxtxSock, data, len, destIP, destPort); // Succeeds
```

UDP_ERR_NOTOPEN_TO_READ

Causes

- Attempting `recvfrom()` on transmit-only socket (`CreateTxUdpSocket`)
- Socket was created for sending but not receiving
- Socket configuration flags incorrect

Solutions:**

- Use `CreateRxUdpSocket()` or `CreateRxTxUdpSocket()` for receiving
- Create separate sockets for different operations
- Verify socket type matches intended operation

```
// BAD: Using transmit-only socket for receiving
IPADDR serverIP = AsciiToIp("192.168.1.100");
int txSock = CreateTxUdpSocket(serverIP, 8080, 0);
recvfrom(txSock, buffer, len, &srcIP, &lp, &rp); // Returns UDP_ERR_NOTOPEN_TO_READ

// GOOD: Use appropriate socket type
int rxSock = CreateRxUdpSocket(8080);
recvfrom(rxSock, buffer, len, &srcIP, &lp, &rp); // Succeeds

// OR: Use bidirectional socket for request/response
int rxtxSock = CreateRxTxUdpSocket(serverIP, 8080, 0);
sendto(rxtxSock, request, reqLen, serverIP, 8080);
recvfrom(rxtxSock, buffer, len, &srcIP, &lp, &rp); // Both succeed
```

10.14.3.4.3.6 Error Checking Best Practices

1. Always Validate Socket Creation

```
int sock = CreateRxUdpSocket(port);
if (sock < 0) {
    // Handle error appropriately
    printf("Socket creation failed: %d\r\n", sock);
    return ERROR_CODE; // Don't continue
}
// Safe to use sock
```

2. Check Operation Return Values

```
int bytesSent = sendto(sock, data, len, destIP, destPort);
if (bytesSent < 0) {
    printf("Send failed: error %d\r\n", bytesSent);
} else if (bytesSent != len) {
    printf("Warning: Partial send (%d of %d bytes)\r\n", bytesSent, len);
}
```

3. Defensive Programming

```
// Store error code in variable for debugging
int result = CreateRxUdpSocket(port);
if (result < 0) {
    // Log detailed error information
    printf("CreateRxUdpSocket(%d) failed with error %d at %s:%d\r\n",
        port, result, __FILE__, __LINE__);

    // Take appropriate recovery action
    switch (result) {
        case UDP_ERR_NOSUCH_SOCKET:
            // Maybe try alternative port
            result = CreateRxUdpSocket(port + 1);
            break;
        // ... other cases ...
    }
}
```

4. Resource Cleanup on Error

```
int sock1 = CreateRxUdpSocket(5000);
if (sock1 < 0) {
    return ERROR_SOCKET1;
}

int sock2 = CreateRxUdpSocket(5001);
if (sock2 < 0) {
    close(sock1); // Clean up first socket
    return ERROR_SOCKET2;
}

// Both sockets valid
// ... use sockets ...

// Cleanup
close(sock1);
close(sock2);
```

10.14.3.4.3.7 Debugging Errors

When encountering UDP errors:

1. Enable System Diagnostics

```
void UserMain(void* pd) {
    init();
    EnableSystemDiagnostics(); // Shows resource usage
    // ... rest of code ...
}
```

2. Check Resource Availability

- Monitor socket count
- Check buffer pool usage
- Verify network interface status

3. Test with Simple Cases

- Start with single socket
- Verify basic send/receive works
- Add complexity incrementally

4. Use Network Tools

- Wireshark to capture packets
- netcat (nc) to test connectivity
- Verify firewall settings

10.14.3.4.3.8 Related Functions

Functions that may return these error codes:

- [CreateRxUdpSocket\(\)](#) - Can return UDP_ERR_NOSUCH_SOCKET
- [CreateTxUdpSocket\(\)](#) - Can return UDP_ERR_NOSUCH_SOCKET
- [CreateRxTxUdpSocket\(\)](#) - Can return UDP_ERR_NOSUCH_SOCKET
- [sendto\(\)](#) - Can return UDP_ERR_NOTOPEN_TO_WRITE or UDP_ERR_NOSUCH_SOCKET
- [recvfrom\(\)](#) - Can return UDP_ERR_NOTOPEN_TO_READ or UDP_ERR_NOSUCH_SOCKET
- [sendtovia\(\)](#) - Can return UDP_ERR_NOTOPEN_TO_WRITE or UDP_ERR_NOSUCH_SOCKET

10.14.3.4.4 UDP Sockets Example

This example demonstrates UDP communication using socket functions instead of the [UDPPacket](#) class.

UDP Sockets Send/Receive Example

Features:

- Bidirectional UDP communication
- Task-based receive handling
- Main loop for sending

```
#include <init.h>
#include <stdlib.h>
#include <string.h>
#include <system.h>
#include <udp.h>
#include <utils.h>

const char *AppName = "UDP Sockets Example";

// Allocate stack space for the listen task
uint32_t UdpReceiveTaskStack[USER_TASK_STK_SIZE];

//
// UDP Receive Task
// Waits for incoming UDP packets and processes them
//
void UdpReceiveTask(void *pd)
{
```

```

int listenPort = (int)pd;

printf("UdpReceiveTask monitoring port %d\r\n", listenPort);

// Create UDP socket for receiving
int udpFd = CreateRxUdpSocket(listenPort);
if (udpFd <= 0)
{
    printf("Error Creating UDP Listen Socket: %d\r\n", udpFd);
    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
else
{
    printf("Listening for UDP packets on port %d\r\n", listenPort);

    while (1)
    {
        IPADDR sourceIpAddress;    // Packet source IP
        uint16_t localPort;        // Local port (destination)
        uint16_t sourcePort;       // Source port
        char buffer[80];

        int len = recvfrom(udpFd, (uint8_t *)buffer, 80,
                           0, &sourceIpAddress, &localPort, &sourcePort);
        buffer[len] = '\0';

        printf("\r\nReceived a UDP packet with %d bytes from: %I\r\n%s\r\n",
               len, sourceIpAddress, buffer);
    }
}

//
// User Main
//
void UserMain(void *pd)
{
    int portNumber;
    IPADDR destIpAddress;
    char buffer[80];

    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    printf("Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());

    // Get destination IP address
    printf("Enter the UDP Server destination IP address: ");
    gets(buffer);
    destIpAddress = AsciiToIp(buffer);
    printf("\r\n");

    // Get port number (used for send and receive)
    printf("Enter the source/destination port number: ");
    gets(buffer);
    portNumber = atoi(buffer);
    printf("\r\n");

    // Create UDP socket for sending
    int udpFd = CreateTxUdpSocket(destIpAddress, portNumber, portNumber);
    if (udpFd <= 0)
    {
        printf("Error Creating UDP Socket: %d\r\n", udpFd);
        while (1)
        {
            OSTimeDly(TICKS_PER_SECOND);
        }
    }
    else
    {
        printf("Sending/Receiving with host %I:%d\r\n", destIpAddress, portNumber);
    }

    // Create UDP receive task (higher priority for responsive reception)
    OSTaskCreateName(UdpReceiveTask,
                    (void *)portNumber,
                    &UdpReceiveTaskStack[USER_TASK_STK_SIZE],
                    UdpReceiveTaskStack,
                    MAIN_PRIO - 1,
                    "UDP Receive");

    printf("Enter data and hit enter to send.\r\n");

    // Main loop: send user input as UDP packets

```

```

while (1)
{
    gets(buffer);
    printf("\r\n");
    printf("Sending \"%s\" using UDP to %I:%d\r\n", buffer, destIpAddress, portNumber);

    sendto(udpFd, (uint8_t *)buffer, strlen(buffer), destIpAddress, portNumber);
    printf("\r\n");
}
}

```

10.14.3.4.5 Socket Function Reference

Receiving**:

```
int udpFd = CreateRxUdpSocket(localPort);
```

```
IPADDR sourceIP;
uint16_t sourcePort, destPort;
char buffer[SIZE];
```

```
int len = recvfrom(udpFd, (uint8_t*)buffer, SIZE,
                  &sourceIP, &destPort, &sourcePort);
```

Sending**:

```
int udpFd = CreateTxUdpSocket(destIP, destPort, sourcePort);
```

```
sendto(udpFd, (uint8_t*)buffer, length, destIP, destPort);
```

10.14.3.4.6 UDP Socket Architecture

Socket-Based UDP Flow:

Receive Path:

Send Path:

10.14.3.4.7 Best Practices Summary

10.14.3.4.8 General Guidelines

1. Protocol Selection:

- Choose TCP for reliability and ordered delivery
- Choose UDP for speed and efficiency
- Consider application-layer reliability over UDP when appropriate

2. Resource Management:

- Always close sockets when done
- Check return values from all network functions
- Handle connection errors gracefully

3. Task Architecture:

- Use separate tasks for listening/receiving
- Set appropriate task priorities
- Consider using `select()` for multiple connections

4. Buffer Management:

- Allocate adequate buffer sizes
- Null-terminate string data
- Use static buffers in tasks to save stack space

5. Error Handling:

- Check socket creation return values
- Handle connection failures
- Implement timeout mechanisms

10.14.3.4.9 Performance Optimization

- Use `select()` for multiple connections (TCP)
- Consider OS_FIFO size for UDP packet bursts
- Set appropriate task priorities for responsive I/O
- Use `ReadWithTimeout()` for connection management

10.14.3.4.10 Security Considerations

- Validate all received data
- Implement authentication when needed
- Use random source port numbers
- Consider connection limits for servers

10.15 SSL/TLS and Certificates

10.15.1 Introduction

This comprehensive guide covers SSL/TLS security implementation on NetBurner embedded devices. Whether you're securing a web interface, IoT communication, or industrial control system, this guide provides practical solutions for establishing encrypted, authenticated connections.

What You'll Learn:**

- Core SSL/TLS concepts explained clearly
- Multiple implementation approaches from simple to advanced
- Certificate management strategies
- Common issues and their solutions
- Production-ready deployment practices

10.15.2 Understanding SSL/TLS Fundamentals

Note: This document uses "SSL" as shorthand for SSL/TLS protocols. Modern implementations use TLS (Transport Layer Security), the successor to SSL.

10.15.3 The Security Problem

In a normal network connection, data travels in plain text. This creates two critical vulnerabilities:

Vulnerability 1: Eavesdropping**

Vulnerability 2: Man-in-the-Middle (MITM)**

10.15.4 How SSL/TLS Solves These Problems

SSL/TLS provides three critical security features:

1. **Encryption:** Data is scrambled so eavesdroppers see gibberish
2. **Authentication:** Verify you're talking to the real server (not an attacker)
3. **Integrity:** Detect if data has been tampered with

10.15.5 The Trust Chain: How Authentication Works

SSL/TLS uses a "chain of trust" similar to how we trust professionals:

10.15.5.1 Real-World Analogy: Trusting a Doctor

10.15.5.2 SSL/TLS Certificate Chain

Key Components of a Certificate:**

1. **Identity** (Common Name/CN) - Who this certificate represents

2. **Public Key** - Like an open padlock anyone can use to encrypt
3. **Signature** - Cryptographic proof from a trusted CA

10.15.6 Public Key Cryptography Simplified

Think of it like a special mailbox:

Critical Security Principle:**

[LOCK] **The system is only as secure as the private key.** If an attacker gets your private key, they can decrypt all traffic and impersonate your device.

10.15.7 Certificate Types at a Glance

Type	Trust Level	Browser Warnings	Best For	Cost
Self-Signed	Low	[!] Yes	Development, testing, internal networks	Free
Private CA	Medium	[!] Yes (until CA installed)	Enterprise deployments, controlled environments	Free
Public CA	High	[OK] No	Production, public-facing devices	Varies
ACME (Let's Encrypt)	High	[OK] No	Production with public DNS	Free

10.15.8 Quick Start Guide

10.15.9 For SSL Servers (Your NetBurner Device)

10.15.9.1 Option 1: Automatic (Recommended for Production)

If you have a public DNS name:**

```
// ACME with Let's Encrypt - Automatic trusted certificates
#include <acmeservlet.h>
```

```
void UserMain(void *pd) {
    init();

    // Configure ACME
    AcmeConfig config;
    config.domain = "mydevice.example.com";
    config.email = "admin@example.com";

    // Automatic certificate issuance and renewal
    StartAcmeHttps(config);

    WaitForActiveNetwork(TICKS_PER_SECOND * 5);
    printf("Secure HTTPS server running\n");

    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}
```

If you only have local/private network:**

```
// Auto-generated self-signed certificate
#include <init.h>
#include <startnet.h>
```

```
void UserMain(void *pd) {
    init();
```

```
// Automatically generates self-signed cert on first run
StartHttps(); // Port 443 by default

WaitForActiveNetwork(TICKS_PER_SECOND * 5);
printf("HTTPS server running (self-signed)\n");

while(1) { OSTimeDly(TICKS_PER_SECOND); }
}
```

10.15.10 For SSL Clients (Connecting to Servers)

```
#include <ssl.h>
#include <nettcp.h>

// CA certificates you trust (example: Let's Encrypt root)
extern const char letsEncryptCA[];
extern const int letsEncryptCA_len;

void ConnectSecurely() {
    // Initialize SSL system
    SslInit();

    // Add trusted CA certificates
    SSL_AddCertToClientCaList(letsEncryptCA, letsEncryptCA_len);

    // Create secure connection
    int fd = connect("api.example.com", 443);
    WOLFSSL* ssl = SSL_connect(fd);

    if (ssl) {
        SSL_write(ssl, "GET / HTTP/1.1\r\n\r\n", 18);
        // ... read response ...
        SSL_close(ssl);
    }
}
```

10.15.11 Certificate Types and Use Cases

10.15.12 Decision Matrix

Need Public Access?

10.15.13 1. Self-Signed Certificates

What It Is:** Device acts as its own Certificate Authority

Visual Flow:**

NetBurner Device

1. Generate Key Pair
2. Create Certificate
3. Sign with Own Key
4. Use **for** Connections

v

Browser/Client

```
[!] Certificate Warning
"Not Trusted"

[Proceed Anyway]
```

When to Use:**

- [YES] Development and testing
- [YES] Single device, few users

- [YES] Internal network only
- [YES] Quick prototyping
- Limitations:**
- [NO] Browser warnings for every user
- [NO] Certificate must be manually installed on each client
- [NO] No central management
- [NO] Looks unprofessional in production

NetBurner Implementation:**

```
// Automatic - just enable HTTPS
StartHttps(); // Self-signed cert auto-generated

// Or manual control
#define ENABLE_AUTOCERT_REGEN // In predef.h
// Regenerates when expired (checked every minute by default)
```

10.15.14 2. Private Certificate Authority (CA)

What It Is:** You create your own CA and sign device certificates

Visual Flow:**

Step 1: Create Your CA

Step 2: Sign Device Certs

Step 3: Deploy

When to Use:**

- [YES] Multiple devices in controlled environment
- [YES] Corporate/enterprise deployment
- [YES] Need certificate management
- [YES] Air-gapped or private networks

Advantages:**

- [YES] One-time CA installation for all clients
- [YES] Central control over certificate issuance
- [YES] Can revoke compromised certificates
- [YES] No external dependencies

Limitations:**

- [NO] More complex initial setup
- [NO] Must manually manage certificate expiration

- [NO] CA certificate must be distributed to all clients

NetBurner Implementation:**

Use the provided scripts in \nburn\CreateCerts\:

```
# Step 1: Create your CA (one time)
cd C:\nburn\CreateCerts\ECDsa
createCA.bat

# Step 2: Create device certificate
createDeviceCert.bat mydevice.example.com

# Step 3: Convert to C++ for NetBurner
compile device.key comp_key comp_key_len key.cpp
compile device.crt comp_cert comp_cert_len cert.cpp
// In your application
extern const unsigned char comp_cert[];
extern const int comp_cert_len;
extern const unsigned char comp_key[];
extern const int comp_key_len;

void UserMain(void *pd) {
    init();

    // Install certificate before starting HTTPS
    SSL_InstallCertificate(comp_cert, comp_cert_len,
                          comp_key, comp_key_len);

    StartHttps();

    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}
```

10.15.15 3. Public CA Certificates

What It Is:** Purchase certificates from trusted authorities (DigiCert, GoDaddy, etc.)

Visual Flow:**

Step 1: Generate CSR

```
Device/Computer
1. Create Key
2. Generate CSR
```

v

Step 2: Submit to CA

```
Certificate Authority
(DigiCert, etc.)
1. Verify Domain
2. Issue Certificate
```

v

Step 3: Install

```
NetBurner Device
1. Install Cert
2. Install Chain
```

When to Use:**

- [YES] Public-facing production devices
- [YES] Need universal trust (no warnings)
- [YES] Customer/client access
- [YES] Professional appearance required

Advantages:**

- [YES] No browser warnings
- [YES] Pre-trusted by all clients
- [YES] Professional appearance

- [YES] Insurance/warranty often included

Limitations:**

- [NO] Annual costs (\$50-\$500+)
- [NO] Manual renewal process
- [NO] Requires public DNS name
- [NO] Validation requirements

Process:**

1. Generate Certificate Signing Request (CSR):

```
openssl genrsa -out device.key 2048
openssl req -new -key device.key -out device.csr
# Enter device domain name as Common Name
```

2. Submit CSR to CA and complete verification

3. Receive certificate and chain files

4. Combine certificate with chain:

```
# Create complete chain file
cat device.crt intermediate.crt root.crt > device_chain.crt
```

5. Convert and install on NetBurner (same as Private CA method)

10.15.16 4. ACME (Automated Certificate Management)

What It Is:** Automated certificate issuance from Let's Encrypt or BuyPass

Visual Flow:**

When to Use:**

- [YES] Production devices with public DNS
 - [YES] Need automatic renewal
 - [YES] Want trusted certs without cost
 - [YES] Device accessible from internet
- Requirements:**
- [YES] Public DNS name pointing to device
 - [YES] Device reachable on port 80 (for validation)

- [YES] NNDK 3.5.0 or later
- Advantages:**
- [YES] Completely automatic
- [YES] Free trusted certificates
- [YES] Auto-renewal every 60 days
- [YES] No manual certificate management

Limitations:**

- [NO] Requires public internet access
- [NO] Must have DNS name (no IP-only)
- [NO] Shorter validity (90 days vs 1 year)

NetBurner Implementation:**

```
#include <acmeservlet.h>

void UserMain(void *pd) {
    init();
    EnableSystemDiagnostics();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Configure ACME settings
    AcmeConfig config;
    config.domain = "iot-device.example.com";
    config.email = "admin@example.com";
    config.acmeServer = ACME_LETSENCRYPT_PRODUCTION;

    // Start HTTPS with automatic ACME management
    int result = StartAcmeHttps(config);

    if (result == 0) {
        printf("ACME HTTPS server started successfully\n");
        printf("Certificate will auto-renew before expiration\n");
    } else {
        printf("ACME setup failed: %d\n", result);
    }

    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}
```

10.15.17 Use Case Decision Table

Scenario	Recommended Method	Why
Development/Testing	Self-Signed	Fastest, simplest
Internal corporate network, 10+ devices	Private CA	Central management, one-time client setup
Public website/API	ACME or Public CA	Trusted by all browsers
Air-gapped system	Private CA or Self-Signed	No external dependencies
IoT fleet with DNS names	ACME	Automatic, scalable, free
Single device, few users	Self-Signed	Adequate for small scale
Requires IP address (no DNS)	Self-Signed or Private CA	ACME requires DNS
Critical infrastructure	Public CA	Professional support, insurance

10.15.18 Implementation Methods

10.15.19 Method 1: Automatic Onboard Certificate Generation

Simplest approach - certificates generated automatically on first use.**

10.15.19.1 How It Works

First Boot / Certificate Needed

10.15.19.2 Basic Implementation

```

#include <init.h>

const char *AppName = "Secure Device";

void UserMain(void *pd) {
    init();
    EnableSystemDiagnostics();

    // Certificate automatically generated on first HTTPS connection
    StartHttps(); // Default port 443

    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    printf("HTTPS Server: %s\n", AppName);
    printf("Certificate auto-generated if needed\n");

    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

10.15.19.3 Advanced: Auto-Regeneration

Enable automatic regeneration when certificates expire:

```

// In your project's predef.h or compile flags:
#define ENABLE_AUTOCERT_REGEN
#define AUTO_CERT_GEN_CHECK (60 * 20) // Check every 20 minutes

// Default settings if not defined:
// - Checks every 1 minute
// - Certificate valid for 1 year
// - Uses SECP384R1 ECC by default

```

10.15.19.4 Customizing Certificate Generation

```

#include <ssl.h>

// Callback for custom certificate attributes
void CustomCertCallback(SslCertAttributes_t *attrs) {
    // Set custom fields
    attrs->country = "US";
    attrs->state = "California";
    attrs->locality = "San Diego";
    attrs->organization = "My Company";
    attrs->commonName = "mydevice.local";

    // Add alternative names
    attrs->altNames = "mydevice.local,192.168.1.100,#LOCAL";
    // #LOCAL = automatically use mDNS .local name
}

void UserMain(void *pd) {
    init();

    // Register custom certificate callback
    SSL_SetCertificateCallback(CustomCertCallback);

    StartHttps();
}

```

```

    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}

```

10.15.20 Method 2: ACME Automated Certificates

Production-ready trusted certificates with automatic renewal.**

10.15.20.1 Complete ACME Example

```

#include <init.h>
#include <acmeservlet.h>
#include <nbrtos.h>

const char *AppName = "ACME Secure Device";

void UserMain(void *pd) {
    init();
    EnableSystemDiagnostics();

    WaitForActiveNetwork(TICKS_PER_SECOND * 10);

    // Ensure DNS is working (critical for ACME)
    printf("Device IP: %s\n", GetIP().c_str());
    printf("Waiting for DNS resolution...\n");

    // Configure ACME
    AcmeConfig config;
    config.domain = "iot-device.example.com"; // Must match DNS
    config.email = "admin@example.com";      // For renewal notices
    config.acmeServer = ACME_LETSENCRYPT_PRODUCTION;
    config.acceptTerms = true;

    // Optional: Use staging server for testing
    // config.acmeServer = ACME_LETSENCRYPT_STAGING;

    printf("Starting ACME certificate process for: %s\n", config.domain);

    int result = StartAcmeHttps(config);

    if (result == 0) {
        printf("[OK] ACME HTTPS server running\n");
        printf("Certificate valid for 90 days\n");
        printf("Auto-renewal occurs at 60 days\n");
    } else {
        printf("[ERR] ACME failed with error: %d\n", result);
        printf("Check: DNS resolution, firewall, port 80 access\n");
    }

    while (1) {
        OSTimeDly(TICKS_PER_SECOND * 60);
        // ACME renewal happens automatically in background
    }
}

```

10.15.20.2 ACME Troubleshooting Checklist

Prerequisites Check:

```

[ ] Device has public IP address
[ ] DNS A record points to device IP
[ ] Port 80 open and accessible from internet
[ ] Port 443 open for final HTTPS
[ ] NTP time synchronized (critical!)
[ ] Sufficient free memory (>50KB)

```

Common Issues:

```

[X] DNS not resolving      -> Check DNS propagation (nslookup)
[X] Port 80 blocked       -> Check firewall rules
[X] Challenge fails       -> Verify HTTP-01 accessibility
[X] Time sync error       -> Enable and wait for NTP
[X] Memory allocation fail -> Check heap usage

```

10.15.21 Method 3: Manual Certificate Installation

For private CAs or purchased certificates.**

10.15.21.1 Step-by-Step Process

Step 1: Generate Certificate Files**

Using NetBurner CreateCerts scripts:

```
# Navigate to CreateCerts directory
cd C:\nburn\CreateCerts\ECDsa

# Create CA (one time, if needed)
createCA.bat

# Create device certificate
createDeviceCert.bat mydevice.example.com
```

```
# Output files:
# - device.key (private key - KEEP SECRET!)
# - device.crt (certificate)
# - ca.crt (CA certificate)
```

Step 2: Convert to C++ Code**

```
# Convert key
compfile device.key comp_key comp_key_len key.cpp

# Convert certificate
compfile device.crt comp_cert comp_cert_len cert.cpp

# Optional: Convert CA for chain
compfile ca.crt comp_ca comp_ca_len ca.cpp
```

Step 3: Add to Project**

```
YourProject/
├── src/
│   ├── main.cpp
│   ├── key.cpp      <- Add these
│   ├── cert.cpp     <- Add these
│   └── ca.cpp       <- Optional
└── makefile
```

Update makefile if using command line builds:

```
CPP_SRC += \
    src/main.cpp \
    src/key.cpp \
    src/cert.cpp
```

Step 4: Install in Code**

```
#include <init.h>
#include <ssl.h>

// External declarations for compiled certificates
extern const unsigned char comp_cert[];
extern const int comp_cert_len;
extern const unsigned char comp_key[];
extern const int comp_key_len;

void UserMain(void *pd)
{
    init();
    EnableSystemDiagnostics();

    // Install certificate BEFORE starting HTTPS
    int result = SSL_InstallCertificate(
        comp_cert, comp_cert_len,
        comp_key, comp_key_len
    );

    if (result == 0) {
        printf("[OK] Certificate installed successfully\n");
    } else {
        printf("[ERR] Certificate installation failed: %d\n", result);
    }

    StartHttps();

    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

10.15.21.2 Installing Certificate Chain

For trusted certificates, install the full chain:

```
// Combine certificate with intermediate and root CAs
extern const unsigned char comp_device_cert[];
extern const int comp_device_cert_len;
extern const unsigned char comp_chain[];
extern const int comp_chain_len;
extern const unsigned char comp_key[];
```

```

extern const int comp_key_len;

void InstallWithChain() {
    // Method 1: Combined file (preferred)
    SSL_InstallCertificate(comp_chain, comp_chain_len,
                          comp_key, comp_key_len);

    // Method 2: Separate installation
    SSL_InstallCertificate(comp_device_cert, comp_device_cert_len,
                          comp_key, comp_key_len);
    SSL_AddIntermediateCert(comp_chain, comp_chain_len);
}

```

10.15.22 Method 4: SSL Client Implementation

Connecting to secure servers with certificate validation.**

10.15.22.1 Basic SSL Client

```

#include <ssl.h>
#include <nettcp.h>

// CA certificate for validation
extern const char trustedCA[];
extern const int trustedCA_len;

void SecureClientConnection()
{
    // Initialize SSL (once at startup)
    SslInit();

    // Add trusted CA certificates
    SSL_AddCertToClientCaList(trustedCA, trustedCA_len);

    // Create TCP connection
    int fd = connect("api.example.com", 443);

    if (fd > 0) {
        // Upgrade to SSL
        WOLFSSL* ssl = SSL_connect(fd);

        if (ssl) {
            printf("[OK] Secure connection established\n");

            // Send data
            const char* request = "GET / HTTP/1.1\r\n"
                                  "Host: api.example.com\r\n"
                                  "\r\n";
            SSL_write(ssl, request, strlen(request));

            // Read response
            char buffer[1024];
            int n = SSL_read(ssl, buffer, sizeof(buffer)-1);
            if (n > 0) {
                buffer[n] = '\0';
                printf("Response: %s\n", buffer);
            }

            SSL_close(ssl);
        } else {
            printf("[ERR] SSL handshake failed\n");
        }
        close(fd);
    }
}

```

10.15.22.2 Advanced: Certificate Verification

```

#include <ssl.h>

// Custom verification callback
int VerifyCertCallback(int preverify_ok, WOLFSSL_X509_STORE_CTX* store) {
    if (!preverify_ok) {
        // Get error details
        int err = X509_STORE_CTX_get_error(store);
        int depth = X509_STORE_CTX_get_error_depth(store);

        printf("Certificate verification failed at depth %d\n", depth);
        printf("Error: %s\n", X509_verify_cert_error_string(err));

        // Decide whether to accept anyway
        // return 1; // Accept despite error (insecure!)
        return 0; // Reject connection (secure)
    }
}

```

```

    }
    return 1; // Accept
}

void SetupSecureClient() {
    SslInit();

    // Add CA certificates
    SSL_AddCertToClientCaList(trustedCA, trustedCA_len);

    // Set verification callback
    SSL_SetVerifyCallback(VerifyCertCallback);

    // Set verification mode
    SSL_SetVerifyMode(SSL_VERIFY_PEER | SSL_VERIFY_FAIL_IF_NO_PEER_CERT);
}

```

10.15.22.3 Loading CAs from Storage

```

#include <effs_fat.h>
#include <ssl.h>

void LoadCAsFromSD() {
    SslInit();

    F_FILE* f = f_open("ca-bundle.crt", "r");
    if (f) {
        // Get file size
        f_seek(f, 0, SEEK_END);
        long size = f_tell(f);
        f_seek(f, 0, SEEK_SET);

        // Read CA bundle
        char* certs = new char[size + 1];
        f_read(certs, 1, size, f);
        certs[size] = '\0';
        f_close(f);

        // Add to trusted list
        SSL_AddCertToClientCaList(certs, size);

        delete[] certs;
        printf("[OK] Loaded CA certificates from SD\n");
    }
}

```

10.15.23 Troubleshooting

10.15.24 Common Browser Warning Messages

10.15.24.1 1. "Your Connection is Not Private"

```

[!] Your connection is not private

Attackers might be trying to steal
your information...

NET::ERR_CERT_AUTHORITY_INVALID

```

Cause:** Certificate not signed by trusted CA

Solutions:**

- [OK] Use ACME for automatic trusted certificates
- [OK] Install your CA certificate on client devices
- [OK] Purchase certificate from public CA
- [!] For testing only: Click "Advanced" -> "Proceed (unsafe)"

10.15.24.2 2. "Certificate Name Mismatch"

```

[!] Certificate doesn't match

Certificate: device.example.com
Accessing: 192.168.1.100

NET::ERR_CERT_COMMON_NAME_INVALID

```

Cause:** Certificate issued for different name/IP

Solutions:**

- [OK] Access device using correct hostname
- [OK] Add Subject Alternative Names (SANs) to certificate
- [OK] Use wildcard certificate (*.example.com)
- [OK] Generate new certificate with correct CN/SAN

Example with multiple names:

```
void CertCallback(SslCertAttributes_t *attrs) {
    attrs->commonName = "device.example.com";
    attrs->altNames = "device.example.com,"
                     "device.local,"
                     "192.168.1.100,"
                     "10.0.0.50";
}
```

10.15.24.3 3. "Certificate Expired"

```
[!] This certificate has expired

Valid Until: Jan 15, 2025
Today:      Feb 20, 2025

NET::ERR_CERT_DATE_INVALID
```

Cause:** Certificate past expiration date

Solutions:**

- [OK] Use ACME for automatic renewal
- [OK] Enable auto-regeneration for self-signed certs
- [OK] Set calendar reminders for manual renewal
- [OK] Check device clock is synchronized (NTP)

10.15.24.4 4. "Certificate Not Yet Valid"

Cause:** Device clock incorrect or certificate future-dated

Solutions:**

```
#include <ntpclient.h>

void UserMain(void *pd) {
    init();

    // Synchronize time BEFORE SSL operations
    SetNTPServer("pool.ntp.org");
    EnableNTP();

    // Wait for time sync
    while (!NTPTimeSet()) {
        OSTimeDly(TICKS_PER_SECOND);
    }

    printf("[OK] Time synchronized\n");

    StartHttps(); // Now SSL will work

    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}
```

10.15.25 SSL Handshake Failures

10.15.25.1 Debugging Connection Issues

```
#include <ssl.h>

void DebugSSLConnection(const char* host, int port) {
    printf("\n=== SSL Debug Info ===\n");
}
```

```

// 1. Test TCP connectivity
printf("Testing TCP connection to %s:%d...\n", host, port);
int fd = connect(host, port);
if (fd < 0) {
    printf("[ERR] TCP connection failed\n");
    return;
}
printf("[OK] TCP connected\n");

// 2. Enable SSL debugging
wolfSSL_Debugging_ON();

// 3. Attempt SSL handshake
printf("Attempting SSL handshake...\n");
WOLFSSL* ssl = SSL_connect(fd);

if (ssl) {
    printf("[OK] SSL handshake successful\n");

    // Get connection details
    WOLFSSL_CIPHER* cipher = SSL_get_current_cipher(ssl);
    printf("Cipher: %s\n", SSL_CIPHER_get_name(cipher));
    printf("Protocol: %s\n", SSL_get_version(ssl));

    SSL_close(ssl);
} else {
    printf("[ERR] SSL handshake failed\n");
    int err = SSL_get_error(ssl, -1);
    printf("Error code: %d\n", err);
}

close(fd);
wolfSSL_Debugging_OFF();
}

```

10.15.25.2 Common Error Codes

Error	Meaning	Solution
-188	ASN parse error	Certificate format invalid
-173	Bad certificate	Corrupted or wrong cert format
-155	No CA match	Add appropriate CA to trust list
-313	Cipher suite mismatch	Update wolfSSL or adjust cipher list
-101	Connection reset	Network issue or server rejected

10.15.26 Certificate Verification Issues

10.15.26.1 Verification Flowchart

SSL Handshake Started

10.15.26.2 Bypass Verification (Development Only!)

```
// [!] WARNING: This is insecure! Only for development!

void InsecureClientSetup() {
    SslInit();

    // Disable certificate verification
    SSL_SetVerifyMode(SSL_VERIFY_NONE);

    printf("[!] Certificate verification DISABLED\n");
    printf("[!] Use only for development/testing\n");
}

// For production, always verify:
void SecureClientSetup() {
    SslInit();
    SSL_AddCertToClientCaList(trustedCA, trustedCA_len);
    SSL_SetVerifyMode(SSL_VERIFY_PEER | SSL_VERIFY_FAIL_IF_NO_PEER_CERT);
}
```

10.15.27 Memory and Resource Issues

10.15.27.1 Memory Requirements

Typical SSL Memory Usage:

Component	Size
SSL Context	~8-12 KB
Certificate Chain	2-8 KB
Per Connection	40-60 KB
Crypto Operations	10-20 KB

Minimum Recommended: 128 KB free heap Comfortable: 256 KB+ free heap

10.15.27.2 Checking Memory

```
#include <system.h>

void CheckMemoryForSSL() {
    uint32_t freeHeap = FreeRTOSMemRemaining();
    uint32_t minFree = FreeRTOSMemMinEver();

    printf("\n=== Memory Status ===\n");
    printf("Current Free: %lu KB\n", freeHeap / 1024);
    printf("Minimum Ever: %lu KB\n", minFree / 1024);

    if (freeHeap < 128 * 1024) {
        printf("[!] WARNING: Low memory for SSL\n");
        printf("    Consider: Reducing buffer sizes\n");
        printf("    Limiting connections\n");
        printf("    Using lighter ciphers\n");
    } else {
        printf("[OK] Sufficient memory for SSL\n");
    }
}
```

10.15.28 Performance Optimization

10.15.28.1 Cipher Suite Selection

```
#include <ssl.h>

// Faster but less secure (use only if needed)
const char* fastCiphers =
    "ECDHE-ECDSA-AES128-GCM-SHA256:"
    "ECDHE-RSA-AES128-GCM-SHA256";

// Balanced (recommended)
const char* balancedCiphers =
    "ECDHE-ECDSA-AES256-GCM-SHA384:"
    "ECDHE-ECDSA-AES128-GCM-SHA256:"
    "ECDHE-RSA-AES256-GCM-SHA384";

// Maximum security (slower)
const char* secureCiphers =
    "ECDHE-ECDSA-CHACHA20-POLY1305:"
```

```

    "ECDHE-ECDSA-AES256-GCM-SHA384";

void ConfigureCiphers() {
    SSL_SetCipherList(balancedCiphers);
    printf("Cipher list configured\n");
}

```

10.15.28.2 Connection Reuse

```

// Reuse SSL context for multiple connections
WOLFSSL_CTX* ctx = nullptr;

void InitSSLContext() {
    if (!ctx) {
        ctx = wolfSSL_CTX_new(wolfTLSv1_2_client_method());
        SSL_AddCertToClientCaList(trustedCA, trustedCA_len);
    }
}

WOLFSSL* CreateConnection(const char* host, int port) {
    InitSSLContext(); // Only runs once

    int fd = connect(host, port);
    if (fd < 0) return nullptr;

    WOLFSSL* ssl = wolfSSL_new(ctx);
    wolfSSL_set_fd(ssl, fd);

    if (wolfSSL_connect(ssl) != SSL_SUCCESS) {
        wolfSSL_free(ssl);
        close(fd);
        return nullptr;
    }

    return ssl;
}

```

10.15.29 Best Practices

10.15.30 Security Principles

10.15.30.1 1. Private Key Protection

Private Key Security Hierarchy
Most Secure: └ Hardware Security Module (HSM) └ Secure Enclave / TPM └ Encrypted Storage Moderate: └ Compiled into firmware └ Flash storage with permissions └ Protected file system Least Secure: └ Plain text on SD card └ Unprotected flash └ Debug accessible memory

Best Practices:**

- [YES] Never store private keys in version control
- [YES] Use different keys for dev/test/production
- [YES] Rotate keys periodically
- [YES] Monitor for unauthorized access
- [NO] Don't log private keys
- [NO] Don't transmit private keys unencrypted
- [NO] Don't reuse keys across devices (except CA)

10.15.30.2 2. Certificate Validation

```
// [X] BAD: Accepting any certificate
SSL_SetVerifyMode(SSL_VERIFY_NONE);

// [OK] GOOD: Proper validation
SSL_SetVerifyMode(SSL_VERIFY_PEER | SSL_VERIFY_FAIL_IF_NO_PEER_CERT);
SSL_AddCertToClientCaList(trustedCA, trustedCA_len);

// [OK] BETTER: With custom verification
int VerifyCallback(int preverify, WOLFSSL_X509_STORE_CTX* store) {
    // Additional checks: expiration, revocation, etc.
    return preverify && CustomSecurityChecks(store);
}
SSL_SetVerifyCallback(VerifyCallback);
```

10.15.30.3 3. Protocol and Cipher Configuration

```
// [X] BAD: Allowing old protocols
SSL_SetMinVersion(SSL_3_0); // SSL is broken!

// [OK] GOOD: Modern protocols only
SSL_SetMinVersion(TLS_1_2);

// [OK] BETTER: Latest protocols
SSL_SetMinVersion(TLS_1_3);

// Configure strong cipher suites
const char* strongCiphers =
    "TLS_AES_256_GCM_SHA384:"           // TLS 1.3
    "TLS_CHACHA20_POLY1305_SHA256:"    // TLS 1.3
    "ECDHE-ECDSA-AES256-GCM-SHA384:"    // TLS 1.2
    "ECDHE-RSA-AES256-GCM-SHA384";      // TLS 1.2

SSL_SetCipherList(strongCiphers);
```

10.15.31 Production Checklist

10.15.31.1 Pre-Deployment

```
[ ] Security Review:
[ ] All private keys properly protected
[ ] Certificate chain complete and valid
[ ] Strong cipher suites configured
[ ] Old protocols disabled (SSL, TLS 1.0/1.1)
[ ] Certificate validation enabled for clients

[ ] Certificate Management:
[ ] Expiration dates documented
[ ] Renewal process established
[ ] Contact information current
[ ] Backup certificates available

[ ] Monitoring Setup:
[ ] Certificate expiration alerts
[ ] Connection failure logging
[ ] Performance metrics
[ ] Security event logging

[ ] Testing Complete:
[ ] Browser compatibility verified
[ ] Client application tested
[ ] Load testing performed
[ ] Failover scenarios tested

[ ] Documentation:
[ ] Certificate inventory maintained
[ ] Configuration documented
[ ] Recovery procedures written
[ ] Contact list updated
```

10.15.31.2 Post-Deployment Monitoring

```
#include <ssl.h>

// Monitor SSL health
void MonitorSSLStatus() {
    uint32_t activeConnections = SSL_GetActiveConnections();
    uint32_t failedHandshakes = SSL_GetFailedHandshakes();
    uint32_t certificateErrors = SSL_GetCertErrors();

    printf("\n=== SSL Status ===\n");
    printf("Active Connections: %lu\n", activeConnections);
}
```

```

printf("Failed Handshakes: %lu\n", failedHandshakes);
printf("Certificate Errors: %lu\n", certificateErrors);

// Check certificate expiration
uint32_t daysUntilExpiry = SSL_GetCertDaysRemaining();
if (daysUntilExpiry < 30) {
    printf("[!] Certificate expires in %lu days!\n", daysUntilExpiry);
    // Trigger renewal process
}

// Alert if too many failures
if (failedHandshakes > 100) {
    printf("[!] High handshake failure rate!\n");
    // Send alert to administrator
}
}
}

```

10.15.32 Development Workflow

10.15.32.1 Recommended Development Cycle

Development Stages
1. Development (Local Network) ↳ Self-Signed Certificates - Fast iteration - No external dependencies 2. Integration Testing ↳ Private CA Certificates - Test certificate chains - Verify validation logic 3. Staging (Pre-Production) ↳ ACME Staging Certs - Test automation - Verify renewal process 4. Production ↳ ACME Production or Public CA - Trusted by all clients - Automatic renewal

10.15.32.2 Configuration Management

```

// Use preprocessor for environment-specific config

#ifdef DEVELOPMENT
    // Development: Self-signed, relaxed validation
    #define SSL_MODE          SSL_SELF_SIGNED
    #define VERIFY_MODE       SSL_VERIFY_NONE
    #define DEBUG_SSL        1

#elif defined(STAGING)
    // Staging: Test ACME, strict validation
    #define SSL_MODE          SSL_ACME_STAGING
    #define VERIFY_MODE       SSL_VERIFY_PEER
    #define DEBUG_SSL        1

#elif defined(PRODUCTION)
    // Production: Full security, monitoring
    #define SSL_MODE          SSL_ACME_PRODUCTION
    #define VERIFY_MODE       SSL_VERIFY_PEER | SSL_VERIFY_FAIL_IF_NO_PEER_CERT
    #define DEBUG_SSL        0
    #define ENABLE_SSL_MONITORING 1

#endif

void ConfigureSSL() {
    #if SSL_MODE == SSL_SELF_SIGNED
        StartHttps(); // Auto-generated cert

    #elif SSL_MODE == SSL_ACME_STAGING
        AcmeConfig config;
        config.acmeServer = ACME_LETSENCRYPT_STAGING;
        StartAcmeHttps(config);

    #elif SSL_MODE == SSL_ACME_PRODUCTION
        AcmeConfig config;
        config.acmeServer = ACME_LETSENCRYPT_PRODUCTION;

```

```

        StartAcmeHttps(config);
    #endif

    SSL_SetVerifyMode(VERIFY_MODE);

    #if DEBUG_SSL
        wolfSSL_Debugging_ON();
    #endif
}

```

10.15.33 Common Pitfalls to Avoid

10.15.33.1 1. Time Synchronization

```

// [X] BAD: Starting SSL before time sync
void UserMain(void *pd) {
    init();
    StartHttps(); // Certificates may appear expired!
    EnableNTP(); // Too late!
}

// [OK] GOOD: Ensure time is synced first
void UserMain(void *pd) {
    init();

    EnableNTP();
    SetNTPServer("pool.ntp.org");

    // Wait for time sync
    uint32_t timeout = 0;
    while (!NTPTimeSet() && timeout++ < 30) {
        OSTimeDly(TICKS_PER_SECOND);
    }

    if (NTPTimeSet()) {
        printf("[OK] Time synchronized\n");
        StartHttps(); // Now safe
    } else {
        printf("[!] Time sync failed, SSL may have issues\n");
    }
}

```

10.15.33.2 2. Certificate Chain Issues

```

// [X] BAD: Installing only device certificate
SSL_InstallCertificate(device_cert, device_cert_len,
                      device_key, device_key_len);
// Clients may not trust the certificate!

// [OK] GOOD: Installing complete chain
// Combine: device cert + intermediate CA + root CA
SSL_InstallCertificate(full_chain, full_chain_len,
                      device_key, device_key_len);

```

10.15.33.3 3. Resource Leaks

```

// [X] BAD: Not cleaning up
void MakeRequest() {
    WOLFSSL* ssl = SSL_connect(fd);
    SSL_write(ssl, data, len);
    // Forgot SSL_close() and close(fd)!
}

// [OK] GOOD: Proper cleanup
void MakeRequest() {
    int fd = connect(host, port);
    if (fd < 0) return;

    WOLFSSL* ssl = SSL_connect(fd);
    if (ssl) {
        SSL_write(ssl, data, len);
        SSL_close(ssl); // Free SSL resources
    }
    close(fd); // Close socket
}

```

10.15.33.4 4. Hardcoded Credentials

```

// [X] VERY BAD: Hardcoded in source
#define CA_KEY "-----BEGIN PRIVATE KEY-----\nMIIE..."

```

```
#define DEVICE_PASSWORD "admin123"

// [OK] BETTER: Compiled externally
extern const char comp_key[];
extern const int comp_key_len;

// [OK] BEST: Retrieved from secure storage
void LoadCredentials() {
    // Read from encrypted flash, secure element, etc.
    ReadSecureKey(keyBuffer, sizeof(keyBuffer));
}
```

10.15.34 Additional Resources

10.15.35 NetBurner Examples

Located in your NNDK installation:

```
C:\nburn\examples\SSL\
+-- acmeservlet\          <- ACME automation
+-- SslOnboardCertGeneration\ <- Auto-generated certs
|   +-- Simple\
|   +-- Advanced\
|   +-- CompiledCa\
+-- SslClientVerifyPeerBasic\ <- Client validation
+-- SslClientVerifyPeerEfs\   <- Loading CAs from storage
+-- CreateCerts\             <- Certificate generation scripts
    +-- ECDSA\
    +-- RSA\
```

10.15.36 Documentation and References

10.15.36.1 Official Documentation

- **wolfSSL Manual:** <https://www.wolfssl.com/documentation/manuals/wolfssl/>
- **NetBurner SSL API:** See `nburn\include\ssl.h`
- **ACME Protocol:** RFC 8555
- **TLS Protocol:** RFC 8446 (TLS 1.3)

10.15.36.2 Educational Resources

Books:**

- *Bulletproof SSL and TLS* by Ivan Ristic
 - *Applied Cryptography* by Bruce Schneier
 - *SSL and TLS: Designing and Building Secure Systems* by Eric Rescorla
- Online:**

10.15.37 Tools and Utilities

10.15.37.1 Certificate Management

- **OpenSSL:** Included in NNDK at \Nburn\gcc\msys\1.0\bin\openssl.exe
- **NetBurner CreateCerts:** Scripts in \nburn\CreateCerts\
- **compfile:** NetBurner utility to convert files to C++ arrays

10.15.37.2 Testing and Debugging

```
# Test SSL/TLS connection
openssl s_client -connect device.example.com:443 -showcerts

# Check certificate details
openssl x509 -in device.crt -text -noout

# Verify private key
openssl rsa -in device.key -check

# Test certificate chain
openssl verify -CAfile ca.crt device.crt
```

- **Let's Debug:** <https://letsdebug.net/> (for ACME troubleshooting)
- **Certificate Decoder:** <https://www.sslshopper.com/certificate-decoder.html>

10.15.38 Quick Reference

10.15.38.1 Essential SSL Functions

```
// Server Setup
StartHttps(); // Auto-generated cert
StartAcmeHttps(config); // ACME automation
SSL_InstallCertificate(cert, key); // Manual install

// Client Setup
SslInit(); // Initialize SSL
SSL_AddCertToClientCaList(ca); // Add trusted CA
SSL_connect(fd); // Secure connection
SSL_SetVerifyMode(mode); // Verification level

// Certificate Management
SSL_CreateNewSelfSignedCert(); // Generate cert
SSL_GetCertDaysRemaining(); // Check expiration
SSL_SetCertificateCallback(fn); // Custom attributes

// Data Transfer
SSL_write(ssl, data, len); // Send data
SSL_read(ssl, buffer, size); // Receive data
SSL_close(ssl); // Close connection

// Debugging
wolfSSL_Debugging_ON(); // Enable debug logs
SSL_get_error(ssl, ret); // Get error code
```

10.15.38.2 Configuration Constants

```
// Verification Modes
SSL_VERIFY_NONE // No validation (insecure!)
SSL_VERIFY_PEER // Validate peer
SSL_VERIFY_FAIL_IF_NO_PEER_CERT // Require peer cert

// Protocol Versions
SSL_3_0 // Deprecated
TLS_1_0 // Deprecated
TLS_1_1 // Deprecated
TLS_1_2 // Minimum recommended
TLS_1_3 // Latest

// ACME Servers
ACME_LETSENCRYPT_STAGING // Testing
ACME_LETSENCRYPT_PRODUCTION // Production
```

```
ACME_BUYPASS_PRODUCTION           // Alternative CA
// Certificate Types
SSL_FILETYPE_PEM                   // Text format
SSL_FILETYPE_DER                   // Binary format
```

Recommended Approach for Most Users:**

1. **Development:** Use auto-generated self-signed certificates
2. **Testing:** Set up private CA for realistic testing
3. **Production:** Deploy ACME if possible, otherwise use public CA

Key Takeaways:**

- [LOCK] Private keys are your most sensitive security asset
- [SYNC] ACME automation eliminates manual certificate management
- [TIME] Time synchronization is critical for SSL/TLS
- [LINK] Complete certificate chains prevent trust issues
- [STAT] Monitor certificate expiration and connection health

10.16 SSH Programming Guide

10.16.1 SSH Programming Guide for NetBurner Devices

10.16.2 Overview

The Secure Shell Protocol (SSH) is a cryptographic network protocol for secure remote access and command execution over unsecured networks. First introduced in 1995, SSH remains the industry standard for secure remote administration.

10.16.2.1 NetBurner SSH Implementation

NetBurner has supported SSH since NNDK 2.0. As of **NNDK 3.3.6**, we've migrated from Dropbear to **wolfSSH**, providing significant improvements:

10.16.2.2 Key Benefits of wolfSSH

Enhanced Security**

- Updated cipher suites and algorithms
- Support for modern cryptographic standards
- Regular security updates

Client Support**

- SSH client functionality now available

- Connect to remote SSH servers from NetBurner devices
- Automated remote management capabilities
Code Efficiency**
- Shared wolfCrypt library with SSL/TLS
- Reduced memory footprint when using both protocols
- Optimized for embedded systems
Simplified Key Management**
- Automatic key generation on device
- Multiple key format support
- Flexible key installation methods

10.16.3 What's New in NNDK 3.3.6+

10.16.3.1 Major Changes Summary

wolfSSH Migration	
[ADDED]	SSH Client Support
[ADDED]	Onboard Key Generation
[ADDED]	UserAuthManager Class
[ADDED]	Enhanced Authentication (keys + passwords)
[IMPROVED]	Modern Cipher Suites
[IMPROVED]	Shared Crypto Library (wolfCrypt)
[CHANGED]	Task Management (CryptoServer)
[REMOVED]	Dropbear-specific Functions

10.16.3.2 Architecture Change

Previous Architecture (NNDK 3.3.5 and earlier):**

New Architecture (NNDK 3.3.6+):**

Key Architectural Improvements:**

- Unified task management through CryptoServer
- Shared cryptographic primitives (wolfCrypt)
- Reduced resource overhead
- Consistent security across protocols

10.16.4 Key Types and Formats

10.16.4.1 Supported Key Types

The SSH library supports both **ECC** (Elliptic Curve Cryptography) and **RSA** keys.

Supported SSH Key Types	
ECC (Elliptic Curve) - RECOMMENDED	
Key Sizes:	160 to 512 bits
Advantages:	- Smaller key size - Faster operations - Lower memory usage
Use Case:	Embedded systems, IoT devices
RSA (Rivest-Shamir-Adleman)	
Default Size:	2048 bits
Optional:	4096 bits (define ENABLE_RSA_4K)
Advantages:	- Widely compatible - Well-established
Use Case:	Legacy system compatibility

10.16.4.1.1 Enabling RSA 4096-bit Keys

To enable 4096-bit RSA key support:

1. Open `<nndk_install>\nbrtos\include\predef.h`
2. Add the following definition:

```
#define ENABLE_RSA_4K
```

1. Rebuild your application

10.16.4.2 Supported Key Formats

Both key types support two formats:

SSH Key Format Support	
PEM Format (Privacy-Enhanced Mail)	
<pre>-----BEGIN RSA PRIVATE KEY----- Base64 encoded key data... -----END RSA PRIVATE KEY-----</pre> - Human readable (text) - Base64 encoding - Easier to copy/paste - Larger file size	
ASN.1/DER Format (Distinguished Encoding Rules)	
<pre>Binary encoded key data (not human readable)</pre> - Binary format - Smaller file size - Faster parsing - More efficient for embedded systems	

10.16.5 Migration Guide

10.16.5.1 Project Configuration

Step 1: Add Required Include Paths**

When building SSH applications in NBEclipse, add the following include paths:

```

${NNDK_ROOT}/libraries/include/ssh
${NNDK_ROOT}/libraries/include/crypto

```

Step 2: Configure in NBEclipse**

Project Configuration Flow:

1. Right-click project
|
v
2. Select "Properties"
|
v
3. Navigate to "C/C++ Build" > "Settings"
|
v
4. Select "Includes" under:
- GNU C Compiler
- GNU C++ Compiler
|
v
5. Click green "+" icon
|
v
6. Add paths:
\${NNDK_ROOT}/libraries/include/ssh
\${NNDK_ROOT}/libraries/include/crypto
|
v
7. Click "Apply"
|
v
8. Clean and rebuild project

10.16.5.2 Removed Functions

The following Dropbear-specific functions have been removed:

Removed Functions
<pre> SshConvertDecodedOpenSSLKey() ├ Purpose: Converted PEM to Dropbear format ├ Reason: No longer needed - native PEM/ASN.1 support └ Action: Remove from code SshSetchansessionrequest() ├ Purpose: Set callback for channel requests ├ Reason: Handled internally by wolfSSH └ Action: Remove callback - automatic handling SshSetTaskPriority() ├ Purpose: Set SSH task priority ├ Reason: Managed by CryptoServer task └ Action: Remove - uses SECURITY_TASK_PRIO </pre>

10.16.5.3 Updated Functions

Replace deprecated functions with their enhanced versions:

10.16.5.3.1 Authentication Function Pointer

Old (Deprecated):**

```

// Old function pointer - password only
typedef int (*sshUserAuthenticateFn)(const char* username, const char* password);

// Old setter
void SshSetUserAuthenticate(sshUserAuthenticateFn fn);

// Old getter
sshUserAuthenticateFn SshGetUserAuthenticate(void);

```

New (Recommended):**

```

// New function pointer - supports password AND key authentication
typedef int (*sshUserAuthenticateWithTypeFn)(const char* username,
                                             const char* authValue,
                                             AuthType authType);

// New setter
void SshSetUserAuthenticateWithType(sshUserAuthenticateWithTypeFn fn);

// New getter

```

```
sshUserAuthenticateWithTypeFn SshGetUserAuthenticateWithType(void);

Migration Example:**
// OLD CODE (NNDK 3.3.5 and earlier)
int MyAuthCallback(const char* username, const char* password) {
    // Only handled password authentication
    if (strcmp(username, "admin") == 0 && strcmp(password, "secret") == 0) {
        return 1; // Success
    }
    return 0; // Failure
}

void setup() {
    SshSetUserAuthenticate(MyAuthCallback);
}

// NEW CODE (NNDK 3.3.6+)
int MyAuthCallbackWithType(const char* username,
                           const char* authValue,
                           AuthType authType) {
    // Handle both password and key authentication
    if (authType == AUTH_TYPE_PASSWORD) {
        if (strcmp(username, "admin") == 0 &&
            strcmp(authValue, "secret") == 0) {
            return 1; // Success
        }
    }
    else if (authType == AUTH_TYPE_KEY) {
        // Validate public key
        if (ValidatePublicKey(username, authValue)) {
            return 1; // Success
        }
    }
    return 0; // Failure
}

void setup() {
    SshSetUserAuthenticateWithType(MyAuthCallbackWithType);
}

Authentication Type Enum:**
typedef enum {
    AUTH_TYPE_PASSWORD, // Password-based authentication
    AUTH_TYPE_KEY,      // Public key authentication
    AUTH_TYPE_UNKNOWN   // Unknown/unsupported type
} AuthType;
```

10.16.6 Key Management

10.16.6.1 Key Installation Methods

SSH keys can be installed using three methods, checked in the following priority order:

Key Selection Priority (Checked in Order):

1. Runtime Callback

`SshSetUserGetKey()` callback
Returns key dynamically

|
| Not set?
v

2. Compiled-In Key

Override `GetPrivateKeyPEM()`
Weak function override

|
| Not overridden?
v

3. Auto-Generated Key

Onboard generated key
Same as SSL/TLS key

10.16.6.2 Method 1: Runtime Callback (Highest Priority)

Use this method for dynamic key selection or key rotation.

```
#include <ssh.h>

// Callback signature
typedef int (*SshUserGetKeyFn)(const char** keyData,
                               int* keyLen,
```

```

        int* keyFormat);

// Example implementation
int GetSshKey(const char** keyData, int* keyLen, int* keyFormat) {
    // Load key from secure storage, file system, etc.
    static const char myKey[] =
        "-----BEGIN EC PRIVATE KEY-----\n"
        "MHcCAQEEIIGN...key data...zqk\n"
        "-----END EC PRIVATE KEY-----\n";

    *keyData = myKey;
    *keyLen = sizeof(myKey) - 1; // Exclude null terminator
    *keyFormat = SSH_KEY_FORMAT_PEM;

    return 1; // Success
}

void UserMain(void* pd) {
    init();

    // Set the callback
    SshSetUserGetKey(GetSshKey);

    // Start SSH server
    StartSsh();

    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}

Key Format Constants:**
#define SSH_KEY_FORMAT_PEM    0 // PEM format
#define SSH_KEY_FORMAT_DER    1 // DER/ASN.1 format

```

10.16.6.3 Method 2: Compiled-In Key (Medium Priority)

Override the weak function to provide a compiled-in key.

```

#include <ssh.h>

// Weak function (defined in SSH library)
// Override this in your application
extern const unsigned char myPrivateKey[];
extern const int myPrivateKeyLen;

// Override the weak function
const char* GetPrivateKeyPEM(void) {
    return (const char*)myPrivateKey;
}

// In a separate file (e.g., ssh_key.cpp)
// Generated using compfile utility
extern const unsigned char myPrivateKey[] = {
    0x2d, 0x2d, 0x2d, 0x2d, 0x2d, // PEM header
    // ... key data ...
};
extern const int myPrivateKeyLen = sizeof(myPrivateKey);

Generating Compiled Key File:**
# Convert PEM key to C array using compfile
compfile ssh_key.pem myPrivateKey myPrivateKeyLen ssh_key.cpp

# Add ssh_key.cpp to your project's makefile
CPP_SRC += src/ssh_key.cpp

```

10.16.6.4 Method 3: Auto-Generated Key (Lowest Priority)

Enable automatic key generation on the device.

```

// The device will automatically generate a key if:
// 1. No callback is set (Method 1)
// 2. GetPrivateKeyPEM() is not overridden (Method 2)
// 3. No existing key is found in storage

// The auto-generated key is the same key used for SSL/TLS
// certificates, reducing storage and memory requirements

void UserMain(void* pd) {
    init();

    // Start SSH - will auto-generate key if needed
    StartSsh();

    printf("SSH server started with auto-generated key\n");

    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}

```

Enable Auto-Regeneration:**

To automatically regenerate expired keys, add to `predef.h`:

```
// Enable automatic key regeneration
#define ENABLE_AUTOCERT_REGEN

// Optional: Set check interval (default: 1 minute)
#define AUTO_CERT_GEN_CHECK (60 * 20) // Check every 20 minutes
```

Key Generation Details:**

- Generated key is stored in non-volatile memory
- Persists across reboots
- Shared with SSL/TLS (same key for both protocols)
- Automatically regenerated when expired (if enabled)
- ECC SECP384R1 by default (configurable)

Related Examples:** See `<nndk_install>/examples/SSL/SslOnboardCertGeneration/` for:

- Simple: Basic auto-generation
- Advanced: Custom key attributes
- CompiledCa: Using a compiled CA

10.16.7 User Authentication

10.16.7.1 UserAuthManager Class

NetBurner provides the `UserAuthManager` class to simplify user credential management.

10.16.7.2 Key Features

Security Features:**

- Passwords are hashed before storage
- Keys are stored securely

- No plain-text credential leakage
- Secure comparison functions
- Flexibility:**
- Custom storage backends via callbacks
- Support for password and key authentication
- User-defined storage format (JSON, binary, etc.)
- In-memory or persistent storage

10.16.7.3 Basic Usage

```
#include <UserAuthManager.h>

// Global instance
UserAuthManager authManager;

// Initialize with storage callbacks
void InitializeAuth() {
    // Set load/save callbacks (see example below)
    authManager.SetLoadCallback(LoadAuthRecords);
    authManager.SetSaveCallback(SaveAuthRecords);

    // Load existing users from storage
    authManager.Load();
}

// Add a user with password
void AddPasswordUser(const char* username, const char* password) {
    if (authManager.AddUser(username, password, AUTH_TYPE_PASSWORD)) {
        printf("User %s added successfully\n", username);
        authManager.Save(); // Persist to storage
    } else {
        printf("Failed to add user %s\n", username);
    }
}

// Add a user with public key
void AddKeyUser(const char* username, const char* publicKey) {
    if (authManager.AddUser(username, publicKey, AUTH_TYPE_KEY)) {
        printf("User %s added with key authentication\n", username);
        authManager.Save();
    } else {
        printf("Failed to add user %s\n", username);
    }
}

// Verify user credentials
int AuthenticateUser(const char* username,
                    const char* authValue,
                    AuthType authType) {
    return authManager.Authenticate(username, authValue, authType);
}

// Remove a user
void RemoveUser(const char* username) {
    if (authManager.RemoveUser(username)) {
        printf("User %s removed\n", username);
        authManager.Save();
    }
}
```

10.16.7.4 Storage Callbacks

Implement custom storage using callbacks:

```
#include <UserAuthManager.h>
#include <njson.h>
#include <UserParams.h>

// Callback type definitions
typedef int (*LoadAuthRecordsFn)(UserAuthManager& manager);
typedef int (*SaveAuthRecordsFn)(UserAuthManager& manager);

// Load users from User Param space (example)
int LoadAuthRecords(UserAuthManager& manager) {
    // Read JSON from User Param space
    const char* jsonData = GetUserParam("SSH_USERS");
    if (!jsonData) return 0;
}
```

```

// Parse JSON and populate manager
ParsedJsonDataSet jsonSet;
if (ParseJsonData(jsonData, jsonSet)) {
    // Extract users from JSON and add to manager
    for (int i = 0; i < jsonSet.m_numDataElements; i++) {
        const char* username = jsonSet.FindName("username", i);
        const char* authData = jsonSet.FindName("auth", i);
        const char* typeStr = jsonSet.FindName("type", i);

        AuthType type = (strcmp(typeStr, "key") == 0) ?
            AUTH_TYPE_KEY : AUTH_TYPE_PASSWORD;

        manager.AddUserHashed(username, authData, type);
    }
    return 1;
}
return 0;
}

// Save users to User Param space (example)
int SaveAuthRecords(UserAuthManager& manager) {
    // Build JSON from manager data
    char jsonBuffer[4096];
    int offset = 0;

    offset += sprintf(jsonBuffer + offset, "{\\"users\\":[");

    // Iterate through users and build JSON
    // (Implementation depends on UserAuthManager API)

    offset += sprintf(jsonBuffer + offset, "]}");

    // Save to User Param space
    return SetUserParam("SSH_USERS", jsonBuffer);
}

// Register callbacks
void InitializeAuthStorage() {
    authManager.SetLoadCallback(LoadAuthRecords);
    authManager.SetSaveCallback(SaveAuthRecords);
    authManager.Load();
}

```

10.16.7.5 Integration with SSH Authentication

```

#include <ssh.h>
#include <UserAuthManager.h>

// Global manager
UserAuthManager g_authManager;

// Authentication callback for SSH
int SshAuthCallback(const char* username,
                   const char* authValue,
                   AuthType authType) {
    // Use UserAuthManager to verify credentials
    int result = g_authManager.Authenticate(username, authValue, authType);

    if (result) {
        printf("SSH: User '%s' authenticated successfully\n", username);
    } else {
        printf("SSH: Authentication failed for user '%s'\n", username);
    }

    return result;
}

void UserMain(void* pd) {
    init();

    // Initialize authentication manager
    g_authManager.SetLoadCallback(LoadAuthRecords);
    g_authManager.SetSaveCallback(SaveAuthRecords);
    g_authManager.Load();

    // Register SSH authentication callback
    SshSetUserAuthenticateWithType(SshAuthCallback);

    // Start SSH server
    StartSsh();

    printf("SSH server running with UserAuthManager\n");

    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}

```

10.16.7.6 Security Best Practices

UserAuthManager Security Features	
[HASH]	Passwords hashed before storage - Never store plain-text passwords - Secure hash algorithms used
[SAFE]	Constant-time comparison - Prevents timing attacks - Secure credential verification
[FLEX]	Pluggable storage - Choose your storage backend - Encrypt at rest if needed - Control access permissions
[KEYS]	Public key support - Store SSH public keys - Key-based authentication - More secure than passwords

Recommendations:**

1. Always hash passwords before storage
2. Use secure storage (encrypted if possible)
3. Implement proper access controls
4. Prefer key-based authentication
5. Regularly audit user accounts
6. Implement account lockout policies
7. Log authentication attempts

10.16.8 Configuration

10.16.8.1 SSH Server Configuration

Basic SSH server setup:

```
#include <init.h>
#include <ssh.h>

const char* AppName = "SSH Server Example";

void UserMain(void* pd) {
    init();

    // Wait for network
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Configure SSH (optional - uses defaults if not called)
    // SshSetPort(22); // Default SSH port

    // Start SSH server
    if (StartSsh() == 0) {
        printf("SSH server started successfully\n");
    } else {
        printf("Failed to start SSH server\n");
    }

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

10.16.8.2 SSH Client Configuration

Connect to remote SSH servers:

```
#include <ssh.h>

void ConnectToRemoteServer() {
    SshClientConfig config;
```

```

// Configure connection
config.hostname = "remote.server.com";
config.port = 22;
config.username = "admin";
config.password = "secret"; // Or use key authentication

// Connect
SSH_CLIENT* client = SshClientConnect(&config);

if (client) {
    printf("Connected to remote SSH server\n");

    // Execute command
    char response[1024];
    int result = SshClientExecute(client, "ls -la",
                                response, sizeof(response));

    if (result > 0) {
        printf("Command output:\n%s\n", response);
    }

    // Disconnect
    SshClientDisconnect(client);
} else {
    printf("Failed to connect to SSH server\n");
}
}

```

10.16.8.3 Advanced Configuration

```

#include <ssh.h>

void ConfigureSshAdvanced() {
    // Set custom port
    SshSetPort(2222);

    // Set connection timeout
    SshSetTimeout(30); // 30 seconds

    // Set maximum connections
    SshSetMaxConnections(5);

    // Enable/disable features
    SshEnablePasswordAuth(true);
    SshEnableKeyAuth(true);

    // Set custom banner
    SshSetBanner("Welcome to NetBurner SSH Server\n");

    // Configure cipher suites (if needed)
    // SshSetCipherList("aes128-ctr,aes256-ctr");

    // Start server with custom configuration
    StartSsh();
}

```

10.16.8.4 Configuration Constants

Common SSH configuration constants:

```

// Default values
#define SSH_DEFAULT_PORT 22
#define SSH_DEFAULT_TIMEOUT 60 // seconds
#define SSH_DEFAULT_MAX_CONNECTIONS 10
#define SSH_DEFAULT_KEY_SIZE 2048 // RSA

// Task priority (defined in constants.h)
#define SECURITY_TASK_PRIO 45 // CryptoServer priority

// Buffer sizes
#define SSH_MAX_USERNAME_LEN 32
#define SSH_MAX_PASSWORD_LEN 64
#define SSH_MAX_COMMAND_LEN 1024
#define SSH_MAX_RESPONSE_LEN 4096

```

10.16.9 Examples and Best Practices

10.16.9.1 Example 1: Basic SSH Server

```

#include <init.h>
#include <ssh.h>

```

```

#include <UserAuthManager.h>

const char* AppName = "Basic SSH Server";
UserAuthManager authManager;

// Simple authentication callback
int AuthUser(const char* username, const char* authValue, AuthType type) {
    return authManager.Authenticate(username, authValue, type);
}

// Initialize with default admin user
void InitDefaultUsers() {
    authManager.AddUser("admin", "admin123", AUTH_TYPE_PASSWORD);
    printf("Default user 'admin' created\n");
}

void UserMain(void* pd) {
    init();

    printf("Starting %s\n", AppName);

    // Wait for network
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Setup authentication
    InitDefaultUsers();
    SshSetUserAuthenticateWithType(AuthUser);

    // Start SSH server (auto-generated keys)
    StartSsh();

    printf("SSH server running on port 22\n");
    printf("Connect with: ssh admin@%s\n", GetIP().c_str());

    while(1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

10.16.9.2 Example 2: SSH Server with Persistent Users

```

#include <init.h>
#include <ssh.h>
#include <UserAuthManager.h>
#include <UserParams.h>
#include <nbjson.h>

UserAuthManager authManager;

// Load users from User Param space
int LoadUsers(UserAuthManager& mgr) {
    const char* jsonData = GetUserParam("SSH_USERS");
    if (!jsonData) return 0;

    ParsedJsonDataSet jsonSet;
    if (ParseJsonData(jsonData, jsonSet)) {
        for (int i = 0; i < jsonSet.m_numDataElements; i++) {
            const char* user = jsonSet.FindName("user", i);
            const char* hash = jsonSet.FindName("hash", i);
            const char* type = jsonSet.FindName("type", i);

            AuthType authType = (strcmp(type, "key") == 0) ?
                AUTH_TYPE_KEY : AUTH_TYPE_PASSWORD;
            mgr.AddUserHashed(user, hash, authType);
        }
        return 1;
    }
    return 0;
}

// Save users to User Param space
int SaveUsers(UserAuthManager& mgr) {
    char json[2048];
    // Build JSON from manager
    // ... implementation ...
    return SetUserParam("SSH_USERS", json);
}

int AuthUser(const char* username, const char* authValue, AuthType type) {
    int result = authManager.Authenticate(username, authValue, type);

    // Log authentication attempts
    if (result) {
        printf("[SSH] Login success: %s\n", username);
    } else {
        printf("[SSH] Login failed: %s\n", username);
    }
}

```

```

    }

    return result;
}

void UserMain(void* pd) {
    init();

    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Setup persistent user storage
    authManager.SetLoadCallback(LoadUsers);
    authManager.SetSaveCallback(SaveUsers);
    authManager.Load();

    // Create default user if none exist
    if (authManager.GetUserCount() == 0) {
        authManager.AddUser("admin", "netburner", AUTH_TYPE_PASSWORD);
        authManager.Save();
        printf("Created default admin user\n");
    }

    // Configure and start SSH
    SshSetUserAuthenticateWithType(AuthUser);
    StartSsh();

    printf("SSH server ready - %d users loaded\n",
        authManager.GetUserCount());

    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}

```

10.16.9.3 Example 3: SSH Client

```

#include <init.h>
#include <ssh.h>

void ExecuteRemoteCommand(const char* host, const char* command) {
    SshClientConfig config;
    config.hostname = host;
    config.port = 22;
    config.username = "admin";
    config.password = "password";

    SSH_CLIENT* client = SshClientConnect(&config);

    if (client) {
        char response[4096];
        int len = SshClientExecute(client, command,
            response, sizeof(response));

        if (len > 0) {
            printf("Response from %s:\n%s\n", host, response);
        } else {
            printf("Command execution failed\n");
        }

        SshClientDisconnect(client);
    }
}

void UserMain(void* pd) {
    init();

    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Execute commands on remote servers
    ExecuteRemoteCommand("192.168.1.100", "uptime");
    ExecuteRemoteCommand("192.168.1.101", "df -h");

    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}

```

10.16.9.4 Example 4: Custom Key Management

```

#include <init.h>
#include <ssh.h>

// Store multiple keys for different purposes
const char* productionKey =
    "-----BEGIN EC PRIVATE KEY-----\n"
    "MHcCAQEE...production key...\n"
    "-----END EC PRIVATE KEY-----\n";

const char* developmentKey =

```

```

"-----BEGIN EC PRIVATE KEY-----\n"
"MHcCAQEE...development key...\n"
"-----END EC PRIVATE KEY-----\n";

// Dynamic key selection callback
int GetSshKey(const char** keyData, int* keyLen, int* keyFormat) {
    // Select key based on environment
    #ifdef PRODUCTION
        *keyData = productionKey;
        *keyLen = strlen(productionKey);
    #else
        *keyData = developmentKey;
        *keyLen = strlen(developmentKey);
    #endif

    *keyFormat = SSH_KEY_FORMAT_PEM;
    return 1;
}

void UserMain(void* pd) {
    init();

    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Set custom key callback
    SshSetUserGetKey(GetSshKey);

    // Start SSH server with selected key
    StartSsh();

    #ifdef PRODUCTION
        printf("SSH: Using production key\n");
    #else
        printf("SSH: Using development key\n");
    #endif

    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}

```

10.16.9.5 Best Practices

SSH Security Best Practices	
[1] Key Management	- Use ECC keys when possible (smaller, faster) - Rotate keys regularly - Never hardcode keys in source code - Store keys securely
[2] Authentication	- Prefer key-based over password authentication - Use strong passwords (12+ characters) - Implement account lockout after failed attempts - Use <code>UserAuthManager</code> for credential storage
[3] Network Security	- Use non-standard ports when possible - Implement IP whitelisting/blacklisting - Set appropriate connection timeouts - Limit maximum concurrent connections
[4] Monitoring	- Log all authentication attempts - Monitor <code>for</code> suspicious activity - Track active sessions - Alert on anomalies
[5] Updates	- Keep NNDK updated <code>for</code> security patches - Review wolfSSH release notes - Test updates in development first

10.16.10 Quick Reference

10.16.10.1 Essential Functions

10.16.10.1.1 Server Functions

```
// Start/Stop SSH server
```

```

int StartSsh(void);
int StopSsh(void);

// Configuration
void SshSetPort(uint16_t port);
void SshSetTimeout(uint32_t seconds);
void SshSetMaxConnections(int max);

// Authentication
void SshSetUserAuthenticateWithType(sshUserAuthenticateWithTypeFn fn);
sshUserAuthenticateWithTypeFn SshGetUserAuthenticateWithType(void);

// Key management
void SshSetUserGetKey(SshUserGetKeyFn fn);

// Legacy (deprecated but still available)
void SshSetUserAuthenticate(sshUserAuthenticateFn fn);
sshUserAuthenticateFn SshGetUserAuthenticate(void);

```

10.16.10.1.2 Client Functions

```

// Connection
SSH_CLIENT* SshClientConnect(SshClientConfig* config);
void SshClientDisconnect(SSH_CLIENT* client);

// Command execution
int SshClientExecute(SSH_CLIENT* client, const char* command,
                    char* response, int maxlen);

// File transfer
int SshClientUpload(SSH_CLIENT* client, const char* localPath,
                   const char* remotePath);
int SshClientDownload(SSH_CLIENT* client, const char* remotePath,
                     const char* localPath);

```

10.16.10.1.3 UserAuthManager Functions

```

// User management
bool AddUser(const char* username, const char* authValue, AuthType type);
bool RemoveUser(const char* username);
bool UserExists(const char* username);
int GetUserCount(void);

// Authentication
int Authenticate(const char* username, const char* authValue,
                AuthType type);

// Storage
void SetLoadCallback(LoadAuthRecordsFn fn);
void SetSaveCallback(SaveAuthRecordsFn fn);
bool Load(void);
bool Save(void);

```

10.16.10.2 Common Patterns

10.16.10.2.1 Pattern 1: Simple Server

```

void UserMain(void* pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);
    StartSsh(); // Auto-generated key, default settings
    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}

```

10.16.10.2.2 Pattern 2: Server with Authentication

```

int AuthCallback(const char* user, const char* auth, AuthType type) {
    return authManager.Authenticate(user, auth, type);
}

void UserMain(void* pd) {
    init();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);
    authManager.Load();
    SshSetUserAuthenticateWithType(AuthCallback);
    StartSsh();
    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}

```

10.16.10.2.3 Pattern 3: Client Connection

```
void ConnectAndExecute(const char* host, const char* cmd) {
    SshClientConfig cfg = {host, 22, "admin", "password"};
    SSH_CLIENT* client = SshClientConnect(&cfg);
    if (client) {
        char buf[1024];
        SshClientExecute(client, cmd, buf, sizeof(buf));
        printf("%s\n", buf);
        SshClientDisconnect(client);
    }
}
```

10.16.10.3 Troubleshooting

Common SSH Issues & Solutions
Connection Refused - Check SSH server is started - Verify port is not blocked by firewall - Confirm device has network connectivity Authentication Failed - Verify credentials are correct - Check authentication callback is registered - Review UserAuthManager configuration - Check auth logs for details Key Not Found - Verify key callback is set (if using) - Check GetPrivateKeyPEM() override - Ensure auto-generation is enabled - Review key priority order Build Errors - Add required include paths: <code>\${NNDK_ROOT}/libraries/include/ssh</code> <code>\${NNDK_ROOT}/libraries/include/crypto</code> - Clean and rebuild project - Check for deprecated function usage Memory Issues - CryptoServer task runs at SECURITY_TASK_PRIO - Check available heap space - Limit concurrent SSH connections - Review cipher suite configuration

10.16.10.4 Debug Logging

Enable SSH debug output:

```
#include <ssh.h>

void UserMain(void* pd) {
    init();

    // Enable SSH debug logging
    SshSetDebugLevel(SSH_DEBUG_VERBOSE);

    // Levels:
    // SSH_DEBUG_NONE      - No debug output
    // SSH_DEBUG_ERROR     - Errors only
    // SSH_DEBUG_WARN      - Warnings and errors
    // SSH_DEBUG_INFO      - Info, warnings, and errors
    // SSH_DEBUG_VERBOSE   - All debug output

    StartSsh();

    while(1) { OSTimeDly(TICKS_PER_SECOND); }
}
```

10.16.10.5 Migration Checklist

When migrating from NNDK 3.3.5 or earlier:

Migration Steps:

```
[ ] Add include paths to project:
    ${NNDK_ROOT}/libraries/include/ssh
    ${NNDK_ROOT}/libraries/include/crypto
```

```

[ ] Remove deprecated functions:
    [ ] SshConvertDecodedOpenSSLKey()
    [ ] SshSetChansessionrequest()
    [ ] SshSetTaskPriority()

[ ] Update authentication code:
    [ ] Replace sshUserAuthenticateFn with
          sshUserAuthenticateWithTypeFn
    [ ] Replace SshSetUserAuthenticate\(\) with
          SshSetUserAuthenticateWithType\(\)
    [ ] Update callback to handle AuthType parameter

[ ] Test key management:
    [ ] Verify key installation method works
    [ ] Test auto-generated keys if used
    [ ] Confirm key format compatibility

[ ] Validate functionality:
    [ ] Test SSH server connections
    [ ] Verify authentication works
    [ ] Test SSH client if used
    [ ] Check memory usage

[ ] Review security:
    [ ] Update cipher suites if needed
    [ ] Review authentication policies
    [ ] Test key rotation procedures
    [ ] Verify logging and monitoring

```

10.16.11 Summary

This guide has covered:

- wolfSSH migration and benefits
- Supported key types and formats
- Migration from NNDK 3.3.5 to 3.3.6+
- Key management strategies
- User authentication with [UserAuthManager](#)
- Configuration and examples
- Best practices and troubleshooting

10.16.11.1 Key Takeaways

SSH Implementation Summary	
[MODERN]	wolfSSH replaces Dropbear
[CLIENT]	SSH client support now available
[SECURE]	Enhanced ciphers and key management
[AUTO]	Automatic key generation supported
[SHARED]	wolfCrypt shared with SSL/TLS
[MANAGED]	UserAuthManager simplifies auth
[FLEXIBLE]	Multiple key installation methods
[UPDATED]	New authentication API available

Recommended Approach:**

1. Use ECC keys for embedded systems
2. Implement key-based authentication
3. Use [UserAuthManager](#) for credentials
4. Enable auto-regeneration in production
5. Monitor authentication attempts
6. Keep NNDK updated

For the latest information and examples, refer to:

- `<nndk_install>/examples/SSH/`
- `<nndk_install>/include/ssh.h`
- NetBurner documentation at <https://www.netburner.com/learn>

10.17 Web Server

10.17.1 NetBurner Web Server Guide

10.17.2 Overview

The NetBurner web server provides a powerful embedded HTTP server with support for both static and dynamic content. The web server architecture integrates seamlessly with your application, allowing real-time data display and interactive control through web pages.

NetBurner Web Server Architecture

10.17.2.1 Key Features

- **Static Content Serving** - HTML, CSS, JavaScript, images
- **Dynamic Content Generation** - Real-time data display
- **C++ Integration** - Direct callback functions
- **Variable Display** - Automatic type handling
- **URL Parsing** - Request parameter processing
- **File System** - Organized resource management

10.17.3 Basic Web Server Setup

10.17.3.1 Project Structure

When you create a NetBurner web application, the following structure is automatically generated:

Project Directory Structure

```

YourProject/
├── src/
│   ├── main.cpp          <— Application entry point
│   └── htmldata.cpp       <— Auto-generated from html/
├── html/
│   ├── index.html        <— Web content directory
│   ├── index.html        <— Default home page
│   ├── styles.css        <— (Optional) Stylesheets
│   ├── script.js         <— (Optional) JavaScript
│   └── images/           <— (Optional) Image assets
│       └── logo.png
  
```

```

├── icon.jpg
└── makefile
    └── Build configuration

```

10.17.3.2 Initial index.html

The Application Wizard creates a basic index.html file:

```

<html>
<body>
The main page for the AppWizard project.
</body>
</html>

```

10.17.3.3 Static Content

All files in the `html/` directory are compiled into your application binary. The web server serves these files when requested by a browser.

Static Content Flow

10.17.3.4 Adding Resources

10.17.3.4.1 Adding Images

Create an `images/` folder in your `html/` directory:

```

html/
├── index.html
├── images/
│   └── logo.jpg

```

Reference images in your HTML:

```

<html>
<body>
    <h1>The main page for the AppWizard project</h1>
    
</body>
</html>

```

10.17.3.4.2 Adding CSS and JavaScript

```

html/
├── index.html
├── styles.css
├── script.js
├── images/

```

styles.css:**

```

body {
    font-family: Arial, sans-serif;
    background-color: #f0f0f0;
}

```

index.html with resources:**

```

<html>
<head>
    <link rel="stylesheet" href="styles.css">
    <script src="script.js"></script>
</head>
<body>
    <h1>My NetBurner Application</h1>
    

```

```
</body>
</html>
```

10.17.3.5 Editing HTML Files in NBEclipse

Right-click on an HTML file and select "Open With" > "Text Editor" to edit the raw HTML content.

10.17.4 Dynamic Web Content

NetBurner provides three HTML tags for dynamic content generation:

Dynamic Content Tags

Tag Type	Purpose	When to Use
CPPCALL	Execute C++ function	Complex logic, control
VARIABLE	Display variable/expr	Data display, sensors
INCLUDE	Link external code	Variable declarations

10.17.4.1 CPPCALL Tag - C++ Callback Functions

The CPPCALL tag executes a C++ function when the web page is served.

10.17.4.1.1 Syntax

```
<!--CPPCALL YourFunctionName -->
```

10.17.4.1.2 Function Signature

```
void YourFunctionName(int sock, PCSTR url)
{
    // sock: TCP socket file descriptor
    // url: Complete URL string from browser
}
```

10.17.4.1.3 Parameters Explained

CPPCALL Function Parameters

Parameter: sock (int)

```
TCP Socket File Descriptor
- Use for writing output
- writestring(sock, ...)
- fprintf(sock, ...)
```

Parameter: url (PCSTR)

```
Complete URL String
"http://192.168.1.100/page?a=1"
- Parse query parameters
- Extract values after '?'
```

10.17.4.1.4 Basic Example

```
main.cpp:**
#include <nbrtos.h>
#include <init.h>
#include <http.h>

void webHelloWorld(int sock, PCSTR url)
{
    writestring(sock, "Hello World");
}

void UserMain(void *pd)
{
    init();
    StartHttp(); // Start web server on port 80

    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}
```

```

}
index.html:**
<html>
<body>
  <h1>The main page for the AppWizard project</h1>
  <p>Message from device: <!--CPPCALL webHelloWorld --></p>
</body>
</html>

```

10.17.4.1.5 Request Flow

CPPCALL Execution Flow

10.17.4.1.6 Advanced CPPCALL Example - URL Parsing

```

void webDeviceControl(int sock, PCSTR url)
{
    // Parse URL for parameters
    // Example: /index.html?action=toggle&pin=23

    if (strstr(url, "action=toggle")) {
        // Extract pin number
        char *pinParam = strstr(url, "pin=");
        if (pinParam) {
            int pinNum = atoi(pinParam + 4);

            // Toggle the pin
            Pins[pinNum].set(!Pins[pinNum].read());

            fprintf(sock, "Pin %d toggled to %s",
                    pinNum,
                    Pins[pinNum].read() ? "HIGH" : "LOW");
        }
    } else if (strstr(url, "action=status")) {
        fprintf(sock, "Device uptime: %lu seconds", Secs);
    } else {
        writestring(sock, "Unknown command");
    }
}

index.html:**
<html>
<body>
  <h1>Device Control</h1>
  <p>
    <a href="?action=toggle&pin=23">Toggle Pin 23</a><br>
    <a href="?action=status">Check Status</a>
  </p>
  <div>Response: <!--CPPCALL webDeviceControl --></div>
</body>
</html>

```

10.17.4.2 VARIABLE Tag - Displaying Variables

The VARIABLE tag displays application variables or expressions on web pages.

10.17.4.2.1 Syntax

```
<!--VARIABLE expression -->
```

10.17.4.2.2 Basic Usage

```
<!-- Display a simple variable -->
<!--VARIABLE TimeTick -->

<!-- Display an expression -->
<!--VARIABLE TimeTick/TICKS_PER_SECOND -->

<!-- Display with calculation -->
<!--VARIABLE (Temperature * 9/5) + 32 -->
```

10.17.4.2.3 Compilation Process

VARIABLE Tag Processing

HTML Source:	Generated Code:
<!--VARIABLE TimeTick -->	WriteHtmlVariable(fd, TimeTick);
<!--VARIABLE TimeTick/ TICKS_PER_SECOND -->	WriteHtmlVariable(fd, TimeTick/TICKS_PER_SECOND);
<!--VARIABLE IPCAST(IpAddress) -->	WriteHtmlVariable(fd, IPCAST(IpAddress));

10.17.4.2.4 Supported Data Types

The following types are automatically handled by WriteHtmlVariable():

```
// Located in: \nburn\include\htmlfiles.h

void WriteHtmlVariable(int fd, char c);
void WriteHtmlVariable(int fd, int i);
void WriteHtmlVariable(int fd, short i);
void WriteHtmlVariable(int fd, long i);
void WriteHtmlVariable(int fd, BYTE b);
void WriteHtmlVariable(int fd, WORD w);
void WriteHtmlVariable(int fd, unsigned long dw);
void WriteHtmlVariable(int fd, const char *);
void WriteHtmlVariable(int fd, MACADDR ip);
```

10.17.4.2.5 Type Handling Overview

Type Conversion Flow

Variable Type	Overloaded Function	Output
char	—> WriteHtmlVariable(fd, c)	—> 'A'
int	—> WriteHtmlVariable(fd, i)	—> 123
const char*	—> WriteHtmlVariable(fd, s)	—> "Hello"
unsigned long	—> WriteHtmlVariable(fd, ul)	—> 4294967295
MACADDR	—> WriteHtmlVariable(fd, mac)	—> 00:03:F4:...

10.17.4.2.6 IP Address Display

Use the IPCAST () helper to convert 32-bit integers to IP address format:

```
<!-- Without IPCAST - displays as integer -->
IP Address: <!--VARIABLE IpAddress -->
<!-- Output: 3232235777 -->

<!-- With IPCAST - displays in dotted notation -->
IP Address: <!--VARIABLE IPCAST(IpAddress) -->
<!-- Output: 192.168.1.1 -->
```

10.17.4.2.7 Complete Example

```
main.cpp:**
#include <init.h>
#include <nbrtos.h>

// Global variables for web display
```

```

int Temperature = 25;
unsigned long Counter = 0;
const char *DeviceStatus = "Running";

void UserMain(void *pd)
{
    init();
    StartHttp();

    while (1) {
        Counter++;
        Temperature = 20 + (Counter % 15); // Simulate changing temp
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

index.html:**

```

<html>
<head>
    <title>Device Status</title>
</head>
<body>
    <h1>Device Status Monitor</h1>

    <table border="1">
        <tr>
            <td>Uptime (seconds):</td>
            <td><!--VARIABLE Secs --></td>
        </tr>
        <tr>
            <td>System Ticks:</td>
            <td><!--VARIABLE TimeTick --></td>
        </tr>
        <tr>
            <td>Temperature (C):</td>
            <td><!--VARIABLE Temperature --></td>
        </tr>
        <tr>
            <td>Counter:</td>
            <td><!--VARIABLE Counter --></td>
        </tr>
        <tr>
            <td>Status:</td>
            <td><!--VARIABLE DeviceStatus --></td>
        </tr>
        <tr>
            <td>IP Address:</td>
            <td><!--VARIABLE IPCAST(IPAddress) --></td>
        </tr>
    </table>
</body>
</html>

```

10.17.4.3 INCLUDE Tag - Linking Variables

To use variables with the VARIABLE tag, your application must link to them. Two methods are available:

Variable Linking Methods

Method 1: htmlvar.h Header

```

Project/
├── src/
│   ├── main.cpp
│   └── htmlvar.h
└── html/
    └── index.html

```

←Link→

Both methods allow
htmldata.cpp to
link to your variables

Method 2: INCLUDE Tag

HTML File:

```
<!--INCLUDE mycustomheader.h -->
```

```

|
v
Project/
├── src/
│   └── mycustomheader.h

```

10.17.4.3.1 Method 1: htmlvar.h Header File

Create htmlvar.h in your project's src/ directory:

htmlvar.h:**

```

#ifndef HTMLVARS_H_
#define HTMLVARS_H_

#include <init.h>

// Declare variables for web display
extern int Temperature;

```

```

extern unsigned long Counter;
extern const char *DeviceStatus;

// Declare function callbacks
const char *webMyVarFunction(int fd, int value);

#endif // HTMLVARS_H_
Project structure:**
Project/
├── src/
│   ├── main.cpp
│   ├── htmlvar.h          <— Add this file
│   └── htmldata.cpp       <— Auto-generated (includes htmlvar.h)
└── html/
    └── index.html

```

10.17.4.3.2 Method 2: INCLUDE Tag in HTML

```

index.html:**
<html>
<!--INCLUDE customheader.h -->
<body>
  <h1>Temperature: <!--VARIABLE Temperature --> C</h1>
</body>
</html>

src/customheader.h:**
#ifndef CUSTOMHEADER_H_
#define CUSTOMHEADER_H_

extern int Temperature;

#endif

```

10.17.4.3.3 Linking Flow

Variable Linking at Compile Time

Step 1: HTML Processing

```
<!--VARIABLE Temp -->
```

Step 2: Code Generation

```
WriteHtmlVariable(fd, Temp);
```

Step 3: Include Headers

```
#include "htmlvar.h"
// or
#include "customheader.h"
```

Step 4: Link Variable

```
extern int Temp;
(declared in header)
```

Step 5: Compilation Success

```
htmldata.cpp links to Temp
in main.cpp
```

10.17.5 Advanced Techniques

10.17.5.1 Function Callbacks with Parameters

The VARIABLE tag can be used for function callbacks that accept parameters, providing more flexibility than CPP-CALL.

10.17.5.1.1 Comparison: CPPCALL vs VARIABLE Functions

CPPCALL vs VARIABLE Function Callbacks

CPPCALL:

Fixed Signature:
void func(int sock, PCSTR url)

Limited Parameters
Can't pass app data

Use for:
- URL parsing
- Control actions
- General callbacks

VARIABLE Function:

Flexible Signature:
const char* func(int fd, int val)
const char* func(int fd, float val)
etc.

Custom Parameters
Can pass any type

Use for:
- Parameterized display
- Formatted output
- Data transformation

10.17.5.1.2 Function Callback Workflow

VARIABLE Function Callback Flow

HTML:

```
<!--VARIABLE myFunc(fd, myVar) -->
```

v

Generated Code:

```
WriteHtmlVariable(fd, myFunc(fd, myVar));
```

v

Your Implementation:

```
const char* myFunc(int fd, int myVar) {
    fdprintf(fd, "Value: %d", myVar);
    return ""; // Return empty string
}
```

10.17.5.1.3 Example: Temperature Formatter

```
htmlvar.h:**
#ifndef HTMLVARS_H_
#define HTMLVARS_H_

#include <init.h>

extern int Temperature;

// Function callback with parameter
const char *FormatTemperature(int fd, int tempC);

#endif

main.cpp:**
#include <nbrtos.h>
#include <init.h>
#include "htmlvar.h"

int Temperature = 25;

const char *FormatTemperature(int fd, int tempC)
{
    // Write formatted output directly to socket
    fdprintf(fd, "<span style='color: ");

    if (tempC < 20) {
        fdprintf(fd, "blue'>Cold: %dC", tempC);
    } else if (tempC < 30) {
        fdprintf(fd, "green'>Normal: %dC", tempC);
    } else {
        fdprintf(fd, "red'>Hot: %dC", tempC);
    }

    fdprintf(fd, "</span>");

    // Return empty string (already wrote to socket)
    return "";
}
```

```

}

void UserMain(void *pd)
{
    init();
    StartHttp();

    while (1) {
        Temperature = 15 + (Secs % 25); // Vary temperature
        OSTimeDly(TICKS_PER_SECOND);
    }
}

index.html:**
<html>
<body>
    <h1>Temperature Monitor</h1>

    <!-- Pass fd and Temperature to function -->
    <p>Current: <!--VARIABLE FormatTemperature(fd, Temperature) --></p>

    <!-- Direct variable display for comparison -->
    <p>Raw value: <!--VARIABLE Temperature --> C</p>
</body>
</html>

```

10.17.5.1.4 Multi-Parameter Function Example

```

htmlvar.h:**
extern int SensorValue;
extern int SensorID;

const char *DisplaySensor(int fd, int id, int value);
main.cpp:**
const char *DisplaySensor(int fd, int id, int value)
{
    fdprintf(fd, "Sensor #%d: %d units", id, value);
    return "";
}

index.html:**
<p><!--VARIABLE DisplaySensor(fd, SensorID, SensorValue) --></p>

```

10.17.5.1.5 Return Value Handling

Function Return Value Options

Option 1: Write to Socket, Return Empty

```

const char *func(int fd, int val) {
    fdprintf(fd, "Data: %d", val);
    return ""; // Nothing more
}

```

↓
v
Output: "Data: 123"

Option 2: Return String for Printing

```

const char *func(int fd, int val) {
    static char buf[80];
    sprintf(buf, "Value: %d", val);
    return buf; // Printed by web
}

```

↓
v
Output: "Value: 123"

Option 3: Both (Write + Return)

```

const char *func(int fd, int val) {
    fdprintf(fd, "Start: ");
    return "End"; // Appended
}

```

↓
v
Output: "Start: End"

10.17.5.2 Custom Data Types

Extend the VARIABLE tag to support user-defined structures and classes.

10.17.5.2.1 Custom Type Flow

Custom Type Support Architecture

Step 1: Define Your Type

```
struct MY_STRUCT {
    int value;
    char name[40];
};

MY_STRUCT myData;
```

Step 2: Declare in htmlvar.h

```
extern MY_STRUCT myData;

void WriteHtmlVariable(int fd,
                      MY_STRUCT s);
```

Step 3: Implement Function

```
void WriteHtmlVariable(int fd,
                      MY_STRUCT s) {
    fprintf(fd, "%s: %d",
           s.name, s.value);
}
```

Step 4: Use in HTML

```
<!--VARIABLE myData -->
```

10.17.5.2.2 Complete Custom Type Example

```
main.cpp:**
#include <nbrtos.h>
#include <init.h>

// Define custom structure
struct SensorData {
    int temperature;
    char location[80];
    uint32_t timestamp;
};

SensorData hallwaySensor;
SensorData laboratorySensor;

// Overload WriteHtmlVariable for custom type
void WriteHtmlVariable(int fd, SensorData sensor)
{
    fprintf(fd, "<div class='sensor'>");
    fprintf(fd, "    <strong>Location:</strong> %s<br>", sensor.location);
    fprintf(fd, "    <strong>Temperature:</strong> %dC<br>", sensor.temperature);
    fprintf(fd, "    <strong>Reading Time:</strong> %lu seconds<br>", sensor.timestamp);
    fprintf(fd, "</div>");
}

void UserMain(void *pd)
{
    init();
    StartHttp();

    // Initialize sensors
    strcpy(hallwaySensor.location, "Main Hallway");
    strcpy(laboratorySensor.location, "Laboratory");

    while (1) {
        hallwaySensor.temperature = 20 + (Secs % 10);
        hallwaySensor.timestamp = Secs;

        laboratorySensor.temperature = 18 + (Secs % 8);
```

```

        laboratorySensor.timestamp = Secs;

        OSTimeDly(TICKS_PER_SECOND);
    }
}

htmlvar.h:**
#ifndef HTMLVARS_H_
#define HTMLVARS_H_

#include <init.h>

struct SensorData {
    int temperature;
    char location[80];
    uint32_t timestamp;
};

extern SensorData hallwaySensor;
extern SensorData laboratorySensor;

// Declare overloaded function
void WriteHtmlVariable(int fd, SensorData sensor);

#endif

index.html:**
<html>
<head>
    <style>
        .sensor {
            border: 1px solid #ccc;
            padding: 10px;
            margin: 10px 0;
            background-color: #f9f9f9;
        }
    </style>
</head>
<body>
    <h1>Multi-Sensor Dashboard</h1>

    <h2>Sensor 1</h2>
    <!--VARIABLE hallwaySensor -->

    <h2>Sensor 2</h2>
    <!--VARIABLE laboratorySensor -->

    <hr>
    <p><small>System Time: <!--VARIABLE Secs --> seconds</small></p>
</body>
</html>

```

10.17.5.2.3 Class-Based Custom Type

```

class DeviceStatus {
public:
    bool online;
    int errorCount;
    const char *version;

    DeviceStatus() : online(true), errorCount(0), version("1.0.0") {}
};

DeviceStatus systemStatus;

// Overload for class
void WriteHtmlVariable(int fd, DeviceStatus status)
{
    fprintf(fd, "<table>");
    fprintf(fd, "<tr><td>Status:</td><td>%s</td></tr>",
        status.online ? "Online" : "Offline");
    fprintf(fd, "<tr><td>Errors:</td><td>%d</td></tr>",
        status.errorCount);
    fprintf(fd, "<tr><td>Version:</td><td>%s</td></tr>",
        status.version);
    fprintf(fd, "</table>");
}

HTML usage:**
<div>
    <h3>System Status</h3>
    <!--VARIABLE systemStatus -->
</div>

```

10.17.6 Best Practices

10.17.6.1 Project Organization

Recommended Project Structure

```

YourProject/
├── src/
│   ├── main.cpp           <— Core application logic
│   ├── htmlvar.h         <— Web variable declarations
│   ├── web_callbacks.cpp  <— CPPCALL implementations
│   ├── web_callbacks.h    <— CPPCALL declarations
│   └── htmldata.cpp       <— Auto-generated (don't edit)
├── html/
│   ├── index.html        <— Main page
│   ├── control.html      <— Control interface
│   ├── status.html       <— Status display
│   ├── styles/
│   │   └── main.css       <— Stylesheets
│   ├── scripts/
│   │   └── main.js        <— JavaScript
│   ├── images/
│   │   ├── logo.png
│   │   └── icons/
└── makefile

```

10.17.6.2 Code Organization

10.17.6.2.1 Separate Web Logic

```

web_callbacks.h:**
#ifndef WEB_CALLBACKS_H_
#define WEB_CALLBACKS_H_

// CPPCALL functions
void webDeviceControl(int sock, PCSTR url);
void webSystemStatus(int sock, PCSTR url);
void webSensorData(int sock, PCSTR url);

// VARIABLE functions
const char *FormatTimestamp(int fd, unsigned long timestamp);
const char *FormatIPAddress(int fd, uint32_t ip);

#endif

web_callbacks.cpp:**
#include "web_callbacks.h"
#include <nbrtos.h>

void webDeviceControl(int sock, PCSTR url)
{
    // Implementation
}

void webSystemStatus(int sock, PCSTR url)
{
    // Implementation
}

// ... etc

```

10.17.6.3 Performance Optimization

Web Server Performance Tips

1. Minimize CPPCALL Processing

```

void fastCallback(int sock,
                  PCSTR url)
{
    // Quick processing
    writestring(sock, data);
    // Exit immediately
}

```

↓
v
Don't block web server thread!

2. Use VARIABLE for Simple Data

```
<!--VARIABLE Temperature -->
```

↓
v

Faster than CPPCALL for display

3. Cache Formatted Strings

```
static char statusBuf[256];
// Update periodically
// in background task
```

↓
v

Reduce real-time formatting

4. Limit Dynamic Content

```
Use static content where
possible (HTML, CSS, JS)
```

10.17.6.4 Security Considerations

Web Security Best Practices

Input Validation

```
void callback(
    int sock,
    PCSTR url) {

    // Validate input
    if (!IsValid(url))
    {
        writestring(
            sock,
            "Invalid");
        return;
    }
}
```

URL Parameter Sanitization

```
void handler(int sock,
             PCSTR url)
{
    // BAD: Direct use
    system(url); // NO!

    // GOOD: Parse & check
    char *param =
        parseParam(url);
    if (isSafe(param)) {
        // Use safely
    }
}
```

Buffer Overflow Prevention

```
char buf[256];

// BAD
sprintf(buf, ...);

// GOOD
sprintf(buf,
        sizeof(buf), ...);
```

Authentication

```
bool authenticated =
    CheckCredentials(url);

if (!authenticated) {
    writestring(sock,
        "Access Denied");
    return;
}
```

10.17.6.5 Error Handling

```
void robustCallback(int sock, PCSTR url)
{
    // Check socket validity
    if (sock < 0) {
        return;
    }

    // Validate URL
    if (!url || strlen(url) == 0) {
        writestring(sock, "Error: Invalid request");
        return;
    }

    // Safe parameter parsing
    char *param = strstr(url, "value=");
    if (!param) {
        writestring(sock, "Error: Missing parameter");
    }
}
```

```

        return;
    }

    // Process with bounds checking
    int value = atoi(param + 6);
    if (value < 0 || value > 100) {
        fdprintf(sock, "Error: Value %d out of range", value);
        return;
    }

    // Success
    fdprintf(sock, "Success: Value set to %d", value);
}

```

10.17.6.6 HTML Best Practices

```

<!-- Good: Clean, organized structure -->
<html>
<head>
    <title>Device Control</title>
    <link rel="stylesheet" href="styles/main.css">
</head>
<body>
    <header>
        <h1>NetBurner Device</h1>
        <p>System Time: <!--VARIABLE Secs --> seconds</p>
    </header>

    <main>
        <section id="status">
            <h2>Status</h2>
            <!--CPPCALL webSystemStatus -->
        </section>

        <section id="control">
            <h2>Control</h2>
            <!--CPPCALL webDeviceControl -->
        </section>
    </main>

    <footer>
        <p>Version: <!--VARIABLE FirmwareVersion --></p>
    </footer>

    <script src="scripts/main.js"></script>
</body>
</html>

```

10.17.6.7 Testing Strategy

Web Application Testing Flow

1. Unit Test Callbacks

Test each CPPCALL
function in
isolation

2. Validate Output

Verify VARIABLE tags
display correctly

3. Test URL Parsing

Various query params
Edge cases

4. Load Testing

Multiple concurrent
connections

5. Security Testing

Invalid inputs

Buffer limits

10.17.6.8 Debugging Tips

```
// Enable debug output in callbacks
void debugCallback(int sock, PCSTR url)
{
    printf("Callback called: %s\r\n", url); // To serial console

    // Parse and display
    char *param = strstr(url, "cmd=");
    if (param) {
        printf("Command parameter: %s\r\n", param);
    }

    // Write response
    writestring(sock, "Response sent");
    printf("Response complete\r\n");
}
```

10.17.6.9 Common Pitfalls to Avoid

Common Mistakes and Solutions

MISTAKE

Using printf() in callback

```
void bad(int sock) {
    printf("Hi");
}
```

Output goes nowhere!

SOLUTION

Use writestring() or fdprintf()

```
void good(int sock) {
    writestring(sock,
        "Hi");
}
```

Output to browser

Forgetting extern

```
// In main.cpp
int Temperature;

// Link error!
```

Declare in htmlvar.h

```
// In htmlvar.h
extern int
    Temperature;
```

htmldata.cpp can link

Blocking in callback

```
void bad(int sock) {
    OSTimeDly(...);
    // Blocks server!
}
```

Quick exit pattern

```
void good(int sock) {
    writestring(sock,
        "OK");
    // Exit fast
}
```

Not validating input

```
int val =
    atoi(url+5);
// May crash!
```

Always validate

```
char *p = strstr(url,
    "val=");
if (p) {
    int val=atoi(p+4);
}
```

10.17.7 Quick Reference

10.17.7.1 Tag Summary

NetBurner Web Tags Quick Reference

Tag	Purpose	Syntax
CPPCALL	Execute C++ function	<!--CPPCALL FuncName --> void FuncName(int sock, PCSTR url)
VARIABLE	Display variable	<!--VARIABLE VarName -->

```

                                or expression      <!--VARIABLE expr -->

INCLUDE                        Link header file    <!--INCLUDE header.h -->
                                for variable access

VARIABLE Function             Parameterized        <!--VARIABLE Func(fd, var) -->
                                callback            const char* Func(int fd,
                                                    int var)

```

10.17.7.2 Function Signatures

```

// CPPCALL signature
void CallbackFunction(int sock, PCSTR url);

// VARIABLE function signature
const char *VariableFunction(int fd, <param_type> param);

// Custom type support
void WriteHtmlVariable(int fd, CustomType data);

```

10.17.7.3 Common Patterns

```

// Pattern 1: Simple status display
void webStatus(int sock, PCSTR url) {
    fdprintf(sock, "Uptime: %lu seconds", Secs);
}

// Pattern 2: URL parameter parsing
void webControl(int sock, PCSTR url) {
    if (strstr(url, "action=reset")) {
        // Handle reset
        writestring(sock, "Device reset");
    }
}

// Pattern 3: Variable formatting
const char *FormatData(int fd, int value) {
    fdprintf(fd, "<b>%d</b>", value);
    return "";
}

// Pattern 4: Custom type display
void WriteHtmlVariable(int fd, MyStruct s) {
    fdprintf(fd, "%s: %d", s.name, s.value);
}

```

10.17.8 Summary

The NetBurner web server provides a powerful platform for embedded web applications:

Web Server Capabilities Overview

10.17.8.1 Key Takeaways

1. **Static content** is compiled into the application binary
2. **CPPCALL** provides flexible callback functions for dynamic control
3. **VARIABLE** tags display real-time data with automatic type handling

4. **Custom types** can be added by overloading WriteHtmlVariable()
5. **Security** and input validation are critical for robust applications
6. **Performance** is maintained by keeping callbacks fast and efficient

10.18 Web Sockets

10.18.1 WebSocket Protocol Implementation for Real-Time Bidirectional Communication

10.18.2 Overview

The NetBurner WebSocket implementation provides full-duplex communication channels over a single TCP connection, enabling real-time data exchange between clients and servers. WebSockets upgrade from HTTP connections and maintain persistent connections for efficient, low-latency bidirectional messaging.

Key features include:

- RFC 6455 compliant WebSocket protocol implementation
- Automatic connection upgrade from HTTP to WebSocket
- Support for text and binary data frames
- Built-in ping/pong for connection health monitoring
- Efficient buffering and flow control
- Support for both client and server roles
- Graceful connection closure with status codes
- Frame fragmentation for large messages

10.18.3 Typical WebSocket Workflow

Server Side:**

1. Register a WebSocket upgrade handler using SetNewWSHandler()
2. In the handler, call [WSUpgrade\(\)](#) to upgrade the HTTP connection
3. Use WSRead() and WSWrite() for bidirectional communication
4. Send periodic [WSPing\(\)](#) frames to monitor connection health
5. Close gracefully with [close\(\)](#) when done

Client Side:**

1. Call WebSocket::Connect() with server hostname/IP and resource path
2. Receive a WebSocket file descriptor on success
3. Use WSRead() and WSWrite() for communication
4. Monitor connection with [WSPing\(\)](#) and [WSWaitForPingReply\(\)](#)
5. Close gracefully with [close\(\)](#) when done

10.18.4 WebSocket Frame Types

The WebSocket protocol supports several frame types:

- **Text frames** (WS_OP_TEXT): UTF-8 encoded text data
- **Binary frames** (WS_OP_BIN): Raw binary data
- **Continuation frames** (WS_OP_CONT): Fragments of a larger message
- **Close frames** (WS_OP_CLOSE): Graceful connection termination
- **Ping frames** (WS_OP_PING): Connection liveness check
- **Pong frames** (WS_OP_PONG): Response to ping frame

Most applications only need to work with text and binary frames, as control frames (ping, pong, close) are handled automatically by the implementation.

10.18.5 Buffering and Flow Control

The WebSocket implementation uses three internal buffers:

- **RX Buffer**: Incoming data from the TCP connection
- **TX Buffer**: Outgoing data waiting to be sent
- **Control Buffer**: Control frames (ping, pong, close)

Buffer sizes are configurable via compile-time constants:

- WS_BUFFER_SEGMENTS: Number of buffer segments (default: 4)
- WS_BUFFER_MIN: Minimum buffer threshold (default: 10)

Use `GetWriteSpace()` to check available TX buffer space before writing large amounts of data.

10.18.6 Connection Health Monitoring

WebSockets provide built-in mechanisms for connection health monitoring:

Ping/Pong Mechanism:**

- [`WSPing\(\)`](#): Send a ping frame to test connection
- [`WSWaitForPingReply\(\)`](#): Block until pong received or timeout
- [`WSGetPingReplyTick\(\)`](#): Retrieve timestamp of last pong for latency calculation

Recommended practice:

- Send periodic pings (e.g., every 30-60 seconds)
- Measure round-trip time to detect network degradation
- Close connection if multiple pings timeout
- Use adaptive ping intervals based on application requirements

10.18.7 Graceful Connection Closure

WebSocket connections should be closed gracefully:

1. Call [`close\(\)`](#) on the WebSocket file descriptor
2. The implementation sends a close frame with an optional status code
3. The peer responds with a close frame

4. The TCP connection is terminated

Common status codes (WS_StatusCode enum):

- WS_STAT_NORM_CLOSE (1000): Normal closure
- WS_STAT_GOING_AWAY (1001): Endpoint going away (server shutdown, browser navigation)
- WS_STAT_PROT_ERROR (1002): Protocol error
- WS_STAT_MSG_TOO_BIG (1009): Message too large to process
- WS_STAT_UNEXPECTED_COND (1011): Unexpected condition prevented request fulfillment

10.18.8 Thread Safety

The WebSocket implementation uses critical sections (OS_CRIT) to protect shared data structures. Multiple tasks can safely operate on different WebSocket connections. However, operations on the same WebSocket from multiple tasks require external synchronization.

Best practices:

- Use one task per WebSocket connection for simplicity
- If multiple tasks access the same WebSocket, use application-level locking
- The implementation handles internal buffer synchronization automatically

10.18.9 Resource Limits

The implementation has compile-time limits:

- Maximum WebSocket connections: WS_MAX_SOCKS (default: 4)
- Check available slots with GetFreeWebSocketCount()
- Each WebSocket consumes buffer memory and a file descriptor
- Consider system resources when determining WS_MAX_SOCKS value

10.18.10 Error Handling

WebSocket functions return negative values on errors:

- Check return values from all WebSocket functions
- WSRead() returns 0 for connection closure, negative for errors
- WSWrite() returns negative if connection is closed or buffer full
- Use errno or implementation-specific error codes for details

Common error scenarios:

- Connection closed by peer (WSRead returns 0 or negative)
- Write buffer full (WSWrite returns negative, check with GetWriteSpace())
- Invalid frame received (protocol error, connection closed)
- Timeout on blocking operations

10.18.11 Security Considerations

WebSocket security best practices:

- Use WSS (WebSocket Secure) over TLS for production deployments
- Validate Origin headers to prevent CSRF attacks
- Implement authentication before [WSUpgrade\(\)](#)
- Rate-limit connections and messages to prevent DoS
- Validate and sanitize all received data
- Set maximum message size limits
- Use secure protocols for sensitive data
- Implement connection timeouts and limits

10.18.12 Performance Optimization

Tips for optimal WebSocket performance:

- Batch small messages when possible to reduce overhead
- Use binary frames for non-text data (more efficient than base64 text)
- Call Flush() explicitly when immediate transmission is needed
- Adjust WS_BUFFER_SEGMENTS for your message patterns
- Use GetWriteSpace() to avoid blocking on full buffers
- Consider message compression for large text payloads (if supported)
- Reuse connections rather than frequent connect/disconnect cycles

10.18.13 Debugging WebSocket Issues

Debug utilities:

- DumpSock(): Display detailed state of a single WebSocket
- DumpSockets(): Display state of all WebSocket connections
- Monitor buffer levels with GetWriteSpace()
- Track connection state with GetState()
- Use ping/pong to measure latency and detect connection issues
- Enable diagnostic output to track frame exchanges

Examples

Example 1: Basic WebSocket Echo Server

```

#include <init.h>
#include <nbrtos.h>
#include <http.h>
#include <websockets.h>

const char *AppName = "WebSocket Echo Server";

// WebSocket task for each connection
void WebSocketEchoTask(void *pd) {
    int wsFd = (int)(intptr_t)pd;
    char buffer[512];

    iprintf("WebSocket echo task started on fd %d\r\n", wsFd);

    while (1) {
        // Read incoming message with 30 second timeout
        int len = WSRead(wsFd, buffer, sizeof(buffer) - 1, TICKS_PER_SECOND * 30);

        if (len > 0) {
            buffer[len] = '\0';
            iprintf("Received: %s\r\n", buffer);

            // Echo the message back
            if (WSWrite(wsFd, buffer, len) < 0) {
                iprintf("Failed to send echo\r\n");
                break;
            }
        } else if (len == 0) {
            iprintf("WebSocket connection closed by peer\r\n");
            break;
        } else {
            iprintf("WebSocket read error or timeout\r\n");
            break;
        }
    }

    close(wsFd);
    iprintf("WebSocket echo task ended\r\n");
}

// HTTP handler for WebSocket upgrade
int HandleWebSocketUpgrade(HTTP_Request *req, int sock) {
    // Upgrade the HTTP connection to WebSocket
    if (WSUpgrade(req, sock) >= 0) {
        iprintf("WebSocket connection established\r\n");

        // Create a task to handle this WebSocket
        OSSimpleTaskCreateWithName(WebSocketEchoTask,
                                   MAIN_PRIO - 1,
                                   (void *) (intptr_t) sock,
                                   "WSEcho");

        return 0; // Success
    } else {
        iprintf("WebSocket upgrade failed\r\n");
        return -1;
    }
}

void UserMain(void *pd) {
    init();
    StartHttp();

    // Register WebSocket endpoint at /ws
    SetNewWSHandler("/ws", HandleWebSocketUpgrade);

    iprintf("%s\r\n", AppName);
    iprintf("WebSocket endpoint: ws://<device-ip>/ws\r\n");

    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

Example 2: WebSocket Client Connection

```

#include <websockets.h>

void WebSocketClientTask(void *pd) {
    // Connect to WebSocket server
    int wsFd = NB::WebSocket::Connect("ws.example.com",
                                       "/api/v1/stream",
                                       "chat", // protocol

```

```

        80,        // port
        false);   // useSSL

if (wsFd < 0) {
    fprintf("Failed to connect to WebSocket server\r\n");
    return;
}

fprintf("Connected to WebSocket server (fd %d)\r\n", wsFd);

// Send a message
const char *msg = "Hello from NetBurner!";
if (WSWrite(wsFd, msg, strlen(msg)) < 0) {
    fprintf("Failed to send message\r\n");
    close(wsFd);
    return;
}

// Wait for response
char buffer[256];
int len = WSRead(wsFd, buffer, sizeof(buffer) - 1, TICKS_PER_SECOND * 10);

if (len > 0) {
    buffer[len] = '\0';
    fprintf("Server response: %s\r\n", buffer);
}

// Clean up
close(wsFd);
fprintf("WebSocket client disconnected\r\n");
}

```

Example 3: WebSocket with Connection Health Monitoring

```

void MonitoredWebSocketTask(void *pd) {
    int wsFd = (int)(intptr_t)pd;
    uint32_t lastPingTime = Secs;
    uint32_t consecutiveFailures = 0;
    const uint32_t PING_INTERVAL_SEC = 30;
    const uint32_t MAX_FAILURES = 3;
    char buffer[512];

    while (1) {
        // Send periodic pings
        if ((Secs - lastPingTime) >= PING_INTERVAL_SEC) {
            uint32_t pingSent;

            if (WSPing(wsFd, 0, &pingSent) >= 0) {
                // Wait for pong with timeout
                if (WSWaitForPingReply(wsFd, TICKS_PER_SECOND * 5) >= 0) {
                    uint32_t pongReceived;
                    if (WSGetPingReplyTick(wsFd, &pongReceived) >= 0) {
                        uint32_t rtt = (pongReceived - pingSent) / (TICKS_PER_SECOND / 1000);
                        fprintf("Ping successful, RTT: %lu ms\r\n", rtt);
                    }
                    consecutiveFailures = 0;
                } else {
                    fprintf("Ping timeout\r\n");
                    consecutiveFailures++;
                }
            } else {
                fprintf("Failed to send ping\r\n");
                consecutiveFailures++;
            }
        }

        lastPingTime = Secs;

        // Check if connection is dead
        if (consecutiveFailures >= MAX_FAILURES) {
            fprintf("Connection appears dead, closing\r\n");
            break;
        }
    }

    // Read messages with short timeout to allow ping checks
    int len = WSRead(wsFd, buffer, sizeof(buffer) - 1, TICKS_PER_SECOND);

    if (len > 0) {
        buffer[len] = '\0';
        fprintf("Received: %s\r\n", buffer);
    } else if (len < 0) {
        fprintf("Read error or connection closed\r\n");
        break;
    }
}

```

```
    close(wsFd);
}
```

Example 4: WebSocket Broadcast Server

```
#define MAX_WS_CLIENTS 10

struct WSClient {
    int fd;
    bool active;
};

WSClient wsClients[MAX_WS_CLIENTS];
OS_CRIT wsClientsCrit;

// Add client to broadcast list
bool AddWSClient(int fd) {
    OSCritEnter(&wsClientsCrit, TICKS_PER_SECOND);

    for (int i = 0; i < MAX_WS_CLIENTS; i++) {
        if (!wsClients[i].active) {
            wsClients[i].fd = fd;
            wsClients[i].active = true;
            OSCritLeave(&wsClientsCrit);
            return true;
        }
    }

    OSCritLeave(&wsClientsCrit);
    return false;
}

// Remove client from broadcast list
void RemoveWSClient(int fd) {
    OSCritEnter(&wsClientsCrit, TICKS_PER_SECOND);

    for (int i = 0; i < MAX_WS_CLIENTS; i++) {
        if (wsClients[i].active && wsClients[i].fd == fd) {
            wsClients[i].active = false;
            break;
        }
    }

    OSCritLeave(&wsClientsCrit);
}

// Broadcast message to all connected clients
void BroadcastMessage(const char *msg, int len) {
    OSCritEnter(&wsClientsCrit, TICKS_PER_SECOND);

    for (int i = 0; i < MAX_WS_CLIENTS; i++) {
        if (wsClients[i].active) {
            if (WSWrite(wsClients[i].fd, msg, len) < 0) {
                fprintf("Failed to send to client %d\r\n", wsClients[i].fd);
            }
        }
    }

    OSCritLeave(&wsClientsCrit);
}

// Task for each WebSocket client
void WSClientTask(void *pd) {
    int wsFd = (int)(intptr_t)pd;
    char buffer[512];

    if (!AddWSClient(wsFd)) {
        fprintf("Too many clients, rejecting connection\r\n");
        close(wsFd);
        return;
    }

    fprintf("Client connected: fd %d\r\n", wsFd);

    while (1) {
        int len = WSRead(wsFd, buffer, sizeof(buffer) - 1, TICKS_PER_SECOND * 30);

        if (len > 0) {
            buffer[len] = '\0';
            fprintf("Broadcasting message from fd %d: %s\r\n", wsFd, buffer);

            // Broadcast to all clients
            BroadcastMessage(buffer, len);
        } else {

```

```

        iprintf("Client disconnected: fd %d\r\n", wsFd);
        break;
    }
}

RemoveWSClient(wsFd);
close(wsFd);
}

int HandleBroadcastWS(HTTP_Request *req, int sock) {
    if (WSUpgrade(req, sock) >= 0) {
        OSSimpleTaskCreateWName(WSCliTask, MAIN_PRIO - 1,
                                (void *) (intptr_t) sock, "WSCliTask");
        return 0;
    }
    return -1;
}

```

Example 5: WebSocket with Authentication and Options

```

#include <http.h>
#include <websockets.h>

// Validate authentication token
bool ValidateAuth(HTTP_Request *req) {
    // Check for Authorization header or query parameter
    const char *token = GetRequestParam(req, "token");
    if (token == NULL) {
        return false;
    }

    // Validate token (simplified)
    return (strcmp(token, "secret_key_12345") == 0);
}

void AuthenticatedWSTask(void *pd) {
    int wsFd = (int) (intptr_t) pd;
    char buffer[1024];

    // Set WebSocket options for text mode
    ws_setopt(wsFd, WS_SO_TEXT);

    iprintf("Authenticated WebSocket connection established\r\n");

    // Send welcome message
    const char *welcome = "{\"type\":\"welcome\",\"message\":\"Connected to secure endpoint\"}";
    WSWrite(wsFd, welcome, strlen(welcome));

    while (1) {
        int len = WSRead(wsFd, buffer, sizeof(buffer) - 1, TICKS_PER_SECOND * 60);

        if (len > 0) {
            buffer[len] = '\0';

            // Process JSON messages or other application protocol
            iprintf("Secure message: %s\r\n", buffer);

            // Echo with status
            char response[1024];
            snprintf(response, sizeof(response),
                    "{\"type\":\"ack\",\"received\":%d}", len);
            WSWrite(wsFd, response, strlen(response));
        } else if (len == 0) {
            iprintf("Client disconnected gracefully\r\n");
            break;
        } else {
            iprintf("Error or timeout\r\n");
            break;
        }
    }

    close(wsFd);
}

int HandleSecureWS(HTTP_Request *req, int sock) {
    // Authenticate before upgrade
    if (!ValidateAuth(req)) {
        iprintf("Authentication failed\r\n");

        writestring(sock, "HTTP/1.1 401 Unauthorized\r\n");
        writestring(sock, "Content-Type: text/plain\r\n\r\n");
        writestring(sock, "Authentication required");
        return -1;
    }
}

```

```

// Upgrade to WebSocket
if (WSUpgrade(req, sock) >= 0) {
    OSSimpleTaskCreateName(AuthenticatedWSTask, MAIN_PRIO - 1,
        (void *) (intptr_t) sock, "WSAuth");
    return 0;
}

return -1;
}

```

Function	Description
WSUpgrade()	Upgrade HTTP connection to WebSocket
WSRead()	Read data from WebSocket (ws_read wrapper)
WSWrite()	Write data to WebSocket (ws_write wrapper)
WSPing()	Send ping frame for connection health check
WSWaitForPingReply()	Wait for pong response with timeout
WSGetPingReplyTick()	Get timestamp of last pong for latency measurement
SetNewWSHandler()	Register WebSocket upgrade handler
NB::WebSocket::Connect()	Create client WebSocket connection
close()	Close WebSocket connection

10.18.14 Configuration and Return Code Definitions

```

#define WS_BUFFER_SEGMENTS 4
#define WS_MAX_SOCKETS 4
#define WS_BUFFER_MIN 10
#define WS_ACCUM_DLY ((TICKS_PER_SECOND / 4) + 1)
#define WS_FLUSH_TIMEOUT 0

#define WS_FIN_BIT 0x80
#define WS_OP_CONT 0x0
#define WS_OP_TEXT 0x1
#define WS_OP_BIN 0x2
#define WS_OP_CLOSE 0x8
#define WS_OP_PING 0x9
#define WS_OP_PONG 0xA

#define WS_SO_TEXT 0x8

```

10.18.14.1 Number of buffer segments allocated for each WebSocket connection.

Each WebSocket connection uses segmented buffers for efficient memory management and flow control. This value determines how many segments are allocated for the receive (RX), transmit (TX), and control buffers.

```
#define WS_BUFFER_SEGMENTS 4
```

Default Value:** 4 segments per buffer

Memory Impact:**

- Each connection uses WS_BUFFER_SEGMENTS segments for three buffers (RX, TX, Control)
 - Total segments per connection: WS_BUFFER_SEGMENTS x 3
 - Adjust based on available memory and expected message sizes
- Tuning Guidelines:**
- Increase for applications with large messages or high throughput
 - Decrease to conserve memory when handling many small messages
 - Each segment is typically sized based on the buffer implementation
 - Consider buffer exhaustion when multiple connections are active

Note

This is a compile-time constant and cannot be changed at runtime

Changing this value requires recompiling the WebSocket library

See also

[WS_MAX SOCKS](#)

[WS_BUFFER_MIN](#)

10.18.14.2 Maximum number of simultaneous WebSocket connections supported.

This defines the compile-time limit for concurrent WebSocket connections that can be active on the device. Each connection consumes memory for buffers and internal state management.

`define WS_MAX SOCKS 4`

Default Value:** 4 connections

Resource Considerations:**

- Each connection uses approximately (WS_BUFFER_SEGMENTS x 3) buffer segments
- Each connection requires a file descriptor and internal state structure
- Total memory usage scales linearly with WS_MAX SOCKS

Tuning Guidelines:**

- Increase for servers handling multiple simultaneous clients
- Decrease to conserve memory on resource-constrained devices
- Use `GetFreeWebSocketCount()` to check available connection slots at runtime
- Consider total system file descriptors and memory when adjusting

Example Memory Calculation:**

```
// Approximate per-connection overhead:
// - Buffers: WS_BUFFER_SEGMENTS x 3 x segment_size
// - State: sizeof(WebSocket) ~= 200+ bytes
// - File descriptor: 1 fd
//
// For WS_MAX SOCKS = 4:
// - Total: 4 connections x overhead_per_connection
```

Note

This is a compile-time constant and cannot be changed at runtime

Exceeding this limit will cause new connection attempts to fail

Use `GetFreeWebSocketCount()` to monitor available slots

Examples

Example: Checking Available Connection Slots

```
int HandleWebSocketUpgrade(HTTP_Request *req, int sock) {
    // Check if we can accept more connections
    int freeSlots = NB::WebSocket::GetFreeWebSocketCount();

    if (freeSlots <= 0) {
        iprintf("No WebSocket slots available (%d/%d used)\r\n",
            WS_MAX SOCKS - freeSlots, WS_MAX SOCKS);

        writestring(sock, "HTTP/1.1 503 Service Unavailable\r\n");
        writestring(sock, "Content-Type: text/plain\r\n\r\n");
        writestring(sock, "Maximum WebSocket connections reached");
        return -1;
    }

    iprintf("Accepting WebSocket connection (%d slots remaining)\r\n", freeSlots);

    if (WSUpgrade(req, sock) >= 0) {
```

```

        OSSimpleTaskCreateName(WebSocketTask, MAIN_PRIO - 1,
                               (void *) (intptr_t) sock, "WSTask");
    return 0;
}

return -1;
}

```

10.18.14.3 Minimum buffer space threshold before triggering buffer management actions.

This defines the minimum number of bytes that should remain available in the transmit buffer before the WebSocket implementation takes buffer management actions, such as flushing pending data or blocking writes.

define WS_BUFFER_MIN 10

Default Value:** 10 bytes

Purpose:**

- Prevents buffer exhaustion by maintaining a minimum safety margin
 - Triggers automatic flush operations when buffer space is low
 - Helps prevent write operations from blocking unnecessarily
- Buffer Management:**
- When available space falls below this threshold, writes may block or flush
 - Use GetWriteSpace() to check available buffer space before large writes
 - Automatic flushing helps maintain data flow even with small buffer margins

Note

This is a compile-time constant affecting buffer management behavior

Setting too high may reduce effective buffer capacity

Setting too low may increase risk of buffer overrun

See also

GetWriteSpace()

Flush()

10.18.14.4 Accumulation delay for batching small writes before transmission.

Time delay (in system ticks) that the WebSocket implementation waits to accumulate small writes before sending them as a single frame. This reduces protocol overhead by batching multiple small writes together.

define WS_ACCUM_DLY ((TICKS_PER_SECOND / 4) + 1)

Default Value:** (TICKS_PER_SECOND / 4) + 1 (approximately 250ms + 1 tick)

Purpose:**

- Reduces frame overhead by combining multiple small writes
- Improves network efficiency for applications with frequent small messages
- Balances latency against protocol overhead

Behavior:**

- Small writes are buffered for up to WS_ACCUM_DLY ticks
- If buffer fills or Flush() is called, data is sent immediately
- Larger writes may bypass accumulation delay

Tuning Considerations:**

- Increase for applications prioritizing throughput over latency
-

- Decrease for real-time applications requiring minimal latency
- Set to 0 to disable accumulation (send every write immediately)
- Call Flush() explicitly to bypass accumulation when needed

Note

Value is in system ticks (convert using TICKS_PER_SECOND)
Explicit Flush() calls override this delay

See also

Flush()

[TICKS_PER_SECOND](#)

[WS_FLUSH_TIMEOUT](#)

10.18.14.5 Timeout value for flush operations (in system ticks).

Specifies the maximum time to wait when flushing buffered WebSocket data. A value of 0 indicates non-blocking flush operations.

`define WS_FLUSH_TIMEOUT 0`

Default Value:** 0 (non-blocking)

Behavior:**

- 0: Flush returns immediately, even if not all data is sent
- Positive value: Flush waits up to specified ticks for data transmission
- Used internally by the Flush() method
- Non-blocking Flush (0):**
- Queues data for transmission but doesn't wait
- Suitable for most applications where blocking is undesirable
- Transmission occurs in background as TCP allows

Note

Value is in system ticks

Most applications should use the default non-blocking behavior

See also

Flush()

[WS_ACCUM_DLY](#)

10.18.14.6 WebSocket frame FIN bit mask indicating final fragment.

The FIN bit is set in the first byte of a WebSocket frame to indicate whether this is the final fragment of a message. According to RFC 6455, the FIN bit is the most significant bit (bit 7) of the first frame byte.

`define WS_FIN_BIT 0x80`

Bit Position:** 0x80 (bit 7 set)

Frame Fragmentation:**

- FIN = 1: This is the final (or only) fragment of the message
- FIN = 0: More fragments follow this one

Usage:**

- Set on single-frame messages (most common case)
- Set on the last frame of a fragmented message
- Clear on continuation frames (except the last one)

Message Fragmentation Example:**

```
// Large message sent in 3 fragments:
// Frame 1: opcode=TEXT, FIN=0 (first fragment)
// Frame 2: opcode=CONT, FIN=0 (middle fragment)
// Frame 3: opcode=CONT, FIN=1 (final fragment)
```

Note

This is typically handled automatically by the WebSocket implementation
Fragmentation allows sending large messages without buffering entirely

See also

[WS_OP_CONT](#)

[WS_OP_TEXT](#)

[WS_OP_BIN](#)

10.18.14.7 WebSocket continuation frame opcode.

Opcode value for continuation frames, which carry subsequent fragments of a message that was started with a TEXT or BINARY frame. Continuation frames allow large messages to be sent in multiple fragments.

define WS_OP_CONT 0x0

Opcode Value:** 0x0

Frame Sequence:**

1. First frame: TEXT or BINARY opcode with FIN=0
2. Middle frames: CONT opcode with FIN=0
3. Final frame: CONT opcode with FIN=1

Rules:**

- Must follow a TEXT or BINARY frame with FIN=0
- Cannot start a new message (must be part of fragmented message)
- All fragments must be same type (all text or all binary)
- Control frames (PING, PONG, CLOSE) cannot be fragmented

Note

The WebSocket implementation typically handles fragmentation automatically
Interleaving control frames between fragments is allowed by RFC 6455

See also

[WS_OP_TEXT](#)

[WS_OP_BIN](#)

[WS_FIN_BIT](#)

10.18.14.8 WebSocket text frame opcode for UTF-8 encoded text data.

Opcode value for frames containing UTF-8 encoded text data. Text frames are used for sending human-readable text messages and JSON data.

```
#define WS_OP_TEXT 0x1
```

Opcode Value:** 0x1

Characteristics:**

- Payload must be valid UTF-8 encoded text
 - Most common frame type for web applications
 - Used for JSON, XML, plain text, and other text protocols
 - Invalid UTF-8 results in protocol error and connection closure
- vs Binary Frames:**
- TEXT: Human-readable, UTF-8 validated, JSON-friendly
 - BINARY: Raw bytes, no encoding constraints, more efficient for non-text

Note

Payload validation ensures UTF-8 compliance (per RFC 6455)

For non-text data, use WS_OP_BIN for better performance

See also

[WS_OP_BIN](#)

[WS_OP_CONT](#)

[WS_SO_TEXT](#)

Expand for Example Usage**Examples**

Example: Sending Text vs Binary Data

```
int wsFd = ...; // WebSocket connection

// Send text data (automatically uses WS_OP_TEXT)
const char *jsonMsg = "{\"temp\":25.5,\"humidity\":60}";
WSWrite(wsFd, jsonMsg, strlen(jsonMsg));

// For binary data, use WS_OP_BIN (implicit)
// Set socket option if needed:
ws_cloption(wsFd, WS_SO_TEXT); // Ensure binary mode

uint8_t binaryData[100];
// ... fill with binary data ...
WSWrite(wsFd, (char*)binaryData, sizeof(binaryData));
```

10.18.14.9 WebSocket binary frame opcode for raw binary data.

Opcode value for frames containing arbitrary binary data. Binary frames are more efficient than text frames for non-textual data as they bypass UTF-8 validation and encoding overhead.

```
#define WS_OP_BIN 0x2
```

Opcode Value:** 0x2

Characteristics:**

- Payload can contain any byte sequence
- No UTF-8 validation performed
- More efficient for images, files, compressed data, etc.
- Commonly used for protocol buffers, MessagePack, CBOR

Use Cases:**

- Binary protocols (Protocol Buffers, MessagePack, BSON)
- Image and media data
- Compressed data
- Encrypted payloads
- Raw sensor data
- Any non-text binary format
- vs Text Frames:**
- BINARY: No encoding overhead, any byte values, faster
- TEXT: UTF-8 validated, human-readable, JSON-compatible

Note

More efficient than Base64-encoding binary data in text frames

No content validation means any byte sequence is valid

See also

[WS_OP_TEXT](#)

[WS_OP_CONT](#)

Expand for Example Usage

Examples

Example 1: Sending Binary Sensor Data

```
struct SensorReading {
    uint32_t timestamp;
    float temperature;
    float humidity;
    uint16_t pressure;
} __attribute__((packed));

void SendSensorData(int wsFd) {
    SensorReading reading;
    reading.timestamp = Secs;
    reading.temperature = 25.5f;
    reading.humidity = 60.0f;
    reading.pressure = 1013;

    // Send as binary frame (more efficient than JSON)
    ws_cloption(wsFd, WS_SO_TEXT); // Ensure binary mode
    WSWrite(wsFd, (char*)&reading, sizeof(reading));
}
```

Example 2: Binary vs Text Efficiency

```
// JSON text approach (less efficient):
// {"timestamp":12345,"temp":25.5,"humidity":60,"pressure":1013}
// = ~65 bytes as text

// Binary approach (more efficient):
// struct: 4 + 4 + 4 + 2 = 14 bytes
// Savings: ~78% size reduction

void CompareTextVsBinary(int wsFd) {
    // Text frame approach
    ws_setoption(wsFd, WS_SO_TEXT);
    char jsonBuf[100];
    int jsonLen = snprintf(jsonBuf, sizeof(jsonBuf),
        "{ \"ts\":%lu, \"t\":%.1f, \"h\":%.1f, \"p\":%d }",
        Secs, 25.5f, 60.0f, 1013);
    WSWrite(wsFd, jsonBuf, jsonLen);
    iprintf("Text frame: %d bytes\r\n", jsonLen);

    // Binary frame approach
    ws_cloption(wsFd, WS_SO_TEXT);
    SensorReading reading = {Secs, 25.5f, 60.0f, 1013};
    WSWrite(wsFd, (char*)&reading, sizeof(reading));
    iprintf("Binary frame: %d bytes\r\n", sizeof(reading));
}
```

Example 3: Sending Image Data

```

void SendImageFrame(int wsFd, uint8_t *imageData, uint32_t imageSize) {
    // Ensure binary mode for image data
    ws_clooption(wsFd, WS_SO_TEXT);

    // Check buffer space
    if (GetWriteSpace() < imageSize) {
        iprintf("Insufficient buffer space\r\n");
        return;
    }

    // Send image as binary frame
    int sent = WSWrite(wsFd, (char*)imageData, imageSize);
    if (sent == imageSize) {
        iprintf("Sent %u byte image\r\n", imageSize);
    } else {
        iprintf("Image send failed\r\n");
    }
}

```

10.18.14.10 WebSocket close frame opcode for connection termination.

Opcode value for close frames, which initiate graceful connection closure. Close frames may include a status code and optional reason string explaining why the connection is being closed.

define WS_OP_CLOSE 0x8

Opcode Value:** 0x8

Closure Handshake:**

1. One endpoint sends CLOSE frame with optional status code
2. Peer responds with CLOSE frame
3. Both endpoints close the underlying TCP connection

Close Frame Format:**

- Bytes 0-1: Status code (optional, see WS_StatusCode enum)
- Bytes 2+: Reason string in UTF-8 (optional)

Common Status Codes:**

- 1000: Normal closure (WS_STAT_NORM_CLOSE)
- 1001: Going away (WS_STAT_GOING_AWAY)
- 1002: Protocol error (WS_STAT_PROT_ERROR)
- 1009: Message too big (WS_STAT_MSG_TOO_BIG)
- 1011: Unexpected condition (WS_STAT_UNEXPECTED_COND)

Note

Close frames are automatically handled by the WebSocket implementation

After sending/receiving CLOSE, no more data frames should be sent

Always close gracefully rather than abruptly terminating TCP connection

See also

WS_STAT_NORM_CLOSE

WS_STAT_GOING_AWAY

10.18.14.11 WebSocket ping frame opcode for connection liveness check.

Opcode value for ping frames, which test connection liveness and measure round-trip time. The recipient must respond with a pong frame containing the same payload.

define WS_OP_PING 0x9

Opcode Value:** 0x9

Ping/Pong Protocol:**

- Sender transmits PING frame with optional payload (up to 125 bytes)
- Recipient must respond with PONG frame echoing the same payload
- Used to verify connection is alive and measure latency

Use Cases:**

- Keep-alive mechanism to prevent idle timeouts
- Connection health monitoring
- Round-trip time measurement
- Network quality assessment

- Dead connection detection

Implementation Notes:**

- Ping frames are control frames and cannot be fragmented
- Payload should be kept small (RFC 6455 recommends ≤ 125 bytes)
- Multiple pings can be outstanding simultaneously
- Pongs should be sent in response order

Note

Use [WSPing\(\)](#) function rather than manually constructing frames

Automatic pong responses are handled by the implementation

See also

[WS_OP_PONG](#)

[WSPing\(\)](#)

[WSWaitForPingReply\(\)](#)

[WSGetPingReplyTick\(\)](#)

Expand for Example Usage

Examples

Example: Connection Health Monitoring

```
void MonitorWebSocketHealth(int wsFd) {
    uint32_t pingSent, pongReceived;

    // Send ping frame (handled by WSPing, not raw WS_OP_PING)
    if (WSPing(wsFd, 0, &pingSent) >= 0) {
        // Wait for pong response
        if (WSWaitForPingReply(wsFd, TICKS_PER_SECOND * 5) >= 0) {
            if (WSGetPingReplyTick(wsFd, &pongReceived) >= 0) {
                uint32_t rtt = (pongReceived - pingSent) / (TICKS_PER_SECOND / 1000);
                fprintf("Connection alive, RTT: %lu ms\r\n", rtt);
            }
        } else {
            fprintf("Ping timeout - connection may be dead\r\n");
        }
    }
}
```

10.18.14.12 WebSocket pong frame opcode for ping response.

Opcode value for pong frames, which are sent in response to ping frames. Pong frames must echo back the exact payload received in the corresponding ping frame.

```
#define WS_OP_PONG 0xA
```

Opcode Value:** 0xA

Ping/Pong Protocol:**

- Automatically sent by implementation when PING is received
- Must contain the same payload as the received PING
- Can also be sent unsolicited as a unidirectional heartbeat

Response Rules:**

- Pong payload must exactly match the ping payload
 - Should be sent as soon as practical after receiving ping
 - Multiple pongs may be needed if multiple pings are received
 - Pongs should be sent in the order pings were received
- Unsolicited Pongs:**
- Can be sent without a corresponding ping (RFC 6455 allows this)
 - Useful as unidirectional heartbeat mechanism
 - Receiving endpoint may ignore unsolicited pongs

Note

Pong responses are typically handled automatically by the WebSocket stack

Applications rarely need to manually send pong frames

Use WSPong() if manual pong transmission is needed

[WS_OP_PING](#)

[WSPing\(\)](#)

[WSWaitForPingReply\(\)](#)

10.18.14.13 WebSocket socket option to enable text frame mode.

Socket option flag to configure a WebSocket connection to send data as text frames (WS_OP_TEXT) rather than binary frames (WS_OP_BIN). This affects the opcode used for outgoing data frames.

```
#define WS_SO_TEXT 0x8
```

Option Value:** 0x8

Behavior:**

- When set: Outgoing frames use WS_OP_TEXT opcode
- When clear: Outgoing frames use WS_OP_BIN opcode

Text Frame Requirements:**

- Payload must be valid UTF-8 encoded text
- Implementation may validate UTF-8 encoding
- Use for JSON, XML, HTML, or plain text data

Functions:**

- `ws_setopt(fd, WS_SO_TEXT)`: Enable text mode
- `ws_clroption(fd, WS_SO_TEXT)`: Enable binary mode
- `ws_getoption(fd)`: Check current option state

When to Use Text Mode:**

- Sending JSON, XML, or other text-based protocols
- Human-readable messages
- When client/server expects text frames
- For maximum compatibility with web browsers

When to Use Binary Mode:**

- Raw sensor data or binary protocols
- Image, audio, video data
- Compressed or encrypted payloads
- Maximum efficiency (no UTF-8 overhead)

Note

Default mode may vary; set explicitly for predictable behavior

Mode can be changed dynamically during connection lifetime

`ws_setopt()`

`ws_clroption()`

`ws_getoption()`

Expand for Example Usage

Examples

Example 1: Setting Text Mode for JSON

```
void SendJSONMessage(int wsFd, const char *jsonStr) {
    // Enable text mode for JSON data
    ws_setopt(wsFd, WS_SO_TEXT);

    // Send JSON string (will use WS_OP_TEXT)
    int sent = WSWrite(wsFd, jsonStr, strlen(jsonStr));
    if (sent > 0) {
        iprintf("Sent JSON: %s\r\n", jsonStr);
    }
}
```

Example 2: Switching Between Text and Binary

```
void SendMixedData(int wsFd) {
    // Send text message
    ws_setopt(wsFd, WS_SO_TEXT);
    const char *textMsg = "{\"type\":\"status\",\"value\":\"ready\"}";
    WSWrite(wsFd, textMsg, strlen(textMsg));

    // Switch to binary mode for sensor data
    ws_clroption(wsFd, WS_SO_TEXT);
    struct {
        uint32_t timestamp;
        float temperature;
    } sensorData = {Secs, 25.5f};
    WSWrite(wsFd, (char*)&sensorData, sizeof(sensorData));

    // Back to text mode for acknowledgment
    ws_setopt(wsFd, WS_SO_TEXT);
    const char *ack = "{\"type\":\"ack\"}";
    WSWrite(wsFd, ack, strlen(ack));
}
```

Example 3: Checking Current Mode

```
void DisplayWebSocketMode(int wsFd) {
    int options = ws_getoption(wsFd);

    if (options & WS_SO_TEXT) {
        iprintf("WebSocket fd %d: TEXT mode (UTF-8)\r\n", wsFd);
    } else {
        iprintf("WebSocket fd %d: BINARY mode\r\n", wsFd);
    }
}
```

Example 4: Application-Specific Protocol

```
// Define message types
enum MessageType {
    MSG_TEXT_JSON,
    MSG_BINARY_PROTOBUF,
    MSG_BINARY_IMAGE
};

void SendMessage(int wsFd, MessageType type, const void *data, int len) {
    switch (type) {
        case MSG_TEXT_JSON:
            // Use text frames for JSON
            ws_setoption(wsFd, WS_SO_TEXT);
            iprintf("Sending as TEXT frame\r\n");
            break;

        case MSG_BINARY_PROTOBUF:
        case MSG_BINARY_IMAGE:
            // Use binary frames for protobuf and images
            ws_cloption(wsFd, WS_SO_TEXT);
            iprintf("Sending as BINARY frame\r\n");
            break;
    }

    int sent = WSWrite(wsFd, (const char*)data, len);
    iprintf("Sent %d bytes\r\n", sent);
}
```

Example 5: WebSocket Mode Configuration Helper

```
// Helper function to configure WebSocket for JSON API
void ConfigureJSONWebSocket(int wsFd) {
    // Set text mode
    ws_setoption(wsFd, WS_SO_TEXT);

    // Verify setting
    int opts = ws_getoption(wsFd);
    if (opts & WS_SO_TEXT) {
        iprintf("WebSocket configured for JSON (text mode)\r\n");
    } else {
        iprintf("ERROR: Failed to set text mode\r\n");
    }
}

// Helper function to configure WebSocket for binary protocol
void ConfigureBinaryWebSocket(int wsFd) {
    // Clear text mode (enable binary)
    ws_cloption(wsFd, WS_SO_TEXT);

    // Verify setting
    int opts = ws_getoption(wsFd);
    if (!(opts & WS_SO_TEXT)) {
        iprintf("WebSocket configured for binary protocol\r\n");
    } else {
        iprintf("ERROR: Failed to clear text mode\r\n");
    }
}
```

Chapter 11

System Diagnostics

11.1 Introduction

System Diagnostics can be viewed from a device's Configuration Server web page (port 20034) by calling the [EnableSystemDiagnostics\(\)](#) function in your application. Diagnostic information includes items such as system definitions, variables, TCP stack status, and RTOS state information.

11.2 Server Page with Diagnostics Enabled

When system diagnostics are enabled, an additional button will appear on the configuration server web page in the lower right corner:

Figure 11.1 Configuration Server With Diagnostics Button

11.3 Configuration Web Page Display

Clicking on the Diagnostics button will display system information. An example of the raw data is shown below:

Figure 11.2 Formatted JSON displayed with Firefox

11.4 Adding Your Own Diagnostic Information

You can add your own diagnostic information using the `MyVarMon()` functions. Please refer to the System Diagnostics example for more details. In the example output in the previous section, the variables below were added to the standard system output:

```
"My Int":4677,  
"My String":"My String",
```

The application code to implement the display from the example is:

```
// Variables to monitor  
int myInt;  
char myString[80];  
  
// Declarations to add variables to Diagnostic Web page  
static DiagVarMon MyIntMon("My Int", myInt);  
static DiagVarMon MyStrMon("My String", myString);
```

Chapter 12

Example Applications

12.1 Example Applications Main Page

Included in your NNDK software installation folder are over 200 examples to aid you in your product development and learning the NetBurner platform, demonstrating functionality such as:

- Web pages, Web servers and Web clients
- TCP client and server
- TLS client and server, certificate, auto cert generation and management
- UDP client and server
- Device configuration
- Real-Time operating system such as semaphore, tasks, queues and critical sections
- JSON
- File system
- VLAN
- Web sockets
- Hardware board locking to secure application code
- Hardware peripherals such as [I2C](#), SPI, UART, USART, 1-Wire, GPIO, ADC, DAC, PWM, Timers
- PPP
- FTP
- SSH
- [MQTT](#)
- ACME certificate support

These are just some of the extensive topics covered. There are a few ways to browse the examples:

1. The HTML and PDF documents
2. Browsing the folder structure in `nburn\examples`
3. When using NBEclipse, you can browse and import examples

There are two main categories of examples:

1. The `\nburn\examples` folder contains examples that can be run on all platforms.

2. The `\nburn\examples\PlatformSpecific` folder contains examples that are specific to a NetBurner product, such as hardware peripherals: [I2C](#), SPI, 1-Wire, ADC, DAC, etc.

Links to the example sections are below, or you can use the tree control structure in the online docs.

12.2 AES

A basic description of AES can be obtained from Wikipedia, and if you are new to AES, you should definitely do some research to understand the implementation. The description below is from Wikipedia:

In cryptography, a block cipher is a symmetric key cipher which operates on fixed-length groups of bits, termed blocks, with an unvarying transformation. When encrypting, a block cipher might take a (for example) 16-bit block of plaintext as input, and output a corresponding 16-bit block of ciphertext. The exact transformation is controlled using a second input - the secret key. Decryption is similar: the decryption algorithm takes, in this example, a 16-bit block of ciphertext together with the secret key, and yields the original 16-bit block of plaintext.

To encrypt messages longer than the block size, a mode of operation is used. Block ciphers can be contrasted with stream ciphers; a stream cipher operates on individual digits one at a time, and the transformation varies during the encryption. The distinction between the two types is not always clear-cut: a block cipher, when used in certain modes of operation, acts effectively as a stream cipher.

This example demonstrates how to use the AES key, encryption, and decryption function calls on a 16 byte block of data. Since AES is a block cipher, all data must be encrypted in 16 byte blocks. If you have more than 16 bytes to transfer, you must break the data into 16 byte blocks, encrypt them (you can use the same key for all blocks), send them, then decrypt them in 16 byte blocks on the other end.

12.3 Application Image Security

12.3.1 Examples for application image security, including:

- Application image Checksum
- Locking an application to a specific board
- Signing an application with a private key so that a new application cannot be programmed without also being signed.

12.3.1.1 Examples

- [Application Image Checksum](#)
- [Board Lock](#)
- [Signed Application](#)

12.3.2 Application Image Checksum

12.3.2.1 Application Image Checksum

12.3.2.1.1 Overview

This application demonstrates how to read and display the flash application image checksum at runtime. The checksum provides a way to verify the integrity of the application image stored in flash memory.

12.3.2.1.2 Features

- Reads the application image checksum from the running application header
- Displays application build information including name and NNDK revision
- Starts an HTTP server for web-based access to checksum information
- Provides both console output and web interface variables

12.3.2.1.3 How It Works

The application uses the NetBurner RTOS system to access the running application image header structure. The checksum is retrieved from the `dwImgSum` field of the application header and displayed in hexadecimal format.

12.3.2.1.3.1 Key Components

- **main.cpp**: Main application code that initializes the system and retrieves the checksum
- **htmlvar.h**: Header file declaring web interface variables

12.3.2.1.3.2 Checksum Access

The application checksum can be accessed at runtime by including the `startup.h` header and reading from the `RunningAppImage` structure:

```
#include <startup.h>
printf("Application Checksum: %#08lx\r\n", RunningAppImage->appHdr.dwImgSum);
```

12.3.2.1.4 Build Process Verification

When building the application, the `flashpack` utility displays the image checksum in its output. This allows you to verify that the runtime checksum matches the build-time checksum.

Example flashpack output:

```
App Header:
Image Address: 0x0040801c
Exec Address: 0x70000001
pExtra: 0x0040801c
Image Length: 0x0007adb0
```

```
Image Checksum: 0xc585db80
Header Checksum: 0x0c46c8e5
Raw image size: 646688 bytes
Compressed size: 503106 bytes
```

The Image Checksum line shows the checksum value that should match the runtime value.

12.3.2.1.5 Application Output

The application provides the following information:

1. **Console Output:** Displays app name, NNDK revision, and checksum via printf statements
2. **Web Variables:** Makes checksum and app info available through HTML variables:
 - `strAppInfo`: Contains app name and NNDK revision
 - `strAppChecksum`: Contains the hexadecimal checksum value

12.3.2.1.6 System Requirements

- NetBurner RTOS system
- Network connectivity for HTTP server functionality
- Flash memory with valid application image

12.3.2.1.7 Usage

1. Build and flash the application to your NetBurner device
2. Connect to the device via serial console to see the output
3. Access the HTTP server to view checksum information via web interface
4. Compare the runtime checksum with the build-time checksum from flashpack output

12.3.2.1.8 Security Considerations

The image checksum provides a basic integrity check for the application image. It can help detect:

- Corruption of the flash memory
- Incomplete or failed firmware updates
- Tampering with the application image

For production systems, consider removing the `EnableSystemDiagnostics()` call as noted in the code comments.

12.3.2.1.9 Technical Details

- The application runs in an infinite loop with 1-second delays
- Network initialization waits up to 5 seconds for active network
- HTTP server is started automatically for web interface access
- Checksum is displayed as an 8-digit hexadecimal value with 0x prefix

12.3.3.2.1.2 Purpose

This application implements a hardware-based authorization system that:

- Prevents unauthorized devices from running the application
- Uses the network interface MAC address as a unique device identifier
- Stores authorization data in the device's UserParam flash space
- Provides runtime verification of device authorization

12.3.3.2.1.3 How It Works

Board Lock Verification Process

1. **Initialize Context:** The application uses a pre-configured MD5 context with specific state values that serve as a company secret
2. **Get MAC Address:** Retrieves the MAC address from the first network interface
3. **Generate Hash:** Updates the MD5 context with the 6-byte MAC address and finalizes the hash
4. **Compare Values:** Compares the generated 16-byte digest with the stored authorization value in flash memory
5. **Return Result:** Returns true if all 16 bytes match, false otherwise

Key Components

YourCompanySecret

A pre-initialized MD5 context containing:

- **ctx_state:** 4x 32-bit state values (2106921824, 3945495657, 2391356351, 2780313164)
- **ctx_count:** 2x 32-bit count values (512, 0)
- **buf:** 64-byte buffer for MD5 operations

CheckBoardLock Function

The core authorization function that:

- Copies the company secret MD5 context
- Retrieves the device MAC address
- Updates MD5 hash with MAC address
- Compares result with stored authorization data

12.3.3.2.1.4 Application Flow

1. **Initialization:** Network stack initialization and system diagnostics enablement
2. **Network Wait:** Waits up to 5 seconds for active network ([DHCP](#))
3. **Authorization Check:** Calls `CheckBoardLock()` to verify device authorization
4. **Status Report:** Prints success or failure message
5. **Main Loop:** Enters infinite loop with 1-second delays

12.3.3.2.1.5 Security Features

- **Unique Device Binding:** Each authorization is tied to a specific MAC address
- **Flash Storage:** Authorization data stored in non-volatile UserParam flash space
- **Company Secret:** Uses proprietary MD5 context as cryptographic seed
- **Runtime Verification:** Checks authorization every time the application starts

12.3.3.2.1.6 Output Messages

- `"Application started"` - Application initialization complete
- `"Board checks ok"` - Device is authorized to run
- `"Board fails lock check"` - Device authorization failed

12.3.3.2.1.7 Technical Requirements

- Network interface support for MAC address retrieval
- MD5 hashing capability
- UserParam flash space for storing authorization data
- Real-time operating system (RTOS) support

12.3.3.2.1.8 Security Considerations

- The application includes system diagnostics which should be removed for production builds
- The company secret values are hardcoded and should be unique per deployment
- Authorization data in flash must be properly programmed during device provisioning

12.3.3.2.1.9 Usage

This application is typically used in embedded systems where device authorization is required before allowing normal operation. The board lock mechanism ensures that only properly authorized hardware can run the application software.

12.3.3.2.1.10 Development Notes

- Remove `EnableSystemDiagnostics()` call for production builds

12.3.3.3 Key Blob

12.3.3.3.1 Key Blob Application

12.3.3.3.1.1 Overview

The Key Blob application is a device-locking security utility that generates a unique MD5-based key blob to bind an application to a specific device. This creates a hardware-specific signature that can be used for software licensing and device authentication purposes.

12.3.3.3.1.2 Purpose

This application creates an MD5 context that can be used to lock an application to a particular device. The generated key blob serves as a unique identifier that ties software to specific hardware, providing a form of copy protection and device authentication.

12.3.3.3.1.3 How It Works

1. **Initialization:** The application initializes the network stack and waits for an active network connection
2. **MD5 Context Creation:** Creates an MD5 context using a secret signing text
3. **Data Processing:** Processes the secret text in 64-byte chunks through the MD5 algorithm
4. **Padding:** When the secret text is shorter than 64 bytes, it pads the remaining space with incremental values
5. **Key Blob Generation:** Outputs the MD5 context state as C code that can be compiled into other applications

12.3.3.3.1.4 Key Components

Secret Signing Text

```
const char *YourSecretSigningText = "This should be your company secret message";
```

This should be replaced with your company's unique secret message for generating device-specific keys.

MD5 Processing

- Processes the secret text in 64-byte blocks
- Pads remaining space with incremental byte values (0, 1, 2, ...)
- Updates the MD5 context with the processed data

Output Format

The application generates C code output containing:

- `ctx_state[4]`: MD5 context state array
- `ctx_count[2]`: MD5 context count array
- Buffer declarations for SSL/TLS support (conditional)
- Complete MD5_CTX constructor call

12.3.3.3.1.5 Usage

1. **Customize Secret Text:** Replace `YourSecretSigningText` with your company's secret message
2. **Compile and Run:** Build the application for your target device
3. **Capture Output:** The application will print the key blob as C code to the console
4. **Integration:** Copy the generated code into your main application for device locking

12.3.3.3.1.6 Example Output

```
/*Your keyblob is:*/
uint32_t ctx_state[4]={1234567890u,987654321u,555666777u,111222333u};
uint32_t ctx_count[2]={128u,0u};
unsigned char buf[64];
#ifdef SSL_TLS_SUPPORT
unsigned char inbuf[64];
unsigned char outbuf[64];
#endif
MD5_CTX YourCompanySecret (ctx_state,ctx_count,buf
#ifdef SSL_TLS_SUPPORT
,inbuf,outbuf
#endif
);
```

12.3.3.3.1.7 Security Considerations

- The secret signing text should be kept confidential
- Each device will generate a unique key blob due to hardware differences
- The generated key blob should be integrated into your application's authentication system
- Consider additional security measures for production deployments

12.3.3.3.1.8 Dependencies

- Network stack initialization
- MD5 hashing library
- System diagnostics (optional, recommended to disable in production)

12.3.3.3.1.9 Network Requirements

- The application waits for [DHCP](#) address assignment
- Network connectivity is required during initialization
- Timeout is set to 5 seconds for network activation

12.3.3.3.1.10 Production Notes

- Consider disabling `EnableSystemDiagnostics()` for production builds
- Ensure the secret signing text is properly secured
- Test the key blob integration thoroughly before deployment
- The application runs in an infinite loop after generating the key blob

12.3.3.3.1.11 Application Flow

1. Initialize network stack
2. Enable system diagnostics (development only)
3. Wait for active network connection
4. Initialize MD5 context
5. Process secret signing text through MD5
6. Generate and output key blob as C code
7. Enter infinite loop

This key blob system provides a foundation for device-specific software licensing and authentication mechanisms.

12.3.3.4 Sign Board

12.3.3.4.1 Sign Board Lock Application

12.3.3.4.1.1 Overview

The Sign Board Lock application is a C++ embedded system program designed to create a unique digital signature that locks an application to a specific hardware device (board). This signature is generated using the device's MAC address and a company-specific secret key, providing a hardware-based authentication mechanism.

12.3.3.4.1.2 Purpose

This application serves as a device binding security measure by:

- Creating a unique signature based on the device's MAC address
- Using MD5 hashing with a pre-configured secret key
- Storing the resulting signature in the device's flash memory
- Preventing the application from running on unauthorized hardware

12.3.3.4.1.3 How It Works

Core Components

1. **Secret Key Configuration:** The application uses a predefined MD5 context (`YourCompanySecret`) containing:
 - State values: {2106921824u, 3945495657u, 2391356351u, 2780313164u}
 - Count values: {512u, 0u}
 - Buffer arrays for processing
2. **MAC Address Retrieval:** The program obtains the MAC address from the first available network interface on the device.
3. **Signature Generation:**
 - Combines the secret key context with the device's MAC address
 - Processes this combination through MD5 hashing
 - Produces a 16-byte unique digest
4. **Storage:** The generated signature is stored in the device's UserParam flash memory space.

Program Flow

1. **Initialization:** Network stack and system diagnostics are initialized
2. **Network Setup:** Waits up to 5 seconds for an active network connection ([DHCP](#))
3. **Board Signing:** Executes the `SignBoardLock()` function to generate and store the signature
4. **Continuous Operation:** Enters an infinite loop with 1-second delays

12.3.3.4.1.4 Key Functions

`SignBoardLock()`

- Creates a copy of the company secret MD5 context
- Retrieves the MAC address from the first network interface
- Updates the MD5 context with the MAC address data
- Finalizes the hash to produce a 16-byte digest
- Saves the digest to flash memory using `SaveUserParameters()`

`UserMain()`

- Main application entry point
- Handles system initialization and network setup
- Calls the board signing function
- Maintains the application in a running state

12.3.3.4.1.5 Technical Details

- **Hash Algorithm:** MD5
- **Signature Length:** 16 bytes
- **MAC Address Length:** 6 bytes

12.3.3.4.1.6 Security Considerations

- The secret key (`YourCompanySecret`) should be unique to your company/application
- The secret key values in the code should be replaced with your own company-specific values

12.3.3.4.1.7 Build Requirements

- Network interface support
- MD5 hashing library
- Flash memory access functions (`SaveUserParameters`)
- RTOS with timing functions (`OSTimeDly`, `TICKS_PER_SECOND`)

12.3.3.4.1.8 Usage Notes

- The application automatically signs the board upon startup
- No user interaction is required during the signing process
- The signature is permanently stored in flash memory
- System diagnostics are enabled by default (should be disabled for production)

12.3.3.4.1.9 Customization

To adapt this application for your use:

1. Replace the `ctx_state` and `ctx_count` values with your company-specific secret
2. Disable system diagnostics for production deployment

12.3.3.4.1.10 Output

The application provides console output indicating:

- "Application started" - when initialization is complete
- "Board signed" - when the signature has been successfully generated and stored

12.3.4 Signed Application

12.3.4.1 Signed Application Example

12.3.4.1.1 Overview

This is a NetBurner embedded application that demonstrates the signed application update capability. The application creates a web server that can receive and validate signed firmware updates using RSA public/private key cryptography.

12.3.4.1.2 Key Features

- **Signed Application Updates:** Validates firmware updates using RSA 1024-bit key pairs
- **Web Server:** Runs an HTTP server on port 80 with a simple web interface
- **Network Stack:** Full TCP/IP networking capabilities
- **Security:** Public key verification to ensure only authorized updates can be installed

12.3.4.1.3 How It Works

The application initializes the network stack, starts an HTTP web server, and registers a public key for validating signed application updates. After 20 seconds of runtime, it registers the signing public key with the system to enable secure firmware updates.

12.3.4.1.3.1 Main Application Flow

1. Initialize the network stack
2. Start HTTP web server on port 80
3. Wait for active network connection (5 second timeout)
4. Display system information
5. After 20 seconds, register the application signing public key
6. Continue running with 1-second heartbeat messages

12.3.4.1.4 Security Model

CRITICAL SECURITY NOTE:** The private key (`signkey.pem`) must NEVER be stored on the target device. It should be kept in a secure location separate from the device. Loss of the private key means you will never be able to update the device firmware again.

12.3.4.1.4.1 Key Requirements

- **Public Key:** Stored in the application binary and used to verify update signatures
- **Private Key:** Kept secure and separate from the device, used only for signing updates
- **Key Isolation:** Signing keys must be different from any other certificates/keys used on the device (e.g., HTTPS certificates)

12.3.4.1.5 Setup Instructions

12.3.4.1.5.1 1. Generate Key Pair

You can use the provided `makekey.bat` script or run these commands manually:

```
openssl genrsa -out signkey.pem 1024
openssl rsa -in signkey.pem -pubout -out src/public.key
set NB_SIGN_KEY=%cd%\signkey.pem
```

12.3.4.1.5.2 2. Command Line Build

For command line compilation and deployment:

```
make sign      # Create signed application
make loadsign  # Load signed application to device
```

12.3.4.1.5.3 3. NBEclipse IDE Setup

If using NetBurner's NBEclipse IDE:

1. Generate the key pair as described above
2. In the directory with your public key, run:
`compile public.key codekey_array codekey_len codekey.cpp`
3. Include the generated `codekey.cpp` file in your NBEclipse project
4. Build your project normally

External Tool Configuration for Signing

After building your project in NBEclipse:

1. Go to **Run > External Tools > External Tools Configurations**
2. Create a new configuration with these settings:
 - **Name:** Sign
 - **Location:** `${env_var:NNDK_ROOT}\pcbin\nbsign.exe`
 - **Working Directory:** Browse to your project workspace
 - **Arguments:** `-k <full_path_to_private_key.pem> -in Release\${project_name}.bin -o Release\${project_name}.signed.bin`
3. Run the "Sign" external tool to create signed binaries

12.3.4.1.6 File Structure

- `main.cpp` - Main application source code
- `makekey.bat` - Script to generate RSA key pair
- `signkey.pem` - RSA private key (1024-bit) - **KEEP SECURE**
- `public.key` - RSA public key for signature verification
- `index.html` - Simple web page served by the HTTP server
- `htmlvar.h` - Header file for HTML variables
- `ReadMe.txt` - Original documentation

12.3.4.1.7 Web Interface

The application serves a simple web page at the device's IP address that displays:

- NetBurner logo
- Device IP address
- "Thank you for NetBurning!" message

12.3.4.1.8 Runtime Output

The application provides console output showing:

- Application name and NNDK revision
- Network status
- 1-second heartbeat with timestamp
- Confirmation when signing key is registered

12.3.4.1.9 Important Security Considerations

1. **Private Key Security:** Never store the private key on the target device
2. **Key Backup:** Securely backup your private key - loss means permanent inability to update
3. **Key Uniqueness:** Use different keys for signing than for other device functions
4. **Secure Key Storage:** Store private keys in a hardware security module or other secure location
5. **Update Validation:** All firmware updates must be properly signed with the corresponding private key

12.3.4.1.10 Dependencies

- NetBurner NNDK (NetBurner Network Development Kit)
- OpenSSL (for key generation)
- Standard NetBurner libraries: init, nbrtos, system, [config_obj](#), nbupdate, iosys

12.3.4.1.11 Compilation Requirements

- NetBurner toolchain
- Access to NetBurner system libraries
- Properly generated public key compiled into the application

This example demonstrates the foundation for a secure firmware update system suitable for production IoT and embedded applications where remote update capability with cryptographic verification is essential.

12.4 Clear Configuration Flash

12.4.1 NetBurner Clear Configuration Flash

12.4.1.1 Overview

This is a simple utility program designed to clear the configuration flash area on NetBurner 3.x devices. The application provides a safe way to reset device configuration parameters to their default values by erasing the configuration flash memory.

12.4.1.2 Purpose

The primary purpose of this application is to:

- Clear the NetBurner 3.x configuration flash area
- Force re-initialization of configuration parameters after device reset
- Provide a clean slate for device configuration

12.4.1.3 Important Limitations

Note

For MOD5441x, NANO54415, and SB800EX devices, This program will NOT clear the configuration parameters used by the Alternate Boot Monitor.

12.4.1.4 Reboot Requirement

Note

After running this program successfully, you must reboot the NetBurner device for the configuration changes to take effect. The cleared flash will cause the device to reinitialize with default configuration parameters upon restart.

12.4.1.5 How It Works

1. **Initialization:** The program initializes the NetBurner system and enables system diagnostics
2. **Network Setup:** Configures discovery server and waits for active network connection (up to 5 seconds)
3. **User Confirmation:** Prompts the user to press any key before proceeding with the flash erase operation
4. **Flash Erase:** Calls `EraseWholeConfigRecord()` to clear the configuration flash area
5. **Completion:** Notifies the user that changes will take effect after reboot
6. **Idle Loop:** Enters an infinite loop, waiting for user to reboot the device

12.4.1.6 Usage Instructions

1. Flash this program to your NetBurner device
2. Run the program
3. When prompted, press any key to confirm the configuration flash erase
4. Wait for the "complete" message
5. Reboot the device to activate the cleared configuration

12.4.1.7 Technical Details

12.4.1.7.1 Dependencies

- NetBurner SDK libraries (`init.h`, `netinterface.h`)
- External function: `EraseWholeConfigRecord()`

12.4.1.7.2 Key Features

- System diagnostics enabled for debugging
- Network discovery server configuration
- User confirmation before destructive operation
- Clear feedback on operation status

12.4.1.7.3 Program Flow

```
- Initialize System
- Setup Network (5 second timeout)
- Wait for User Input
- Erase Configuration Flash
- Display Completion Message
- Wait for Reboot (Infinite Loop)
```

12.4.1.8 Safety Considerations

- The program requires user confirmation before erasing flash
- Configuration changes only take effect after a device reboot
- System diagnostics are enabled (should be disabled for production use)
- The program includes appropriate wait states and feedback messages

12.4.1.9 Development Notes

- Contains system diagnostics that should be removed for production code
- Uses standard NetBurner SDK functions and conventions
- Implements proper error handling and user feedback

12.5 Configuration

Examples to demonstrate how to:

- Customize the configuration server
- Set configuration parameters via web page and through the application code

Examples:

- [Application Data](#)
- [Config and System Params](#)
- [Config Web Interfaces](#)
- [Detached Config Object](#)
- [Change Notify](#)
- [Config Class Receive Notification](#)

12.5.1 Application Data

The examples in this directory show how to use the configuration system to create, modify, and store persistent data values that can be used in user applications.

- [BasicConfigVariables](#) - Shows how to create, modify and store basic config variable types with the config system
- [ConfigClass](#) - Expands on [BasicConfigVariables](#), and shows how to create new class types that inherit from base config objects, and how they can be combined together to create complex objects
- [CustomRangeLimit](#) - Shows how to extend NetBurner's config objects with custom behaviors like min/max checking.

See also

[config_int_limit](#)

- [NestingConfigObjects](#) - Expands on [ConfigClass](#), and shows how config objects can be grouped together to create a nested hierarchy of data

Examples:

- [Basic Config Variables](#)
- [Config Class](#)

12.5.1.1 Basic Config Variables

12.5.1.1.1 BasicConfigVariable - Config Tree Demo

A NetBurner embedded systems application demonstrating the use of persistent configuration variables through an interactive serial interface.

12.5.1.1.1.1 Overview

This application showcases the NetBurner config system, which provides persistent storage for both system-defined boot parameters and user-defined variables. The config system maintains values across power cycles, making it ideal for storing device settings, calibration data, and application parameters.

12.5.1.1.1.2 Features

- **Persistent Configuration Storage:** Variables maintain their values after power cycling
- **Interactive Serial Interface:** Menu-driven system for viewing and modifying config values
- **Dynamic Variable Management:** Create and delete config variables at runtime
- **Config Tree Visualization:** View the complete configuration hierarchy
- **Multiple Data Types:** Support for strings, integers, and unsigned integers

12.5.1.1.1.3 Configuration Variable Types

The application demonstrates usage of several config object types:

- `config_string` - String values
- `config_int` - Signed integer values
- `config_uint` - Unsigned integer values
- `config_bool` - Boolean values
- `config_double` - Double precision floating point
- `config_chooser` - Multiple choice options
- `config_pass` - Password fields
- `config_IPADDR4` - IPv4 addresses
- `config_IPADDR6` - IPv6 addresses
- `config_MACADR` - MAC addresses

12.5.1.1.1.4 Application Structure

Global Configuration Variables

The application defines three global configuration variables:

```
static config_string gSingleString(appdata, "MyString", "SName");
config_int gMyOwnVal(appdata, 199, "MyOwnValue");
config_uint gMyOwnuVal(appdata, 299, "MyOwnuValue");
```

Each variable is initialized with:

- Parent container (appdata)
- Default value
- Unique identifier name

Serial Commands

The application provides an interactive menu system accessible via serial interface:

Command	Description
C	Show Config Tree - Display complete configuration hierarchy
S	Show and Set gSingleString - View/modify string variable
V	Show and Set gMyOwnVal - View/modify signed integer variable
U	Show and Set gMyOwnuVal - View/modify unsigned integer variable
N	New/Create dynamic variable - Create new config variable at runtime
D	Delete dynamic variable - Remove dynamically created variable
Q	Query dynamic variable - Check if dynamic variable exists and show value
?	Show Command List - Display available commands

12.5.1.1.1.5 Build Requirements

Dependencies

- NetBurner SDK
- Standard C++ compiler with C++11 support
- NetBurner libraries:
 - `arp.h` - ARP protocol support
 - `http.h` - HTTP server functionality
 - `init.h` - System initialization
 - `netinterface.h` - Network interface management
 - `serial.h` - Serial communication
 - `config_server.h` - Configuration system

Compilation

Compile using the NetBurner development environment with standard build tools. Ensure all NetBurner libraries are properly linked.

12.5.1.1.1.6 Usage

Initial Setup

1. Flash the application to your NetBurner device
2. Connect via serial interface (typically 115200 baud)
3. Wait for network initialization (up to 5 seconds)

Startup Information

Upon boot, the application displays:

- Build timestamp
- Current IP address
- Auto-IP address
- Gateway address

- Config storage usage statistics

Interactive Operation

1. **View Configuration Tree:** Use command `C` to see the complete hierarchy
2. **Modify Variables:** Use commands `S`, `V`, or `U` to change values
3. **Dynamic Variables:** Use `N` to create, `D` to delete, and `Q` to query runtime variables
4. **Help:** Use `?` to display the command menu

Example Session

```
Config Tree Demo built at 12:34:56 on Jan 15 2025
'?' for commands
IP:          192.168.1.100
AutoIP :     169.254.1.100
Gateway:     192.168.1.1
```

Config space used: 1024 of 8192 bytes (max)

```
Command List
-----
C) Show Config Tree
S) Show and Set gSingleString
V) Show and Set gMyOwnVal
U) Show and Set gMyOwnuVal
N) New/Create dynamic variable
D) Delete dynamic variable
Q) Query dynamic variable
?) Show Command List
```

```
Read char S
SName old value: MyString
Enter new value: Hello World

SName new value: Hello World
```

12.5.1.1.1.7 Key Features

Persistent Storage

All configuration changes are automatically saved to non-volatile storage using `SaveConfigToStorage()`. Values persist across power cycles and system resets.

Dynamic Variable Management

The application demonstrates creating config variables at runtime using the `new` operator and properly registering them with `FixNonStaticObject()`.

Network Integration

The application initializes network interfaces and displays connection information, showing integration with NetBurner's networking stack.

System Diagnostics

Built-in system diagnostics are enabled for development and debugging purposes.

12.5.1.1.1.8 Important Notes

Variable Naming

- Each config variable must have a unique identifier name
- Duplicate names can cause issues within the config tree
- Use descriptive names for better organization

Memory Management

- Static config variables are automatically managed
- Dynamic variables require explicit cleanup using `delete`
- Call `FixNonStaticObject()` for dynamically created variables

Thread Safety

The application runs in a single-threaded context with periodic delays using `OSTimeDly()`.

12.5.1.1.1.9 Troubleshooting

Common Issues

1. **Network Connection:** Ensure proper network configuration if IP addresses show as 0.0.0.0
2. **Serial Interface:** Verify baud rate and connection settings
3. **Config Storage:** Monitor storage usage to avoid exceeding maximum capacity
4. **Variable Names:** Ensure unique naming to prevent config tree conflicts

Development Tips

- Remove `EnableSystemDiagnostics()` for production builds
- Adjust `TICKS_PER_SECOND` delays based on application requirements
- Use config tree display (C command) to verify variable organization

12.5.1.2 Config Class

12.5.1.2.1 Config Class Application

12.5.1.2.1.1 Overview

This NetBurner application demonstrates the use of the config system for creating and managing persistent configuration variables. The config system provides a way to store both system-defined settings (like network configuration) and user-defined custom variables that persist across power cycles.

12.5.1.2.1.2 Features

- **Custom Config Classes:** Demonstrates inheritance from `config_obj` to create structured configuration objects
- **Persistent Storage:** All configuration values are automatically saved to non-volatile storage
- **Interactive Menu System:** Serial port interface for viewing and modifying configuration values
- **Config Tree Visualization:** Display the complete configuration hierarchy
- **Network Integration:** Shows network interface information on startup

12.5.1.2.1.3 Architecture

Config Object Types

The application uses several NetBurner config object types:

- `config_obj` - Base container object for grouping other config objects
- `config_bool` - Boolean values
- `config_int` - Integer values
- `config_double` - Double precision floating point values
- `config_string` - String values
- `config_chooser` - Multiple choice selections
- `config_pass` - Password fields
- `config_IPADDR4` - IPv4 addresses
- `config_IPADDR6` - IPv6 addresses
- `config_MACADR` - MAC addresses

Class Hierarchy

The application defines a hierarchy of config classes:

```
config_obj
- TempRange
  - m_maxTemp (default: 100)
  - m_setTemp (default: 30)
  - m_minTemp (default: 10)
- Thermostat (inherits from TempRange)
  - m_tempRec1 (default: 101)
  - m_tempRec2 (default: 102)
  - m_active (default: true)
  - m_location (default: "Warehouse 1")
  - m_tempScale (default: "Fahrenheit")
```

Key Classes

TempRange

Base class for temperature-related configuration:

- `m_maxTemp`: Maximum temperature setting
- `m_setTemp`: Target temperature setting
- `m_minTemp`: Minimum temperature setting

Thermostat

Extended thermostat configuration inheriting from TempRange:

- `m_tempRec1` and `m_tempRec2`: Temperature recording values
- `m_active`: Enable/disable flag
- `m_location`: Physical location description
- `m_tempScale`: Temperature scale selection (Fahrenheit/Celsius/Kelvin)

cfg_class_slot and cfg_class_slots

Example classes for slot-based configuration:

- `cfg_class_slot`: Individual slot with enabled flag and name
- `cfg_class_slots`: Container for multiple slot configurations

12.5.1.2.1.4 Serial Interface Commands

The application provides an interactive menu system accessible via serial port:

Command	Description
C	Show complete config tree
L	Show and set thermostat location
M	Show and set thermostat max temperature
N	Show and set thermostat min temperature
S	Show and set thermostat set temperature
T	Show thermostat recorded temperatures
?	Show command list

12.5.1.2.1.5 Usage

1. **Power On**: The application initializes the network interface and displays network information
2. **Menu Access**: Connect to the serial port and press ? to see available commands
3. **Configuration**: Use the menu commands to view and modify configuration values
4. **Persistence**: All changes are automatically saved to non-volatile storage

12.5.1.2.1.6 Network Information

On startup, the application displays:

- Current IP address
- AutoIP address
- Gateway address
- Build timestamp

12.5.1.2.1.7 Important Notes

Config Object Rules

1. **Unique Names:** Each config object must have a unique name to avoid conflicts in the config tree
2. **Global Scope:** Config objects should be declared at global scope for proper initialization
3. **ConfigEndMarker:** Must be placed after all config data members in each class
4. **Default Values:** All config members should be given appropriate default values

12.5.1.2.1.8 Build Information

- **Application Name:** ConfigClass
- **Build Date/Time:** Displayed on startup
- **Platform:** NetBurner embedded system

12.5.1.2.1.9 Dependencies

The application requires the following NetBurner libraries:

- [arp.h](#) - ARP protocol support
- [http.h](#) - HTTP server functionality
- [init.h](#) - System initialization
- [netinterface.h](#) - Network interface management
- [serial.h](#) - Serial port communication
- [config_server.h](#) - Configuration system

12.5.1.2.1.10 Development Notes

This example builds upon the BasicConfigVariable example and demonstrates more advanced config system usage with custom classes and inheritance. It serves as a foundation for applications requiring persistent configuration management with structured data organization.

12.5.1.3 Custom Range Limit Config Variables

12.5.1.3.1 Custom Range Limit Configuration Demo

A NetBurner embedded application demonstrating advanced configuration system capabilities with custom validation objects and range-limited configuration variables.

12.5.1.3.1.1 Overview

This application showcases the NetBurner Config system by implementing custom configuration object classes that extend the base [config_obj](#) functionality. The demo specifically focuses on creating configuration variables with custom validation logic, including a novel color brightness validator.

12.5.1.3.1.2 Key Features

Built-in Configuration Objects

The application demonstrates several built-in NetBurner configuration object types:

- `config_string_limit` - String with length constraints (1-10 characters)
- `config_int_limit` - Integer with range validation (-200 to 200)
- `config_uint_limit` - Unsigned integer with range validation (0 to 300)
- `config_double_limit` - Double with range and precision validation (-10.0 to 10.0, 0.01 step)
- `config_pass_limit` - Password field with length constraints (5-128 characters)

Custom Configuration Object: Color Brightness Validator

The centerpiece of this demo is the `config_color_brightlimit` class, which validates HTML color strings based on perceived brightness:

- Accepts hex color strings in format `#rrggbb` (e.g., `#00ccff`)
- Calculates perceived brightness using ITU-R Recommendation BT.601 coefficients
- Enforces minimum and maximum brightness thresholds
- Provides meaningful error messages for invalid inputs

Brightness Calculation

The luminance calculation uses the ITU standard coefficients:

$$\text{Luminance} = (0.2582 * R + 0.66 * G + 0.0818 * B) * 100 / 255$$

Configuration Variables

The application defines several global configuration variables:

Variable	Type	Default	Range/Limit	Description
<code>gSingleString</code>	<code>config_string_limit</code>	"SNameLimit"	1-10 chars	String length demo
<code>gMyOwnVal</code>	<code>config_int_limit</code>	199	-200 to 200	Integer range demo
<code>gMyOwnuVal</code>	<code>config_uint_limit</code>	299	0 to 300	Unsigned int range demo
<code>gMyOwndVal</code>	<code>config_double_limit</code>	9.0	-10.0 to 10.0	Double precision demo
<code>gMyOwnpVal</code>	<code>config_pass_limit</code>	""	5-128 chars	Password field demo
<code>gMyDarkColor</code>	<code>config_color← _brightlimit</code>	"#331122"	0-50% brightness	Dark color validator
<code>gMyLightColor</code>	<code>config_color← _brightlimit</code>	"#cceeef"	50-100% brightness	Light color validator

12.5.1.3.1.3 Interactive Commands

The application provides a serial console interface with the following commands:

- **C** - Show Config Tree: Display the complete configuration hierarchy
- **S** - Show and Set `gSingleString`: Modify the string limit example
- **V** - Show and Set `gMyOwnVal`: Modify the integer limit example
- **U** - Show and Set `gMyOwnuVal`: Modify the unsigned integer limit example

- **N** - New/Create dynamic variable: Create a new config variable at runtime
- **D** - Delete dynamic variable: Remove the dynamically created variable
- **Q** - Query dynamic variable: Display the value of the dynamic variable
- **?** - Show Command List: Display available commands

12.5.1.3.1.4 Technical Implementation

Custom Validation Logic

The `config_color_brightlimit` class demonstrates several advanced concepts:

1. **Server-side Validation:** The `TestNewValue()` method provides robust server-side validation with custom error messages
2. **Client-side Schema:** The `ExtendedSchema()` method adds HTML pattern validation for web-based configuration
3. **Operator Overloading:** Multiple assignment operators handle different input types while maintaining validation
4. **Error Reporting:** Uses `LogParseError()` to provide user-friendly error messages

Dynamic Configuration Management

The application shows how to:

- Create configuration objects dynamically at runtime
- Properly manage memory for dynamic config objects
- Use `FixNonStaticObject()` for runtime-created config variables

12.5.1.3.1.5 Web Interface Integration

The configuration system automatically generates a web-based configuration interface at the device's IP address. The custom validation rules are enforced both in the web UI (client-side) and on the device (server-side).

12.5.1.3.1.6 Network Information

Upon startup, the application displays:

- Device IP address
- AutoIP address
- Gateway address
- Configuration space usage statistics

12.5.1.3.1.7 Building and Running

This application is designed for NetBurner embedded systems. Ensure you have:

- NetBurner development environment installed
- Compatible NetBurner hardware platform
- Network connectivity for web-based configuration access

12.5.1.3.1.8 Configuration Storage

All configuration changes are automatically persisted to non-volatile storage using the NetBurner configuration system. Changes survive device reboots and power cycles.

12.5.1.3.1.9 Use Cases

This demo is particularly useful for:

- Learning NetBurner configuration system concepts
- Implementing custom validation logic for configuration parameters
- Creating domain-specific configuration objects
- Understanding client-server validation patterns
- Building robust embedded configuration systems

12.5.1.3.1.10 Error Handling

The application includes comprehensive error handling for:

- Invalid color format strings
- Out-of-range brightness values
- Network connectivity issues
- Memory management for dynamic objects

12.5.1.3.1.11 Extension Points

The framework demonstrated here can be extended to create custom validators for:

- IP address ranges
- Time/date validation
- File path validation
- Custom protocol parameters
- Hardware-specific constraints

12.5.1.4 Nesting Config Objects

12.5.1.4.1 NetBurner Config System - Nesting Config Objects

12.5.1.4.1.1 Overview

This application demonstrates the NetBurner configuration system, specifically showcasing how configuration objects can be nested to create hierarchical data structures. The config system is used to store both boot/interface information and user-defined persistent variables in flash memory as JSON data.

12.5.1.4.1.2 Application Description

The **NestingConfigObjects** example builds upon the basic ConfigClass example by creating nested configuration classes that demonstrate a real-world thermostat control system. The application models a group of thermostats, each with their own temperature settings, location information, and operational parameters.

12.5.1.4.1.3 Class Hierarchy

The application uses a three-level inheritance and nesting structure:

1. TempRange (Base Class)

- **Purpose:** Defines basic temperature range parameters
- **Members:**
 - `m_maxTemp`: Maximum temperature (default: 100)
 - `m_setTemp`: Set temperature (default: 30)
 - `m_minTemp`: Minimum temperature (default: 10)

2. Thermostat (Extends TempRange)

- **Purpose:** Represents a complete thermostat with additional features
- **Members:**
 - Inherits all TempRange members
 - `m_tempRec1`: Temperature record 1 (default: 101)
 - `m_tempRec2`: Temperature record 2 (default: 102)
 - `m_active`: Active status (default: true)
 - `m_location`: Location string (default: "Warehouse 1")
 - `m_tempScale`: Temperature scale chooser (Fahrenheit/Celsius/Kelvin)

3. ThermoGroup (Container Class)

- **Purpose:** Groups multiple thermostats together
- **Members:**
 - `thermo_1`: First thermostat instance
 - `thermo_2`: Second thermostat instance

12.5.1.4.1.4 Available Config Object Types

The NetBurner config system supports the following object types:

- `config_obj`: Base container object for other objects
- `config_bool`: Boolean values
- `config_int`: Integer values
- `config_double`: Double precision floating point
- `config_string`: String values
- `config_chooser`: Multiple choice options
- `config_pass`: Password fields
- `config_IPADDR4`: IPv4 addresses
- `config_IPADDR6`: IPv6 addresses
- `config_MACADR`: MAC addresses

12.5.1.4.1.5 Interactive Commands

The application provides a serial console interface with the following commands:

- **C**: Show complete configuration tree
- **L**: Show and set thermostat locations
- **M**: Show and set maximum temperatures
- **N**: Show and set minimum temperatures
- **S**: Show and set target temperatures
- **T**: Display recorded temperature values
- **?**: Show command list

12.5.1.4.1.6 Key Features

Persistent Storage

- All configuration changes are automatically saved to flash memory
- Data persists across power cycles and system resets
- Storage format is JSON for human readability

Hierarchical Organization

- Nested structure allows logical grouping of related parameters
- Each object has a unique name for identification
- Clear parent-child relationships in the configuration tree

Real-time Updates

- Configuration changes take effect immediately
- Interactive console allows runtime modification
- No need to restart the application after changes

12.5.1.4.1.7 Usage Instructions

1. **Compile and Deploy:** Build the application and deploy to your NetBurner device
2. **Connect Serial Console:** Use a terminal program to connect at 115200 baud
3. **View Network Info:** The application displays IP address, AutoIP, and gateway on startup
4. **Access Commands:** Type '?' to see available commands
5. **Modify Settings:** Use the letter commands to update thermostat parameters
6. **View Configuration:** Use 'C' to display the complete configuration tree

12.5.1.4.1.8 Important Notes

- **Unique Names:** Each config object must have a unique name to avoid conflicts
- **Global Scope:** Config objects should be declared at global scope
- **ConfigEndMarker:** Always include this marker after the last data member in each class
- **Automatic Persistence:** Changes are automatically saved to flash storage

12.5.1.4.1.9 Development Guidelines

When extending this example:

1. Always use unique names for config objects
2. Place `ConfigEndMarker` after the last data member in each class
3. Attach config objects to the `appdata` config object for proper integration
4. Use appropriate default values that make sense for your application
5. Consider the hierarchical structure when designing your config classes

12.5.1.5 FS_BulkStore

12.5.1.5.1 Config FS BulkStore Application

12.5.1.5.1.1 Overview

The Config FS BulkStore application demonstrates how to use the `config_fs_bulkstore` class to store large binary blobs in a filesystem while managing their contents through the NetBurner configuration system. This example shows how to handle persistent storage of large data objects that might exceed the limitations of the standard configuration space.

12.5.1.5.1.2 Features

- **Bulk Storage Management:** Store large binary data blobs in the filesystem
- **Configuration Integration:** Manage bulk storage objects via the NetBurner config system
- **Flexible Storage Options:** Support for both fixed and movable storage paths
- **File System Operations:** Built-in commands for file manipulation (`cat`, `rm`, `fsls`)
- **Command-Line Interface:** Interactive serial console with argument parsing
- **Network Support:** Full network stack initialization with diagnostics

12.5.1.5.1.3 Architecture

Core Components

1. **config_fs_bulkstore:** Main class for managing large binary blobs
 - Stores data in filesystem while providing config system interface
 - Supports both fixed and movable storage paths
 - Handles runtime path changes when configured as movable
2. **Argument Parser:** Robust command-line argument parsing system
 - Supports various data types (`int`, `uint`, `string`, `bool`, `flags`)
 - Handles quoted arguments and escape sequences
 - Provides detailed error reporting
3. **Console Commands:** File system management commands
 - `cat`: Display file contents
 - `rm`: Delete files
 - `fsls`: List filesystem contents with tree structure

Configuration Objects

The application creates two bulk storage objects:

```
// Fixed path bulk store
static config_fs_bulkstore gMyBulkStore{
    appdata, "/MyBulkStore.bin", false, "MyBulkStore"
};

// Movable path bulk store
static config_fs_bulkstore gMyMovableBulkStore{
    appdata, "/MyMoveableBulkStore.bin", true, "MyMovableBulkStore", NULL, false
};
```

12.5.1.5.1.4 Usage

Starting the Application

1. The application initializes the filesystem (if not already available)
2. Sets up the network stack with diagnostics enabled
3. Waits for network connectivity (up to 5 seconds)
4. Drops to serial configuration mode for interactive use

Available Commands

- **cat** <file_path>: Display the contents of a file
- **rm** <file_path>: Delete a file from the filesystem
- **fsls**: List all files and directories in a tree structure
- **help**: Show available commands (inherited from config system)

Command Line Features

The argument parser supports:

- **Flags**: Single character flags (e.g., -a, -v)
- **Quoted Arguments**: Single and double quotes with escape sequences
- **Multiple Data Types**: Integers, unsigned integers, strings, booleans
- **Optional/Required Parameters**: Flexible parameter definitions

12.5.1.5.1.5 Build Requirements

- NetBurner development environment
- Platform with filesystem support (or EDFS Std filesystem)
- Standard C++ compiler support

12.5.1.5.1.6 Configuration Space

The application reports configuration space usage on startup:

- Shows current usage vs. maximum available space
- Helps monitor config system utilization

12.5.1.5.1.7 Error Handling

The argument parser provides detailed error messages:

- Unknown flag identification
- Too few/many arguments detection
- Invalid argument format reporting
- Clear error location indication

12.5.1.5.1.8 Network Features

- Full network stack initialization
- [ARP](#) and HTTP protocol support
- System diagnostics enabled for debugging
- 5-second network connectivity timeout

12.5.1.5.1.9 File System Integration

The application integrates with the NetBurner filesystem:

- Automatic filesystem initialization on platforms without native support
- Full file manipulation capabilities
- Recursive directory traversal
- File size reporting

12.5.1.5.1.10 Example Usage

```
Config Tree Demo built at 12:34:56 on Jan 01 2024
'?' for commands

Config space used: 1024 of 65536 bytes (max)
Aborted to Serial Config (BOOT) to continue boot
type help for commands
> cat /MyBulkStore.bin
> fsls
> rm /temporary_file.txt
```

12.5.1.5.1.11 Technical Details

Memory Management

- Uses NetBurner's SMPool buffer system for efficient memory usage
- Configurable buffer sizes for different operations
- Automatic buffer cleanup and management

Threading

- Main application runs in continuous loop with 1-second delays
- Uses NetBurner's OSTimeDly for cooperative multitasking
- Thread-safe configuration system integration

Platform Support

- Conditional filesystem initialization based on platform capabilities
- Portable across different NetBurner hardware platforms
- Configurable for different storage backend implementations

12.5.1.5.1.12 Development Notes

This application serves as a reference implementation for:

- Integrating large data storage with NetBurner's config system
- Building interactive command-line interfaces
- Implementing argument parsing
- Managing filesystem operations in embedded systems

12.5.2 Config and System Params

The examples in this directory show how to access and modify system values through the configuration system.

- ShowConfig - Shows how to view the entire JSON config blob
- ModifyBoot - Shows how to view and modify the Boot system values through the global config variable `monitor_config`
- ModifyEthernet - Shows how to view and modify the interface system values (default is typically Ethernet0) through the config system
- Disable system features and network ports

Examples

- [Disable System Features](#)
- [Modify Boot](#)
- [Modify Ethernet Interface](#)
- [Show Configuration](#)

12.5.2.1 Disable System Features

12.5.2.1.1 Disable System Features

A NetBurner example application that demonstrates how to disable various system networking features for enhanced security. This application allows users to disable features like AutoIP, Discovery Server, PING/Echo responses, and web services to reduce the attack surface and prevent these services from appearing in network security scans.

12.5.2.1.1.1 Overview

The DisableSysFeatures application provides an interactive command-line interface to control system networking features that may be undesirable in production environments. By disabling these features, administrators can:

- Close unnecessary network ports
- Reduce visibility in network security scans
- Minimize attack vectors
- Implement security best practices for embedded devices

12.5.2.1.1.2 Features

System Settings Control

The application allows runtime configuration of the following networking features:

- **AutoIP:** Automatic IP address assignment when [DHCP](#) is unavailable
- **Discovery Server:** NetBurner's `discover.netburner.com` service registration
- **PING/Echo Responses:** ICMP ping and UDP echo port responses
- **Configuration Persistence:** Save changes to flash memory

Interactive Menu System

The application provides a simple command-line interface with the following options:

1. Show current system settings
2. Disable networking features
3. Re-enable networking features
4. Save configuration to flash memory

12.5.2.1.1.3 Configuration Options

AutoIP Disabling

```
ib->ip4.autoip = false;
```

Disables automatic IP address assignment, preventing the device from self-assigning an IP when DHCP is unavailable.

Discovery Server Disabling

```
ib->discovery_server = "";
```

Prevents the device from registering with NetBurner's discovery service at discover.netburner.com.

PING and Echo Response Disabling

```
ib->supress_default_responses = true;
```

Disables responses to ICMP ping requests and UDP echo port communications.

Web Server Control

Web services can be disabled by not calling `StartHttp()` and `StartHttps()` functions in `UserMain()`. For HTTPS-only operation:

```
StartHttps(443, 0); // HTTPS on 443, HTTP disabled
```

Configuration Server Control

The device configuration web interface can be disabled by removing the `EnableSecureConfigServer()` call, or configured for HTTPS-only access:

```
EnableSecureConfigServer(true); // HTTPS only  
EnableSecureConfigServer(false); // Both HTTP and HTTPS
```

12.5.2.1.1.4 Usage

Runtime Operation

1. Compile and load the application onto your NetBurner device
2. Connect via serial console
3. Use the interactive menu to view and modify system settings
4. Save changes to flash memory using the 'S' command

Commands

- **1**: Display current system settings
- **2**: Disable AutoIP, Discovery Server, and PING/Echo responses
- **3**: Re-enable all networking features
- **S**: Save current configuration to flash memory
- **?**: Show command menu

12.5.2.1.1.5 Security Considerations

Network Hardening

This application is particularly useful for:

- Production deployments requiring minimal network exposure
- Environments with strict security scanning requirements
- IoT devices that need to minimize their network footprint
- Systems requiring compliance with security standards

Alternative Configuration Methods

These settings can also be configured through:

- The device's Configuration Server web page (if enabled)
- Direct modification of configuration parameters
- Factory default settings

12.5.2.1.1.6 Application Structure

Key Components

- **showSystemSettings()**: Displays current networking feature states
- **disableSystemSettings()**: Disables AutoIP, Discovery Server, and PING/Echo
- **enableSystemSettings()**: Re-enables all networking features
- **Interactive Menu Loop**: Provides user interface for runtime control

Network Interface Management

The application uses the first available network interface (`GetFirstInterface()`) for configuration. For multi-interface systems, additional logic would be needed to select and configure specific interfaces.

12.5.2.1.1.7 Use Cases

Production Environments

- Embedded systems requiring minimal network services
- Industrial control systems with security requirements
- IoT devices deployed in sensitive network environments

Security Testing

- Verification of disabled services
- Network security scan preparation
- Compliance testing and validation

Development and Testing

- Feature testing during development
- Network behavior verification
- Security configuration validation

12.5.2.1.1.8 Notes

- Changes made through the application interface are runtime modifications
- Use the 'S' command to persist changes to flash memory
- Configuration Server access may be required for certain changes if the application interface is unavailable
- Network security scans should be performed after disabling features to verify effectiveness

12.5.2.2 Modify Boot

12.5.2.2.1 NetBurner Configuration System - Boot Parameter Modification

12.5.2.2.1.1 Overview

This application demonstrates how to view and modify system boot configuration parameters on NetBurner embedded devices. The program provides an interactive command-line interface for managing persistent system settings such as baud rates, boot delays, authentication credentials, and other boot-related parameters.

12.5.2.2.1.2 Application Name

`SystemParamsModifyBoot`

12.5.2.2.1.3 Purpose

The NetBurner config system stores both system-defined boot and interface information (like default baud rates and current IP settings) as well as user-defined persistent variables. This example specifically focuses on accessing and modifying the "Boot" configuration record through a menu-driven interface.

12.5.2.2.1.4 Key Features

- **Interactive Menu System:** Command-line interface with single-character commands
- **Real-time Configuration Updates:** Changes are immediately saved to persistent storage
- **Web Interface Integration:** Configuration changes can be viewed via web browser
- **Multiple Data Types:** Supports string, integer, and boolean configuration parameters
- **Network Information Display:** Shows current IP configuration on startup

12.5.2.2.1.5 Supported Configuration Parameters

Boot Configuration Options

- **Abort Command (A):** Set the command string used to abort boot process
- **Baud Rate (B):** Configure serial communication baud rate
- **Boot Delay (D):** Set delay time before boot process begins
- **User Credentials (P):** Set system username and password
- **Quiet Boot (Q):** Enable/disable quiet boot mode (boolean)

System Information

- **Config Tree (C):** Display the complete configuration tree structure
- **Help (?):** Show available commands

12.5.2.2.1.6 Technical Implementation

Core Components

1. Configuration Data Types:

- `config_string`: For text-based settings
- `config_int`: For numeric values
- `config_bool`: For true/false settings

2. Key Functions:

- `UpdateConfigString()`: Handle string parameter updates

- `UpdateConfigInt()`: Handle integer parameter updates
- `UpdateConfigBool()`: Handle boolean parameter updates
- `ShowTree()`: Display configuration tree structure
- `SaveConfigToStorage()`: Persist changes to storage

3. External Dependencies:

- `MonitorRecord monitor_config`: Global variable exposing boot config values
- NetBurner system libraries for networking, serial communication, and configuration management

12.5.2.2.1.7 Usage Instructions

Getting Started

1. **Build and Deploy**: Compile the application and deploy it to your NetBurner device
2. **Serial Connection**: Connect to the device via serial port (default: 115200 baud)
3. **Network Setup**: Ensure the device is connected to the network (5-second timeout for network initialization)

Interactive Commands

Once the application starts, you'll see network information and a command prompt. Enter any of the following single characters:

- `A` - Modify abort boot command string
- `B` - Change baud rate setting
- `C` - Display configuration tree
- `D` - Set boot delay value
- `P` - Update username and password
- `Q` - Toggle quiet boot mode
- `?` - Show command list

Web Interface

The application also provides a web interface for viewing configuration changes:

- Navigate to `http://[device-ip]:20034` in your web browser
- Refresh the page to see updated values after making changes via the command line

12.5.2.2.1.8 Configuration Flow

1. **Display Current Value**: Shows the existing configuration value
2. **User Input**: Prompts for new value entry
3. **Validation and Assignment**: Processes and assigns the new value
4. **Automatic Save**: Calls `SaveConfigToStorage()` to persist changes
5. **Confirmation**: Displays the updated value

12.5.2.2.1.9 Network Information Display

On startup, the application displays:

- Current IP Address
- Auto-assigned IP Address
- Gateway Address

12.5.2.2.1.10 Build Information

The application displays build timestamp information showing when it was compiled, helping with version tracking and debugging.

12.5.2.2.1.11 Important Notes

- **Serial Port Management:** The application closes and reopens the serial port to ensure proper communication
- **System Diagnostics:** Includes diagnostic capabilities (should be disabled for production)
- **Persistent Storage:** All configuration changes are immediately saved to non-volatile storage
- **Network Dependency:** Waits up to 5 seconds for network activation before proceeding

12.5.2.2.1.12 Error Handling

The application includes basic input validation and handles:

- String input with automatic null termination
- Integer conversion from string input
- Boolean parsing (accepts 'T'/t' for true, anything else for false)

12.5.2.3 Modify Ethernet Interface

12.5.2.3.1 ModifyEthernet Configuration Example

12.5.2.3.1.1 Overview

This NetBurner example demonstrates how to view and modify Ethernet interface configuration parameters using the embedded system configuration system. The application provides an interactive command-line interface for managing network settings that are stored persistently in the device's configuration record.

12.5.2.3.1.2 Features

- Interactive command-line interface for network configuration
- Persistent storage of configuration changes
- Real-time modification of network parameters
- Configuration tree visualization
- Support for multiple IP configuration modes
- Automatic configuration validation and saving

12.5.2.3.1.3 Project Structure

```
ModifyEthernet/  
├── src/  
│   ├── main.cpp      # Main application with interactive interface  
│   └── makefile       # Build configuration
```

12.5.2.3.1.4 Architecture

System Components

Configuration Data Flow

12.5.2.3.1.5 Configurable Parameters

Network Settings

The application allows modification of the following network parameters:

IPv4 Static IP Address

- **Command:** A
- **Type:** IP Address ([config_IPADDR4](#))
- **Description:** Device's static IP address
- **Example:** 192.168.1.100

IPv4 Static IP Gateway

- **Command:** G
- **Type:** IP Address ([config_IPADDR4](#))
- **Description:** Network gateway address
- **Example:** 192.168.1.1

IPv4 Static IP Mask

- **Command:** M
- **Type:** IP Address ([config_IPADDR4](#))
- **Description:** Subnet mask
- **Example:** 255.255.255.0

IPv4 Mode

- **Command:** O
- **Type:** Chooser ([config_chooser](#))
- **Description:** IP configuration mode
- **Options:** Static, [DHCP](#), AutoIP

Device Identity**Device Name**

- **Command:** N
- **Type:** String ([config_string](#))
- **Description:** Human-readable device identifier
- **Example:** "Production_Controller_01"

Discovery Settings**Discover Server URL**

- **Command:** U
- **Type:** String ([config_string](#))
- **Description:** Discovery server endpoint
- **Example:** "http://discovery.company.com/devices"

12.5.2.3.1.6 Command Interface**Available Commands**Command List

```

A) Show and Set IPv4 Static IP Address
C) Show Config Tree
G) Show and Set IPv4 Static IP Gateway
M) Show and Set IPv4 Static IP Mask
N) Show and Set Device Name
O) Show and Set IPv4 Mode
U) Show and Set Discover Server URL
?) Show Commands

```

12.5.2.3.1.7 Function Reference

Core Update Functions

UpdateConfigString(config_string &confStr)

Purpose: Updates string-based configuration parameters

- Displays current value
- Prompts for new value via serial input
- Updates configuration parameter
- Saves changes to persistent storage

UpdateConfigInt(config_int &confInt)

Purpose: Updates integer-based configuration parameters

- Displays current value
- Prompts for new numeric value
- Converts string input to integer
- Saves changes to persistent storage

UpdateConfigIpaddr(config_IPADDR4 &confIp)

Purpose: Updates IP address configuration parameters

- Displays current IP address in dotted decimal notation
- Prompts for new IP address string
- Converts string to IP address format
- Validates and saves changes

UpdateConfigChooser(config_chooser &confChooser)

Purpose: Updates chooser-based configuration parameters

- Displays current selection
- Shows available choices
- Validates user input against allowed options
- Saves valid selection

Utility Functions

ShowCommandList ()

Purpose: Displays available command menu

- Lists all interactive commands
- Shows command letters and descriptions
- Called on startup and when '?' is pressed

ShowTree ()

Purpose: Displays configuration tree structure

- Shows hierarchical configuration layout
- Useful for debugging and understanding config structure
- External function (implementation not shown in main.cpp)

Main Application Function

UserMain (void *pd)

Main application entry point that:

- Initializes network stack with `init ()`
- Enables system diagnostics
- Waits for active network connection
- Configures serial port for console interaction
- Displays initial network information
- Implements main command processing loop

12.5.2.3.1.8 Technical Implementation

Serial Console Setup

Serial Configuration:

Baud Rate: 115200
Data Bits: 8
Stop Bits: 1
Parity: None
Flow Control: No

The application reconfigures the serial port during initialization:

1. Closes existing serial connection
2. Reopens with 115200 baud rate
3. Uses standard input/output for user interaction

Configuration Persistence

All configuration changes are automatically saved using:

`SaveConfigToStorage () ;`

This function:

- Writes changes to non-volatile storage
- Ensures persistence across device reboots
- Provides immediate effect of configuration changes

Network Interface Access

The application uses the first available network interface:

```
InterfaceBlock *firstInterface = GetInterfaceBlock(GetFirstInterface());
```

This approach:

- Automatically selects the primary network interface (typically Ethernet0)
- Provides access to all interface configuration parameters
- Works with different NetBurner hardware platforms

12.5.2.3.1.9 Usage Examples

Setting IP Address

```
Read char A
IPv4Address old value: 192.168.1.100
Enter new value: 192.168.1.200

IPv4Address new value: 192.168.1.200
```

Changing IP Mode

```
Read char O
IPv4Mode old value: Static
Enter new value. Choices are {Static,DHCP,AutoIP}: DHCP

IPv4Mode new value: DHCP
```

Setting Device Name

```
Read char N
DeviceName old value: NetBurner_Device
Enter new value: Production_Controller

DeviceName new value: Production_Controller
```

12.5.2.3.1.10 Build Instructions

1. Prerequisites:

- NetBurner development environment installed
- Target NetBurner hardware platform
- Serial console application (115200 baud)

2. Building:

```
make clean
make
```

3. Deployment:

```
make load DEVIP=<device_ip_address>
```

4. Console Connection:

- Connect serial cable to device
- Open terminal at 115200 baud
- Reset device to see startup messages

12.5.2.3.1.11 Development Notes

Dependencies

Required NetBurner system libraries:

- [arp.h](#) - ARP protocol support
- [http.h](#) - HTTP protocol support

- `init.h` - System initialization
- `netinterface.h` - Network interface management
- `serial.h` - Serial communication
- `config_server.h` - Configuration system
- `stdlib.h` - Standard C library functions

Build Configuration

- **Application Name:** SystemParamsModifyEthernet
- **Source Files:** src/main.cpp
- **Target Platform:** All NetBurner platforms
- **Build System:** Standard NetBurner makefile

Memory Considerations

- Configuration parameters are stored in device flash memory
- Changes are persistent across power cycles
- No additional RAM allocation required for configuration storage
- Serial input buffers are statically allocated (80 bytes for strings, 25 bytes for integers)

Error Handling

The application includes basic error handling:

- Input validation for chooser parameters
- Automatic null termination of string inputs
- Configuration save verification
- Network initialization checks

12.5.2.3.1.12 Security Considerations

Important Security Notes**:

- Serial console access provides full configuration control
- No authentication mechanism implemented
- Consider adding access control for production environments
- Configuration changes take effect immediately without confirmation

12.5.2.3.1.13 Compatibility

- Compatible with all NetBurner embedded platforms
- Requires NetBurner RTOS version 3.x or later
- Works with Ethernet and Wi-Fi interfaces
- Supports IPv4 configuration (IPv6 not included in this example)

12.5.2.4 Show Configuration

12.5.2.4.1 System Configuration Display Application

12.5.2.4.1.1 Overview

The System Configuration Display Application is an embedded C++ program designed to demonstrate how to read and display system configuration settings stored in JSON format. This application provides a simple command-line interface for examining device configuration data and memory usage statistics.

12.5.2.4.1.2 Features

- **Configuration Tree Display:** Read and display the complete system configuration structure in JSON format
- **Memory Usage Monitoring:** Show how much memory is being used by configuration settings versus total available space
- **Network Information:** Display current network interface settings including IP address, AutoIP, and Gateway
- **Interactive Command Interface:** Simple character-based menu system for user interaction

12.5.2.4.1.3 Application Details

Main Components

- **Application Name:** ShowSystemConfiguration
- **Primary Function:** Configuration system exploration and diagnostics
- **Interface:** Serial port communication with command-driven menu system

System Configuration

The configuration system stores critical device settings including:

- Device boot parameters
- Network interface settings
- Serial interface configuration
- All settings stored in JSON format for easy parsing and modification

Network Features

The application automatically:

- Waits for active network connection (5-second timeout)
- Displays current network configuration on startup
- Shows IP address, AutoIP, and Gateway settings for the first network interface

12.5.2.4.1.4 User Interface

Available Commands

Command	Description
C	Show Configuration Tree (displays complete JSON structure)
S	Show Configuration Memory Usage (current usage vs. available space)
?	Show Command List (displays this help menu)

Command Operation

1. Launch the application

2. Wait for network initialization
3. Review displayed network information
4. Use single-character commands to interact with the system
5. Commands are case-insensitive

12.5.2.4.1.5 Technical Implementation

Dependencies

The application includes several system libraries:

- `http.h` - HTTP protocol functionality
- `init.h` - System initialization
- `netinterface.h` - Network interface management
- `serial.h` - Serial communication
- `stdlib.h` - Standard library functions
- `config_server.h` - Configuration management system

Key Functions

- `ShowTree()` - Displays the configuration tree structure in JSON format
- `ShowConfigMemoryUsage()` - Reports memory usage statistics
- `ShowCommandList()` - Displays available user commands
- `UserMain()` - Main application loop and initialization

System Diagnostics

The application enables system diagnostics by default, which should be disabled for production deployments to optimize performance and reduce debug output.

12.5.2.4.1.6 Memory Management

The application provides real-time monitoring of configuration memory usage through the `ConfigSize()` and `ConfigMaxSize()` functions, allowing administrators to:

- Monitor current configuration storage usage
- Understand available configuration space
- Plan for configuration expansion
- Identify potential memory constraints

12.5.2.4.1.7 Network Initialization

The application implements a robust network startup sequence:

1. Initialize core system components
2. Enable system diagnostics (development mode)
3. Wait for network to become active (5-second timeout)
4. Display network configuration information
5. Enter interactive command mode

12.5.2.4.1.8 Usage Example

```
Config Tree Demo built at 12:34:56 on Jan 01 2025
'?' for commands

IP:           192.168.1.100
AutoIP :      169.254.1.1
Gateway:      192.168.1.1

Command List
-----
C = Show Config Tree
S = Show Config Memory Usage
? = Show Commands

Configuration Memory Used: 1024 bytes, out of 8192 bytes
```

12.5.2.4.1.9 Development Notes

- The application runs in a continuous loop, checking for user input every 250ms
- All user commands are processed immediately when characters are available
- System diagnostics are enabled for development and debugging purposes
- The application is designed for embedded systems with limited resources

12.5.2.4.1.10 Production Considerations

Before deploying to production:

1. Remove or disable `EnableSystemDiagnostics()` call
2. Consider adjusting the network timeout based on your environment
3. Implement proper error handling for network initialization failures
4. Add logging mechanisms for configuration changes if needed

12.5.2.4.1.11 Build Information

The application displays build timestamp information on startup, showing both compilation time and date for version tracking and debugging purposes.

12.5.3 Config Web Interfaces

The system configuration web page interface is located on network port number 20034. These example demonstrate how to provide the same configuration interface as part of the application web server (default port numbers are 80 or 443 for SSL/TLS), so that the configuration web pages are consistent with the rest of the application web interface.

Examples:

- [Basic Web Config](#)
- [Basic Web Config with SSL/TLS](#)
- [Config Tags](#)
- [Custom Web Config](#)
- [Custom Web System Config](#)
- [HTML Only Configuration](#)

12.5.3.1 Basic Web Config

The system configuration web page interface is located on network port number 20034. This example demonstrates how to provide the same configuration interface as part of your application web server on port 80 (or 443 for SSL/TLS), so that you can customize it to be consistent with the rest of your application web pages.

The web page is dynamically generated, and provides access to view and/or modify boot and interface settings, such as default serial port baud rates and IP addresses, as well as application specific data.

The code used to generate and process the web form is in `html/index.html`. This example does not use any external JavaScript libraries, and all of the form generation code is located at the bottom of `index.html`. For a more advanced example that utilized Bootstrap and jQuery, please see the CustomWebConfig example.

Currently available config objects that can be used are as follows:

- `config_obj` // base object, used as a container for other objects
- `config_bool` // boolean
- `config_int` // integer
- `config_double` // double float
- `config_string` // string
- `config_chooser` // multiple choice option
- `config_pass` // password
- `config_IPADDR4` // IP4 Address
- `config_IPADDR6` // IP6 Address
- `config_MACADR` // MAC Address

Note that because we are only processing the config object, we are able to avoid writing a custom POST handler that is used in the other examples. If you include more to your web interface than is provided here, that will need to be incorporated as well.

12.5.3.2 Basic Web Config with SSL/TLS

This example is identical to the BasicWebConfig example with the addition of SSL/TLS. Please refer to that example documentation for a description of how the configuration server mirror operates.

Certificates can be handled a number of ways:

- Automatically with ACME (preferred)
- Auto generation feature of the NetBurner ssl/tls library
- Self-signed and either compiled into the application or uploaded to a file system.

To simplify things, this example provides files for a compiled certificate and key, named `ServerCert.cpp` and `ServerKey.cpp`.

To generate your own self-signed certificates, use the script files in the `\nburn\CreateCerts` folder:

- `makeca.bat` to generate a Certificate Authority certificate and key
- `makeserver.bat` to generate the HTTPS server certificate and key

For the common name (CN), use the IP address of your device, then copy the generated `.cpp` files to your project's `src` folder.

Please refer to the `\nburn\examples\ssl` folder for more advanced SSL/TLS certificate handling.

12.5.3.3 Config Tags

12.5.3.3.1 HTML Configuration Web Application

12.5.3.3.1.1 Overview

This application demonstrates how to create a web-based configuration interface for embedded systems using dynamic HTML content tags. It provides a complete example of displaying and modifying configuration variables through a web browser interface.

The example demonstrates how to obtain just the raw data from the board, as well as how it can be styled using Bootstrap and CSS. While VARIABLE and CPPCALL HTML tags can be used to present the same information, the CONFIG tags simplify things by combining the data with HTML code to create input fields, tables and value displays.

12.5.3.3.1.2 Features

Dynamic Web Content Tags

The application showcases three main configuration tags:

- **CONFIGVALUE** - Displays configuration variable values
- **CONFIGINPUT** - Creates input fields for modifying variables
- **CONFIGTABLE** - Generates HTML tables with configuration data

Web Interface Options

- **Raw Configuration View** - Shows configuration data as it comes directly from the module
- **Styled Configuration View** - Presents the same data with Bootstrap CSS styling and tabbed interface

Configuration Variable Types

- **config_uint** - Unsigned integer configuration values
- **config_string** - String configuration values
- System configuration variables (IP addresses, network settings, etc.)

12.5.3.3.1.3 File Structure

```
/
- main.cpp           # Main application code
- htmlvars.h         # Configuration variable declarations
- index.html         # Main landing page
- raw_config.html    # Raw configuration display
- styled_config.html # Bootstrap-styled configuration
```

12.5.3.3.1.4 Configuration Variables

The application defines two custom configuration variables:

1. gMyOwnuVal (config_uint)

- Default value: 299
- Name: "MyOwnuValue"
- Description: "This is the hint for my value"

2. gMyOwnStrVal (config_string)

- Default value: "My Test String"
- Name: "MyOwnString"
- Description: "This is the hint for my string"

12.5.3.3.1.5 Web Interface

Main Page (index.html)

The entry point provides navigation to two different views of the configuration system:

- Link to styled configuration page (Bootstrap-enhanced)
- Link to raw configuration page (unstyled, raw data)

Raw Configuration Page (raw_config.html)

Demonstrates basic usage of configuration tags:

- Display values using CONFIGVALUE tags
- Create input forms using CONFIGINPUT tags
- Generate tables using CONFIGTABLE tags
- Show system variables like IP addresses

Styled Configuration Page (styled_config.html)

Features a modern Bootstrap-based interface with:

- Tabbed navigation (Display Values, Input Fields, Tables)
- Responsive design with Bootstrap CSS
- Enhanced styling and user experience
- Code examples with syntax highlighting

12.5.3.3.1.6 Form Handling

The application provides two approaches for handling form submissions:

Simple Handler (Recommended)

```
HttpPostConfigVariableHandler post1Form("post1.html", "index.html");
HttpPostConfigVariableHandler post2Form("post2.html", "index.html");
```

Custom Callback Handler

```
HttpPostVariableListCallback postForm1("post1.html", ConfigPostCallBack);
```

The custom callback approach allows for more complex processing, including:

- Handling non-configuration variables
- Custom reboot logic
- Advanced form validation

12.5.3.3.1.7 Configuration Tag Usage

Display Values

```
<!-- Using configuration path -->
<!--CONFIGVALUE "Config/AppData/MyOwnuValue" -->

<!-- Using variable reference -->
<!--CONFIGVALUE gMyOwnuVal -->

<!-- System variables with formatting -->
<!--CONFIGVALUE "Config/Sys/NetIf/Ethernet0/IPv4/ActiveAddr",16 -->
```

Input Fields

```
<!-- Individual input fields -->
<!--CONFIGINPUT gMyOwnuVal -->
<!--CONFIGINPUT gMyOwnStrVal -->
```

Tables

```
<!-- Individual variable tables -->
<!--CONFIGTABLE gMyOwnStrVal -->
<!--CONFIGTABLE gMyOwnuVal -->

<!-- System configuration sections -->
<!--CONFIGTABLE enet0.ip4 -->
<!--CONFIGTABLE "Config/Reboot" -->
```

12.5.3.3.1.8 Key Features

Read-Only Variables

Some system variables are flagged as read-only (fConfigReadOnly flag). These variables:

- Display their current values
- Cannot be modified through HTML input fields
- Are shown in tables but without editable controls

Reboot Handling

The application includes automatic reboot functionality:

- Uses the system-defined `rebooter` variable
- Displays a "Rebooting" message before restart
- Handles graceful connection closure

Network Integration

- Waits for active network before starting
- Supports HTTP server functionality
- Handles TCP connection management

12.5.3.3.1.9 Dependencies

Required Headers

- `<init.h>` - System initialization
- `<iosys.h>` - I/O system functions
- `<netinterface.h>` - Network interface management
- `<config_obj.h>` - Configuration object system
- `<httppost.h>` - HTTP POST handling
- `<tcp.h>` - TCP connection management

Web Assets

- Bootstrap CSS (`bootstrap.min.css`)
- Bootstrap JavaScript (`bootstrap.bundle.min.js`)
- jQuery (`jquery-3.3.1.min.js`)

12.5.3.3.1.10 Usage

1. **Compile and Deploy** the application to your embedded system
2. **Connect to Network** - The application waits for network connectivity
3. **Access Web Interface** - Navigate to the device's IP address in a web browser
4. **Choose Interface Style:**
 - Click "Config Elements Styled Using Bootstrap and CSS" for modern interface
 - Click "Config Data As It Comes From the Module" for raw data view
5. **Modify Configuration** - Use the forms to change variable values
6. **Save Changes** - Click "SaveConfig" to persist changes

12.5.3.3.1.11 Technical Notes

Form Processing

- POST requests are handled by registered callback functions
- Configuration variables are automatically parsed and validated
- Changes are saved to persistent storage
- Optional reboot functionality for system-level changes

Error Handling

- Invalid configuration values are rejected
- Network connectivity is verified before operation
- TCP connections are properly managed and closed

Performance

- Minimal memory footprint
- Efficient HTML generation
- Responsive web interface

12.5.3.3.1.12 Example Configuration Paths

Application Data

- `Config/AppData/MyOwnValue` - Custom integer value
- `Config/AppData/MyOwnString` - Custom string value

System Configuration

- `Config/Sys/NetIf/Ethernet0/IPv4/ActiveAddr` - Current IP address
- `Config/Reboot` - System reboot flag
- `enet0.ip4` - IPv4 configuration section

12.5.3.4 Custom Web Config

12.5.3.4.1 Custom Web Config System

12.5.3.4.1.1 Overview

This is an advanced embedded web configuration system built for NetBurner devices. It provides a modern, responsive web interface for managing device configuration objects, combining C++ backend configuration management with a JavaScript/jQuery frontend. The system allows users to configure thermostat settings, email notifications, and other application-specific parameters through a web browser.

This example is an advanced version BasicWebConfig example that implements the content with JavaScript and jQuery. It also demonstrates how to store and display custom application data in the AppData section.

Configuration objects are created when the device first boots, then they are stored so they are persist after the device has been power cycled. The web interface adds custom styling beyond the basic server presentation to view and set the values. The

Note

Because we are only processing the config object, we are able to avoid writing a custom POST handler that is used in the other examples. If you include more to your web interface than is provided here, a post handler may be required.

12.5.3.4.1.2 Features

- **Modern Web Interface:** Bootstrap-based responsive design with tabbed navigation
- **Persistent Configuration:** Configuration objects are stored and persist after power cycles
- **Real-time Updates:** Dynamic form generation from JSON configuration data
- **Multiple Configuration Types:** Support for various data types including integers, strings, booleans, IP addresses, and dropdown selections
- **Serial Port Interface:** Command-line interface for local configuration management
- **Automatic Network Setup:** [DHCP](#) support with automatic IP configuration

12.5.3.4.1.3 Architecture

Backend (C++)

The application is built around a hierarchical configuration system using C++ classes:

Configuration Object Types

- [config_obj](#) - Base container object for organizing other configuration objects
- [config_bool](#) - Boolean values
- [config_int](#) - Integer values
- [config_double](#) - Double precision floating point values
- [config_string](#) - String values
- [config_chooser](#) - Multiple choice dropdown options
- [config_pass](#) - Password fields
- [config_IPADDR4](#) - IPv4 addresses
- [config_IPADDR6](#) - IPv6 addresses
- [config_MACADR](#) - MAC addresses

Application Classes

Thermostat1 Class**

- `m_maxTemp` - Maximum temperature setting (default: 100)
- `m_setTemp` - Target temperature setting (default: 30)
- `m_minTemp` - Minimum temperature setting (default: 10)
- `m_powerMax` - Maximum power setting (default: 200)
- `m_active` - Thermostat active status (default: true)

Thermostat2 Class** (extends Thermostat1)

- Inherits all Thermostat1 properties
- `m_tempRec1` - Temperature record 1 (default: 101)
- `m_tempRec2` - Temperature record 2 (default: 102)

EmailNotify Class**

- `m_normal` - Normal notification email address
- `m_emergency` - Emergency notification email address
- `m_choose` - Action chooser (Alert, TurnOff, Crash options)

Frontend (HTML/JavaScript)

The web interface features:

- **Responsive Design:** Bootstrap-based layout that adapts to different screen sizes
- **Tabbed Interface:** Separate tabs for Application Data, Boot Config, and Network Config
- **Dynamic Form Generation:** Forms are automatically generated from JSON configuration data
- **Real-time Updates:** Changes are immediately reflected in the configuration system

12.5.3.4.1.4 Serial Port Commands

The application provides a command-line interface through the serial port:

- `C` - Show complete configuration tree
- `E` - Show email notification settings
- `F` - Show and modify email normal contact address
- `N` - Show IP address for first network interface
- `S` - Show and modify global string setting
- `T` - Show thermostat 1 settings
- `V` - Show and modify global integer value
- `2` - Show thermostat 2 settings
- `6` - Show all interface IP addresses and system time
- `?` - Display command list

12.5.3.4.1.5 Web Interface Usage

1. **Access the Interface:** Navigate to the device's IP address in a web browser
2. **Application Data Tab:** Configure thermostat settings, email notifications, and custom application parameters
3. **Boot Config Tab:** Modify system boot configuration parameters
4. **Network Config Tab:** View and configure network interface settings (some fields are read-only)
5. **Update Records:** Click "Update Record" button to save changes to persistent storage

12.5.3.4.1.6 Configuration Data Flow

1. **Initialization:** Configuration objects are created with default values on first boot
2. **Storage:** Configuration data is automatically saved to persistent storage
3. **Web Access:** HTTP server provides JSON endpoints for configuration data
4. **Form Generation:** JavaScript dynamically creates forms based on JSON structure
5. **Updates:** Form submissions update the JSON data and save to persistent storage

12.5.3.4.1.7 Technical Requirements

- NetBurner embedded device with network capability
- HTTP server support
- Serial port interface (115200 baud)
- Bootstrap CSS framework
- jQuery JavaScript library

12.5.3.4.1.8 Network Configuration

The system automatically configures network settings:

- [DHCP](#) client for automatic IP assignment
- HTTP server on port 80
- AutoIP support for link-local addressing
- Gateway and DNS configuration

12.5.3.4.1.9 Security Considerations

- Password fields are automatically detected and masked in the web interface
- Some network configuration fields are read-only to prevent accidental network disconnection
- Configuration changes require explicit user action (Update Record button)

12.5.3.4.1.10 Customization

To extend the system:

1. Create new configuration classes inheriting from appropriate base types
2. Add objects to the global configuration tree
3. Ensure each object has a unique name
4. The web interface will automatically generate forms for new configuration objects

12.5.3.4.1.11 Build Information

The application displays build timestamp and provides network status information including:

- Primary IP address
- AutoIP address
- Gateway address
- System uptime

12.5.3.5 Custom Web System Config

12.5.3.5.1 Custom System Config Server

A NetBurner RTOS-based embedded web application that demonstrates how to customize the device's system configuration server interface.

12.5.3.5.1.1 Overview

This application shows how to create a custom system configuration interface that runs on NetBurner's network port 20034, separate from the main application web interface on port 80. Unlike typical configuration examples that integrate configuration pages into the application's web interface, this example demonstrates how to customize the device's built-in system configuration server with custom branding, logos, and web page content.

Note

You can have both a custom System Configuration Page on port 20034 and a custom Web Configuration Page on port 80 active at the same time.

12.5.3.5.1.2 Features

- **Dual Web Interfaces:**
 - Main application web server on port 80 (based on SimpleHtml)
 - Custom system configuration server on port 20034
- **Custom Branding:** Ability to customize logos and web page content
- **System Configuration:** Access to device configuration through customized interface
- **File Override System:** Uses NetBurner's overload procedure for customization
- **System Diagnostics:** Integrated diagnostic capabilities for system monitoring
- **Network Management:** Automatic network initialization and connection handling
- **Real-Time Operation:** Built on NetBurner RTOS for reliable real-time performance

12.5.3.5.1.3 Hardware Requirements

- NetBurner embedded module/board
- Network connectivity (Ethernet)
- Compatible with NetBurner NNDK (NetBurner Network Development Kit)

12.5.3.5.1.4 Software Dependencies

- NetBurner RTOS
- NetBurner Network Development Kit (NNDK)
- Required NetBurner libraries:
 - `init.h` - System initialization
 - `nbrtos.h` - RTOS functions
 - `system.h` - System utilities

12.5.3.5.1.5 Quick Start

1. **Run as Demo:** The application includes a sample LOGO.gif file and can be built and run immediately to see the customization in action
2. **View Results:**
 - Browse to port 80 for the main application
 - Browse to port 20034 to see the custom system configuration interface
3. **Add Your Customizations:** Replace the sample files with your own branding elements

12.5.3.5.1.6 Application Flow

1. **Initialization:** System and network stack initialization
2. **Diagnostics:** Enables system diagnostic features
3. **HTTP Server:** Starts the web server for configuration access
4. **Network Wait:** Waits up to 5 seconds for active network connection
5. **Status Display:** Shows application name and NNDK revision information
6. **Main Loop:** Continuous operation with 1-second intervals

12.5.3.5.1.7 Customizable System Files

The system configuration interface can be customized by overriding these files located in `\nburn\nbrtos\source`:

- **LOGO.gif** - Logo displayed on the configuration page
- **ROOT.html** - JavaScript root configuration page
- **RAW.html** - Low-level HTML page with links to configuration and UI.html that displays the entire JSON object
- **UI.html** - Displays the entire JSON configuration object

12.5.3.5.1.8 Customization Process

This application uses NetBurner's **overload procedure** for customization:

1. Create the override directory structure: `override\nbrtos\source`
2. Copy the files you want to customize into this directory
3. Modify the files as needed
4. Build the application - your custom files will be compiled into the application

Example: Custom Logo

A sample LOGO.gif file is provided in the application's `src` folder. To use it:

1. Copy the LOGO.gif to `override\nbrtos\source\` folder
2. Build and run the application
3. View the custom logo on port 20034

12.5.3.5.1.9 Usage

1. **Build and Deploy:** Build and deploy the application to your NetBurner device
2. **Main Application:** Access the basic web page on port 80
3. **System Configuration:** Access the custom configuration interface on port 20034
4. **Customization:** The system configuration page will display your custom modifications

12.5.3.5.1.10 Port Configuration

- **Port 80:** Main application web interface (SimpleHtml-based)
- **Port 20034:** Custom system configuration server

12.5.3.5.1.11 Configuration

The application automatically:

- Initializes network connectivity
- Starts HTTP services on default ports
- Enables diagnostic capabilities

12.5.3.5.1.12 Development Notes

- **Production Deployment:** Consider removing `EnableSystemDiagnostics()` for production builds
- **Network Timeout:** 5-second network connection timeout is configured
- **Main Loop:** 1-second delay in main loop for efficient resource usage
- **File Compilation:** Logo and HTML files are converted to .cpp files and compiled into the application
- **Branding Strategy:** You can combine both custom application and custom system configuration for complete product branding
- **Demo Ready:** The application includes a sample LOGO.gif and can be run as-is to demonstrate customization

12.5.3.5.1.13 Build Information

The application displays:

- Application name: "Custom System Config Server"
- NNDK revision information at startup

12.5.3.6 HTML Only Configuration

12.5.3.6.1 HTML Only Configuration Application

12.5.3.6.1.1 Overview

This is a simple web-based configuration application that provides an HTML interface for configuring network settings and system parameters. The application runs on port 80 and allows users to modify configuration values through a web form interface.

12.5.3.6.1.2 Features

- **Web-based Configuration:** Simple HTML form interface for configuration management
- **Network Configuration:** Supports IPv4 network settings (enet0.ip4)
- **Reboot Control:** Checkbox option to reboot system after updating configuration values
- **Styled Interface:** Clean, professional styling with a modern table design
- **Remote Console:** Enables remote console access for debugging and monitoring

12.5.3.6.1.3 File Structure

```
main.cpp      # Main application entry point
index.html    # Configuration form interface
style.css     # Styling for the web interface
```

12.5.3.6.1.4 Application Components

main.cpp

The main application file that:

- Initializes the network stack
- Enables system diagnostics
- Starts the HTTP server on port 80
- Waits for active network connection
- Enables remote console access
- Implements the HTML post configuration handler

index.html

The web interface that provides:

- Configuration form with POST method to `postcfg.html`
- Table-based layout for configuration parameters
- Network IP configuration section (enet0.ip4)
- Reboot option checkbox
- Submit button to save configuration

style.css

Styling that includes:

- Clean, modern table design with shadow effects
- Alternating row colors for better readability
- Green accent color (#009879) for headers and borders
- Responsive font sizing and spacing
- Active row highlighting capability

12.5.3.6.1.5 Configuration Options

The application currently supports:

1. **Network Configuration** (`enet0.ip4`)
 - IPv4 network settings for ethernet interface
2. **System Reboot** (`rebooter`)
 - Checkbox to enable automatic reboot after configuration changes

12.5.3.6.1.6 Technical Details

- **Framework:** NetBurner NNDK (NetBurner Network Development Kit)
- **Web Server:** Built-in HTTP server on port 80
- **Configuration Handler:** `HtmlPostConfigVariableHandler` class
- **Network Stack:** NetBurner real-time network stack
- **System:** Real-time operating system (NBRTOS)

12.5.3.6.1.7 Usage

1. Connect to the device's IP address via web browser
2. Navigate to the configuration page (`index.html`)
3. Modify the desired configuration parameters
4. Check the reboot option if system restart is needed
5. Click "SaveConfig" to apply changes

12.5.3.6.1.8 Development Notes

- The application uses NetBurner's configuration system with `<!--CONFIGTABLE-->` directives
- Additional configuration objects can be added by including appropriate header files
- System diagnostics are enabled (should be removed for production)
- The application includes a 5-second timeout for network initialization

12.5.3.6.1.9 Customization

To add additional configuration parameters:

1. Include the appropriate header files in `index.html`
2. Add new `<!--CONFIGTABLE-->` entries for your configuration objects
3. Rebuild and deploy the application

12.5.3.6.1.10 Dependencies

- NetBurner NNDK framework
- Standard NetBurner libraries ([init.h](#), [nbrtos.h](#), [system.h](#), etc.)
- HTTP POST handling library
- Remote console library

12.5.4 Detached Config Object

This example demonstrates how to create JSON configuration objects (data or structures) in a "detached" mode, meaning they do not appear in the web page configuration screen, nor are they saved, but are exposed via individual web pages. In Detached mode they are created at boot time and can be modified and used by the application. The example will:

- Create a number of configuration object classes
- Use the classes to create Detached configuration objects
- For reference, shows how they would be exposed in the normal configuration tree
- Expose those objects as web pages containing the JSON information

For example, if your device IP address is 10.1.1.10, opening a web browser and typing "10.1.1.10/set.json" will display that object and it's data:

```
ctrl_set
Hset
  D 0
  I 0.0001
  P 1
Vset
  D 0
  I 0.0001
  P 1
rev 0
```

12.5.4.1 Detached Config Example

12.5.4.1.1 Overview

This NetBurner application demonstrates how to create JSON configuration objects in "detached" mode. In detached mode, configuration objects are created at boot time and can be modified and used by the application, but they do not appear in the Configuration Server web interface and may or may not be saved to persistent storage depending on the application requirements. However, they can, and usually are, used by individual web pages.

12.5.4.1.2 Features

- Creates multiple configuration object classes with different data types
- Demonstrates both detached and normal configuration modes
- Exposes configuration objects as individual JSON web pages
- Includes examples of inheritance between configuration classes

12.5.4.1.3 Configuration Classes

12.5.4.1.3.1 TempRange

Base class for temperature-related configuration:

- `MaxTemp`: Maximum temperature (integer, default: 100)
- `SetTemp`: Set temperature (integer, default: 30)
- `MinTemp`: Minimum temperature (integer, default: 10)

12.5.4.1.3.2 Thermostat

Extends `TempRange` with additional thermostat-specific settings:

- `Active`: Enable/disable thermostat (boolean, default: true)
- `Location`: Physical location (string, default: "Warehouse 1")
- `TempScale`: Temperature scale chooser (Fahrenheit/Celsius/Kelvin, default: Fahrenheit)

12.5.4.1.3.3 PIDSet

PID controller configuration:

- **P**: Proportional term (double, default: 1.0)
- **I**: Integral term (double, default: 0.0001)
- **D**: Differential term (double, default: 0.0)

12.5.4.1.3.4 ControlSet

Container for PID control settings:

- **Hset**: Horizontal PID settings
- **Vset**: Vertical PID settings
- **rev**: Settings revision number (integer, default: 0)

12.5.4.1.4 Configuration Modes

The application supports two modes controlled by the `DETACHED_MODE` preprocessor definition:

12.5.4.1.4.1 Detached Mode (Default)

- Configuration objects are created with the `detached` parameter
- Objects are not exposed in the configuration tree
- Objects are not saved to persistent storage
- Objects are accessible via individual web pages

12.5.4.1.4.2 Normal Mode

- Configuration objects are created under the `appdata` parent
- Objects appear in the standard configuration tree
- Objects are saved to persistent storage

12.5.4.1.5 Web Interface

The application exposes three JSON endpoints:

- `<device_ip>/set.json` - Displays the `ControlSet` object
- `<device_ip>/thermo.json` - Displays the `Thermostat` object
- `<device_ip>/anint.json` - Displays a simple integer configuration

12.5.4.1.5.1 Example JSON Output

Accessing `<device_ip>/set.json` displays:

```
ctrl_set
  Hset
    D    0
    I    0.0001
    P    1
  Vset
    D    0
    I    0.0001
    P    1
  rev   0
```

12.5.4.1.6 Usage

1. Build and deploy the application to your NetBurner device
2. Wait for network initialization (up to 5 seconds)
3. Open a web browser and navigate to:
 - http://<device_ip>/set.json
 - http://<device_ip>/thermo.json
 - http://<device_ip>/anint.json

12.5.4.1.7 Application Structure

main.cpp	- Main application code with configuration classes
ReadMe.txt	- Original documentation
index.html	- Basic web page with NetBurner branding

12.5.4.1.8 Build Requirements

- NetBurner development environment
- Standard NetBurner libraries:
 - [nbrtos.h](#)
 - [http.h](#)
 - [init.h](#)
 - [netinterface.h](#)

12.5.4.1.9 Key Concepts Demonstrated

1. **Configuration Object Classes:** How to create custom configuration classes that inherit from [config_obj](#)
2. **Detached Configuration:** Creating configuration objects that exist only in memory
3. **Web Exposure:** Using `HtmlConfigExposer` to make configuration objects accessible via HTTP
4. **Inheritance:** How configuration classes can extend other configuration classes
5. **Multiple Data Types:** Support for integers, doubles, booleans, strings, and choosers

12.5.4.1.10 Notes

- The `ConfigEndMarker` must be placed after all configuration members in each class
- Configuration objects can be nested within other configuration objects
- The application name is set to "Detached Config Example"
- Network initialization waits up to 5 seconds before starting the HTTP server

12.5.5 Change Notify

12.5.5.1 Config Notify Application

12.5.5.1.1 Overview

This application demonstrates how to use configuration objects with change notification callbacks in an embedded system. The program creates basic configuration variables and registers callbacks to be notified when these variables change.

12.5.5.1.2 Features

- **Configuration Management:** Creates and manages different types of configuration variables (string, integer, unsigned integer)
- **Change Notifications:** Implements callback notifications when configuration values are modified
- **Interactive Menu System:** Provides a command-line interface for viewing and modifying configuration values
- **Dynamic Configuration:** Supports creating and deleting configuration variables at runtime
- **Network Integration:** Displays network interface information on startup

12.5.5.1.3 Configuration Variables

The application creates three main configuration objects:

1. **gSingleString** - A string configuration variable with default value "SName"
2. **gMyOwnVal** - An integer configuration variable with default value 199
3. **gMyOwnuVal** - An unsigned integer configuration variable with default value 299

12.5.5.1.4 Command Interface

The application provides an interactive menu system with the following commands:

- **C** - Show Config Tree: Displays the complete configuration tree
- **S** - Show and Set gSingleString: View and modify the string configuration
- **V** - Show and Set gMyOwnVal: View and modify the integer configuration
- **U** - Show and Set gMyOwnuVal: View and modify the unsigned integer configuration
- **N** - New/Create dynamic variable: Creates a new dynamic configuration variable
- **D** - Delete dynamic variable: Removes the dynamic configuration variable
- **Q** - Query dynamic variable: Displays the value of the dynamic variable
- **?** - Show Command List: Displays all available commands

12.5.5.1.5 Notification System

The application implements a notification callback system that:

- Uses a semaphore-based notification mechanism
- Registers callbacks for all configuration variables
- Provides real-time notification when any monitored configuration value changes
- Displays a message when a configuration change is detected

12.5.5.1.6 Technical Implementation

12.5.5.1.6.1 Key Components

- **Configuration Objects:** Uses `config_string`, `config_int`, and `config_uint` types
- **Callback System:** Implements `ConfigNotificationCallBack` for change notifications
- **Semaphore Synchronization:** Uses `OS_SEM` for thread-safe notification handling
- **Storage Management:** Automatically saves configuration changes to persistent storage

12.5.5.1.6.2 Memory Management

- Static configuration objects are created at global scope
- Dynamic configuration objects can be created and destroyed at runtime
- Non-static objects require calling `FixNonStaticObject()` method

12.5.5.1.6.3 Network Information

On startup, the application displays:

- IP address of the first network interface
- AutoIP address
- Gateway address
- Configuration space usage statistics

12.5.5.1.7 Usage

1. **Startup:** The application initializes network interfaces and displays system information
2. **Command Entry:** Enter single character commands to interact with the configuration system
3. **Value Modification:** Follow prompts to enter new values for configuration variables
4. **Notification Monitoring:** The system automatically notifies when values change

12.5.5.1.8 Build Information

The application displays build timestamp information on startup, showing when the code was compiled.

12.5.5.1.9 Example Workflow

1. Start application and view initial configuration
2. Use 'C' command to see the complete config tree
3. Use 'S', 'V', or 'U' commands to modify configuration values
4. Observe notification messages when values change
5. Use 'N' to create dynamic variables and 'D' to delete them
6. Use 'Q' to query dynamic variable values

12.5.6 Config Class Receive Notification

12.5.6.1 Config Notify Class Example

12.5.6.1.1 Overview

This NetBurner application demonstrates the use of the config system with notification capabilities. The config system stores both system-defined boot and interface information (such as default BaudRate and current IP settings) and provides a framework for users to define and store their own persistent variables.

This example extends the basic ConfigClass functionality by implementing a notification system that alerts when any configuration variables change.

12.5.6.1.2 Features

- **Persistent Configuration Storage:** Variables are automatically saved to non-volatile storage
- **Change Notifications:** Automatic notifications when configuration values are modified
- **Interactive Command Interface:** User-friendly commands to view and modify settings
- **Hierarchical Configuration:** Demonstrates inheritance with TempRange and Thermostat classes

12.5.6.1.3 Application Structure

12.5.6.1.3.1 Classes

TempRange

A base configuration class that defines temperature-related settings:

- `m_maxTemp`: Maximum temperature threshold (default: 100)
- `m_setTemp`: Set point temperature (default: 30)
- `m_minTemp`: Minimum temperature threshold (default: 10)

Thermostat

Extends `TempRange` and implements `ConfigNotificationObject`:

- Inherits all `TempRange` variables
- `m_tempRec1`: Temperature record 1 (default: 101)
- `m_tempRec2`: Temperature record 2 (default: 102)
- `m_active`: Active status flag (default: true)
- `m_location`: Thermostat location string (default: "Warehouse 1")
- `m_tempScale`: Temperature scale chooser (Fahrenheit/Celsius/Kelvin)

12.5.6.1.3.2 Key Features

Notification System

The `Thermostat` class implements a `Notify()` method that is automatically called whenever any of its configuration variables change. This provides real-time awareness of configuration modifications.

Interactive Commands

The application provides a command-line interface with the following options:

- `C` - Show complete configuration tree
- `L` - View and set thermostat location
- `M` - View and set maximum temperature
- `N` - View and set minimum temperature
- `S` - View and set target temperature
- `T` - Display recorded temperatures
- `?` - Show command list

12.5.6.1.4 Usage

1. **Startup**: The application initializes the network interface and displays current IP settings
2. **Interactive Mode**: Enter commands to view or modify configuration values
3. **Automatic Saving**: All changes are automatically saved to persistent storage
4. **Notifications**: The system prints a message whenever configuration values change

12.5.6.1.5 Network Information

On startup, the application displays:

- Current IP address
- AutoIP address
- Gateway address

12.5.6.1.6 Technical Implementation

12.5.6.1.6.1 Configuration Storage

- Uses NetBurner's config system for persistent storage
- Automatic serialization/deserialization of configuration objects
- Thread-safe access to configuration variables

12.5.6.1.6.2 Notification Mechanism

- Implements `ConfigNotificationObject` interface
- Automatic registration for change notifications
- Custom `Notify()` method for handling configuration changes

12.5.6.1.6.3 Input Processing

- Non-blocking character input using `charavail()`
- User-friendly prompts for value modification
- Automatic type conversion and validation

12.5.6.1.7 Building and Running

This application is designed for NetBurner embedded systems and requires:

- NetBurner SDK and toolchain
- Network-capable NetBurner hardware platform
- Serial terminal for user interaction

The application runs continuously, processing user commands and maintaining configuration state across power cycles.

12.5.6.1.8 Example Output

```
Config Tree Demo built at 12:34:56 on Jan 01 2025
'?' for commands
IP:          192.168.1.100
AutoIP :     169.254.1.100
Gateway:     192.168.1.1

Command List
-----
C) Show Config Tree
L) Show and Set Thermostat Location
M) Show and Set Thermostat Max Temp
N) Show and Set Thermostat Min Temp
S) Show and Set Thermostat Set Temp
T) Show Thermostat Recorded Temps
?) Show Command List
```

12.5.6.1.9 Notes

- All configuration objects should be created at global scope
- Each configuration member must have a unique name within the config tree
- The `ConfigEndMarker` is required after the last data member in each config class
- Changes trigger both the notification system and automatic storage saves

12.6 DNS Device Name

12.6.1 DNS Device Name Application

12.6.1.1 Overview

This NetBurner application demonstrates how to programmatically set a device name that can be used for DNS resolution on a network. The device name is automatically generated using the device's MAC address and stored in the flash configuration.

The device name is stored in the device's Flash System Configuration. There are two ways to give your device a name:

1. Use the configuration web interface, which is your device's `<device ip address>:20034`.
2. You can change the configuration flash setting in your application. You will then need to reboot the device for the name to take effect.

This example demonstrates how to change the device name in an application.

Note

This is not the same as a .local or WINS device name. The network must have a DNS and [DHCP](#) server.

12.6.1.2 Features

- Automatically generates a unique device name based on MAC address
- Stores device name in flash configuration for persistence
- Provides network identification for [DHCP](#) and DNS services
- Simple web interface access for manual configuration

12.6.1.3 How It Works

The application performs the following operations:

1. **Device Initialization:** Sets up the network interface and enables HTTP services
2. **MAC Address Retrieval:** Gets the MAC address from the first available network interface (typically Ethernet0)
3. **Name Generation:** Creates a device name using the format `NetBurner-XXXX` where XXXX represents the last two octets of the MAC address in hexadecimal
4. **Configuration Storage:** Compares the generated name with the current flash configuration and updates it if different
5. **Persistence:** Saves the new configuration to storage and notifies that a reboot is required

12.6.1.4 Device Naming

12.6.1.4.1 Automatic Naming Convention

- Format: `NetBurner-XXXX`
- Example: `NetBurner-848F` (where 848F are the last two bytes of the MAC address)

12.6.1.4.2 Manual Configuration Options

You can also set the device name manually through:

1. **Web Interface:** Access `<device_ip_address>:20034` in your browser
2. **Application Code:** Modify the flash configuration programmatically (as demonstrated in this example)

12.6.1.5 Network Integration

12.6.1.5.1 DHCP Integration

When the device requests an IP address from a [DHCP](#) server, it sends:

- MAC address
- Device name (optional, but supported)

The [DHCP](#) server maintains a table with MAC address, IP address, and device name for each device.

12.6.1.5.2 DNS Resolution

For the device name to be resolvable via DNS:

- **Windows Server:** Configure [DHCP](#) and DNS server integration through dialog settings
- **Linux/Unix:** May require additional configuration for DHCP-DNS integration
- **Without DNS Server:** Manually add entries to the `lmhosts` file on each PC

12.6.1.5.3 Windows WINS Protocol

Windows machines can use the proprietary WINS protocol for name resolution, where one Windows PC maintains the table of MAC addresses, IP addresses, and names.

12.6.1.6 Sample Output

```
Interface 1, Ethernet0, MAC:00:03:f4:0b:84:8f
Current device name from flash configuration: "MODM7AE70SX-848F"
Assigning device name: NetBurner-848F
Reboot device for new device name to take effect

Primary network interface configured for DHCP
MAC Address = 00:03:f4:0b:84:8f
Type "A" to abort boot

Interface 1, Ethernet0, MAC:00:03:f4:0b:84:8f
Current device name from flash configuration: "NetBurner-848F"
New name already matches configuration
```

12.6.1.7 Key Functions

12.6.1.7.1 CreateDnsDeviceName(char *deviceName, uint32_t maxLen)

- Retrieves the first network interface information
- Displays current configuration
- Generates new device name from MAC address
- Updates flash configuration if name has changed
- Saves configuration to storage

12.6.1.7.2 UserMain(void *pd)

- Initializes the system and network
- Enables HTTP services
- Waits for network connectivity
- Calls the device naming function
- Enters main application loop

12.6.1.8 Important Notes

- **Reboot Required:** After changing the device name, a reboot is necessary for the new name to take effect
- **Name Length:** Maximum device name length is 32 characters
- **Network Dependencies:** Requires active network connection and [DHCP](#) configuration
- **Persistence:** Device name is stored in flash memory and survives power cycles

12.6.1.9 Building and Deployment

This application is designed for NetBurner embedded systems and requires:

- NetBurner development environment
- Compatible NetBurner hardware module
- Network connection with [DHCP](#) server

12.6.1.10 Use Cases

- Network device identification and management
- Simplified device access by name instead of IP address
- Integration with existing DNS infrastructure
- Automated device provisioning in larger networks

12.6.1.11 Additional Information on DNS Naming

When a network device (such as the NetBurner module) requests an IP address from a [DHCP](#) Server, the device sends it MAC address and an optional device name (this is supported by your NetBurner device). The [DHCP](#) Server supplies the dynamic IP address and maintains a table containing the MAC address, IP address and device name for each device that has accepted a [DHCP](#) lease.

The purpose of a DNS server is to convert a name into an IP address. To do this it must get the information from your [DHCP](#) Server. On windows server platforms that run both a [DHCP](#) server and DNS server, this can be configured in a dialog box. On Linux it may be more complicated. Basically, every time the [DHCP](#) server gives out a new dynamic IP address it updates the DNS server. If you are not using [DHCP](#), and are assigning static IP addresses, then you must update the DNS server with the entries manually (i.e. name and IP address).

If you do not have a DNS server, you can modify the `lmhosts` file on your PC to add the IP address and name of each network device you want to address by name. You would need to do this on every PC that wants to use the name.

Windows has a proprietary protocol called WINS (only Microsoft products can use it). Windows machines can have a name, and the protocol enables windows machines to talk to one another. This is achieved by having one windows PC maintain the table of MAC address, IP address and names.

12.7 DHCP

DHCP Examples:

- [DHCP Client - Change IP Address](#)
- [DHCP Client - Test DHCP](#)
- [DHCP Server \(DHCPD\)](#)
- [DHCP Client - Change IP Address Via Webpage](#)

12.7.1 DHCP Client - Change IP Address

Demonstrate how to view IP address and change between [DHCP](#) and static IPv4 IP settings.

12.7.1.1 DHCP Client - Change IP Address Application

12.7.1.1.1 Overview

This application demonstrates how to dynamically switch between [DHCP](#) and static IPv4 IP address configurations on a NetBurner embedded device. It provides an interactive menu system through the serial port that allows users to view current network settings and change between addressing modes without requiring a system reboot.

12.7.1.1.2 Features

- **Interactive Serial Menu:** Control the application through a simple command-line interface
- **Real-time IP Configuration:** Switch between [DHCP](#) and static IP modes during runtime
- **DHCP State Monitoring:** Display current [DHCP](#) client state and lease information
- **Network Status Display:** View comprehensive IPv4 settings including IP address, subnet mask, gateway, and DNS servers
- **Optional WiFi Support:** Configurable WiFi functionality (disabled by default)
- **Web Server Integration:** Built-in HTTP server for web-based management

12.7.1.1.3 Supported Address Modes

The application supports the following IPv4 addressing modes:

- **DHCP:** Automatic IP address assignment from [DHCP](#) server
- **DHCP w/ Fallback:** [DHCP](#) with fallback to static configuration if [DHCP](#) fails
- **Static:** Manual IP address configuration
- **Disabled:** Network interface disabled

12.7.1.1.4 Menu Options

The application provides a simple menu system with the following options:

1. **Display Runtime Settings:** Shows current IPv4 configuration, [DHCP](#) state, and network interface information
2. **Change to Static Address Mode:** Switches to static IP configuration using settings from the configuration record
3. **Change to [DHCP](#) Address Mode:** Enables [DHCP](#) client and obtains IP address automatically

12.7.1.1.5 Configuration Methods

12.7.1.1.5.1 Method 1: Using Configuration Record (Default)

The application reads static IP settings from the device's configuration record stored in flash memory. This is the recommended approach as it allows settings to persist across reboots.

12.7.1.1.5.2 Method 2: Application-Defined Settings (Optional)

Alternatively, you can define static IP settings directly in the application code by:

1. Uncommenting the `#define` statements for static IP values
2. Uncommenting the `AssignStaticIpv4Values()` function call
3. Modifying the IP addresses to match your network environment

```
#define STATIC_IP "10.1.1.222"  
#define STATIC_MASK "255.255.255.0"  
#define STATIC_GATE "10.1.1.1"  
#define STATIC_DNS1 "10.1.1.1"  
#define STATIC_DNS2 "8.8.8.8"
```

12.7.1.1.6 Switching Between Modes

12.7.1.1.6.1 Changing from DHCP to Static

1. Static settings are read from the configuration record
2. Address mode is set to "Static"
3. Configuration is saved to flash memory
4. Runtime settings are updated immediately (no reboot required)

12.7.1.1.6.2 Changing from Static to DHCP

1. Static settings can remain intact (they won't affect [DHCP](#) operation)
2. Address mode is set to "DHCP" or "DHCP w/ Fallback"
3. Configuration is saved to flash memory
4. [DHCP](#) client is restarted to obtain new lease

12.7.1.1.7 DHCP State Information

The application monitors and displays the following [DHCP](#) client states:

- **DHCP not started:** System initialization incomplete
- **DHCP Discover:** Searching for [DHCP](#) servers
- **DHCP Offer:** Received offer from [DHCP](#) server
- **DHCP Acknowledge:** Accepted [DHCP](#) offer
- **DHCP Complete:** Successfully obtained valid lease
- **DHCP Renew/Rebind:** Lease renewal process
- **DHCP Failed:** Could not obtain [DHCP](#) lease

12.7.1.1.8 Optional Features

12.7.1.1.8.1 WiFi Support

WiFi functionality can be enabled by uncommenting the `#define USE_WIFI (1)` directive. This requires:

- WiFi driver initialization
- QSPI interface configuration
- Appropriate WiFi hardware support

12.7.1.1.8.2 System Diagnostics

The application includes system diagnostics for debugging purposes. For production deployments, consider removing the `EnableSystemDiagnostics()` call.

12.7.1.1.9 Network Interface Information

The application displays comprehensive network information including:

- Device name and application name
- Current addressing mode (DHCP/Static)
- IPv4 addresses (current and configured)
- Subnet mask
- Default gateway
- Primary and secondary DNS servers
- Link status and connectivity information

12.7.1.1.10 Usage Instructions

1. **Build and Deploy:** Compile the application and deploy to your NetBurner device
2. **Connect Serial Terminal:** Connect to the device's serial port (typically 115200 baud)
3. **Wait for Network:** The application waits up to 5 seconds for network initialization
4. **Use Menu System:** Enter menu options (1, 2, or 3) to interact with the application
5. **Monitor Changes:** View real-time network configuration changes

12.7.1.1.11 Technical Details

- **NNDK Compatibility:** Built for NetBurner Network Development Kit
- **Memory Management:** Uses configuration server for persistent settings storage
- **Network Stack:** Integrates with NetBurner's TCP/IP stack
- **Threading:** Runs in NetBurner's multi-tasking environment
- **Error Handling:** Includes proper error checking and state management

12.7.1.1.12 Development Notes

- The application uses NetBurner-specific APIs and data structures
- Format warnings for `HI` and `I` parameters are intentionally suppressed
- The code follows NetBurner's naming conventions and coding standards
- IPv6 support is conditionally compiled based on `IPV6` preprocessor definition

12.7.1.1.13 Prerequisites

- NetBurner development board with Ethernet interface
- NetBurner Network Development Kit (NNDK)
- Serial terminal application for user interaction
- Network infrastructure with [DHCP](#) server (for [DHCP](#) mode testing)

This application serves as both a practical network management tool and a comprehensive example of NetBurner's networking capabilities for embedded developers.

12.7.2 DHCP Client - Test DHCP

12.7.2.1 DHCP Test Application

12.7.2.1.1 Overview

This application demonstrates advanced [DHCP](#) (Dynamic Host Configuration Protocol) client functionality by providing direct control and monitoring of [DHCP](#) services. Unlike simple applications that use the `GetDhcpAddress()` function, this example creates and manages a [DHCP](#) object directly, giving you fine-grained control over the [DHCP](#) process.

12.7.2.1.2 Purpose

The application serves both educational and testing purposes:

- **Educational:** Shows internal [DHCP](#) workings by displaying UDP packet information and [DHCP](#) variables
- **Testing:** Provides interactive control over [DHCP](#) services for debugging and validation
- **Demonstration:** Illustrates how to access and manipulate [DHCP](#) object properties programmatically

12.7.2.1.3 Key Features

12.7.2.1.3.1 DHCP State Monitoring

The application displays comprehensive [DHCP](#) state information including:

- `DHCP_NOTSTARTED` - System not initialized
- `DHCP_DISCOVER` - Discovering [DHCP](#) servers
- `DHCP_OFFER` - Responding to server offers
- `DHCP_ACK` - Acknowledging offers
- `DHCP_INIT` - Reinitializing
- `DHCP_CMPL` - Valid lease obtained
- `DHCP_RENEW` - Lease renewal in progress
- `DHCP_REBIND` - Rebinding after failed renewal
- `DHCP_RELEASE` - Releasing lease
- `SBOOTP_TRANSMITTING/DONE` - BOOTP fallback states
- `DHCP_FAILED` - Failed to obtain lease

12.7.2.1.3.2 Interactive Menu System

The application provides a command-line interface with the following options:

- `**t**` - Display remaining lease time and timing information
- `**s**` - Show detailed [DHCP](#) status (debug mode only)
- `**v**` - Validate current [DHCP](#) lease
- `**1**` - Set system timer to 5 seconds before renew time
- `**2**` - Set system timer to 5 seconds before rebind time
- `**3**` - Set system timer to 5 seconds before lease expiration
- `**4**` - Force [DHCP](#) renewal
- `**5**` - Force [DHCP](#) rebinding
- `**a**` - Show [ARP](#) table

12.7.2.1.3.3 Advanced Timing Control

The application allows manipulation of [DHCP](#) timing for testing scenarios:

- Simulate approaching renewal deadlines
- Test rebinding behavior
- Verify lease expiration handling
- Force state transitions for validation

12.7.2.1.4 Technical Implementation

12.7.2.1.4.1 Architecture

- Creates a global [DHCP](#) object variable
- Uses semaphore monitoring for [DHCP](#) completion
- Accesses private class variables for detailed debugging (educational purposes only)
- Integrates with the NetBurner network stack

12.7.2.1.4.2 Debug Information

When debug mode is enabled, the application displays:

- UDP packet details
- Internal [DHCP](#) variables
- Low-level state information
- Timing and lease parameters

12.7.2.1.5 Setup and Configuration

12.7.2.1.5.1 Debug Mode Setup

To enable detailed debugging information:

1. Edit `\nburn\system\dhcpc.cpp`
2. Uncomment the line: `#define DHCP_DEBUG 1`
3. Rebuild the application

Warning

Comment out `#define DHCP_DEBUG 1` when finished with testing. This should not be enabled in production applications.

12.7.2.1.5.2 Build Configuration

- The application uses conditional compilation with `DHCPTTEST_DEBUG`
- System diagnostics are enabled for development (consider removing for production)
- Serial output is directed to UART0 by default (viewable with MTTTY)

12.7.2.1.6 Usage

1. Flash the application to your NetBurner device
2. Connect via serial terminal (MTTTY recommended)
3. The application will automatically start [DHCP](#) and display the menu
4. Use the menu commands to interact with and test [DHCP](#) functionality
5. Monitor the output for state changes and debugging information

12.7.2.1.7 Educational Value

This application is designed to teach:

- [DHCP](#) protocol states and transitions
- Lease timing and renewal processes
- Error handling and fallback mechanisms
- Network debugging techniques
- Embedded network programming patterns

For comprehensive [DHCP](#) protocol information, refer to RFC 2131.

12.7.2.1.8 Development Notes

- Application name appears as "DHCPTTest" in IPSetup
- Uses NetBurner-specific APIs and classes
- Demonstrates both high-level and low-level [DHCP](#) access patterns
- Shows proper integration with the NetBurner timeout management system

12.7.2.1.9 Warning

This example accesses private class variables of the [DHCP](#) object for educational purposes. This approach is **NOT recommended** for production applications and should only be used for learning and debugging.

12.7.2.1.10 Dependencies

- NetBurner RTOS and network stack
- Serial communication support
- [DHCP](#) client library
- [ARP](#) functionality modify the system timer, and display dhcp status.

12.7.3 DHCP Server (DHCPD)

12.7.3.1 DHCP Server Application (DHCPD)

12.7.3.1.1 Overview

This NetBurner application demonstrates how to create and deploy a [DHCP](#) (Dynamic Host Configuration Protocol) Server on your NetBurner device. The application provides automatic IP address assignment to devices on your network, making it useful for creating standalone networks or testing environments.

12.7.3.1.2 Features

- **DHCP Server Implementation:** Creates a fully functional [DHCP](#) server that can assign IP addresses to network clients
- **Conflict Detection:** Automatically detects existing [DHCP](#) servers on the network before starting to prevent conflicts
- **Web Interface:** Includes an HTTP server for potential configuration and monitoring
- **Network Diagnostics:** Built-in system diagnostics for troubleshooting
- **Multi-Interface Support:** Can operate on different network interfaces

12.7.3.1.3 How It Works

12.7.3.1.3.1 Startup Sequence

1. **Network Initialization:** The application initializes the network stack and waits for an active network connection
2. **DHCP Server Detection:** Scans the network for existing [DHCP](#) servers to avoid conflicts
3. **User Intervention:** If another [DHCP](#) server is detected, the application prompts the user to resolve the conflict
4. **Server Launch:** Once no conflicts are detected, launches the [DHCP](#) server on the specified interface
5. **Continuous Operation:** Runs indefinitely, serving [DHCP](#) requests

12.7.3.1.3.2 Key Components

- **FindOtherDHCPServer():** Implements network scanning to detect existing [DHCP](#) servers
 - Sends [DHCP](#) DISCOVER messages to probe for active servers
 - Uses a 5-second timeout to wait for responses
 - Returns true if another server is found, false otherwise
- **AddMyDHCPServer():** Initializes and starts the [DHCP](#) server functionality
 - Operates on the specified network interface
 - Handles [DHCP](#) client requests and IP address allocation
- **DhcpServCheck():** Callback function for processing [DHCP](#) responses during server detection

12.7.3.1.4 Usage

12.7.3.1.4.1 Compilation and Deployment

1. Ensure you have the NetBurner development environment set up
2. Include the necessary NetBurner libraries:
 - `dhcpd.h` - DHCP server functionality
 - `dhcpinternals.h` - Internal DHCP structures
 - `netinterface.h` - Network interface management
 - Standard NetBurner system libraries
3. Compile and flash to your NetBurner device

12.7.3.1.4.2 Operation

1. **Power on** your NetBurner device
2. The application will automatically:
 - Initialize network services
 - Check for existing DHCP servers
 - Prompt you if conflicts are detected
3. **If conflicts exist:** Disable other DHCP servers on the network and press any key to retry
4. **Once running:** The device will serve DHCP requests to network clients

12.7.3.1.4.3 Network Configuration

- The DHCP server will operate on the first available network interface by default
- Client devices connecting to the network will automatically receive IP addresses
- The web server runs on port 80 for potential configuration access

12.7.3.1.5 Important Considerations

12.7.3.1.5.1 Production Deployment

- **Remove diagnostics:** The code includes `EnableSystemDiagnostics()` which should be removed for production use
- **Security:** Consider implementing access controls if deploying in production environments
- **Network planning:** Ensure the IP address pool doesn't conflict with other network infrastructure

12.7.3.1.5.2 Network Conflicts

- **Multiple DHCP servers** on the same network can cause IP address conflicts
- Always verify no other DHCP servers are active before deployment
- Common sources of DHCP servers include routers, other embedded devices, and server systems

12.7.3.1.6 Dependencies

- NetBurner NNDK (NetBurner Network Development Kit)
- Custom memory allocation module (`MyAlloc.h`)
- Standard NetBurner networking libraries

12.7.3.1.7 Technical Details

- **Language:** C++
- **Platform:** NetBurner embedded devices
- **Threading:** Uses NetBurner RTOS (Real-Time Operating System)
- **Network Stack:** NetBurner TCP/IP stack
- **Memory Management:** Custom buffer management for DHCP packets

12.7.3.1.8 Troubleshooting

12.7.3.1.8.1 Common Issues

1. **There is an active DHCP server on this net**
 - Another DHCP server is detected on the network
 - Disable other DHCP servers or move to an isolated network segment
2. **Network timeout during startup**
 - Check network connectivity and cable connections
 - Verify network interface configuration
3. **Clients not receiving IP addresses**
 - Confirm DHCP server started successfully
 - Check network segmentation and VLAN configuration
 - Verify firewall settings aren't blocking DHCP traffic

12.7.3.1.8.2 Debug Information

The application outputs status messages to the console including:

- Application name and NNDK revision information
- DHCP server conflict detection results
- Startup progress indicators

12.7.4 DHCP Client - Change IP Address Via Webpage

12.7.4.1 DHCP Client - Change IP Address Via Webpage

This application demonstrates how to view and change IPv4 IP settings between DHCP and static configurations using both a web interface and serial console interface.

12.7.4.1.1 Overview

The application allows users to:

- View current runtime IP settings and DHCP status
- Switch between DHCP and static IP address modes
- Configure IP settings through a web-based interface
- Monitor network interface status and configuration
- Handle multiple network interfaces (Ethernet, WiFi)

12.7.4.1.2 Key Features

12.7.4.1.2.1 Web Interface

- **Interactive Configuration:** Web-based form (`changeip.html`) for modifying IP settings
- **Real-time Status:** Display current IP addresses, [DHCP](#) state, and interface information
- **Automatic Redirection:** After configuration changes, the web interface automatically redirects to the new IP address
- **Multi-interface Support:** Handles multiple network interfaces simultaneously

12.7.4.1.2.2 Serial Console Interface

- **Runtime Settings Display:** View current IPv4 settings for all interfaces
- **[DHCP](#) State Monitoring:** Real-time [DHCP](#) client status information
- **Manual Mode Switching:** Change between [DHCP](#) and static modes via console commands
- **Network Link Status:** Monitor physical network connection status

12.7.4.1.2.3 DHCP Client Features

- **Full [DHCP](#) State Machine:** Complete implementation with all [DHCP](#) states
- **[DHCP](#) with Fallback:** Option to fall back to static IP if [DHCP](#) fails
- **Lease Management:** Automatic [DHCP](#) lease renewal and rebinding
- **BOOTP Support:** Fallback to BOOTP protocol when [DHCP](#) is unavailable

12.7.4.1.3 File Structure

- `main.cpp`: Main application with serial console interface and core networking logic
- `web.cpp`: Web server implementation with form handling and IP configuration management
- `ip_util.h`: Utility functions for IP address display and network operations

12.7.4.1.4 Configuration Modes

12.7.4.1.4.1 DHCP Mode

- Automatically obtains IP address from [DHCP](#) server
- Handles lease renewal and network changes
- Supports [DHCP](#) with fallback to static configuration

12.7.4.1.4.2 Static Mode

- Uses pre-configured static IP settings
- Settings stored in configuration flash memory
- Can be configured via web interface or application code

12.7.4.1.4.3 Runtime vs. Persistent Settings

- **Runtime Changes:** Immediate effect without reboot
- **Persistent Changes:** Saved to flash memory and survive reboots
- **Configuration Storage:** Uses built-in configuration server for settings persistence

12.7.4.1.5 Usage Instructions

12.7.4.1.5.1 Changing from DHCP to Static:

1. Access the web interface or serial console
2. Read current static settings from configuration record
3. Set address mode to "Static"
4. Save configuration to flash memory
5. Choose to reboot or apply runtime settings immediately

12.7.4.1.5.2 Changing from Static to DHCP:

1. Access the web interface or serial console
2. Set address mode to "DHCP" or "DHCP w Fallback"
3. Save configuration to flash memory
4. Choose to reboot or restart [DHCP](#) client immediately

12.7.4.1.5.3 Serial Console Commands:

- **1:** Display current runtime IPv4 settings
- **2:** Change to static address mode (without reboot)
- **3:** Change to [DHCP](#) address mode (without reboot)

12.7.4.1.6 Technical Implementation

12.7.4.1.6.1 DHCP State Machine

The application implements a complete [DHCP](#) client state machine with the following states:

- `SDHCP_NOTSTARTED`: System not initialized
- `SDHCP_DISCOVER`: Discovering [DHCP](#) servers
- `SDHCP_OFFER`: Processing server offers
- `SDHCP_ACK`: Acknowledging lease
- `SDHCP_CMPL`: [DHCP](#) lease complete
- `SDHCP_RENEW`: Renewing lease
- `SDHCP_REBIND`: Rebinding after renewal failure
- `SDHCP_RELEASE`: Releasing lease
- `SDHCP_FAILED`: [DHCP](#) process failed

12.7.4.1.6.2 Web Server Integration

- **HTTP Server:** Built-in web server on port 80
- **Form Processing:** POST request handling for configuration changes
- **Dynamic Content:** Real-time display of network interface status
- **Redirect Logic:** Automatic redirection after IP address changes

12.7.4.1.6.3 Network Interface Management

- **Multi-interface Support:** Handles ethernet and WiFi interfaces
- **Interface Discovery:** Automatic detection of available interfaces
- **Configuration Persistence:** Settings saved across reboots
- **Runtime Flexibility:** Changes can be applied with or without reboot

12.7.4.1.7 Optional Features

12.7.4.1.7.1 WiFi Support

- Uncomment `#define USE_WIFI (1)` to enable WiFi functionality
- Requires additional WiFi driver initialization
- Supports dual ethernet/WiFi configurations

12.7.4.1.7.2 Custom Static IP Assignment

- Option to define static IP values in application code
- Alternative to using configuration server settings
- Useful for embedded applications with fixed network requirements

12.7.4.1.8 Dependencies

- NetBurner NNDK (NetBurner Network Development Kit)
- Standard C++ libraries
- NetBurner networking stack
- Configuration server module
- HTTP server module

12.7.4.1.9 Build Configuration

The application uses pragma directives to suppress GCC warnings for NetBurner-specific format specifiers (`HI`, `I`) used in network address printing.

12.7.4.1.10 Network Diagnostics

The application includes comprehensive network diagnostics:

- Interface status monitoring
- Link state detection
- IP address validation
- **DHCP** lease status tracking
- Network connectivity verification

12.8 DNS Client

12.8.1 DNS Client Application

12.8.1.1 Overview

This is a DNS (Domain Name System) client example application for NetBurner embedded devices. The application demonstrates how to resolve domain names to IP addresses using both IPv4 and IPv6 protocols.

12.8.1.2 Features

- **Dual-stack DNS resolution:** Supports both IPv4 and IPv6 address resolution
- **Interactive interface:** Prompts user for domain names to resolve via serial terminal
- **Network interface validation:** Automatically checks network configuration before attempting DNS queries
- **Comprehensive error handling:** Provides detailed error messages for various DNS failure scenarios
- **Real-time network status:** Displays current network interface status and configuration

12.8.1.3 Application Functions

12.8.1.3.1 Core DNS Functions

The application uses three main NetBurner DNS functions:

1. **GetHostByName()** - General DNS resolution (returns first available IP address)
2. **GetHostByName() with IPv4** - Specific IPv4 address resolution
3. **GetHostByName() with IPv6** - Specific IPv6 address resolution (AAAA records)

12.8.1.3.2 Key Components

12.8.1.3.2.1 ExecuteDNSRequest(char *name)

Performs DNS lookups for a given domain name using all three resolution methods:

- General IP resolution
- IPv4-specific resolution
- IPv6-specific resolution (when not compiled with IPV4ONLY flag)

12.8.1.3.2.2 CanInterfaceDoDNS(int ifNumber)

Validates that a network interface has the required configuration for DNS:

- Active network link
- Configured DNS server IP address
- Configured network gateway

12.8.1.3.2.3 UserMain(void *pd)

Main application loop that:

- Initializes the network stack
- Waits for active network connection
- Validates network interface capabilities
- Provides interactive DNS lookup interface

12.8.1.4 Prerequisites

For the application to function properly, your NetBurner device must have:

1. **Active network connection** - Physical link must be established
2. **Valid IP configuration** - IP address, subnet mask, and gateway
3. **DNS server configuration** - Either from [DHCP](#) or static configuration
4. **Internet access** - Required to reach external DNS servers

12.8.1.5 Usage Instructions

12.8.1.5.1 Setup

1. Connect your NetBurner device to the network
2. Start MTTY (NetBurner's terminal program)
3. Connect to the debug serial port
4. Load and run the DNS client application

12.8.1.5.2 Operation

1. The application will display the network interface status
2. If the network is properly configured, you'll be prompted to enter a domain name
3. Type a domain name (e.g., `www.netburner.com`) and press Enter
4. The application will display the resolved IP addresses for IPv4 and IPv6 (if available)

12.8.1.5.3 Example Domain Names to Test

The application suggests several interesting test cases:

- **google.com** - Resolves both IPv4 and IPv6 addresses
- **ipv6.vm1.test-ipv6.com** - IPv6-only resolution
- **www.netburner.com** - NetBurner's website (recommended test)

12.8.1.6 Error Handling

The application provides specific error messages for common DNS failures:

- **DNS_TIMEOUT** - DNS server did not respond within 5 seconds
- **DNS_NOSUCHNAME** - Domain name does not exist
- **Other DNS errors** - Displays error code for debugging

12.8.1.7 Network Interface Diagnostics

The application performs comprehensive network diagnostics:

```
Interface[eth0]:  
Link UP  
Has a DNS address (8.8.8.8)  
Has a Gateway address (192.168.1.1)  
This interface is capable of doing DNS!
```

If any component is missing, it will be flagged as a problem.

12.8.1.8 Compilation Options

- **IPV4ONLY** - Define this flag to disable IPv6 functionality and compile for IPv4-only environments

12.8.1.9 Technical Details

- **DNS timeout:** 5 seconds per query
- **Buffer size:** 128 characters for domain name input
- **Network wait:** Up to 10 seconds for network interface activation
- **System diagnostics:** Enabled for debugging (should be disabled in production)

12.8.1.10 Troubleshooting

12.8.1.10.1 Common Issues

1. **Found no interface capable of doing DNS**

- Check physical network connection
- Verify IP configuration ([DHCP](#) or static)
- Ensure DNS server is configured
- Confirm gateway is set

2. **DNS_TIMEOUT errors**

- Check internet connectivity
- Verify DNS server is reachable
- Check firewall settings

3. **DNS_NOSUCHNAME errors**

- Verify domain name spelling
- Try a known good domain like `google.com`

12.8.1.10.2 Network Configuration

Ensure your NetBurner device has proper network configuration:

- Valid IP address
- Correct subnet mask
- Proper gateway configuration
- DNS server IP address (often provided by [DHCP](#))

12.8.1.11 Application Flow

1. Initialize network stack
2. Enable system diagnostics
3. Wait for active network (up to 10 seconds)
4. Check each network interface for DNS capability
5. If capable interface found, enter interactive mode
6. Accept domain names from user and perform DNS lookups
7. Display results and repeat

This application serves as both a functional DNS client and a diagnostic tool for network connectivity issues on NetBurner embedded devices.

12.9 Embedded Flash File System (EFFS)

Embedded Flash File System (EFFS) examples. There are two types of file systems:

- EFFS FAT: A FAT 32 file system used for flash memory cards
- EFFS STD: A power fail-safe file system that resides in the flash memory of the module itself

Example Catagories:

- [FAT File System \(EFFS-FAT\)](#)
- [Standard File System \(EFFS-STD\)](#)

12.9.1 FAT File System (EFFS-FAT)

EFFS FAT32 Examples:

- [Application Update](#)
- [Basic](#)
- [FTP](#)
- [HTTP](#)
- [HTML Variables](#)
- [Multiple Tasks](#)
- [Performance Tests](#)
- [RAM Drive](#)

12.9.1.1 Application Update

This application demonstrates how to update a NetBurner application in onboard flash memory from an external SD flash card. The application will look for a file on the flash card with the name specified by APPFILENAME. Use MTTTY to monitor the serial output of your NetBurner device. If this file is found, an application update can be performed by typing a character in response to the MTTTY prompt.

Note

All EFFS FAT examples require that you add the Embedded Flash File System File Allocation Table (EFFS FAT) library to your project: [Add a Library to a Project](#)

12.9.1.2 Basic

12.9.1.2.1 EFFS-FAT-Basic File System Example

12.9.1.2.1.1 Overview

This program demonstrates basic file system operations for SD/MMC and Compact Flash cards using the Embedded Flash File System with File Allocation Table (EFFS-FAT) library. The application provides a comprehensive example of external flash storage management on embedded systems.

Note

All EFFS FAT examples require that you add the Embedded Flash File System File Allocation Table (EFFS FAT) library to your project: [Add a Library to a Project](#)

12.9.1.2.1.2 Features

The application demonstrates the following file system operations:

- **Drive Mounting:** Initialize and mount external storage devices
- **Space Management:** Determine used and free file space on the storage device
- **File Creation:** Create new files on the external storage
- **Data Writing:** Write data to files on the storage device
- **Data Reading:** Read data from files on the storage device
- **Drive Unmounting:** Safely unmount the storage device

12.9.1.2.1.3 Supported Storage Types

The application supports multiple storage interfaces:

- **SD/MMC Cards:** Secure Digital and MultiMediaCard support
- **Compact Flash Cards:** CompactFlash card support
- **Multi-drive configurations:** For modules with onboard flash sockets

12.9.1.2.1.4 Hardware Compatibility

The application includes specific support for:

- MOD5441X modules
- SBE70LC modules
- Other NetBurner modules with MMC/SD or CFC interfaces

12.9.1.2.1.5 Program Flow

1. **Initialization:** Network stack initialization and system diagnostics
2. **File System Entry:** Register the current task for file system access
3. **External Flash Initialization:** Initialize the CFC or SD/MMC drive
4. **Status Display:** Show file space usage statistics
5. **Directory Listing:** Display existing files and directories
6. **Read/Write Operations:** Perform file system read and write tests
7. **Cleanup:** Unmount the file system and release resources

12.9.1.2.1.6 Important Notes

File System Access

- The `f_enterFS()` function must be called in every task that accesses the file system
- This function should only be called once per task before any other file system operations
- Up to 10 tasks can simultaneously access the file system (can be increased)
- Tasks can be removed from file system access using `f_releaseFS()`

Web Server Limitations

- For web server functionality with external storage, refer to the EDFS-HTTP example

Library Requirements

Note

All EDFS FAT examples require adding the Embedded Flash File System File Allocation Table (EDFS FAT) library to your project.

12.9.1.2.1.7 Output

The program displays status information through the debug serial port, including:

- Program startup messages
- File system statistics
- Directory contents
- Read/write operation results
- Program completion status

12.9.1.2.1.8 Usage

1. Ensure your NetBurner module has the appropriate external flash interface (SD/MMC or CFC)
2. Insert a compatible flash card into the module
3. Build and deploy the application to your NetBurner module
4. Monitor the debug serial output for program status and results
5. Reset the device to repeat the demonstration

12.9.1.2.1.9 Build Configuration

The application uses preprocessor definitions to determine the storage type:

- `USE_MMC`: Enable MMC/SD card support
- `USE_CFC`: Enable Compact Flash card support
- `MULTI_MMC`: Enable multi-drive MMC support (for specific modules)

12.9.1.2.1.10 File Structure

- `main.cpp`: Main application code with `UserMain()` function
- `ReadMe.txt`: Original documentation
- `FileSystemUtils.h`: Header file for file system utility functions

12.9.1.2.1.11 Error Handling

The application includes proper error handling for:

- File system mounting/unmounting operations
- File access operations
- Network initialization timeouts
- Resource cleanup

Note

After completing all operations, the program enters an infinite loop and must be reset to repeat the demonstration.

12.9.1.3 FTP

This program illustrates file system and FTP operations for SD Flash cards:

- Mounting a flash drive
- Determining amount of used and free file space
- FTP access. We recommend Filezilla or WinScp

Status messages will be sent out the debug serial port.

Modules with an onboard microSD flash socket should use the multi MMC header files and functions because the modules are capable of supporting both onboard and external flash cards (even if your application only uses one).

Note

All EDFS FAT examples require that you add the Embedded Flash File System File Allocation Table (EDFS FAT) library to your project: [Add a Library to a Project](#)

12.9.1.3.1 FTP File System Application

12.9.1.3.1.1 Overview

This application demonstrates file system and FTP operations for SD Flash cards on NetBurner embedded systems. It provides a complete example of mounting flash drives, managing file operations, and enabling FTP access for remote file management.

12.9.1.3.1.2 Features

File System Operations

- Mount and initialize external flash drive
- Display directory contents and file listings
- Read and display text files
- Format flash cards (with confirmation prompt)
- Monitor disk space usage (used/free space statistics)
- Support for both long filenames and 8.3 format

FTP Server

- Built-in FTP server running on port 21
- Remote file access via FTP clients (recommended: FileZilla or WinSCP)
- Concurrent file system access for local operations and FTP
- Task-based priority management for FTP operations

System Features

- Network initialization with [DHCP](#) support
- NTP time synchronization with manual fallback
- Timezone configuration support
- Interactive command-line interface
- System diagnostics and debug output

12.9.1.3.1.3 Supported Hardware

Flash Card Types

- **SD/MMC Cards:** Secure Digital and MultiMediaCard support

Module Compatibility

- **MOD5441X:** Onboard microSD flash socket
- **SBE70LC:** Onboard microSD flash socket
- Other NetBurner modules with external flash card support

12.9.1.3.1.4 Command Interface

The application provides an interactive menu system accessible via the debug serial port:

Command	Description
D	Display Directory - Shows all files and folders on the flash card
E	Display TestFile.txt - Shows contents of the test file
F	Format SD Flash card - Formats the card (WARNING: destroys all data)
S	Display Space usage - Shows used and free space statistics
T	Display system Time - Shows current system time and date
?	Display Menu - Shows the command menu

12.9.1.3.1.5 Time Configuration

The application includes timezone support with examples for US time zones:

```
// Eastern Time
tzsetchar("EST5EDT4,M3.2.0/02:00:00,M11.1.0/02:00:00");

// Central Time
tzsetchar("CST6CDT5,M3.2.0/02:00:00,M11.1.0/02:00:00");

// Mountain Time
tzsetchar("MST7MDT6,M3.2.0/02:00:00,M11.1.0/02:00:00");

// Pacific Time (default)
tzsetchar("PST8PDT7,M3.2.0/02:00:00,M11.1.0/02:00:00");
```

12.9.1.3.1.6 Setup Requirements

Library Dependencies

- **EFS FAT Library:** Embedded Flash File System with File Allocation Table support
- `FatFile` Must be added to your NetBurner Eclipse project before compilation (`libFatFile.a`)

Hardware Setup

1. Insert SD/MMC card into the appropriate socket
2. Ensure network connection for [DHCP](#) and NTP functionality
3. Connect debug serial cable for command interface

Network Configuration

- [DHCP](#) client automatically obtains IP address
- FTP server accessible on port 21
- 5-second timeout for network initialization

12.9.1.3.1.7 File System Architecture

Multi-Drive Support

Modules with onboard microSD sockets use multi-MMC drivers to support both:

- Onboard flash cards
- External flash cards
- Simultaneous access to multiple cards

Task Management

- Main application runs at `MAIN_PRIO`
- FTP server runs at `FTP_PRIO (MAIN_PRIO - 2)`
- Up to 10 tasks can access the file system concurrently
- Each task must call `f_enterFS()` before file operations

12.9.1.3.1.8 Usage Examples

Basic File Operations

1. Start the application
2. Wait for network initialization
3. Use 'D' command to view directory contents
4. Use 'S' command to check available space
5. Use 'E' command to view test file contents

FTP Access

1. Connect FTP client to the device's IP address on port 21
2. Browse and transfer files using standard FTP commands
3. Simultaneous local and remote access is supported

Formatting Flash Cards

1. Use 'F' command from the menu
2. Confirm with 'Y' when prompted
3. **WARNING:** This will erase all data on the card

12.9.1.3.1.9 Technical Notes

- All file system operations require prior call to `f_enterFS()`
- Debug output is sent to the serial port
- System diagnostics are enabled (disable for production)
- NTP synchronization attempts before falling back to manual time setting
- Long filename support depends on compilation flags

12.9.1.3.1.10 Recommended FTP Clients

- **FileZilla:** Free, cross-platform FTP client
- **WinSCP:** Windows-based secure file transfer client

12.9.1.3.1.11 Build Configuration

Compile-time options:

- `USE_MMC`: Enable SD/MMC support
- `USE_CFC`: Enable Compact Flash support
- `MOD5441X` or `SBE70LC`: Enable multi-drive support for onboard sockets
- `F_LONGFILENAME`: Enable long filename support

12.9.1.4 HTTP

12.9.1.4.1 Overview

This example demonstrates how to use the EFS-FAT file system with SD cards. This file system is different than the EFS-STD file system which uses onboard flash chip memory.

Note

All EFS FAT examples require that you add the Embedded Flash File System File Allocation Table (EFS FAT) library to your project: [Add a Library to a Project](#)

12.9.1.4.2 EFS HTTP Application

A NetBurner embedded application that provides HTTP web server and FTP server functionality with SD/MMC/CFC flash card file system support using the EFS-FAT (Embedded Flash File System - File Allocation Table) library.

12.9.1.4.2.1 Overview

This application demonstrates comprehensive file system operations on embedded NetBurner devices, combining local file system management with network-based file access through HTTP and FTP protocols. The application supports multiple flash card types and provides both command-line and web-based interfaces for file operations.

12.9.1.4.2.2 Supported Hardware

The application automatically detects and configures support for different flash card types:

- **MMC/SD Cards:** Standard MultiMediaCard and Secure Digital cards
- **Multi-MMC:** Multiple MMC support for MOD5441X and SBE70LC modules
- **CFC:** CompactFlash Card support
- **SDHC:** Secure Digital High Capacity cards (NANO54415, SB800EX)

12.9.1.4.2.3 Core Features

File System Operations

- **File Management:** Create, read, write, and display text files
- **Directory Operations:** List directory contents and navigate file structure
- **Format Support:** Format flash cards (with data loss warning)
- **Space Monitoring:** Display file system usage statistics
- **File I/O Testing:** Built-in tests for `fgets()`, `fputs()`, and `fprintf()` functions

Network Services

- **HTTP Web Server:** Serves files from flash card with MIME type support
- **FTP Server:** Full FTP access for file upload/download operations
- **NTP Time Sync:** Automatic time synchronization for accurate file timestamps
- **DHCP Support:** Automatic network configuration

Web Interface Features

- **Directory Browsing:** Web-based file and directory listing
- **File Serving:** Direct file access through HTTP URLs
- **MIME Type Support:** Configurable MIME types via `MIME.txt` file or built-in defaults
- **Index Page Priority:** Automatic detection of `index.html` files

12.9.1.4.2.4 Application Structure

Main Components

1. **main.cpp:** Core application logic and command-line interface
2. **web.cpp:** HTTP server callbacks and web interface implementation
3. **Supporting Libraries:** `FileSystemUtils`, `effs_time`, `http_f` modules

Command-Line Interface

The application provides an interactive serial menu with the following options:

Command	Function
D	Display directory contents
E	Display <code>TestFile.txt</code> contents
F	Format SD flash card (destructive operation)
G	Run <code>fgets()</code> test on <code>TestFile.txt</code>
H	Run <code>fputs()</code> test on <code>TestFile.txt</code>
P	Run <code>fprintf()</code> test
S	Display file system space usage
T	Display current system time
?	Display command menu

12.9.1.4.2.5 Network Configuration

HTTP Server

- **Default Port:** 80
- **File Serving:** Direct access to files on flash card
- **Directory Listing:** Append `/DIR` to any URL for directory view
- **MIME Support:** Configurable content types

FTP Server

- **Default Port:** 21
- **Full Access:** Upload, download, and manage files
- **Long Filename Support:** Automatic detection and notification

Time Synchronization

- **Primary:** NTP server synchronization
- **Fallback:** Manual time setting if NTP fails
- **Time Zones:** Configurable (defaults to PST8PDT7)

12.9.1.4.2.6 File System Details

EFS-FAT Integration

- **Multi-Task Support:** Up to 10 tasks can access the file system
- **Thread Safety:** Proper file system entry/exit for each task
- **Drive Management:** Automatic drive selection based on hardware type

MIME Type Handling

The application supports MIME types through two mechanisms:

1. **MIME.txt File:** User-configurable MIME type definitions on the flash card
2. **Built-in Types:** Hard-coded support for common file types:
 - `jpg > image/jpeg`
 - `gif > image/gif`
 - `htm/html > text/html`
 - `xml > text/xml`
 - `css > text/css`
 - `mp4 > video/mp4`

12.9.1.4.2.7 Building and Configuration

Prerequisites

- NetBurner NNDK (NetBurner Network Development Kit)
- EFS-FAT library (FatFile.a)
- Compatible NetBurner hardware platform

Build Configuration

The flash card type is configured in `cardtype.h`. Modify the following defines:

- `USE_MMC`: For MMC/SD card support
- `USE_CFC`: For CompactFlash support
- `USE_SDHC`: For SDHC support
- `MULTI_MMC`: For multiple MMC support

Library Dependencies

Add to your makefile:

```
XTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libFatFile.a
DBXTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libFatFile.a
```

Or in NBEclipse, add "FatFile" to the GCC Linker Libraries.

12.9.1.4.2.8 Usage Examples

Web Interface Access

- **Default Page:** `http://[device-ip]/`
- **Directory Listing:** `http://[device-ip]/DIR`
- **Specific File:** `http://[device-ip]/filename.ext`
- **Subdirectory:** `http://[device-ip]/subdir/DIR`

FTP Access

Connect using any FTP client (e.g., FileZilla):

- **Host:** Device IP address
- **Port:** 21
- **Mode:** Standard FTP

Serial Interface

Connect via terminal emulator (MTTTY, PuTTY, etc.):

- **Baud Rate:** As configured for your NetBurner device
- **Interactive Menu:** Use single-letter commands

12.9.1.4.2.9 File Priority and Web Pages

When accessing the web interface, pages are served in the following priority order:

1. `index.html` file on flash card
2. First available `*.html` file on flash card
3. Generated directory listing page

12.9.1.4.2.10 Technical Specifications

Memory Usage

- **HTTP Buffer:** 32KB aligned buffer for file transfers
- **Temporary Buffer:** 256-byte buffer for line reading operations

Task Priorities

- **HTTP Server:** `HTTP_PRIO`
- **FTP Server:** `FTP_PRIO (MAIN_PRIO - 2)`
- **Main Application:** `MAIN_PRIO`

Performance Considerations

- File system searches occur for each HTTP request when serving from flash card
- For better performance, consider caching file system structure in memory
- `MIME.txt` lookups are not cached; keep the file small and organized by frequency

12.9.1.4.2.11 Error Handling

The application includes comprehensive error handling for:

- File system initialization failures
- Network service startup issues
- File access permissions and availability
- Flash card formatting operations

12.9.1.4.2.12 Security Notes

- FTP server provides full file system access
- Web server can serve any file accessible on the flash card
- Format operation permanently deletes all data
- No authentication mechanisms are implemented in this example

12.9.1.4.2.13 Troubleshooting

Common Issues

1. **File System Not Mounting:** Check flash card insertion and format
2. **NTP Sync Failure:** Verify network connectivity and DNS resolution
3. **FTP Connection Issues:** Check firewall settings and network configuration
4. **Web Pages Not Loading:** Verify file presence and MIME type configuration

Debug Information

The application provides extensive debug output through the serial interface, including:

- URL parsing details
- File system operation results
- Network service status
- MIME type resolution information

Note

If *.html files exist on the flash card, then the program will always access the first available web page file by default.

12.9.1.5 HTML Variables

This example program sets up HTTP access to the FAT file system on SD Flash cards.
To run this example:

1. Compile the example for your chosen flash card in cardtype.h. The NetBurner development board supports SD Flash cards.
2. Copy index.html and MIME.txt from the example's root directory onto your flashcard, or put your own there.
3. When the program runs, status messages will be displayed on the module debug serial port.

4. You can view the files on the flash card with any web browser by typing in the IP address of the module at the "/DIR" folder Example: "http://10.1.1.57/DIR").
5. When accessing the module via browser, what web pages will be displayed depends on the following order and their availability on the flash card:
 - index.html files
 - The first available .html file
 - A web page list of all directories and files that exist on the flash card

Note

If .html files exist on the flash card, then the program will always access the first available web page file by default. If you want to access the web page list of all existing directories and files on the flash card, then you type in the URL of the module, followed by "/dir" (Example: "http://10.1.1.57/dir").

12.9.1.6 Multiple Tasks

This program illustrates basic file system operations for SD Flash cards for multiple tasks:

- Mounting a drive
- Determining amount of used and free file space
- Creating files
- Writing data
- Reading data
- Unmounting a drive

When the program executes it will display program status information through the debug serial port.

Note

All EDFS FAT examples require that you add the Embedded Flash File System File Allocation Table (EDFS FAT) library to your project: [Add a Library to a Project](#)

12.9.1.7 Performance Tests

This example is used to test the speed of the EDFS FAT file system for operations such as file creation and data storage speed. All testing was done on a MOD54415.

Hardware:

- MOD54415-100IR on MOD-DEV-70 development board
- Kingston microSDHC 32GB Class 4, with MidroSC Adapter

Software: NetBurner tools revision 2.8.6 Date: February 7, 2018

Test results for file creation:

- 1 file: 15ms
- 100 files: 32ms
- 1,000 files: 93ms

Test results for data transfer, using 1MB of data:

- Write speed: 0.61 MBytes per second
- Read speed: 2.18 MBytes per second

12.9.1.8 RAM Drive

This program illustrates basic file system operations for RAM drives:

- Mounting a drive
- Determining amount of used and free file space
- Creating files
- Writing data
- Reading data
- Un-mounting a drive

When the program executes it will display program status information through the debug serial port.

This example is similar to the EFFECTS-BASIC example, but uses a RAM drive for the file system. The RAM drive configuration is located in the 'ramdrvMcf.cpp' source file.

To build any of the EFFECTS- examples to use the RAM drive, add the 'ramdrvMcf.cpp' file to the build list and modify 'cardType.h' to define USE_RAM instead of USE_MMC and set the EXT_FLASH_DRV_NUM to the correct RAM drive number.

The RAM drive supports 12, 16 and 32 bit file systems. The most commonly used size is 12-bit, which supports drive sizes from 50k up to 2.8MB. If you change the FAT size, you must make the corresponding change in the function: `int fstat = f_format(RAM_DRV_NUM, F_FAT12_MEDIA);`

To change the RAM drive file size, edit `ramdrv_mcf.cpp`.

Minimum RAM drive file system sizes: FAT12: 50KB (most commonly used) FAT16: 2.8MB FAT32: 32MB

Note

All EFFECTS FAT examples require that you add the Embedded Flash File System File Allocation Table (EFFECTS FAT) library to your project: [Add a Library to a Project](#)

12.9.2 Standard File System (EFFECTS-STD)

Examples for on-chip flash file system:

- [EFFECTS-STD HTTP](#)

12.9.2.1 EFFECTS-STD HTTP

12.9.2.1.1 Overview

This example demonstrates how to use the EFFECTS-STD on-chip flash file system. This file system is different than the EFFECTS-FAT file system which is a FAT32 file system that works with SD Flash cards.

12.9.2.1.1.1 Application Functionality

- Creation of a text file from within the application named "TestFile.txt"
- Display of the text file
- Read/Write test of the text file
- Display of file space and amount used
- Format of the file system
- Read/Write of a diagnostics text file. This will be the data displayed on the System Diagnostics web page if that feature is enabled.

12.9.2.1.1.2 Network Functionality

- NTP is used to set the system time and time zone so that file time stamps are correct.
- HTTP web page interface and file display. If you use FTP to put in your own index.html page, it will be used in place of the example default page.
- FTP Server for file access. You can use client programs such as FileZilla to upload/download files

Note

Running the example in an environment where the device has Internet access will enable the Network Time Protocol (NTP) to automatically set the time. Otherwise, you can set the time manually through the serial port menu.

12.9.2.1.1.3 File System Size

The example provides suggested file system sizes based on the total amount of available flash memory in each product. For example, the MODM7AE70 has a total of 2MB and 128k is allocated in the example. The MOD5441x products has 32MB total flash, and 1MB is used for the file system.

The flash chip configuration header files are located in the "flashChip" folder of the EFFS-STD example:

Platform	Header File	Total Flash	Example EFFS Size
MODM7AE70, SBE70LC	SAME70↔ Q21.h	2MB	128K
MOD54415, MOD54417	MX29GL256↔ F.h	32MB	1MB
NANO54415, SB800EX	MX25L6406↔ E.h	8MB	1MB

Please refer to the header files if you wish to change the size of the file system.

Note

The EFFS-STD manual, "EFFS-STD-R1p91.pdf", is located in the "\nburn\docs" folder.

12.9.2.1.2 Building The Example

12.9.2.1.2.1 NBEclipse With Example Import Feature or Command Line

If you build a new project and use the NBEclipse Example Import feature, all settings will be take care of automatically. If you are building using the example makefile on the command line, the makefile contains all necessary settings.

12.9.2.1.2.2 Adding EFFS-STD Functionality to an Existing NBEclipse Project

There are two steps to add EFFS-STD to your project.

1. Add the StdFFile.a library to the GCC Linker
2. Reserve space in the Flash memory for the file system

The first step is the same for all platforms:

- Right click on your project.
- Navigate to C/C++ Build > Settings > GNC C/C++ Linker > Libraries.
- In the Libraries section, add "StdFFile". Note there is no .a extension.

The second step is described in the following sections.

MODM7AE70, SBE70LC Platforms

The "Locate Application at Fixed Address in Flash" feature must be enabled. This will disable the background Flash erase feature, would will erase the flash file system sectors.

- Right-click on the project and select "Properties"
- Navigate to C/C++ Build > Settings > NB Flashpack > General
- Check the checkbox for "Locate Application at Fixed Address in Flash"

NANO54415, SB800EX Platforms

The CompCode Flag settings are used to reserve space in the memory map for the file system.

- Right click on your project.
- Navigate to C/C++ Build > Settings > NBCompCode > General
- Modify the memory address range field from:
COMPCODEFLAGS = 0x04000 0x800000 // Original
to
COMPCODEFLAGS = 0x04000 0x700000 // Reserve space for file system

The first address parameter is the start of application space, and the second is the start of file system space

MOD54415, MOD54417 Platforms

The CompCode Flag settings are used to reserve space in the memory map for the file system.

- Right click on your project.
- Navigate to C/C++ Build > Settings > NBCompCode > General
- Modify the memory address range field from:
COMPCODEFLAGS = 0xC0040000 0xC2000000 // Original
to
COMPCODEFLAGS = 0xC0040000 0xC1F00000 // Reserve space for file system

The first address parameter is the start of application space, and the second is the start of file system space

12.9.2.1.2.3 Adding EFS-STD Functionality to a Makefile

There are two steps:

1. Add the EFS-STD Library
2. Add the compcode flags (SB800EX, NANO54415, MOD5441x) or enable application fixed address (MODM7AE70, SBE70LC)

Add the EFS-STD Library

```
XTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libStdFFFile.a
DBXTRALIB = $(NNDK_ROOT)/platform/$(PLATFORM)/original/lib/libStdFFFile.a
```

MODM7AE70, SBE70LC Platforms

Enable "Locate Application at Fixed Address in Flash" with: EXTRAPACKARGS += -cflag C:3

NANO54415, SB800EX Platforms

Modify the memory address range field from:

COMPCODEFLAGS = 0x04000 0x800000 // Original

to

COMPCODEFLAGS = 0x04000 0x700000 // Reserve space for file system

MOD54415, MOD54417 Platforms

Modify the memory address range field from:

COMPCODEFLAGS = 0xC0040000 0xC2000000 // Original

to

COMPCODEFLAGS = 0xC0040000 0xC1F00000 // Reserve space for file system

12.9.2.1.3 Running the Example

The application provides access through an interactive serial port menu, web page, and FTP.

12.9.2.1.3.1 Serial Interface

- Run MTTTY or some other serial terminal program and connect to the device
- Status messages will be displayed as well as an interactive menu. If this is the first time the application has been run, the file system will be formatted.
- You can experiment with the various menu options.

12.9.2.1.3.2 Web Server (HTTP)

- The default web page will provide various interactive options and information display.
- Entering the IP address followed by "/DIR" (eg. <http://10.1.1.57/DIR>) will display the file directory
- The web server will display the default page based on what is in the file system in the following order: – The `index.html` (will supersede `index.html` file compiled into the application) – The first available `*.html` file
- Use FTP (see below) to upload your own `index.html` file and it will replace the application default.

12.9.2.1.3.3 FTP Operation

Connection to the device with a FTP client such as FileZilla will enable you to upload, download and view files.

12.10 Ethernet

Ethernet examples:

- [Manual Configuration](#)

12.10.1 Manual Configuration

12.10.1.1 Ethernet Manual Configuration Test Application

12.10.1.1.1 Overview

This application demonstrates how to manually configure Ethernet speed and duplex settings instead of using the default autonegotiation mode. The program provides an interactive command-line interface for testing different Ethernet configurations and includes network diagnostic tools.

12.10.1.1.2 Features

12.10.1.1.2.1 Ethernet Configuration Options

- **Autonegotiation mode** - Automatically negotiates optimal speed and duplex
- **100Mbps Full Duplex** - High-speed bidirectional communication
- **100Mbps Half Duplex** - High-speed unidirectional communication
- **10Mbps Full Duplex** - Standard speed bidirectional communication
- **10Mbps Half Duplex** - Standard speed unidirectional communication

12.10.1.1.2.2 Network Diagnostic Tools

- **ARP Cache Display** - Shows the Address Resolution Protocol cache
- **Network Counters** - Displays various network statistics
- **Ethernet Register Dump** - Shows low-level Ethernet hardware registers
- **Ping Functionality** - Tests network connectivity to specified IP addresses
- **Link Status Monitor** - Displays current Ethernet link state and configuration
- **System Timer** - Shows OS tick counter and uptime

12.10.1.1.3 Usage

12.10.1.1.3.1 Interactive Menu Commands

After starting the application, use these single-character commands:

```
1 - Set Autonegotiate mode
2 - Set 100Mbps Full Duplex
3 - Set 100Mbps Half Duplex
4 - Set 10Mbps Full Duplex
5 - Set 10Mbps Half Duplex
A - Show ARP Cache
C - Show Counters
E - Show Ethernet Registers
P - Ping (Example: "P 192.168.1.1")
W - Show OS Seconds Counter
? - Display Menu
```

12.10.1.1.3.2 Ping Command Examples

- **P** - Ping the default gateway
- **P 192.168.1.1** - Ping a specific IP address
- **P 10.0.0.1** - Ping another specific address

12.10.1.1.4 Technical Details

12.10.1.1.4.1 Platform Support

- Supports NetBurner embedded systems
- Special handling for MCF5441X multi-port Ethernet devices
- Primary port configuration for multi-port devices

12.10.1.1.4.2 Network Protocols

- **IPv4** - Full support with [DHCP](#), static, and auto-IP configuration
- **IPv6** - Complete IPv6 support including:
 - Link-local addresses
 - Router-assigned addresses
 - [DHCP](#) v6 addresses
 - Static addresses
 - DNS configuration

Warning

Manual Ethernet configuration is not available in debug mode. The application will display a warning message when attempting to change settings while debugging.

12.10.1.1.5 File Structure

- `main.cpp` - Main application with command interface and Ethernet configuration
- `ip_util.cpp` - IP address utility functions for display and web interface
- `ip_util.h` - Header file for IP utilities

12.10.1.1.6 Network Information Display

12.10.1.1.6.1 IPv4 Details

- IP address and subnet mask
- Primary and secondary DNS servers
- Default gateway
- Auto-IP configuration status

12.10.1.1.6.2 IPv6 Details

- Link-local addresses
- Router-assigned prefixes
- [DHCP](#) v6 leases with timing information
- Static address assignments
- DNS server information

12.10.1.1.6.3 Interface Status

- Link state (UP/DOWN)
- Current speed (10/100 Mbps)
- Duplex mode (Full/Half)
- MAC address information

12.10.1.1.7 Web Interface

The application includes a web server component that displays network configuration through a browser interface. The web page shows:

- Complete interface information
- Clickable links for IPv4 and IPv6 addresses
- [DHCP](#) lease timing details
- DNS server assignments

12.10.1.1.8 System Requirements

- NetBurner RTOS environment
- Ethernet hardware interface
- Serial port for command interface
- Optional web browser for web interface access

12.10.1.1.9 Notes

- The application waits up to 5 seconds for network initialization on startup
- System diagnostics are enabled by default (should be disabled for production)
- All network interfaces are automatically detected and configured
- Link status is continuously monitored and displayed

12.11 Exception Try/Catch

12.11.1 Exception Try/Catch Application

12.11.1.1 Overview

This example program demonstrates how to use C++ exceptions in an embedded NetBurner RTOS environment. The application throws a runtime exception and catches it, displaying the error message to stdout for debugging purposes.

12.11.1.2 Application Details

Application Name:** ExceptionTryCatch

The main application performs the following operations:

1. Initializes the system and enables diagnostics
2. Waits for network connectivity (5 second timeout)
3. Throws a `runtime_error` exception with the message "Error"
4. Catches the exception and displays the error message
5. Enters an infinite loop with 1-second delays

12.11.1.3 Key Features

- Demonstrates proper C++ exception handling with try/catch blocks
- Uses standard C++ exception types (`runtime_error`, `exception`)
- Integrates with NetBurner RTOS system initialization
- Outputs results to stdout for debugging via MTTY on the debug serial port

12.11.1.4 Output

When run, the application will display:

```
Throwing an exception...  
An exception occurred. Exception: Error
```

12.11.1.5 Compilation Requirements

Note

C++ exceptions are disabled by default in NetBurner applications to keep application size small. To use exceptions, you must enable them during compilation.

12.11.1.5.1 Required Compiler Flags

The following flags must be added to the GNU C++ compiler options:

- `-fexceptions` - Enables C++ exception handling
- `-frtti` - Enables Run-Time Type Information (required for exceptions)

12.11.1.5.2 How to Enable Exceptions

1. Right-click on your project in the IDE
2. Select "Properties"
3. Navigate to "GNU C++ Compiler"
4. Select "Miscellaneous"
5. In the "Other Flags" field, add: `-fexceptions -frtti`

Warning

If these flags are not enabled, the compiler will notify you in the output console window.

12.11.1.6 Dependencies

- NetBurner RTOS headers ([init.h](#), [nbrtos.h](#))
- Standard C++ iostream library
- Standard C++ exception handling

12.11.1.7 Usage

This example is primarily educational and demonstrates the proper setup and usage of C++ exceptions in a NetBurner embedded environment. The output can be monitored using MTTTY connected to the debug serial port.

12.11.1.8 Development Notes

- System diagnostics are enabled in this example but should be removed for production code
- The application waits for network connectivity before proceeding
- Exception handling adds overhead, so consider the trade-offs for production applications

12.12 External IRQ

12.12.1 External IRQ Example

12.12.1.1 Overview

This example application demonstrates how to configure and use external interrupt (IRQ) functionality on NetBurner embedded platforms. The program sets up a GPIO pin to trigger an external interrupt, allowing you to test interrupt handling in real-time through a simple serial terminal interface.

12.12.1.2 Supported Platforms

- **MOD5441x** (MOD54415, MOD54417, SB800EX)
- **NANO54415**
- **MODM7AE70**
- **SBE70LC**
- **SOMRT1061**

12.12.1.3 Hardware Setup

12.12.1.3.1 Required Connection

A **jumper wire** must be placed between the GPIO output pin and the desired interrupt input pin for each platform:

12.12.1.3.1.1 MOD5441x Platforms

- **GPIO Output:** J2.33
- **Available IRQ Inputs:**
 - IRQ 1: J2.45
 - IRQ 2: J2.43
 - IRQ 3: J2.26 (default in code)
 - IRQ 6: J2.47

12.12.1.3.1.2 NANO54415

- **GPIO Output:** Pin 12 (Dev board P2.12)
- **Available IRQ Inputs:**
 - IRQ 2: Pin 50 (Dev board P1.50)
 - IRQ 3: Pin 49 (Dev board P1.49) (default in code)

12.12.1.3.1.3 MODM7AE70

- **GPIO Output:** P2.15 (connected to first LED on MOD-DEV-70 board)
- **IRQ Input:** P2.8 (configurable to any GPIO pin)

12.12.1.3.1.4 SBE70LC

- **GPIO Output:** J1[4]
- **IRQ Input:** J1[3]

12.12.1.3.1.5 SOMRT1061

- **GPIO Output:** Pin 86 (connected to first LED on DEV-S61 board)
- **IRQ Input:** Pin 14

12.12.1.4 How It Works

12.12.1.4.1 Interrupt Mechanism

1. The application configures a GPIO pin as an output (initially high)
2. Another pin is configured as an external interrupt input
3. When you trigger an interrupt via the menu, the GPIO output goes low
4. This transition triggers the external interrupt
5. The Interrupt Service Routine (ISR) executes:
 - Sets the GPIO pin back to high
 - Increments the interrupt counter
6. The main loop displays the current interrupt count

12.12.1.4.2 Interrupt Service Routine (ISR)

The ISR behavior varies by platform:

MCF5441x Platforms (MOD5441x, NANO54415):**

```
void ExternalISR()
{
    // Set GPIO pin high and increment counter
    IrqCounter++;
}
```

ARM Platforms (MODM7AE70, SBE70LC, SOMRT1061):**

```
void ExternalISR(int port, int portPin)
{
    // Records which port/pin triggered the interrupt
    gRxIrqPort = port;
    gRxIrqPortPin = portPin;
    IrqCounter++;
}
```

12.12.1.5 User Interface

The application provides a simple command-line menu accessible via serial terminal (MTTTY or similar):

12.12.1.5.1 Available Commands

- **T** - Trigger interrupt by setting GPIO low
- **?** - Display the main menu
- **Enter** - Display current interrupt count

12.12.1.5.2 Menu Output

```
----- Main Menu -----
T - Trigger interrupt by writing GPIO low
? - Display Menu
<enter> - Display interrupt count

Number of interrupts: [count]
Last Irq: port=[x], pin=[y] // ARM platforms only
```

12.12.1.6 Configuration Options

12.12.1.6.1 IRQ Priority Levels

- **MCF5441x:** Fixed priority levels (1=lowest, 7=highest)
- **ARM Platforms:** Configurable priority (1=highest, 7=lowest, default=4)

12.12.1.6.2 IRQ Trigger Modes (ARM Platforms)

```
#define IRQ_POLARITY_HIGH_LEVEL    2
#define IRQ_POLARITY_RISING_EDGE  1
#define IRQ_POLARITY_EITHER_EDGE  0
#define IRQ_POLARITY_FALLING_EDGE -1 // Used in example
#define IRQ_POLARITY_LOW_LEVEL    -2
```

12.12.1.7 Building and Running

1. **Hardware Setup:** Connect jumper wire between GPIO output and IRQ input pins
2. **Compile:** Build the project using NetBurner development tools
3. **Deploy:** Flash the application to your NetBurner module
4. **Connect:** Use MTTTY or serial terminal (115200 baud) to interact
5. **Test:** Use menu commands to trigger interrupts and monitor counts

12.12.1.8 Key Functions Used

- `SetPinIrq()` - Configures pin for external interrupt detection
- `SetPortIrqPriority()` - Sets interrupt priority level (ARM platforms)
- GPIO pin configuration functions (platform-specific)

12.12.1.9 Important Notes

- The Edge Port Flag Register is automatically cleared by the `SetPinIrq()` implementation
- On ARM platforms, all GPIO pins on the same port share the same IRQ priority level
- The example uses falling edge detection by default on ARM platforms
- System diagnostics are enabled for debugging (remove for production)

12.12.1.10 Troubleshooting

- **No interrupts triggered:** Verify jumper wire connections
- **Unexpected behavior:** Check that only one IRQ input is uncommented in the code
- **Serial issues:** Ensure correct baud rate (115200) and terminal settings

This example serves as a foundation for implementing external interrupt handling in your own NetBurner applications.

12.13 Extra FD Circular Buffer

12.13.1 NetBurner Extra File Descriptor Circular Buffer

12.13.1.1 Overview

This application demonstrates how to implement a custom I/O device using NetBurner's Extra File Descriptor system. The example creates a circular buffer that can be accessed using standard file operations like `read()` and `write()`, making it behave like any other file descriptor in the system. The Extra File Descriptors are defined in the `'iointernal.h'` header file.

Note

If you have an I/O device and wish to use interrupts, after adding the appropriate interrupt code that is specific to your device, you would use `USER_ENTER_CRITICAL` and `USER_EXIT_CRITICAL` to protect the internal data structures.

12.13.1.2 Key Features

- **Custom I/O Device:** Implements a circular buffer as a file descriptor
- **Thread-Safe Operations:** Uses critical sections for multi-task safety
- **Overwrite Mode:** Configurable buffer overflow handling
- **Terminator-Based Flushing:** Intelligent buffer management for line-based data
- **Standard File Operations:** Compatible with `read()`, `write()`, and `fdprintf()`

12.13.1.3 Architecture

12.13.1.3.1 Core Components

1. **CircularBufferObject:** Main data structure containing:

- Read/write indices for buffer management
- Data buffer pointer and size
- Critical section for thread safety
- Overwrite configuration settings

2. **I/O Functions:**

- `CircularBufferRead()`: Reads data from the circular buffer
- `CircularBufferWrite()`: Writes data to the circular buffer
- `CircularBufferClose()`: Cleanup when closing the file descriptor

3. **Utility Functions:**

- `CircularBufferInit()`: Initializes the buffer and returns a file descriptor
- `CircularBufferFlushBytes()`: Flushes data up to a terminator byte
- `CircularBufferRawPrint()`: Debug function to display raw buffer contents

12.13.1.3.2 Buffer Management

The circular buffer uses two indices:

- **Read Index:** Points to the next byte to be read
 - **Write Index:** Points to the next position for writing
- Buffer States**:
- Empty: `readIndex == writeIndex`
 - Full: `(writeIndex + 1) % bufferSize == readIndex`

12.13.1.4 Configuration Options

12.13.1.4.1 Overwrite Mode

- **Enabled:** When buffer is full, old data is automatically overwritten
- **Disabled:** Write operations fail when buffer is full

12.13.1.4.2 Terminator Byte

When overwrite mode is enabled, you can specify a terminator byte (e.g., `'` for line-based data). When the buffer becomes full, data is flushed up to this terminator instead of byte-by-byte, making it ideal for line-oriented protocols.

12.13.1.5 Usage Example

```
// Initialize buffer
const uint32_t bufferSize = 256;
char dataBuffer[bufferSize];
CircularBufferObject circBuffer;

// Create file descriptor with overwrite enabled and newline terminator
int fd = CircularBufferInit(&circBuffer, dataBuffer, bufferSize, true, '\n');

// Write data
fdprintf(fd, "Hello World\n");

// Read data
char readBuffer[100];
int bytesRead = read(fd, readBuffer, sizeof(readBuffer));
```

12.13.1.6 Test Functions

The application includes two test functions:

12.13.1.6.1 TestBufferFull()

Demonstrates buffer overflow behavior by writing more data than the buffer can hold, then reading it back to show how the system handles full buffer conditions.

12.13.1.6.2 TestBufferLineMode()

Tests the terminator-based flushing feature by sending line-terminated messages and displaying the raw buffer contents to show how data is managed.

12.13.1.7 File Descriptor Status Management

The implementation uses NetBurner's file descriptor status functions:

- `SetDataAvail (fd) / ClrDataAvail (fd)`: Indicates data ready for reading
- `SetWriteAvail (fd) / ClrWriteAvail (fd)`: Indicates space available for writing
- `SetHaveError (fd) / ClrHaveError (fd)`: Error status management

These functions are interrupt-safe and integrate with NetBurner's I/O system.

12.13.1.8 Thread Safety

All buffer operations are protected by critical sections using NetBurner's `OS_CRIT` class, ensuring safe operation in multi-task environments.

12.13.1.9 Debug Features

- Compile-time debug flag (`circBufDebug`) for detailed operation logging
- Raw buffer print function for visualizing buffer contents
- Detailed status reporting during read/write operations

12.13.1.10 Configuration

Key configuration parameters in `main.cpp`:

- `dataBufferSize`: Buffer size (set to 10 for testing, increase for production)
- `enableOverwrite`: Set to `true` for automatic overwrite mode
- `overwriteTermByte`: Terminator character for intelligent flushing

12.13.1.11 Integration Notes

This example demonstrates the NetBurner Extra File Descriptor system defined in `iointernal.h`. The same pattern can be used to create custom I/O devices for:

- Serial communication protocols
- Custom data logging
- Inter-task communication buffers
- Hardware device abstraction

12.13.1.12 Files

- `main.cpp`: Main application and test functions
- `ExtraFdCircBuffer.h`: Header file with structure definitions
- `ExtraFdCircBuffer.cpp`: Implementation of circular buffer operations

12.14 FileDescriptor

These series of examples provide code utilizing file descriptors.
JSON Examples:

- [Extra FD Circular Buffer](#)
- [FDBuffer](#)
- [fdprintf - printf to file descriptor](#)
- [FdToNBString](#)

12.15 Extra FD Circular Buffer

12.15.1 NetBurner Extra File Descriptor Circular Buffer

12.15.1.1 Overview

This application demonstrates how to implement a custom I/O device using NetBurner's Extra File Descriptor system. The example creates a circular buffer that can be accessed using standard file operations like `read()` and `write()`, making it behave like any other file descriptor in the system. The Extra File Descriptors are defined in the '`iointernal.h`' header file.

Note

If you have an I/O device and wish to use interrupts, after adding the appropriate interrupt code that is specific to your device, you would use `USER_ENTER_CRITICAL` and `USER_EXIT_CRITICAL` to protect the internal data structures.

12.15.1.2 Key Features

- **Custom I/O Device:** Implements a circular buffer as a file descriptor
- **Thread-Safe Operations:** Uses critical sections for multi-task safety
- **Overwrite Mode:** Configurable buffer overflow handling
- **Terminator-Based Flushing:** Intelligent buffer management for line-based data
- **Standard File Operations:** Compatible with `read()`, `write()`, and `fdprintf()`

12.15.1.3 Architecture

12.15.1.3.1 Core Components

1. **CircularBufferObject**: Main data structure containing:

- Read/write indices for buffer management
- Data buffer pointer and size
- Critical section for thread safety
- Overwrite configuration settings

2. **I/O Functions**:

- `CircularBufferRead()`: Reads data from the circular buffer
- `CircularBufferWrite()`: Writes data to the circular buffer
- `CircularBufferClose()`: Cleanup when closing the file descriptor

3. **Utility Functions**:

- `CircularBufferInit()`: Initializes the buffer and returns a file descriptor
- `CircularBufferFlushBytes()`: Flushes data up to a terminator byte
- `CircularBufferRawPrint()`: Debug function to display raw buffer contents

12.15.1.3.2 Buffer Management

The circular buffer uses two indices:

- **Read Index**: Points to the next byte to be read
- **Write Index**: Points to the next position for writing

Buffer States**:

- **Empty**: `readIndex == writeIndex`
- **Full**: `(writeIndex + 1) % bufferSize == readIndex`

12.15.1.4 Configuration Options

12.15.1.4.1 Overwrite Mode

- **Enabled**: When buffer is full, old data is automatically overwritten
- **Disabled**: Write operations fail when buffer is full

12.15.1.4.2 Terminator Byte

When overwrite mode is enabled, you can specify a terminator byte (e.g., `'\n'` for line-based data). When the buffer becomes full, data is flushed up to this terminator instead of byte-by-byte, making it ideal for line-oriented protocols.

12.15.1.5 Usage Example

```
// Initialize buffer
const uint32_t bufferSize = 256;
char dataBuffer[bufferSize];
CircularBufferObject circBuffer;

// Create file descriptor with overwrite enabled and newline terminator
int fd = CircularBufferInit(&circBuffer, dataBuffer, bufferSize, true, '\n');

// Write data
fdprintf(fd, "Hello World\n");

// Read data
char readBuffer[100];
int bytesRead = read(fd, readBuffer, sizeof(readBuffer));
```

12.15.1.6 Test Functions

The application includes two test functions:

12.15.1.6.1 TestBufferFull()

Demonstrates buffer overflow behavior by writing more data than the buffer can hold, then reading it back to show how the system handles full buffer conditions.

12.15.1.6.2 TestBufferLineMode()

Tests the terminator-based flushing feature by sending line-terminated messages and displaying the raw buffer contents to show how data is managed.

12.15.1.7 File Descriptor Status Management

The implementation uses NetBurner's file descriptor status functions:

- `SetDataAvail (fd) / ClrDataAvail (fd)`: Indicates data ready for reading
- `SetWriteAvail (fd) / ClrWriteAvail (fd)`: Indicates space available for writing
- `SetHaveError (fd) / ClrHaveError (fd)`: Error status management

These functions are interrupt-safe and integrate with NetBurner's I/O system.

12.15.1.8 Thread Safety

All buffer operations are protected by critical sections using NetBurner's `OS_CRIT` class, ensuring safe operation in multi-task environments.

12.15.1.9 Debug Features

- Compile-time debug flag (`circBufDebug`) for detailed operation logging
- Raw buffer print function for visualizing buffer contents
- Detailed status reporting during read/write operations

12.15.1.10 Configuration

Key configuration parameters in `main.cpp`:

- `dataBufferSize`: Buffer size (set to 10 for testing, increase for production)
- `enableOverwrite`: Set to `true` for automatic overwrite mode
- `overwriteTermByte`: Terminator character for intelligent flushing

12.15.1.11 Integration Notes

This example demonstrates the NetBurner Extra File Descriptor system defined in `iointernal.h`. The same pattern can be used to create custom I/O devices for:

- Serial communication protocols
- Custom data logging
- Inter-task communication buffers
- Hardware device abstraction

12.15.1.12 Files

- `main.cpp`: Main application and test functions
- `ExtraFdCircBuffer.h`: Header file with structure definitions
- `ExtraFdCircBuffer.cpp`: Implementation of circular buffer operations

12.15.2 FDBuffer

12.15.2.1 NetBurner FDBuffer Example

12.15.2.1.1 Overview

This example demonstrates how to use the NetBurner FDBuffer class to capture and manipulate data from file descriptors (fd) that would normally be used for direct I/O operations. The FDBuffer class allows you to intercept data streams and store them in a local buffer for debugging, logging, or further processing.

12.15.2.1.2 Purpose

Many NetBurner libraries utilize file descriptors for data input/output transmission, including:

- TCP connections
- WebSockets
- HTTP communications
- FTP transfers
- Email operations
- Serial communications
- Configuration system

This example shows how to capture I/O data from an fd to a buffer instead of using the fd as originally intended by a library. This technique is particularly useful for:

- Debugging network communications
- Logging system data
- Capturing configuration information
- Storing data for later transmission or processing

12.15.2.1.3 How It Works

The application demonstrates capturing the system's configuration JSON object using an FDBuffer:

1. **Initialization**: The application initializes the network stack and starts the HTTP server
2. **Buffer Setup**: Creates an FDBuffer object and associated data buffer
3. **Data Capture**: Uses the config system to write JSON data to the FDBuffer instead of directly to a socket or serial port
4. **Data Retrieval**: Reads the captured data from the FDBuffer into a local buffer
5. **Data Output**: Displays the captured JSON configuration data via serial output

12.15.2.1.4 Key Components

12.15.2.1.4.1 FDBuffer Class

- Defined in `fd_adapter.h`
- Associates a buffer with a file descriptor
- Supports standard file descriptor functions: `read()`, `write()`, `close()`
- By default, can dynamically allocate up to 20 pool buffers
- Each pool buffer stores `ETHER_BUFFER_SIZE` (1548) bytes
- Total default storage capacity: 30,960 bytes
- Storage limit can be increased by modifying `MAX_FDBUFFER_FIFO_BUFFERS` macro

12.15.2.1.4.2 Application Features

- **Pretty Print Option:** Toggle between formatted JSON (with indentation) and compact single-line output
- **Buffer Management:** Proper allocation, usage, and cleanup of file descriptors
- **Error Handling:** Checks buffer size constraints and provides appropriate error messages
- **Dual Output Methods:** Demonstrates both direct fd writing and printf-style output

12.15.2.1.5 Code Structure

12.15.2.1.5.1 Main Functions

1. **UserMain():** Primary application entry point
 - Initializes network stack and HTTP server
 - Sets up FDBuffer and data buffer
 - Captures config JSON data
 - Outputs captured data to serial port
2. **Buffer Operations:**
 - `myFdbufferObject.GetActiveFD()`: Allocates file descriptor
 - `root.RenderToFd()`: Writes config JSON to FDBuffer
 - `myFdbufferObject.SpaceUsed()`: Returns stored data size
 - `read()`: Reads data from FDBuffer to local buffer
 - `close()`: Releases file descriptor back to pool

12.15.2.1.5.2 Configuration Variables

- `dataBufferSize`: Size of local data buffer (4096 bytes)
- `prettyPrint`: Boolean flag for JSON formatting style

12.15.2.1.6 Usage Examples

12.15.2.1.6.1 Basic Usage

The application automatically captures and displays the system configuration JSON when started.

12.15.2.1.6.2 Alternative Streaming Method

The code includes an alternative approach that streams directly to stdout without using a local buffer:

```
int stdout_fd = CurrentStdioFD(1);
myFdbufferObject.StreamTo(stdout_fd);
```

12.15.2.1.7 Build Requirements

- NetBurner NNDK (Network Development Kit)
- Compatible NetBurner hardware platform
- Standard NetBurner libraries and headers

12.15.2.1.8 Key Headers Required

- `predef.h`: Platform definitions
- `config_obj.h`: Configuration system
- `fdprintf.h`: File descriptor printf functions
- `iointernal.h`: I/O internal functions

12.15.2.1.9 Error Handling

The application includes error checking for:

- Buffer size limitations
- File descriptor allocation
- Data read/write operations
- Network initialization timeouts

12.15.2.1.10 Best Practices Demonstrated

1. **Memory Management:** Proper clearing of buffers and FDBuffer objects
2. **Resource Cleanup:** Closing file descriptors after use to return them to the pool
3. **Error Checking:** Validating buffer sizes and operation return values
4. **Documentation:** Clear comments explaining each operation

12.15.2.1.11 Potential Applications

This technique can be extended for:

- Network packet inspection
- Configuration backup to persistent storage (flash, SD card)
- Remote data transmission (email, syslog, FTP)
- Real-time debugging and monitoring
- Data logging and analysis

12.15.3 fdprintf - printf to file descriptor

12.15.3.1 fdprintf Example Application

12.15.3.1.1 Overview

This application demonstrates the use of file descriptors for serial port communication using the NetBurner RTOS platform. It showcases how to close, open, and print to file descriptors, specifically focusing on serial port operations with formatted output.

Note

While this example uses a serial file descriptor, `fdprintf()` can be used with any file descriptor, such as dynamic web page output. A serial port is used here for simplicity, but the web examples make extensive use of `fdprintf()`.

12.15.3.1.2 Functionality

The application performs the following operations:

1. **Serial Port Initialization:** Configures and opens serial ports for data communication and debug output
2. **File Descriptor Management:** Demonstrates proper handling of file descriptors for serial communication
3. **Formatted Output:** Uses `fdprintf()` to send formatted data to serial ports
4. **Network Integration:** Initializes HTTP server and waits for network connectivity
5. **Continuous Operation:** Runs in a loop, outputting timestamp data every second

12.15.3.1.3 Configuration

12.15.3.1.3.1 Serial Port Settings

- **Data Serial Port:** Port 0
- **Debug Serial Port:** Port 0 (shared with data port in this example)
- **Baud Rate:** 115200 bps
- **Data Bits:** 8
- **Stop Bits:** 1
- **Parity:** None

12.15.3.1.3.2 Network Settings

- **Network Timeout:** 5 seconds wait for active network connection
- **HTTP Server:** Enabled

12.15.3.1.4 Key Features

12.15.3.1.4.1 File Descriptor Operations

- Opens serial ports using `OpenSerial()`
- Closes existing serial connections with `SerialClose()`
- Manages separate file descriptors for data and debug output
- Replaces standard I/O streams (stdin, stdout, stderr) with custom file descriptors

12.15.3.1.4.2 Output Functionality

- Sends formatted timestamp data every second
- Uses `fdprintf()` for formatted output to specific file descriptors
- Outputs current system time in seconds with carriage return and line feed

12.15.3.1.4.3 System Integration

- Initializes NetBurner system components
- Enables system diagnostics (recommended to disable for production)
- Integrates with HTTP server functionality
- Waits for network connectivity before main operation

12.15.3.1.5 Code Structure

12.15.3.1.5.1 Main Components

1. **Global Variables:**

- `fddebug`: File descriptor for debug output
- `fdserial`: File descriptor for serial data I/O

2. **InitializeSerialPorts():**

- Configures serial port settings
- Opens communication channels
- Redirects standard I/O streams

3. **UserMain():**

- Main application entry point
- Initializes system components
- Runs continuous operation loop

12.15.3.1.6 Usage

The application automatically:

1. Initializes the NetBurner system
2. Starts HTTP server
3. Waits for network connectivity
4. Configures serial ports
5. Begins continuous timestamp output

12.15.3.1.7 Output Format

The application outputs timestamps in the following format:

`Secs: [timestamp]`

Where `[timestamp]` is the current system time in seconds since startup.

12.15.3.1.8 Development Notes

- System diagnostics are enabled by default (consider disabling for production)
- Both data and debug ports use the same serial port (Port 0) in this configuration
- The application demonstrates proper file descriptor management for embedded systems
- Standard I/O streams are redirected to custom file descriptors for better control

12.15.4 FdToNBString

12.15.4.1 File Descriptor to NBString Example

12.15.4.1.1 Overview

This NetBurner application demonstrates how to capture file descriptor I/O data to an [NBString](#) object instead of using the file descriptor as originally intended by a library. This technique is useful for logging, debugging, or printing data to serial output.

The example utilizes the `NBStringBuilder` class which associates a buffer with a file descriptor that can then be used with API's that utilize file descriptors. The `NBStringBuilder` class is defined in [nbstring.h](#). The `NBStringBuilder` class supports the use of file descriptor functions defined in [iosys.h](#) such as: [read\(\)](#), [write\(\)](#), and [close\(\)](#).

12.15.4.1.2 Purpose

Many NetBurner libraries utilize file descriptors (fd) for data input/output transmission, including:

- TCP
- WebSockets
- HTTP
- FTP
- Serial communication
- Configuration system

This example shows how to redirect file descriptor data to a local [NSString](#) variable for further processing.

12.15.4.1.3 Key Components

12.15.4.1.3.1 NSStringBuilder Class

- Associates a buffer with a file descriptor
- Defined in [nbsstring.h](#)
- Supports standard file descriptor functions from [iosys.h](#) (read, write, close)
- Enables capturing fd data to [NSString](#) objects

12.15.4.1.3.2 System Diagnostics Integration

- Uses [EnableSystemDiagnostics\(\)](#) to maintain a diagnostics data set as JSON
- Demonstrates writing diagnostics data to an [NSString](#) instead of TCP socket or serial
- Default diagnostics data set is approximately 2.6KB but can grow based on:
 - Number of tasks
 - Socket usage
 - User-defined variables in diagnostic set

12.15.4.1.4 Application Flow

1. Initialization

- Network stack initialization
- Enable system diagnostics
- Start HTTP server on port 80
- Wait for active network connection

2. User Interaction

- Prompts user to press any key to print system diagnostics
- Waits for user input via [getchar\(\)](#)

3. Data Capture Process

- Reserves 8KB buffer space (overkill for default diagnostics but safe)
- Allocates file descriptor from fd pool
- Writes system diagnostics data to NSStringBuilder object
- Moves data from NSStringBuilder to [NSString](#) variable
- Closes the allocated file descriptor

4. Output

- Prints captured diagnostics data to serial output
- Data is now available for other uses (storage, transmission, etc.)

12.15.4.1.5 Memory Considerations

- **Buffer Size:** 8192 bytes (8KB) reserved for diagnostics data
- **Default Size:** ~2.6KB for basic diagnostics
- **Growth Factors:** Additional tasks, sockets, and user variables increase size

12.15.4.1.6 Potential Use Cases

Once captured in an `NBString`, the diagnostics data can be:

- Stored to persistent storage (flash memory, SD card)
- Transmitted remotely (email, syslog, FTP)
- Logged for debugging purposes
- Processed or filtered before use

12.15.4.1.7 Key APIs Used

- `EnableSystemDiagnostics()` - Enables system diagnostic data collection
- `NBStringBuilder::reservespace()` - Allocates buffer space
- `NBStringBuilder::GetActiveFD()` - Gets file descriptor for the builder
- `pDiagServer()` - Writes diagnostics data to specified file descriptor
- `NBStringBuilder::moveTo()` - Transfers data to `NBString` object
- `close()` - Closes file descriptor

12.15.4.1.8 Network Features

- HTTP server enabled on default port 80
- Waits up to 5 seconds for active network connection
- Network stack fully initialized before main loop

12.15.4.1.9 Usage

1. Build and deploy the application to NetBurner hardware
2. Connect to the device via serial terminal
3. Press any key when prompted to capture and display system diagnostics
4. The diagnostics JSON data will be printed to the serial output

12.16 FTP

FTP can be run with or without a file system. The examples in this section do not use a file system. These are useful for applications such as:

- Simple download of data as a file by a FTP client, such as measurement readings.
- Updating an application image.
- Viewing web or interface data in a file format.

Since there is no file system, these examples use callback functions to handle the various FTP transactions, such as reading, writing and listing a file. If you do not wish to use the callback scheme, please refer to the file system examples described below.

Examples of FTP using a file system take advantage of the Embedded Flash File System (EFFS). These examples are located in the "\nburn\examples\EFFS" folder. There are two types of file systems:

- EFFS FAT (File Allocation Table), which is a FAT32 file system used by external flash cards.
- EFFS STD (Standard File System), which is a custom file system that runs in the onboard flash memory of the NetBurner device.

FTP in this section:

- [FTP Client](#)
- [Display HTML Files \(FTPD\)](#)
- [Simple FTP Server \(FTPD\)](#)

12.16.1 FTP Client

12.16.1.1 FTP Client Example

A NetBurner embedded FTP client application that demonstrates basic FTP operations including connecting to a server, directory navigation, file listing, file creation, and file retrieval.

Note

For FTP and SFTP using the EFFS file systems, refer to examples in the \nburn\examples\EFFS folder

12.16.1.1.1 Overview

This application connects to an FTP server and performs the following operations:

1. Establishes an FTP connection to a specified server
2. Changes to a remote directory called "test1"
3. Retrieves and displays the directory listing
4. Creates a sample file named "WriteTest.txt" with test content
5. Reads back the created file and displays its contents

12.16.1.1.2 Features

- FTP server connection with authentication
- Directory navigation and listing
- File upload (creation) capability
- File download and content display
- Error handling and command result validation
- Timeout handling for network operations

12.16.1.1.3 Hardware Requirements

- NetBurner embedded device with network connectivity
- Active network connection

12.16.1.1.4 Software Requirements

- NetBurner RTOS (nbrtos)
- NetBurner system libraries including:
 - `init.h`
 - `system.h`
 - `ftp.h`
 - `string.h`
 - `iosys.h`
 - `netinterface.h`

12.16.1.1.5 Setup Requirements

Before running this application, ensure the following prerequisites are met:

1. **FTP Server Access:** You need access to a functioning FTP server
2. **Authentication:** Valid username and password for the FTP server
3. **Directory Structure:** A directory named "test1" must exist on the FTP server
4. **Permissions:** Write permissions must be granted to the "test1" directory
5. **Configuration:** Update the configuration defines in `main.cpp` (see Configuration section)

12.16.1.1.6 Configuration

Before compiling and running the application, modify the following defines in `main.cpp` to match your FTP server setup:

```
#define SERVER_IP_ADDR "10.1.1.193" // Replace with your FTP server IP
#define FTP_PORT 21 // Standard FTP port (usually 21)
#define USER "username" // Replace with your FTP username
#define PASS "password" // Replace with your FTP password
#define WRITE_TEST_FILE "WriteTest.txt" // Test file name
```

12.16.1.1.7 Application Flow

1. **Initialization:** The application initializes the NetBurner system and waits for an active network connection
2. **FTP Connection:** Establishes a connection to the FTP server using the configured credentials
3. **Directory Change:** Changes to the "test1" directory on the remote server
4. **Directory Listing:** Retrieves and displays the contents of the "test1" directory
5. **File Creation:** Creates a new file "WriteTest.txt" with sample content:
 - "This is a test file"
 - "This is line 2 of the test file"
 - "Last Line"
6. **File Retrieval:** Downloads and displays the contents of the newly created file
7. **Cleanup:** Closes the FTP session and enters an infinite loop

12.16.1.1.8 Key Functions

12.16.1.1.8.1 ShowFileContents(int fdr)

Reads data from a file descriptor and displays it to stdout (debug serial port). Handles the data stream in 255-byte chunks with a 20-second timeout.

12.16.1.1.8.2 UserMain(void *pd)

The main application function that orchestrates all FTP operations. Includes comprehensive error handling and status reporting.

12.16.1.1.9 Error Handling

The application includes robust error handling for:

- FTP session initialization failures
- Directory change failures
- File listing failures
- File creation failures
- File retrieval failures
- Command result validation (expects FTP code 226 for successful operations)

12.16.1.1.10 Output

The application provides detailed console output including:

- Connection status messages
- Directory listing contents
- File creation confirmation
- File content display
- Error messages with specific error codes

12.16.1.1.11 Timeout Configuration

All FTP operations use a 5-second timeout (5 * TICKS_PER_SECOND) to prevent hanging on network issues.

12.16.1.1.12 Production Notes

- The application enables system diagnostics which should be removed for production code
- Consider implementing more sophisticated error recovery mechanisms for production use
- Hardcoded credentials should be replaced with secure configuration methods in production

12.16.1.1.13 Compilation

Compile this application using the NetBurner development tools with the standard NetBurner RTOS libraries linked.

12.16.1.1.14 Troubleshooting

Common issues and solutions:

1. **Connection Failures:** Verify IP address, port, username, and password
2. **Directory Not Found:** Ensure "test1" directory exists on the FTP server
3. **Permission Denied:** Verify write permissions to the target directory
4. **Network Issues:** Check network connectivity and firewall settings
5. **Timeout Errors:** Consider increasing timeout values for slow network connections

12.16.2 Display HTML Files (FTPD)

12.16.2.1 FTPD HTML Expose Application

12.16.2.1.1 Overview

This application creates a read-only FTP server that exposes HTML files from an embedded system as a browsable file system. It's designed for embedded systems using a network stack and provides both web server functionality and FTP access to HTML content.

Note

For FTP and SFTP using the EDFS file systems, refer to examples in the `\nburn\examples\EDFS` folder

12.16.2.1.2 Features

- **FTP Server:** Runs on port 21 with read-only access to HTML files
- **Web Server:** HTTP server running on port 80
- **Network Integration:** Uses [DHCP](#) for automatic IP configuration
- **File System Emulation:** Creates a virtual directory tree from compiled HTML files
- **Cross-Platform Access:** Files accessible via web browsers and FTP clients

12.16.2.1.3 Application Components

12.16.2.1.3.1 Core Functionality

The application initializes a network stack and starts two main services:

1. **HTTP Web Server** - Provides web-based access and status information
2. **FTP Server** - Exposes HTML files as a read-only file system

12.16.2.1.3.2 File System Structure

The application builds a virtual file system from HTML files that are compiled into the application:

- Creates a tree structure with directories and files
- Supports nested directory hierarchies
- File metadata includes size and basic permissions
- Directory navigation follows standard FTP conventions

12.16.2.1.3.3 Key Functions

Network Services

- `UserMain()` - Main application entry point, initializes services
- `webDisplayFtpLink()` - Displays FTP access URL on web pages

Directory Tree Management

- `BuildDirTree()` - Constructs file system tree from HTML data
- `GetDir()` - Locates directories in the virtual file system
- `getDirString()` - Formats file/directory information for FTP clients

FTP Server Callbacks

- `FTPD_ListFile()` - Lists files in a directory
- `FTPD_ListSubDirectories()` - Lists subdirectories
- `FTPD_DirectoryExists()` - Checks if directory exists
- `FTPD_SendFileToClient()` - Transfers files to FTP clients
- `FTPD_FileExists()` - Verifies file existence
- `FTPDSessionStart()` - Handles FTP client connections
- `FTPDSessionEnd()` - Manages session cleanup

12.16.2.1.4 Usage

12.16.2.1.4.1 Accessing Files

1. **Via Web Browser:** Navigate to the device's IP address
2. **Via FTP Client:** Connect to `ftp://[device-ip]` using any FTP client
3. **FTP URL:** The application displays the FTP URL format as `ftp://[ip-address]`

12.16.2.1.4.2 Browser Compatibility

Starting in 2020, some web browsers have begun blocking direct FTP access. In such cases:

- Use dedicated FTP client applications such as FileZilla
- Access files through the web server interface instead

12.16.2.1.4.3 Authentication

The current implementation accepts all FTP connections without password verification. For production use, implement proper authentication in `FTPDSessionStart()`.

12.16.2.1.5 Technical Details

12.16.2.1.5.1 Dependencies

- Network stack initialization (`init.h`)
- FTP server library (`ftpd.h`)
- HTML file system (`htmlfiles.h`)
- Network interface management (`netinterface.h`)

12.16.2.1.5.2 Memory Management

- Dynamic allocation for directory and file structures
- Linked list implementation for file system hierarchy
- Cleanup handled automatically on application termination

12.16.2.1.5.3 Configuration

- FTP Server Port: 21
- HTTP Server Port: 80 (default)
- Task Priority: `MAIN_PRIO - 1` (higher than main task)
- Network Timeout: 5 seconds for `DHCP`

12.16.2.1.5.4 Read-Only Operations

The following FTP operations are supported:

- Directory listing (LIST, NLST)
- File download (RETR)
- Directory navigation (CWD, PWD)
- File existence checking

12.16.2.1.5.5 Unsupported Operations

These FTP operations always return failure:

- File upload (STOR)
- File deletion (DELE)
- Directory creation (MKD)
- Directory deletion (RMD)
- File renaming (RNFR/RNTO)

12.16.2.1.6 System Requirements

- Embedded system with network capability
- Network stack supporting TCP/IP
- Sufficient RAM for file system tree structure
- HTML files compiled into application data

12.16.2.1.7 Development Notes

This is an advanced application requiring knowledge of:

- FTP protocol implementation
- Embedded network programming
- File system navigation concepts
- HTML file management in embedded systems

The complexity primarily involves managing virtual directory structures and handling FTP client requests for file navigation and display.

12.16.2.1.8 Status Output

The application provides diagnostic information via serial port:

- Network initialization status
- FTP server startup confirmation
- IP address assignment
- Session start/end notifications
- System diagnostics (should be disabled for production)

12.16.2.1.9 Example Output

```
Started FTP Server
You can use a web browser to view files at URL "ftp://192.168.1.100"
Building the tree...
Ending session 1
```

12.16.3 Simple FTP Server (FTPD)

12.16.3.1 Simple FTP Server (FTPD) - Trivial Implementation

12.16.3.1.1 Overview

This is a lightweight FTP server implementation designed for NetBurner embedded systems. Unlike traditional FTP servers that rely on file systems, this trivial implementation uses callback functions to handle FTP operations, making it ideal for downloading system information and uploading configuration data without requiring persistent storage.

Note

For FTP and SFTP using the EDFS file systems, refer to examples in the `\nburn\examples\EDFS` folder

12.16.3.1.2 Features

- **No File System Required:** Operates entirely through callback functions
- **Lightweight Design:** Minimal memory footprint suitable for embedded systems
- **Debug Output:** Status messages and data are sent to the debug serial port
- **Fixed File Operations:**
 - Download: Single file named `ReadFile.txt` with customizable content
 - Upload: Accepts ASCII text files named `WriteFile.txt` (displayed via serial port)

12.16.3.1.3 Technical Details

12.16.3.1.3.1 Application Configuration

- **Application Name:** FTPD Trivial
- **FTP Port:** 21 (standard FTP port)
- **Priority:** MAIN_PRIO - 1

12.16.3.1.3.2 Supported Operations

File Download

- **Available File:** `ReadFile.txt`
- **Content:** Fixed string "This will be the contents of `ReadFile.txt`"
- **Customization:** Content can be modified to include dynamic system information

File Upload

- **Accepted File:** `WriteFile.txt` (ASCII text only)
- **Storage:** File content is not stored in memory
- **Output:** Uploaded content is displayed on the debug serial port

Directory Operations

- **Listing:** Returns single file entry for `ReadFile.txt`
- **Permissions:** Simulated as `rw-rw-rw-`
- **Timestamps:** Fixed to "Jan 01 00:00"

12.16.3.1.3.3 Authentication

- **Method:** Basic callback-based authentication
- **Default Behavior:** Accepts any username/password combination
- **Customization:** Authentication logic can be modified in `FTPDSessionStart()`

12.16.3.1.4 Code Structure

12.16.3.1.4.1 Main Functions

- `UserMain()`: Application entry point, initializes and starts FTP server
- `FTPD_ListFile()`: Handles FTP LIST command
- `FTPD_SendFileToClient()`: Manages file download requests
- `FTPD_GetFileFromClient()`: Processes file upload requests
- `FTPD_FileExists()`: Checks file availability
- `FTPD_AbleToCreateFile()`: Validates file creation permissions

12.16.3.1.4.2 Helper Functions

- `getdirstring()`: Formats directory listing entries
- `ShowFileContents()`: Displays uploaded file content to serial port

12.16.3.1.4.3 Unsupported Operations

The following FTP operations return `FTPD_FAIL`:

- Directory creation/deletion
- File deletion
- File renaming
- File size queries
- Subdirectory operations

12.16.3.1.5 Usage

12.16.3.1.5.1 Compilation and Deployment

1. Include required NetBurner headers: `ftpd.h`, `init.h`, `iosys.h`, `nbrtos.h`
2. Compile with NetBurner development tools
3. Deploy to NetBurner device

12.16.3.1.5.2 Testing

1. Connect FTP client to device IP address on port 21
2. Use any username/password (authentication passes by default)
3. Test operations:
 - `ls` or `dir`: Lists `ReadFile.txt`
 - `get ReadFile.txt`: Downloads the fixed content file
 - `put WriteFile.txt`: Uploads file (content displayed on serial port)

12.16.3.1.5.3 Serial Port Monitoring

Use a terminal application like `mtty` to monitor:

- Server startup messages
- File upload content
- Debug information

12.16.3.1.6 Customization

12.16.3.1.6.1 Dynamic Content

Modify the `READ_FILEDATA` constant or the `FTPD_SendFileToClient()` function to provide dynamic system information such as:

- Device status
- Sensor readings
- Configuration parameters
- Log data

12.16.3.1.6.2 Authentication

Enhance the `FTPD_SessionStart()` function to implement:

- User validation against stored credentials
- IP address filtering
- Session logging

12.16.3.1.6.3 File Operations

Extend functionality by:

- Supporting multiple downloadable files
- Implementing file storage for uploads
- Adding configuration file handling

12.16.3.1.7 Dependencies

- NetBurner RTOS
- NetBurner FTP daemon library
- Standard C library functions

12.16.3.1.8 Notes

- This implementation is designed for development and lightweight applications
- Remove `EnableSystemDiagnostics()` call for production deployment
- For file system-based FTP implementations, refer to examples in the `\nburn\examples\FFS` folder
- All FTP operations are logged to the debug serial port for monitoring and troubleshooting

12.16.3.1.9 Related Examples

For more advanced FTP server implementations using the EFS file system, see the NetBurner examples in the EFS folder which provide full file system integration and persistent storage capabilities.

12.17 GDB Debugger

12.17.1 NetBurner GDB Demo Application

12.17.1.1 Overview

This is a simple demonstration application designed to run on NetBurner network-enabled hardware platforms. The application serves as a basic example for testing and using the GDB debugger with NetBurner devices. Debugging can be done two ways:

1. NBEclipse: Debugging is done through the graphical IDE
2. Command Line: Debugging is done from a command prompt using commandline GDP on port 2159

12.17.1.2 Application Description

The GDB Demo application provides a minimal but functional embedded program that:

- Initializes the NetBurner network stack
- Starts a web server on the default port (80)
- Waits for network connectivity through [DHCP](#)
- Continuously displays runtime statistics to the serial console

12.17.1.3 Features

- **Network Initialization:** Automatically configures network settings
- **Web Server:** Built-in HTTP server for web-based interaction
- **System Diagnostics:** Enabled for debugging purposes
- **Runtime Monitoring:** Displays uptime information every 250ms
- **Serial Output:** Provides real-time feedback via default serial port

12.17.1.4 Hardware Requirements

- NetBurner network-enabled hardware platform
- Serial connection for console output
- Network connection (Ethernet)

12.17.1.5 Software Requirements

- NetBurner development environment
- GDB debugger support
- Compatible toolchain for NetBurner platforms

12.17.1.6 Application Behavior

Upon startup, the application will:

1. Initialize the network stack
2. Enable system diagnostics
3. Start the HTTP web server
4. Wait up to 5 seconds for network connectivity
5. Display "GDB Demo Application started" message
6. Enter main loop displaying runtime statistics

12.17.1.7 Console Output

The application continuously outputs the following information:

```
GDB Demo Application started  
Seconds since boot: X, Ticks since boot: Y
```

Where:

- X represents the number of seconds since the application started
- Y represents the system tick count since boot

12.17.1.8 Usage

This application is primarily intended for:

- **Debugging Practice:** Learning to use GDB with NetBurner hardware
- **System Testing:** Verifying basic network and system functionality
- **Development Reference:** Example of minimal NetBurner application structure

12.17.1.9 Development Notes

- System diagnostics are enabled for debugging purposes
- Consider disabling diagnostics for production deployment
- The application runs in an infinite loop for continuous monitoring
- Output update rate is 4 times per second (250ms intervals)

12.17.1.10 File Structure

- `main.cpp` - Main application source code
- `ReadMe.txt` - Original documentation (Doxygen format)

12.17.1.11 Building and Deployment

Follow standard NetBurner development procedures to build and deploy this application to your target hardware platform.

12.18 General Purpose I/O

These general GPIO examples apply to multiple NetBurner platforms. Please refer to the "Example Applications > Platform Specific" section of this document for additional GPIO examples specific to your particular NetBurner platform.

Examples in this section:

- [GPIO Blink](#)
- [General Purpose I/O Service](#)

12.18.1 GPIO Blink

12.18.1.1 GPIO Blink Application

12.18.1.1.1 Overview

The GPIO Blink application is a simple demonstration program that showcases the basic operation of GPIO pins using the NetBurner [PinIO](#) class. This example blinks one of the indicator LEDs on the device carrier board in a continuous loop.

Note

This example uses a bsp include file for LED pin mapping: `#include <bsp_devboard.h> // A project header that contains the mapping of LED pins`

12.18.1.1.2 Application Details

Application Name:** Blink

Purpose:** Basic GPIO pin control demonstration

Target Platform:** NetBurner embedded systems

12.18.1.1.3 Functionality

The application performs the following operations:

1. **System Initialization:** Initializes the NetBurner system and enables system diagnostics
2. **Status Output:** Displays the application name and NNDK revision information via serial output
3. **GPIO Configuration:** Configures LED1 pin as a GPIO output
4. **LED Blinking Loop:** Continuously blinks the LED with the following pattern:
 - Turn LED ON (drive pin LOW) for 1 second
 - Turn LED OFF (drive pin HIGH) for 1 second
 - Repeat indefinitely

12.18.1.1.4 Code Structure

12.18.1.1.4.1 Key Components

- **System Headers:** Includes necessary NetBurner system libraries for initialization, timing, and GPIO control
- **Pin Configuration:** Uses the [PinIO](#) class to configure and control GPIO pins
- **BSP Integration:** Leverages board support package definitions for LED pin mapping
- **RTOS Integration:** Utilizes NetBurner RTOS timing functions for precise delays

12.18.1.1.4.2 Main Functions

- `UserMain()`: The primary application entry point that handles all initialization and the main execution loop
- LED control through direct pin assignment operations
- System diagnostic output for debugging and monitoring

12.18.1.1.5 Hardware Requirements

- NetBurner development board with carrier board
- At least one indicator LED (LED1) available on the carrier board
- Serial connection for viewing diagnostic output

12.18.1.1.6 Technical Notes

This example is intentionally simplified to demonstrate basic GPIO concepts. For more advanced GPIO usage, refer to:

- **GpioServer Example:** More comprehensive GPIO functionality demonstration
- **PinIO Documentation:** Complete API reference for the [PinIO](#) class
- **Platform Specific Examples:** GPIO examples tailored to specific NetBurner platforms

12.18.1.1.7 Build Requirements

- NetBurner NNDK (NetBurner Network Development Kit)
- Compatible NetBurner hardware platform
- Standard NetBurner development environment

12.18.1.1.8 Usage

1. Compile and load the application onto your NetBurner device
2. Connect a serial terminal to view system output
3. Observe LED1 blinking at 1-second intervals
4. Monitor serial output for application name and NNDK version information

12.18.1.1.9 Expected Output

Serial console will display:

```
Application: Blink  
NNDK Revision: [Current NNDK Version]
```

The LED1 indicator will blink continuously with a 1-second on/off cycle.

12.18.1.1.10 Learning Objectives

This example teaches:

- Basic GPIO pin configuration using [PinIO](#) class
- Simple output control for driving LEDs
- NetBurner system initialization procedures
- RTOS timing and delay functions
- Board support package integration

12.18.1.1.11 Further Development

While this example covers basic GPIO output, the [PinIO](#) class supports many additional features including input reading, interrupt handling, and advanced pin functions. Consult the NetBurner documentation for expanded GPIO capabilities and platform-specific implementations. Please refer to the "Example Applications > Platform Specific" section of the NetBurner Documentation for additional GPIO examples specific to your particular NetBurner platform.

12.18.2 General Purpose I/O Service

Example to control GPIO pins through command interface.

12.18.2.1 GPIO Service Application

A NetBurner embedded system application for controlling General Purpose I/O (GPIO) pins through a command-line interface.

Note

For platform-specific GPIO examples and advanced usage, refer to the "Example Applications > Platform Specific" section in the NetBurner Documentation.

12.18.2.1.1 Overview

This application provides a serial command interface for configuring and controlling GPIO signals on NetBurner modules. It sets up a command parser on the default serial port, allowing users to interact with GPIO pins in real-time through simple text commands.

12.18.2.1.2 Features

- Real-time GPIO pin control via serial terminal
- Support for multiple NetBurner platforms with automatic connector detection
- Command history with navigation (Ctrl+D, Ctrl+U, Ctrl+R)
- Interactive help system
- Web server integration for network diagnostics

12.18.2.1.3 Supported Operations

The application supports the following GPIO operations:

- **HI** - Set a pin to logic high (3.3V/5V)
- **LO** - Set a pin to logic low (0V)
- **TGL** - Toggle a pin's current state
- **OUT** - Configure a pin as an output
- **IN** - Configure a pin as an input (high impedance)
- **RD** - Read the current state of a pin
- **HELP** - Display available commands

12.18.2.1.4 Platform Support

The application automatically adapts to different NetBurner platforms:

- **MODM7AE70**: Uses P2 connector with [PinIO::PIN_FN_OUT](#) function
- **NANO54415 & SB800EX**: Uses main connector (Pins) with PIN_GPIO function
- **Other platforms**: Uses J2 connector with PIN_GPIO function

12.18.2.1.5 Hardware Requirements

- NetBurner development module
- Serial terminal connection (debug/status port)
- GPIO-capable pins on the target connector

Warning

Not all pins on every NetBurner device can function as GPIO. Consult your specific device datasheet for GPIO capabilities and pin assignments.

12.18.2.1.6 Software Requirements

- NetBurner NNDK (NetBurner Network Development Kit)
- MTTTY or compatible serial terminal software
- Network connection for web server functionality (optional)

12.18.2.1.7 Building and Installation

1. Build the project using the NetBurner development environment
2. Load the compiled application onto your NetBurner device
3. Connect to the device's debug/status port using a serial terminal
4. The application will automatically start and display the command prompt

12.18.2.1.8 Usage Examples

12.18.2.1.8.1 Basic Pin Control

```
> HI 5          # Set pin 5 high
P2[5]_out: 1

> LO 3          # Set pin 3 low
P2[3]_out: 0

> TGL 7         # Toggle pin 7
P2[7]_out: 1
```

12.18.2.1.8.2 Pin Configuration

```
> OUT 2         # Configure pin 2 as output
> IN 4          # Configure pin 4 as input
> RD 4          # Read pin 4 state
P2[4]_in: 0
```

12.18.2.1.8.3 Interactive Features

- Press **Enter** on empty line to repeat last command
- Use **Ctrl+D** to navigate to previous command in history
- Use **Ctrl+U** to navigate to next command in history
- Use **Ctrl+R** to recall and execute previous command
- Use **Backspace** to edit current command

12.18.2.1.9 Command Reference

Command	Syntax	Description
HI	HI <pin>	Set specified pin to logic high
LO	LO <pin>	Set specified pin to logic low
TGL	TGL <pin>	Toggle pin state (repeatable with Enter)
OUT	OUT <pin>	Configure pin as output driver
IN	IN <pin>	Configure pin as high-impedance input
RD	RD <pin>	Read pin state (repeatable with Enter)
HELP	HELP	Display command help

12.18.2.1.10 Application Architecture

12.18.2.1.10.1 Key Components

- **Command Parser:** Processes serial input and maps to function calls
- **GPIO Abstraction:** Platform-independent pin control interface
- **Command History:** Circular buffer storing recent commands
- **Network Stack:** Built-in web server for diagnostics

12.18.2.1.10.2 Memory Usage

- Command buffers: 5 buffers x 80 characters each
- Read buffer: 256 bytes
- Minimal stack usage for embedded operation

12.18.2.1.11 Network Features

The application includes built-in network functionality:

- HTTP web server on port 80
- **DHCP** client for automatic IP assignment
- System diagnostics accessible via web interface
- 5-second network initialization timeout

12.18.2.1.12 Error Handling

- Graceful handling of invalid commands with "Unrecognized command" message
- Parameter validation for pin numbers
- Safe defaults for missing parameters
- Non-blocking serial input processing

12.18.2.1.13 Development Notes

- All commands are case-insensitive (automatically converted to uppercase)
- Pin numbers are parsed as decimal integers
- The application runs in an infinite loop with 1-second intervals
- Platform-specific macros handle connector and function differences

12.19 I2C

The `examples/I2C` folder contains platform-agnostic [I2C](#) examples for the new [Wire Interface](#).

- Wire
 - [PAC193X](#)
 - [PicKit Serial I2C Demo Board](#)
 - [RV3032 I2C Real-Time Clock](#)
 - [Wire Address Scan](#)
 - SparkFun Qwiic - examples for SparkFun Qwiic devices (compatible with the SOMRT1061 Development board's Qwiic connector)
 - * [SparkFun Qwiic Alphanumeric Display](#)
 - * [SparkFun Qwiic Joystick](#)
 - * [SparkFun Qwiic KeyPad](#)
 - * [SparkFun Qwiic OLED Display](#)

See the `examples/PlatformSpecific` folder for older [I2C](#) examples for each platform:

- [I2C](#) for MCF5441x-based Modules such as MOD5441x, NANO54415, SB800EX
- [I2C](#) for SAME70-based Modules such as MODM7AE70 and SBE70LC

12.19.1 PAC193X

`<examples/I2C/Wire/PAC193X>`

12.19.1.1 PAC193x Energy Monitor

12.19.1.1.1 Overview

This application demonstrates the use of the PAC193x Energy Monitor IC used onboard the SOMRT1061 development platform. The PAC193x is a multi-channel power/energy monitor that provides accurate measurements of voltage, current, power, and energy consumption.

12.19.1.1.2 Hardware Requirements

- SOMRT1061 development board with onboard PAC193x IC
- [I2C](#) interface for communication
- 24.9 milliohm sense resistor (default configuration)

12.19.1.1.3 Features

The application provides comprehensive power monitoring capabilities including:

- **Voltage Monitoring:** Bus voltage measurements in millivolts
- **Current Sensing:** Current measurements in milliamps through sense resistor
- **Power Calculation:** Instantaneous and average power in milliwatts
- **Energy Tracking:** Energy consumption in milliwatt-hours
- **Device Identification:** Product ID, Manufacturer ID, and Revision ID readout

12.19.1.1.4 Application Flow

1. Initialization

- Initialize I2C communication
- Configure PAC193x with default settings
- Read and display device identification information

2. Continuous Monitoring

- Updates all measurement values every 4 seconds
- Displays comprehensive power statistics
- Shows system tick counter for timing reference

12.19.1.1.5 Configuration Details

12.19.1.1.5.1 Default Settings

- **I2C Address:** 0x10
- **Sense Resistor:** 24.9 milliohms
- **Sample Rate:** Configurable (8, 64, 256, or 1024 samples/second)
- **Channels:** Channel 1 active, channels 2-4 disabled
- **Update Interval:** 4 seconds

12.19.1.1.5.2 Register Configuration

- NEG_PWR register: 0x00 (no negative power detection)
- CTRL register: 0x02 (control settings)
- CHANNEL_DIS register: 0x70 (disable channels 2-4)
- SLOW register: 0x20 (timing configuration)

12.19.1.1.6 Measurement Output

The application displays the following measurements:

```
Product      ID: 0x##
Manufacturer ID: 0x##
Revision     ID: 0x##
```

```
Read start:
Voltage      (mV) = ###.#####
Vsense       (mV) = #.#####
Current      (mA) = #.#####
Raw Power    (HEX) = 0x#####
Power        (mW) = #.#####
Avg Power    (mW) = #.#####
Raw Power Acc = 0x#####
Acc Count    = 0x#####
Energy       (mWh) = #.#####
```

12.19.1.1.7 Key Functions

12.19.1.1.7.1 Setup Functions

- `SetupPwrMon()`: Initializes I2C and PAC193x, reads device IDs
- `pwrMon.begin()`: Configures PAC193x registers and performs initial refresh

12.19.1.1.7.2 Measurement Functions

- `UpdateVoltage()`: Reads bus voltage
- `UpdateVsense()`: Reads sense voltage across resistor
- `UpdateCurrent()`: Calculates current from sense voltage
- `UpdatePower()`: Calculates instantaneous power
- `UpdateAvgPower()`: Calculates average power from accumulator
- `UpdateEnergy()`: Calculates energy consumption

12.19.1.1.8 Error Handling

The library includes comprehensive error handling with the following error codes:

- 0: No error
- -1: I2C read communication error
- -2: I2C write communication error
- -3: Invalid sense resistor value (zero or negative)
- -4: Invalid sample rate selection

12.19.1.1.9 Technical Specifications

12.19.1.1.9.1 Voltage Measurement

- **Range:** 0-32V
- **Resolution:** 16-bit
- **LSB:** $32000\text{mV} / 65536 = \sim 0.488\text{mV}$

12.19.1.1.9.2 Current Measurement

- **Method:** Sense voltage across precision resistor
- **Sense Voltage Range:** +/-100mV
- **Resolution:** 16-bit
- **Calculation:** $\text{Current} = (\text{Vsense} / \text{Rsense}) * 1,000,000 \text{ uA}$

12.19.1.1.9.3 Power Measurement

- **Method:** Digital multiplication of voltage and current
- **Resolution:** 28-bit
- **Accumulation:** 48-bit accumulator for average calculations

12.19.1.1.10 Library Architecture

The PAC193x library provides both raw register access and calculated real-world values:

- **Raw Functions:** Direct register values for maximum precision
- **Calculated Functions:** Converted values in standard engineering units
- **Flexible Configuration:** Multiple constructor options for different setups
- **I2C Abstraction:** Compatible with standard Wire library interface

12.19.1.1.11 Usage Example

```
#include "PAC193x.h"

PAC193x pwrMon(Wire, 100000); // Use Wire interface with 100k I2C speed

void setup() {
    Wire.begin();
    pwrMon.begin();

    // Read device information
    pwrMon.UpdateProductID();
    pwrMon.UpdateManufacturerID();
    pwrMon.UpdateRevisionID();
}

void loop() {
    // Update all measurements
    pwrMon.UpdateVoltage();
    pwrMon.UpdateCurrent();
    pwrMon.UpdatePower();
    pwrMon.UpdateEnergy();

    // Access measured values
    float voltage = pwrMon.Voltage; // mV
    float current = pwrMon.Current; // mA
    double power = pwrMon.Power; // mW
    float energy = pwrMon.Energy; // mWh

    delay(1000);
}
```

12.19.1.1.12 File Structure

- `main.cpp`: Main application demonstrating PAC193x usage
- `PAC193x.h`: Library header with class definition and register addresses
- `PAC193x.cpp`: Library implementation with all measurement functions

12.19.2 PicKit Serial I2C Demo Board

12.19.2.1 PicKit I2C Serial Demo Board Application

12.19.2.1.1 Overview

This application demonstrates interfacing with the Microchip PicKit Serial I2C Demo Board using NetBurner's I2C Wire library. The demo showcases communication with 5 different Microchip I2C peripherals connected to the board.

12.19.2.1.2 Supported I2C Peripherals

The application interfaces with the following I2C devices:

1. **24LC0B EEPROM** - 2Kbit (256 x 8) non-volatile memory
2. **MCP9800 Temperature Sensor** - 12-bit resolution temperature measurement
3. **MCP23008 GPIO Port Expander** - 8-bit I/O expander connected to LEDs
4. **TC1321 DAC** - 10-bit Digital-to-Analog Converter (0-2.5V range)
5. **MCP3221 ADC** - 12-bit Analog-to-Digital Converter

12.19.2.1.3 I2C Addressing

The application uses 7-bit I2C addressing as follows:

Device	Datasheet Address	Application Address
24LC0B EEPROM	0xA0	0x50
MCP9800 Temperature	0x92	0x49
MCP23008 GPIO	0x40	0x20

Device	Datasheet Address	Application Address
TC1321 DAC	0x90	0x48
MCP3221 ADC	0x9A	0x4D

Note: The application right-shifts datasheet addresses by 1 to remove the R/W bit for NetBurner [I2C](#) compatibility.*

12.19.2.1.4 Features

12.19.2.1.4.1 Interactive Menu System

The application provides a serial console menu with the following options:

- **1** - Erase EEPROM (fills with 0xFF)
- **2** - Read EEPROM (displays all 256 bytes)
- **3** - Write incrementing sequence to EEPROM (0x00-0xFF)
- **A** - Read ADC value and display as voltage
- **D** - DAC Test (prompts for 10-bit value input)
- **T** - Read Temperature Sensor (Celsius and Fahrenheit)

12.19.2.1.4.2 Automatic LED Sequencing

The application continuously cycles through the 8 LEDs connected to the MCP23008 GPIO expander, creating a moving light pattern that updates every 0.5 seconds.

12.19.2.1.5 Technical Details

12.19.2.1.5.1 EEPROM Operations

- Supports page writes up to 8 bytes at a time
- Implements write completion polling
- Handles write cycles automatically for larger data blocks
- 256-byte total capacity

12.19.2.1.5.2 Temperature Sensor

- Configured for 12-bit resolution
- Reads temperature in 2's complement format
- Converts to both Celsius and Fahrenheit
- Displays raw register data for debugging

12.19.2.1.5.3 DAC Operations

- 10-bit resolution (0-1023 range)
- 2.5V reference voltage
- Interactive value input with range validation
- Voltage output calculation and display

12.19.2.1.5.4 ADC Operations

- 12-bit resolution
- 3.3V reference voltage
- Automatic voltage conversion and display
- Raw register data output

12.19.2.1.6 Hardware Requirements

- NetBurner development board with I2C capability
- Microchip PicKit Serial I2C Demo Board
- Serial console connection for menu interaction

12.19.2.1.7 Important Notes

12.19.2.1.7.1 RTC Conflict Warning

The application includes a warning about I2C address conflicts with real-time clock (RTC) devices commonly found on NetBurner development boards. The RTC at address 0x51/0xA2 conflicts with the PicKit EEPROM address range and will not be functional when the PicKit board is connected.

12.19.2.1.7.2 Error Handling

The application includes comprehensive I2C error handling with descriptive status codes:

- `wire_success` - Operation completed successfully
- `wire_data_too_big` - Data size exceeds buffer limits
- `wire_NACK_on_address` - Device did not acknowledge address
- `wire_NACK_on_data` - Device did not acknowledge data
- `wire_other_error` - General I2C error
- `wire_timeout` - Communication timeout

12.19.2.1.8 Building and Running

1. Include the necessary NetBurner libraries and headers
2. Compile with the NetBurner toolchain
3. Flash to NetBurner device
4. Connect serial console at appropriate baud rate
5. Connect PicKit Serial I2C Demo Board to I2C bus
6. Use menu options to interact with peripherals

12.19.2.1.9 Code Structure

The application is organized into functional modules:

- **Main Menu System** - User interface and command processing
- **Device-Specific Functions** - Individual handlers for each I2C peripheral
- **Utility Functions** - ASCII conversion, buffer display, error handling
- **LED Animation** - Background LED sequencing task

12.19.3 RV3032 I2C Real-Time Clock

<examples/I2C/Wire/RTC-RV3032>

Supported Platforms: SOMRT1061 with DEV-SOMRT1061

External Real-Time Clock example using the Micro Crystal RV3032 RTC connected to the I2C bus, such as with the SOMRT1061-200IR on the DEV-SOMRT1061 development board containing the RV3032.

The example uses the Wire interface class for I2C operation, and requires an Internet connection to obtain the current time with NTP.

- Creates a NtpClientServlet instance to run as a background task in the configuration server.
- Reads the time stored in the RTC
- Compares the two values and sets the RTC to the NTP time if there is a difference of 2 minutes or more.

12.19.3.1 There are multiple I2C peripherals on each NetBurner platform as indicated in the tables below. The first

line is the default.

12.19.3.1.1 SOMRT1061

SCL	SOMRT PIN	SDA	SOMRT PIN	Pin Func	Module
Pin_EMC_12	9	Pin_EMC_11	10	PIN_FN↔ _2	4
Pin_SD_B0_00	27	Pin_SD_B0_01	26	PIN_FN↔ _2	3
Pin_AD_B1_00	40	Pin_AD_B1_01	41	PIN_FN↔ _3	1
Pin_AD_B1_07	47	Pin_AD_B1_06	46	PIN_FN↔ _1	3
Pin_EMC_22	83	Pin_EMC_21	84	PIN_FN↔ _2	3

12.19.3.1.2 MODM7AE70

Module	SCL	SDA
I2C0	P2.42	P2.39
I2C1	P2.12	P2.22
I2C2	P2.23	P2.26

12.19.3.1.3 SBE70LC

Module	SCL	SDA
I2C0	17	16

12.19.3.1.4 MOD5441X

Module	SCL	SDA
I2C0	J2.42	J2.39
I2C1	J2.41	J2.44

12.19.3.1.5 NANO54415

Module	SCL	SDA
I2C0	27	29

Module	SCL	SDA
I2C1	22	20
I2C4	26	24
I2C5	34	32

12.19.3.1.6 SB800EX

Module	SCL	SDA
I2C4	5	4

12.19.4 Wire Address Scan

12.19.4.1 I2C Wire Scan Application

12.19.4.1.1 Overview

This application scans the [I2C](#) bus for connected devices and displays their addresses using the Wire interface. It's a diagnostic utility that helps verify hardware connections and understand [I2C](#) device addressing.

12.19.4.1.2 Features

- Scans all valid [I2C](#) addresses (0x01 to 0x7F)
- Reports found device addresses in hexadecimal format
- Includes web server functionality for remote monitoring
- Provides network diagnostics capabilities

12.19.4.1.3 How It Works

The application performs the following operations:

1. **System Initialization:** Initializes the network stack and starts a web server on port 80
2. **Network Setup:** Waits for an active network connection
3. **I2C Scanning:** Sends ping requests to each address in the [I2C](#) address space
4. **Device Detection:** When a device responds with an acknowledgment (ACK), its address is recorded
5. **Results Display:** Outputs all found device addresses to the console

12.19.4.1.4 I2C Address Scanning Process

The scan covers addresses 1 through 127 (0x01 to 0x7F) in the 7-bit [I2C](#) address space. For each address, the application:

- Sends a request using `Wire.ping(address)`
- Waits for an acknowledgment from the device
- Records the address if a response is received

12.19.4.1.5 Output Format

For example, the application outputs scan results in the following format:

```
Doing scan
I2C Devices[01,48,68]
Scan done found 3 devices
```

Where:

- Device addresses are displayed in hexadecimal format
- Multiple addresses are comma-separated
- Total count of found devices is reported

12.19.4.1.6 Use Cases

This utility is particularly helpful for:

- **Hardware Verification:** Confirming that I2C devices are properly connected and powered
- **Address Discovery:** Identifying the actual addresses of connected I2C devices
- **Troubleshooting:** Diagnosing I2C communication issues
- **Documentation:** Understanding device addressing schemes in datasheets

12.19.4.1.7 Technical Notes

12.19.4.1.7.1 Address Format

Some I2C device datasheets include the read/write bit as part of the address specification, while others do not. This scanner reports the base 7-bit address without the read/write bit.

12.19.4.1.7.2 Address Range

- **Valid Range:** 0x01 to 0x7F (1 to 127 decimal)
- **Reserved Addresses:** 0x00 and addresses above 0x7F are not scanned as they are reserved or invalid

12.19.4.1.7.3 Network Features

The application includes network capabilities:

- Web server running on port 80
- System diagnostics enabled
- Network connection monitoring

12.19.4.1.8 Dependencies

- NNDK (NetBurner Network Development Kit)
- Wire library for I2C communication
- System libraries for network and timing functions

12.19.4.1.9 Building and Running

1. Compile the application using the NNDK toolchain
2. Flash to your NetBurner device
3. Connect to the device console to view scan results
4. Optionally access the web interface for remote monitoring

12.19.4.1.10 Example Output

```
Web Application: I2C Wire Scan
NNDK Revision: [version]
Doing scan
I2C Devices[20,3C,50]
Scan done found 3 devices
```

This example shows three I2C devices found at addresses 0x20, 0x3C, and 0x50.

12.19.4.1.11 Troubleshooting

If no devices are found:

- Check I2C wiring (SDA, SCL, power, ground)
- Verify pull-up resistors on SDA and SCL lines
- Confirm device power supply voltages
- Check for proper ground connections
- Verify device addresses in datasheets

12.19.4.1.12 File Structure

- `main.cpp`: Main application source code
- Web interface files (auto-generated by NNDK)

12.19.5 SparkFun Qwiic Alphanumeric Display

12.19.5.1 SparkFun Qwiic Alphanumeric Display Application

12.19.5.1.1 Overview

This application demonstrates the basic usage of the SparkFun Qwiic Alphanumeric Display (COM-16919) with NetBurner's RTOS platform. The program initializes the display, shows a welcome message, and then continuously displays a running seconds counter.

12.19.5.1.2 Hardware Requirements

- NetBurner development board with I2C/Wire support
- SparkFun Qwiic Alphanumeric Display (COM-16919)
- Qwiic connector cable or appropriate I2C wiring

12.19.5.1.3 Features

- Network stack initialization with web server capabilities
- I2C communication with the alphanumeric display
- Real-time display of system uptime in seconds
- Connection status verification
- System diagnostics enabled for development

12.19.5.1.4 Application Flow

1. Initialization Phase

- Initialize the network stack
- Enable system diagnostics
- Wait for active network connection (up to 25 seconds)
- Start HTTP web server on default port 80
- Initialize I2C Wire interface

2. Display Setup

- Initialize the HT16K33 display controller
- Verify display connection

- Display "NBRN" as initial message
- Wait 1 second before starting main loop

3. Main Loop

- Continuously monitor system seconds counter
- Update display with current seconds (modulo 10000)
- Print status dots to console every second

12.19.5.1.5 Code Structure

12.19.5.1.5.1 Key Components

- `SerialIf` `Serial` - Serial interface for debug output
- `TwoWire` `Wire` - `I2C` communication interface
- `HT16K33` `disp` - SparkFun alphanumeric display controller
- `UserMain()` - Main application entry point

12.19.5.1.5.2 Display Operations

The application uses the SparkFun Alphanumeric Display library which provides:

- `begin()` - Initialize display
- `isConnected()` - Check connection status
- `print()` - Display text/numbers

12.19.5.1.5.3 Network Features

The application includes network capabilities:

- Web server on port 80
- Network diagnostics
- Connection monitoring

12.19.5.1.6 Usage

1. Connect the SparkFun Qwiic Alphanumeric Display to your NetBurner board via `I2C`
2. Compile and upload the application
3. Monitor the serial console for:
 - Application name and NNDK revision
 - Display initialization status
 - Connection verification
 - Running status dots
4. Observe the display showing:
 - Initial "NBRN" message
 - Continuous seconds counter (0-9999, then repeats)

12.19.5.1.7 Console Output

The application provides debug information via serial console:

```
Web Application: SparkFunAlphaDisplay
NNDK Revision: [version]
Begin True/false
Connected True/false
. . . . (status dots every second)
```

12.19.5.1.8 Development Notes

- System diagnostics are enabled for development purposes
- Consider removing `EnableSystemDiagnostics()` for production builds
- The web server functionality is initialized but not actively used in this example
- Display shows seconds modulo 10000 to fit the 4-digit alphanumeric format

12.19.5.1.9 Dependencies

- NetBurner RTOS libraries
- SparkFun Alphanumeric Display library
- Standard I2C/Wire libraries

12.19.5.1.10 Troubleshooting

1. **Display not initializing:** Check [I2C](#) connections and power
2. **Connection false:** Verify proper [I2C](#) address and wiring
3. **Network timeout:** Ensure network configuration is correct
4. **No display updates:** Check that the main loop is running and seconds counter is incrementing

12.19.5.1.11 Related Documentation

This example is part of the NetBurner [I2C](#) examples collection: `examples/I2C/Wire/SparkFunQwiic/↔AlphaDisplay`

For more information about the SparkFun Qwiic Alphanumeric Display, refer to the SparkFun documentation for COM-16919.

12.19.6 SparkFun Qwiic Joystick

12.19.6.1 SparkFun Qwiic Alphanumeric Display Application

12.19.6.1.1 Overview

This application demonstrates integration between NetBurner's RTOS platform and the SparkFun Qwiic Alphanumeric Display (COM-16919). The program initializes both network services and the [I2C](#) display, then continuously shows a running seconds counter on the 4-digit alphanumeric display.

12.19.6.1.2 Hardware Requirements

- NetBurner development board with I2C/Wire support
- SparkFun Qwiic Alphanumeric Display (COM-16919)
- Qwiic connector cable or appropriate [I2C](#) wiring connections

12.19.6.1.3 Key Features

- **Network Integration:** Full network stack initialization with HTTP web server
- **I2C Communication:** Direct interface with HT16K33 display controller
- **Real-time Display:** Live system uptime counter (0-9999 seconds, cycling)
- **Connection Verification:** Automatic display connectivity checking
- **Development Diagnostics:** Built-in system diagnostics for debugging

12.19.6.1.4 Application Architecture

12.19.6.1.4.1 Initialization Sequence

1. Network Setup

- Initialize NetBurner network stack
- Enable system diagnostics for development
- Wait up to 25 seconds for active network connection
- Start HTTP web server on default port 80

2. Display Configuration

- Initialize I2C Wire interface
- Configure HT16K33 display controller
- Verify display connection status
- Display initial "NBRN" message
- Pause 1 second before entering main loop

3. Main Operation Loop

- Monitor system seconds counter continuously
- Update display with current seconds (modulo 10000)
- Output status indicators to console

12.19.6.1.4.2 Core Components

```
SerialIf Serial;    // Debug output interface
TwoWire Wire;       // I2C communication bus
HT16K33 disp;       // SparkFun display controller
```

12.19.6.1.4.3 Display Operations

The application utilizes the SparkFun Alphanumeric Display library:

- `begin()` - Initialize display hardware
- `isConnected()` - Verify I2C connection
- `print()` - Display text and numeric values

12.19.6.1.5 Usage Instructions

12.19.6.1.5.1 Hardware Setup

1. Connect the SparkFun Qwiic Alphanumeric Display to your NetBurner board
2. Use either Qwiic connector cable or manual I2C wiring (SDA/SCL)
3. Ensure proper power connections

12.19.6.1.5.2 Software Deployment

1. Compile the application using NetBurner development tools
2. Upload the compiled firmware to your NetBurner board
3. Monitor serial console for initialization status

12.19.6.1.5.3 Expected Behavior

Serial Console Output:**

```
Web Application: SparkFunAlphaDisplay
NNDK Revision: [version number]
Begin True/false
Connected True/false
. . . . (status dots every second)
```

Display Sequence:**

1. Initial display shows "NBRN" for 1 second
2. Continuous seconds counter (0000-9999, then cycles back to 0000)
3. Updates every second with current system uptime

12.19.6.1.6 Code Structure

12.19.6.1.6.1 Main Function Flow

```
void UserMain(void *pd)
{
    // Network and system initialization
    init();
    EnableSystemDiagnostics();
    WaitForActiveNetwork(TICKS_PER_SECOND * 25);
    StartHttp();

    // Display setup and verification
    Wire.begin();
    disp.begin();
    disp.isConnected(0);

    // Main operational loop
    while (1) {
        // Monitor and display seconds counter
    }
}
```

12.19.6.1.6.2 Timing Considerations

- Network timeout: 25 seconds maximum wait
- Display update rate: Every 1 second
- Initial display pause: 1 second
- Console status output: Every second

12.19.6.1.7 Development Notes

12.19.6.1.7.1 Production Considerations

- Remove `EnableSystemDiagnostics()` for production builds
- Consider adding error handling for network failures

12.19.6.1.7.2 Display Limitations

- 4-digit alphanumeric format limits counter to 0-9999
- Counter automatically cycles back to 0000 after reaching 9999
- Display uses modulo arithmetic: `Secs % 10000`

12.19.6.1.7.3 Network Features

- HTTP web server runs on port 80
- Network diagnostics enabled for development
- Connection monitoring with timeout protection

12.19.6.1.8 Troubleshooting

12.19.6.1.8.1 Common Issues

Display Not Initializing**

- Check I2C connections (SDA/SCL pins)
- Verify power supply to display
- Confirm I2C address conflicts
Connection Status False**
- Verify proper I2C wiring
- Check display power connections
- Ensure correct I2C address (default for HT16K33)
Network Timeout**
- Verify network configuration
- Check Ethernet cable connections
- Confirm network settings in NetBurner configuration
No Display Updates**
- Verify main loop execution
- Check that seconds counter is incrementing
- Confirm I2C communication is functioning

12.19.6.1.8.2 Debug Information

The application provides comprehensive debug output:

- Application name and NNDK revision
- Display initialization status
- Connection verification results
- Real-time status indicators (dots every second)

12.19.6.1.9 Dependencies

12.19.6.1.9.1 Required Libraries

- NetBurner RTOS core libraries
- SparkFun Alphanumeric Display library
- Standard I2C/Wire communication libraries
- Network stack libraries

12.19.6.1.10 Technical Specifications

12.19.6.1.10.1 Display Controller

- **Chip:** HT16K33 LED controller
- **Interface:** I2C communication
- **Display Type:** 4-digit alphanumeric
- **Update Rate:** 1 Hz (every second)

12.19.6.1.10.2 Network Services

- **Web Server:** HTTP on port 80
- **Connection Timeout:** 25 seconds
- **Diagnostics:** Development mode enabled

12.19.6.1.10.3 System Integration

- **Platform:** NetBurner RTOS
- **Communication:** [I2C](#) (Wire library)
- **Timing:** RTOS tick-based scheduling

12.19.6.1.11 Related Documentation

- SparkFun Qwiic Alphanumeric Display (COM-16919) datasheet
- NetBurner RTOS documentation
- HT16K33 LED controller specifications
- [I2C](#) communication protocols

12.19.7 SparkFun Qwiic KeyPad

12.19.7.1 SparkFun Qwiic KeyPad Application

12.19.7.1.1 Overview

This application demonstrates the basic use of the SparkFun Qwiic KeyPad (COM-15290) with an embedded system using the NetBurner NNDK (Network Development Kit). The application provides a simple interface to read button presses from the keypad and display them via serial output.

12.19.7.1.2 Hardware Requirements

- NetBurner development board with [I2C](#) support
- SparkFun Qwiic KeyPad (COM-15290)
- Qwiic connection cable

12.19.7.1.3 Features

- **[I2C](#) Communication:** Uses the Wire library for [I2C](#) communication with the keypad
- **Web Server:** Includes a basic HTTP web server on port 80
- **Network Stack:** Full network stack initialization with diagnostics
- **Real-time Button Detection:** Continuously monitors for button presses
- **Serial Output:** Displays button presses and status information via serial interface
- **Connection Monitoring:** Verifies keypad connectivity on startup

12.19.7.1.4 Application Behavior

12.19.7.1.4.1 Initialization Sequence

1. Initializes the network stack
2. Enables system diagnostics
3. Starts HTTP web server on port 80
4. Waits for active network connection (5 second timeout)
5. Initializes [I2C](#) communication
6. Attempts to connect to the SparkFun Qwiic KeyPad
7. Verifies connection status

12.19.7.1.4.2 Runtime Operation

- Continuously polls the keypad for button presses
- Updates the internal FIFO buffer to handle multiple key presses
- Displays pressed keys in square brackets via serial output: `[key]`
- Prints a dot (.) every second as a heartbeat indicator
- Runs indefinitely until system reset

12.19.7.1.4.3 Serial Output Examples

```
Web Application: SparkFunKeypad
NNDK Revision: [version]
Begin True
Connected True
[1][2][3]....[A][B]....
```

12.19.7.1.5 Code Structure

12.19.7.1.5.1 Key Components

- **Serial Interface:** `SerialIf Serial` - handles serial communication
- **Keypad Object:** `KEYPAD key` - SparkFun keypad library instance
- **I2C Interface:** `TwoWire Wire` - [I2C](#) communication handler

12.19.7.1.5.2 Main Functions

- `init()` - Network stack initialization
- `key.begin()` - Keypad initialization
- `key.isConnected()` - Connection verification
- `key.getButton()` - Button press detection
- `key.updateFIFO()` - Internal buffer management

12.19.7.1.6 Dependencies

- NetBurner NNDK framework
- SparkFun Qwiic Keypad Arduino Library
- Wire library for [I2C](#) communication
- Standard NetBurner system libraries ([init.h](#), [nbtos.h](#), [system.h](#))

12.19.7.1.7 Setup Instructions

1. Connect the SparkFun Qwiic KeyPad to your NetBurner board via I2C/Qwiic interface
2. Compile and flash the application to your NetBurner device
3. Open a serial terminal to monitor output
4. The application will automatically initialize and begin monitoring for key presses
5. Press keys on the keypad to see output in the serial terminal

12.19.7.1.8 Troubleshooting

12.19.7.1.8.1 Common Issues

- ****"Begin false"**: Keypad initialization failed** - check I2C connections
- ****"Connected false"**: Keypad not detected** - verify power and I2C address
- **No key output**: Check FIFO buffer and polling frequency

12.19.7.1.8.2 Debug Tips

- Verify I2C connections and pull-up resistors
- Check keypad I2C address (default is typically 0x4B)
- Ensure proper power supply to the keypad
- Monitor serial output for initialization status messages

12.19.7.1.9 Technical Notes

- The application uses a 1ms delay in the main loop for efficient polling
- Button presses are buffered internally by the keypad library
- The web server functionality provides additional networking capabilities
- System diagnostics can be disabled for production builds by removing `EnableSystemDiagnostics()`

12.19.8 SparkFun Qwiic OLED Display

12.19.8.1 SparkFun Qwiic OLED Display - Analog Clock

This application demonstrates the use of a SparkFun Qwiic OLED Display to create an analog clock interface using the NetBurner platform.

12.19.8.1.1 Overview

The SparkFun OLED Display example creates a real-time analog clock that displays the current time with traditional clock hands (hour, minute, and second hands). The clock face includes numeric markers at the 12, 3, 6, and 9 o'clock positions.

12.19.8.1.2 Supported Hardware

This application supports multiple SparkFun Qwiic OLED display models:

- QwiicMicroOLED (default)
- QwiicTransparentOLED
- QwiicNarrowOLED
- Qwiic1in3OLED

Note: Only one display type should be uncommented in the source code at a time.

12.19.8.1.3 Features

- **Real-time analog clock display** with hour, minute, and second hands
- **Configurable clock speed** - adjustable from real-time to accelerated modes
- **Automatic time progression** - seconds, minutes, and hours increment automatically
- **Circular clock face** with numeric position markers
- **Network connectivity** with built-in web server support
- **System diagnostics** integration

12.19.8.1.4 Configuration

12.19.8.1.4.1 Initial Time Settings

The clock can be initialized with custom time values:

```
int hours = 11;      // Initial hour (0-11, 12-hour format)
int minutes = 50;    // Initial minutes (0-59)
int seconds = 30;    // Initial seconds (0-59)
```

12.19.8.1.4.2 Clock Speed

The clock update rate can be adjusted using the `CLOCK_SPEED` constant:

- Set to 1 for rapid/demo mode
- Set to 1000 for approximately real-time operation (1 second intervals)

12.19.8.1.5 Hardware Requirements

- NetBurner development board with I2C/Wire support
- SparkFun Qwiic OLED Display (one of the supported models)
- Qwiic connection cable or appropriate I2C wiring

12.19.8.1.6 Key Components

12.19.8.1.6.1 Libraries Used

- [SparkFun_Qwiic_OLED.h](#) - SparkFun OLED display library
- [Wire.h](#) - I2C communication library
- [Arduino.h](#) - Arduino compatibility layer for NetBurner
- NetBurner RTOS libraries ([nbrtos.h](#), [system.h](#), [init.h](#))

12.19.8.1.6.2 Main Functions

- `initClockVariables()` - Calculates display positioning and sizing constants
- `updateTime()` - Handles time progression (seconds -> minutes -> hours)
- `drawArms()` - Renders the clock hands using trigonometric calculations
- `drawFace()` - Draws the clock border and numeric markers
- `UserMain()` - Main application loop with network initialization

12.19.8.1.7 Display Details

The clock automatically adapts to the display dimensions:

- **Clock radius** is calculated based on available screen space
- **Hand lengths** are proportional to the clock radius:
 - Second hand: 100% of available radius
 - Minute hand: 70% of available radius
 - Hour hand: 50% of available radius
- **Numeric markers** are positioned at cardinal directions (12, 3, 6, 9)

12.19.8.1.8 Network Features

The application includes full network stack initialization:

- Web server on port 80
- 5-second network connection timeout
- System diagnostics enabled
- Compatible with NetBurner's web-based configuration

12.19.8.1.9 Usage

1. Connect the SparkFun Qwiic OLED display to the NetBurner board via [I2C](#)
2. Uncomment the appropriate display type in the source code
3. Adjust initial time and clock speed settings if desired
4. Compile and upload the application
5. The analog clock will begin displaying immediately upon successful initialization

12.19.8.1.10 Error Handling

The application includes basic error handling:

- Display initialization failure detection
- Infinite loop protection if hardware initialization fails
- Serial output for debugging and status reporting

12.19.8.1.11 File Structure

- `main.cpp` - Main application source code
- `ReadMe.txt` - Basic project documentation
- This README provides comprehensive application documentation

12.19.8.1.12 Technical Notes

- The clock uses trigonometric functions to calculate hand positions
- Display updates occur in a non-blocking loop structure
- The application maintains compatibility with NetBurner's RTOS environment
- [I2C](#) communication is handled through the standard Wire library interface

12.20 IP Address Object (IPADDR)

12.20.1 FunWithIPADDR - NetBurner IP Address Object Example

12.20.1.1 Overview

`FunWithIPADDR` is a C++ demonstration application that showcases the NetBurner IPADDR object functionality. This application demonstrates how to work with IP addresses in a dual-stack (IPv4/IPv6) environment using NetBurner's unified IPADDR object system.

Note

In rare cases in which you want to create an object of a specific type, you can create objects as `IPADDR4` or `IPADDR6`. However, we highly recommend using `IPADDR` for all your IP addresses. Note that if you are using a `printf()` style format specifier, you must use `"%HI"` instead of `"%I"` and pass in a `IPADDR4` object, otherwise the value displayed will be 0.0.0.0.

12.20.1.2 What is IPADDR?

The `IPADDR` object is a C++ class that provides a unified interface for handling both IPv4 and IPv6 addresses without requiring separate code paths. This design enables applications to support both IP versions seamlessly, with the object automatically determining the appropriate operations based on the assigned address type.

12.20.1.2.1 Key Features

- **Dual-stack support:** Single object handles both IPv4 and IPv6 addresses
- **Automatic type detection:** Member functions automatically call appropriate IPv4 or IPv6 implementations
- **Unified printf formatting:** Custom `I` format specifier for easy display
- **Null address handling:** Built-in methods to check for and set null addresses
- **Type-specific objects:** Optional `IPADDR4` and `IPADDR6` for specialized use cases

12.20.1.3 Application Functionality

The application demonstrates the following IPADDR capabilities:

12.20.1.3.1 1. Basic Address Assignment and Display

- Creates `IPADDR` objects for both IPv4 and IPv6 addresses
- Uses `SetFromAscii()` to assign addresses from string literals
- Displays addresses using the custom `I` printf format specifier

12.20.1.3.2 2. Member Function Usage

- Demonstrates the `print()` member function for address output
- Shows how the same function works for both IPv4 and IPv6 addresses

12.20.1.3.3 3. Null Address Handling

- Tests for null addresses using `IsNull()` member function
- Demonstrates setting addresses to null with `SetNull()`

12.20.1.3.4 4. Type-Specific Objects (IPADDR4)

- Shows creation of `IPADDR4` objects for IPv4-specific needs
- Demonstrates the required `HI` format specifier for `IPADDR4` objects

12.20.1.3.5 5. IPv6 Static Methods (Conditional)

- When IPv6 is enabled, shows usage of `AsciiToIp6()` static method

12.20.1.4 Code Examples

12.20.1.4.1 Creating and Using IPADDR Objects

```
// IPv4 address
IPADDR ipaddrIPv4;
ipaddrIPv4.SetFromAscii("192.168.1.4");
iprintf("IPv4 Address: %I\r\n", ipaddrIPv4);

// IPv6 address
IPADDR ipaddrIPv6;
ipaddrIPv6.SetFromAscii("2001:0db8:85a3:0000:0000:8a2e:0370:0006");
iprintf("IPv6 Address: %I\r\n", ipaddrIPv6);
```

12.20.1.4.2 Null Address Checking

```
if (ipaddrIPv4.IsNull())
    iprintf("Address is null\r\n");
else
    iprintf("Address: %I\r\n", ipaddrIPv4);
```

12.20.1.4.3 Using Type-Specific Objects

```
IPADDR4 ipaddrIPADDR4;
ipaddrIPADDR4.SetFromAscii("192.168.4.4");
// Note: Must use %HI for IPADDR4 objects
iprintf("IPADDR4: %HI\r\n", ipaddrIPADDR4);
```

12.20.1.5 Important Notes

12.20.1.5.1 Printf Format Specifiers

- Use `I` for general IPADDR objects
- Use `HI` for `IPADDR4` objects (failure to do so will display 0.0.0.0)
- The `I` format works with all printf variants (printf, iprintf, sprintf, etc.)

12.20.1.5.2 Best Practices

- Use the generic IPADDR class for most applications
- Only use `IPADDR4` or `IPADDR6` when type-specific functionality is required
- Always check for null addresses when necessary
- The unified approach reduces code complexity and maintenance

12.20.1.6 Application Flow

1. **Initialization:** Sets up the NetBurner system and network stack
2. **Network Wait:** Waits up to 5 seconds for active network connectivity
3. **HTTP Start:** Initializes the HTTP server
4. **IPADDR Demonstrations:** Runs through various IPADDR usage examples
5. **Main Loop:** Enters an infinite loop with 1-second delays

12.20.1.7 Build Requirements

- NetBurner development environment
- NetBurner RTOS ([nbrtos.h](#))
- HTTP support ([http.h](#))
- Standard C++ compiler with NetBurner extensions

12.20.1.8 System Features Used

- System diagnostics (enabled for debugging)
- Network stack initialization
- HTTP server functionality
- Custom printf formatting

12.21 IPv6

IPv6 Examples:

- [DHCPv6](#)

12.21.1 DHCPv6

12.21.1.1 DHCPv6 Client Application

12.21.1.1.1 Overview

This application demonstrates the implementation of a DHCPv6 (Dynamic Host Configuration Protocol for IPv6) client using the NetBurner NNDK (NetBurner Network Development Kit). The application showcases various callback functions for requesting, adding, and processing DHCPv6 options in an IPv6 network environment.

12.21.1.1.2 Application Name

IPv6-DHCPv6**

12.21.1.1.3 Purpose

The DHCPv6 client application serves as a comprehensive example of how to:

- Implement DHCPv6 client functionality in embedded systems
- Configure and handle DHCPv6 callback functions
- Request specific DHCPv6 options from servers
- Process DHCPv6 reply messages
- Manage device naming for [DHCP](#) offers
- Display IPv6 address information

12.21.1.1.4 Key Features

12.21.1.1.4.1 DHCPv6 Client Callbacks

The application implements three main callback functions in the `NB::V6::DHCPv6` namespace:

1. ****Option Request Callback (AddORO)****
 - Returns additional options to receive from the DHCPv6 server
 - Configured to request: Preference, DNS Servers, and Domain List options
 - The returned list must be NULL-terminated
2. ****Request Option Callback (AddSendOption)****
 - Allows setting additional options for outgoing DHCPv6 messages
 - Can determine message type using `msg.GetType()`
 - Currently contains example code for FQDN options (commented out)

3. ****Reply Callback (GetReply)****

- Called when Reply messages are received and verified
- Processes DHCPv6 options that the system requires
- Provides debug output for received messages

12.21.1.1.4.2 Device Naming

- Uses the `DEVICE_NAME` parameter from configuration settings for DHCP offers
- Automatically generates device names if not configured (when `autoDeviceName` is enabled)
- Format: `NB_[PlatformName]_[Last3MacBytes]`
- Automatically saves configuration and reboots when creating new device names

12.21.1.1.4.3 Network Interface Management

- Waits for active network connection (10-second timeout)
- Retrieves and displays the first available network interface
- Shows device name used for DHCP offers

12.21.1.1.5 Required Dependencies

12.21.1.1.5.1 NetBurner Libraries

- `init.h` - Initialization functions
- `nbrtos.h` - NetBurner Real-Time OS
- `netinterface.h` - Network interface management
- `system.h` - System functions
- `config_server.h` - Configuration management
- `ipv6/dhcpv6_internal.h` - DHCPv6 internal definitions
- `ip_util.h` - IP utility functions

12.21.1.1.5.2 Compilation Requirements

- IPv6 support must be enabled (`IPV6` preprocessor definition)
- Application will display an error message if IPv6 is disabled

12.21.1.1.6 Usage

12.21.1.1.6.1 Startup Sequence

1. Initialize system and enable diagnostics
2. Wait for active network connection
3. Start HTTP server
4. Check and configure device name if necessary
5. Set up DHCPv6 callbacks
6. Display application information
7. Enter interactive mode

12.21.1.1.6.2 Interactive Mode

- Press Enter to display current IPv6 address information
- Application continuously monitors and displays network status
- Note: Routable addresses may take several seconds to receive

12.21.1.1.6.3 Debug Information

- Enable `DHCP_DEBUG` in `dhcpv6_internal.h` and recompile the library to see full DHCPv6 messages
- System diagnostics are enabled by default (should be disabled for production)

12.21.1.1.7 DHCPv6 Options Requested

The application is configured to request the following DHCPv6 options:

- `OPT_PREFERENCE` - Server preference values
- `OPT_DNS_SERVERS` - DNS server addresses
- `OPT_DOMAIN_LIST` - Domain search list

12.21.1.1.8 Configuration

12.21.1.1.8.1 Device Name Configuration

- Set `DEVICE_NAME` in the network interface configuration
- If not set and `autoDeviceName` is enabled, the application will:
 1. Generate a name based on platform and MAC address
 2. Save the configuration
 3. Automatically reboot the device

12.21.1.1.8.2 Network Interface

- Application uses the first available network interface
- Displays the interface's MAC address and device name
- Waits up to 10 seconds for network activation

12.21.1.1.9 Build Configuration

12.21.1.1.9.1 Preprocessor Definitions

- `IPV6` must be defined for the application to function
- Without IPv6 support, the application will display an error message

12.21.1.1.9.2 Production Considerations

- Remove `EnableSystemDiagnostics()` call for production builds
- Disable `DHCP_DEBUG` in production environments
- Consider disabling automatic device name generation (`autoDeviceName = false`)

12.21.1.1.10 Example Output

```
Application: IPv6-DHCPv6
NNDK Revision: [Version]
DHCP Offer Name: [DeviceName]
Type the enter key to display address information
Note that routable addresses may take a few seconds to receive

Reply Callback
[DHCPv6 debug information if enabled]
[IPv6 address information]
```

12.21.1.1.11 Error Handling

- Graceful handling of missing device names
- Automatic configuration and reboot when needed
- Network timeout protection (10-second wait)
- IPv6 availability checking

12.21.1.1.12 Files

- `main.cpp` - Main application implementation
- `ReadMe.txt` - Original documentation
- `ip_util.h` - IP utility functions (referenced)

12.21.1.1.13 Technical Notes

- The application uses the NetBurner RTOS task system
- Memory management follows NetBurner guidelines
- All DHCPv6 option arrays must be statically allocated (not stack-based)
- The library automatically prevents duplicate options from being sent

12.22 JSON

These series of examples provide code for a JSON server running on a NetBurner device, "demo.netburner.com", and JSON client examples for GET, POST, loading applications and HTML. If you type "demo.netburner.com" in your web browser and can see a JSON server, you can run the client examples against it.

- [JSON Lexer](#)

JSON Examples:

- [NetBurner Demo Server for JSON Client Examples](#)
- [Get JSON Object From Server](#)
- [Get Non-JSON Object From Server](#)
- [Get JSON Object From Server](#)
- [JSON Linter Test](#)
- [Post JSON to Server and Display Result](#)
- [Post JSON to Server](#)
- [Get Application Image and Load it From a Web Server](#)
- [Simple JSON HTML Example](#)
- [Simple JSON Post Receiver Example](#)

12.22.1 JSON Lexer

The examples here show how to use the [JSON Lexer](#) classes, [ParsedJsonDataSet](#) and [JsonRef](#), to build and interact with JSON data sets.

JSON Lexer Examples:

- [JSON Array](#)
- [JSON Array with Objects](#)
- [Parse Test](#)

12.22.1.1 JSON Array

12.22.1.1.1 JSON Array Application

12.22.1.1.1.1 Overview

This application demonstrates how to use the JSON Lexer library classes [ParsedJsonDataSet](#) and [JsonRef](#) to create and access JSON array information. The program builds a JSON array with numeric data and then reads back the stored values.

12.22.1.1.1.2 Application Details

Application Name:** JsonArray

The application showcases the fundamental operations of:

- Building JSON data structures programmatically
- Storing arrays within JSON datasets
- Accessing and iterating through JSON array elements
- Converting JSON data to native data types

12.22.1.1.1.3 Code Structure

Main Components

BuildJsonArray ()

This function demonstrates the JSON array creation process:

- Initializes the JSON data set building process
- Creates an array named "FirstArray"
- Populates the array with integers 0-9
- Finalizes the array and dataset construction

ReadJsonArray ()

This function shows how to access and iterate through JSON array data:

- Retrieves a reference to the "FirstArray"
- Iterates through array elements using index-based access
- Converts JSON values to native double format
- Prints each array element with its index

UserMain()

The main application entry point that:

- Initializes the system
- Enables system diagnostics
- Waits for network connectivity (5 seconds)
- Orchestrates the build and read operations
- Displays the complete JSON object structure
- Enters an infinite loop with 1-second delays

12.22.1.1.1.4 Expected Output

When executed, the application will:

1. Display "Application started" message
2. Show "Build JSON Object:" followed by the complete JSON structure
3. Display each array element in the format: "[index]: [value]"
4. Show "End of Array Reached" when iteration completes

Example output format:

```
Application started

Build JSON Object:
[JSON structure display]

  0: 0
  1: 1
  2: 2
  ...
  9: 9
End of Array Reached
```

12.22.1.1.1.5 Dependencies

The application requires:

- `init.h` - System initialization functions
- `json_lexer.h` - JSON parsing and manipulation library
- Network stack (uses `DHCP` and network timing functions)
- RTOS functionality (uses `OSTimeDly` and `TICKS_PER_SECOND`)

12.22.1.1.1.6 Key Features

- **Dynamic JSON Construction:** Build JSON arrays programmatically at runtime
- **Type Safety:** Automatic conversion between JSON and native data types
- **Iterator Support:** Easy traversal of array elements using index notation
- **Validation:** Built-in validity checking for array elements
- **Debug Output:** Complete JSON object structure printing capability

12.22.1.1.1.7 Usage Notes

- The application waits for network initialization before proceeding
- System diagnostics are enabled for development/debugging purposes
- The main loop runs indefinitely with 1-second intervals
- Array elements are accessed using standard bracket notation
- The `Valid()` method is used to detect the end of array iteration

12.22.1.1.1.8 Technical Implementation

The application leverages the JSON Lexer library's object-oriented approach to JSON manipulation, using:

- `ParsedJsonDataSet` for the main JSON container
- `JsonRef` for element references and access
- Method chaining for efficient array construction
- Implicit type conversion for data access

12.22.1.2 JSON Array with Objects

12.22.1.2.1 JSON Array with Objects Example

12.22.1.2.1.1 Overview

This application demonstrates how to use the JSON Lexer classes `ParsedJsonDataSet` and `JsonRef` to create and access arrays containing sub-objects. The program creates a JSON array with 10 objects, each containing two key-value pairs, and then reads back the data to display it.

12.22.1.2.1.2 Application Details

Application Name:** JsonArrayWithObjects

The program showcases the following JSON manipulation capabilities:

- Building JSON arrays programmatically
- Adding objects as array elements
- Accessing array elements by index
- Reading object properties within arrays

12.22.1.2.1.3 Code Structure

Main Functions

`BuildJsonArray()`

Creates a JSON array named "FirstArray" containing 10 objects. Each object has:

- Key "a" with value equal to the loop index (0-9)
- Key "b" with value equal to the loop index multiplied by 10 (0, 10, 20, ..., 90)

`ShowObject(JsonRef element)`

Displays the contents of a single object by printing its "a" and "b" values.

`ReadJsonArrayWithObj()`

Iterates through the "FirstArray" and displays each object's contents using the `ShowObject()` function.

UserMain(void *pd)

Main entry point that:

1. Initializes the system
2. Enables system diagnostics
3. Waits for network connectivity
4. Builds the JSON array
5. Prints the complete JSON object
6. Reads and displays the array contents
7. Enters an infinite loop

12.22.1.2.1.4 JSON Structure Created

The application creates a JSON structure similar to:

```
{
  "FirstArray": [
    { "a": 0, "b": 0 },
    { "a": 1, "b": 10 },
    { "a": 2, "b": 20 },
    ...
    { "a": 9, "b": 90 }
  ]
}
```

12.22.1.2.1.5 Dependencies

- [init.h](#) - System initialization
- [json_lexer.h](#) - JSON parsing and manipulation classes

12.22.1.2.1.6 Usage

The application automatically runs when started and will:

1. Display startup message
2. Build and print the JSON object
3. Read through the array and display each object's contents
4. Continue running indefinitely

12.22.1.2.1.7 Key Classes Used

- [ParsedJsonDataSet](#): Main class for building and storing JSON data
- [JsonRef](#): Reference class for accessing JSON elements and navigating the structure

12.22.1.3 Parse Test**12.22.1.3.1 JSON Parser Test Application****12.22.1.3.1.1 Overview**

This application demonstrates the usage of a JSON lexer and parser library, specifically showcasing how to use the [ParsedJsonDataSet](#) and [JsonRef](#) classes to create and access JSON information. The program is designed as a test application that parses a complex JSON structure and demonstrates various access methods and type checking capabilities.

12.22.1.3.1.2 Application Details

- **Application Name:** JsonParseTest
- **Main File:** main.cpp
- **Purpose:** Parse Test demonstration for JSON Lexer classes

12.22.1.3.1.3 Features

The application demonstrates the following JSON parsing capabilities:

1. JSON Data Structure

The program works with a complex nested JSON structure that includes:

- Boolean values (SUCCESS, b3, aftaav)
- Null values (ACTION, b4)
- Numeric values (integers and floats)
- String values
- Nested objects (JDATA, bar, b2, s4, wa)
- Arrays (av, a, z)
- Mixed-type arrays containing numbers, strings, objects, and nested arrays

2. Access Methods

The application demonstrates two primary methods for accessing JSON data:

Explicit Type Enforcement

```
int32_t j = pjd.object("wa").name("a")[5].name("z")[1];
const char *str = pjd.object("wa").name("a")[4];
NBString nbs = pjd.object("JDATA").object("bar").object("b2").object("s4").name("Sub4a");
```

Simplified Access (Without Type Enforcement)

```
j = pjd("wa")("a")[5]("z")[1];
str = pjd("wa")("a")[4];
nbs = (const char*)(pjd("JDATA")("bar")("b2")("s4")("Sub4a"));
```

3. Type Checking

The application includes comprehensive type checking capabilities:

- `IsNumber()` - Check if value is numeric
- `IsObject()` - Check if value is a JSON object
- `IsNull()` - Check if value is null
- `IsArray()` - Check if value is an array
- `IsBool()` - Check if value is boolean
- `IsString()` - Check if value is a string

4. Error Handling

The application demonstrates proper error handling for:

- Non-existent objects and properties
- Invalid parse attempts
- Validation using `JsonRef.Valid()` method

12.22.1.3.1.4 JSON Structure Example

The embedded JSON data structure includes:

```
{
  "SUCCESS": true,
  "ACTION": null,
  "JDATA": {
    "foo": 7,
    "bar": {
      "b1": "Sb1",
      "b2": {
        "s1": "Sub1",
        "s2": "Sub2",
        "s3": "Sub3",
        "s4": {
          "Sub4a": "Test4a",
          "Sub4b": "Test4b"
        },
        "s5": "Sub5",
        "s6": "Sub6"
      },
      "b3": true,
      "b4": null
    },
    "bogus": "Bstring",
    "nubog": 1234.57,
    "av": [1, 2, 3, 4, 5, 6, 7, 8, 9, 10],
    "aftaav": true
  },
  "wa": {
    "a": [1, 2, 3, 4, "bob",
      {"b": "c", "z": [1, 2, 3]},
      [12, 10, 9, "zoro"],
      93]
  }
}
```

12.22.1.3.1.5 Key Classes

ParsedJsonDataSet

- Main class for parsing and storing JSON data
- Supports initialization from character array data
- Provides `PrintObject()` method for debugging
- Supports both explicit and simplified access methods

JsonRef

- Reference class for accessing JSON elements
- Provides type checking methods
- Includes validation through `Valid()` method
- Supports automatic type conversion

12.22.1.3.1.6 Usage Pattern

1. **Initialize:** Create a `ParsedJsonDataSet` object with JSON data
2. **Access:** Use either explicit or simplified syntax to navigate the JSON structure
3. **Validate:** Check if the parse was successful using `Valid()`
4. **Type Check:** Verify data types before processing
5. **Extract:** Convert to appropriate C++ types (`int32_t`, `const char*`, `NBString`, etc.)

12.22.1.3.1.7 System Requirements

- Embedded system environment (references to [DHCP](#), network waiting)
- NetBurner platform (references to [NBString](#), system diagnostics)
- Real-time operating system (OSTimeDly, TICKS_PER_SECOND)

12.22.1.3.1.8 Build Dependencies

- [init.h](#) - System initialization
- [json_lexer.h](#) - JSON parsing library

12.22.1.3.1.9 Example Output

The application provides detailed console output showing:

- Parsed integer values from nested structures
- String extraction from various JSON locations
- Error handling for non-existent properties
- Type validation results
- Success/failure status of parse operations

12.22.2 NetBurner Demo Server for JSON Client Examples

12.22.2.1 NetBurner Demo Server

12.22.2.1.1 Overview

This is a comprehensive demonstration server application for the NetBurner platform that showcases various embedded web server capabilities including JSON handling, SSL/TLS support, tide calculations, and sunrise/sunset computations. The application serves as the backend for JSON client examples and provides a rich set of web services.

12.22.2.1.2 Features

12.22.2.1.2.1 Core Web Services

- **HTTP and HTTPS Server:** Dual protocol support with SSL/TLS encryption
- **JSON API Endpoints:** RESTful JSON services for client applications
- **Authentication System:** Multi-level access control with user authentication
- **Real-time Data Logging:** Stores and retrieves POST request data with timestamps

12.22.2.1.2.2 Specialized Functionality

- **Tide Calculations:** Real-time tide height computations
- **Astronomical Calculations:** Sunrise and sunset time calculations based on geographic coordinates
- **Time Zone Support:** Configurable time zone handling with NTP synchronization
- **Data Visualization:** Time-series data plotting for tide information

12.22.2.1.2.3 Security Features

- **SSL/TLS Encryption:** Secure communication channels
- **Access Control:** Password-protected endpoints with different security levels
- **Let's Encrypt Integration:** Automatic SSL certificate management via ACME protocol

12.22.2.1.3 API Endpoints

12.22.2.1.3.1 JSON Services

- `GetJson*` - Returns basic JSON response
- `PGetJson*` - Protected JSON endpoint requiring authentication
- `Post*` - Accepts JSON POST requests
- `PPost*` - Protected JSON POST endpoint
- `JPost*` - JSON POST with JSON response
- `PJPost*` - Protected JSON POST with JSON response

12.22.2.1.3.2 Data Retrieval

- `Show*` - HTML table view of stored POST data
- `JShow*` - JSON view of stored POST data
- `PlShow*` - JSON payload display for specific POST entries

12.22.2.1.3.3 Content Types

- `Text` - Plain text responses
- `Html` - HTML formatted responses
- `PText` - Protected text endpoint
- `PHtml` - Protected HTML endpoint

12.22.2.1.4 Configuration

12.22.2.1.4.1 Geographic Settings

- **Latitude:** Default 32.9834953 (North positive)
- **Longitude:** Default 117.2651886 (West negative)
- **Time Zone:** Default "PST8PDT7" (Pacific Standard/Daylight Time)

12.22.2.1.4.2 SSL Configuration

- **Certificate:** Requires valid SSL certificate and private key
- **Domain:** Configured for demo.netburner.com
- **ACME Support:** Automatic certificate renewal via Let's Encrypt

12.22.2.1.5 Data Storage

The application maintains a circular buffer of POST request data including:

- Timestamp (local and UTC)
- Client IP address
- Security status (HTTP/HTTPS)
- Request URL
- JSON payload data

Maximum storage: 256 entries with automatic rollover

12.22.2.1.6 Authentication Levels

1. **Level 0:** No authentication required
2. **Level 1:** HTTPS required (SSL/TLS encryption)
3. **Level 2:** Username/password authentication ("user"/"password")
4. **CONFIG_ACCESS_GROUP:** System-configured credentials

12.22.2.1.7 Real-time Calculations

12.22.2.1.7.1 Tide Calculations

- Continuous tide height monitoring
- 3-minute interval updates
- Historical data plotting
- Day/night awareness for display

12.22.2.1.7.2 Solar Calculations

- Sunrise/sunset times for specified coordinates
- Equation of time calculations
- Solar declination and hour angle computations
- Daylight/darkness detection

12.22.2.1.8 Build Requirements

12.22.2.1.8.1 Dependencies

- NetBurner development environment
- SSL certificate and private key files
- Network connectivity for NTP synchronization

12.22.2.1.8.2 Libraries Used

- [crypto/ssl.h](#) - SSL/TLS support
- [json_lexer.h](#) - JSON parsing
- [nbtime.h](#) - NTP time synchronization
- [httppost.h](#) - HTTP POST handling
- [acmeRFC8555Servlet.h](#) - Let's Encrypt ACME protocol

12.22.2.1.9 Network Configuration

The application automatically:

- Obtains IP address via [DHCP](#)
- Synchronizes time via NTP
- Starts both HTTP (port 80) and HTTPS (port 443) servers
- Enables system diagnostics

12.22.2.1.10 Usage

12.22.2.1.10.1 Deployment

1. Flash the application to a NetBurner device
2. Ensure SSL certificates are properly configured
3. Connect to network with internet access for NTP
4. Access via web browser at device IP address

12.22.2.1.10.2 Testing

- Use HTTP clients to test JSON endpoints
- Monitor POST data via Show* endpoints
- Verify SSL functionality with HTTPS connections

12.22.2.1.11 Development Notes

This application serves as a reference implementation demonstrating:

- Embedded web server best practices
- JSON API design patterns
- SSL/TLS integration
- Real-time data processing
- Astronomical calculation algorithms
- Time zone handling in embedded systems

Warning

This project requires a valid SSL certificate and private key to build successfully. The certificate should be configured for the target domain (default: demo.netburner.com).

12.22.3 Get JSON Object From Server

12.22.3.1 Get JSON From Server Application

A NetBurner embedded application that demonstrates retrieving JSON objects from various web servers and displaying the parsed results.

12.22.3.1.1 Overview

This application showcases HTTP client functionality on NetBurner embedded systems by fetching JSON data from multiple endpoints and parsing the responses. It demonstrates both HTTP and HTTPS requests, as well as authenticated requests using basic authentication.

12.22.3.1.2 Features

- **HTTP/HTTPS Support:** Fetches data from both secure and non-secure endpoints
- **JSON Parsing:** Automatically parses JSON responses and displays structured output
- **Authentication:** Supports basic HTTP authentication for protected endpoints
- **Error Handling:** Includes custom error reporting for HTTP failures
- **Multiple Data Sources:** Demonstrates various types of JSON APIs including:

- Simple configuration data
- Real-time earthquake data from USGS
- IP address information
- Custom NetBurner demo endpoints

12.22.3.1.3 Tested Endpoints

The application includes several predefined URLs for testing:

1. NetBurner Demo Endpoints:

- <http://demo.netburner.com/ut.json> - Simple JSON object
- <https://demo.netburner.com/ut.json> - Same endpoint over HTTPS
- <http://demo.netburner.com/GetJson> - Custom JSON endpoint
- <http://demo.netburner.com/PGetJson> - Password-protected endpoint
- <https://demo.netburner.com/PGetJson> - Secure password-protected endpoint

2. Public APIs:

- https://earthquake.usgs.gov/earthquakes/feed/v1.0/summary/4.5_↔day.geojson - USGS earthquake data
- <http://httpbin.org/ip> - IP address information
- <https://httpbin.org/ip> - Same over HTTPS

12.22.3.1.4 Code Structure

12.22.3.1.4.1 Main Components

- **Network Initialization:** Sets up the NetBurner network stack and waits for [DHCP](#)
- **HTTP Client:** Uses NetBurner's webclient library for HTTP requests
- **JSON Parser:** Leverages the built-in JSON lexer for parsing responses
- **Error Reporting:** Custom error handler for HTTP failures

12.22.3.1.4.2 Key Functions

- `GetAndDisplay()`: Core function that fetches and displays JSON from a given URL
- `MyReport()`: Custom error reporting function for HTTP failures
- `UserMain()`: Main application entry point

12.22.3.1.5 Usage

12.22.3.1.5.1 Building and Running

1. Compile the application using the NetBurner development environment
2. Flash the application to your NetBurner device
3. Monitor the serial output to see the JSON responses

12.22.3.1.5.2 Authentication

For password-protected endpoints, the application uses basic HTTP authentication:

```
GetAndDisplay(url5, "user", "password");
```

12.22.3.1.5.3 Customization

To test additional endpoints, modify the URL constants at the top of `main.cpp`:

```
const char *url_custom = "https://your-api-endpoint.com/data.json";
```

Then add the call in `UserMain()`:

```
GetAndDisplay(url_custom);
```

12.22.3.1.6 Dependencies

- NetBurner Runtime Library
- NetBurner HTTP Client Library ([webclient/http_funcs.h](#))
- NetBurner JSON Parser ([json_lexer.h](#))
- NetBurner Initialization Library ([init.h](#))

12.22.3.1.7 Output Format

The application displays:

1. The URL being requested
2. The parsed JSON object in a structured format
3. Any HTTP errors encountered

Example output:

```
Getting web site [https://httpbin.org/ip]
{
  "origin": "192.168.1.100"
}
```

12.22.3.1.8 Error Handling

The application includes comprehensive error handling:

- HTTP status code reporting
- Network connectivity checks
- JSON parsing error detection
- Timeout handling (60-second timeout per request)

12.22.3.1.9 Network Requirements

- Active network connection (Ethernet or WiFi)
- [DHCP](#) configuration (automatic IP assignment)
- Internet access for external APIs
- DNS resolution capability

12.22.3.1.10 Development Notes

- The application uses a 60-second timeout for all HTTP requests
- System diagnostics are enabled for debugging (should be disabled in production)
- The main loop includes a 1-second delay between iterations
- All URLs are tested sequentially at startup

12.22.4 Get Non-JSON Object From Server

12.22.4.1 Get Non-JSON From Server

A NetBurner embedded application that demonstrates retrieving non-JSON content from web servers using HTTP GET requests.

12.22.4.1.1 Overview

This application showcases how to use the NetBurner platform's HTTP client functionality to fetch various types of content from remote servers. The program demonstrates both authenticated and non-authenticated HTTP requests, making it useful for learning web client development on embedded systems.

12.22.4.1.2 Features

- HTTP GET requests to multiple endpoints
- Basic authentication support (username/password)
- Network initialization and [DHCP](#) configuration
- System diagnostics integration
- Response display and error handling

12.22.4.1.3 Application Flow

1. **Network Initialization:** Initializes the network stack and waits for [DHCP](#) address assignment
2. **HTTP Requests:** Makes GET requests to five different endpoints:
 - <http://demo.netburner.com/Html> - HTML content (no auth)
 - <http://demo.netburner.com/Text> - Text content (no auth)
 - <http://demo.netburner.com/PHtml> - Protected HTML content (requires auth)
 - <http://demo.netburner.com/PText> - Protected text content (requires auth)
 - <http://demo.netburner.com/SHtml.html> - Static HTML file (no auth)
3. **Response Processing:** Displays the retrieved content or error messages
4. **Continuous Operation:** Enters an infinite loop with 1-second delays

12.22.4.1.4 Authentication

The application demonstrates HTTP Basic Authentication for protected resources using:

- Username: `user`
- Password: `password`

12.22.4.1.5 Key Components

12.22.4.1.5.1 Functions

- `GetAndDisplay()`: Core function that performs HTTP GET requests and displays results
- `UserMain()`: Main application entry point that handles initialization and request sequencing

12.22.4.1.5.2 Dependencies

- [init.h](#) - Network stack initialization
- [json_lexer.h](#) - JSON parsing utilities (included but not used in this example)
- [webclient/http_funcs.h](#) - HTTP client functions

12.22.4.1.6 Configuration

- **Buffer Size:** 5000 bytes for response storage
- **Timeout:** 60 seconds for HTTP requests
- **Network Timeout:** 5 seconds for [DHCP](#) address acquisition

12.22.4.1.7 Build Requirements

- NetBurner development environment
- Network connectivity for testing
- Access to demo.netburner.com endpoints (or modify URLs for your own test servers)

12.22.4.1.8 Usage

1. Compile and flash the application to your NetBurner device
2. Ensure network connectivity is available
3. Monitor the serial output to see HTTP request results
4. The application will continuously run, making the requests once at startup

12.22.4.1.9 Output Format

For each successful request, the output shows:

```
Getting web site [URL]
Result = [number_of_bytes]
[response_content]
```

For failed requests:

```
Getting web site [URL]
Failed to contact server
```

12.22.4.1.10 Notes

- System diagnostics are enabled by default (consider disabling for production)
- HTTP diagnostics are available but commented out
- The application demonstrates handling both public and password-protected content
- Response content is displayed as raw text/HTML

12.22.4.1.11 Example Applications

This code pattern can be adapted for:

- Web scraping on embedded systems
- API data retrieval
- Remote configuration updates
- Status monitoring from web services
- Integration with web-based dashboards

12.22.5 JSON Linter Test

12.22.5.1 JSON Linter Test Application

12.22.5.1.1 Overview

This is a JSON linting test application built for NetBurner embedded systems. The application serves as a comprehensive test suite for validating JSON parsing capabilities, testing both valid JSON files (that should pass) and invalid JSON files (that should fail) to ensure the JSON parser correctly identifies various syntax errors and edge cases.

It will test all `bad*.json` and `pass*.json` files in `html` directory. To add additional tests add a bad or pass files to the `html` directory. `pass*.json` files are expected to pass and `bad*.json` are expected to fail.

Note

Some failures are considered warnings; they not legal JSON but we parse them for this test anyway.

12.22.5.1.2 Application Architecture

The application is built on the NetBurner RTOS platform and includes:

- **Web Server Integration:** Starts an HTTP server on port 80
- **Network Stack:** Full TCP/IP networking capabilities
- **JSON Parser Testing:** Comprehensive validation of JSON syntax
- **File System Integration:** Embedded file system containing test JSON files

12.22.5.1.3 Test Files

The application includes 47 JSON test files categorized into two groups:

12.22.5.1.3.1 Valid JSON Files (Should Pass)

- **pass1.json:** Comprehensive JSON test pattern with various data types, escape sequences, and formatting
- **pass2.json:** Deeply nested array structure (19 levels deep)
- **pass3.json:** Simple object validation test
- **pass4.json:** Complex configuration object with nested structures (network configuration example)

12.22.5.1.3.2 Invalid JSON Files (Should Fail)

Original Test Suite

- **bad1.json:** Invalid escape sequences (`\a`, `\x`, incomplete `\u` sequences)
- **bad2.json:** Unclosed arrays and objects, extra closing braces
- **bad3.json:** Missing opening brace
- **bad4.json:** Trailing commas in objects and arrays
- **bad5.json:** Invalid number formats (leading `+`, trailing decimals, hex notation, Infinity, NaN)
- **bad6.json:** Missing values after commas
- **bad7.json:** Missing commas between object properties
- **bad8.json:** Unquoted property names
- **bad9.json:** Complex nested errors (missing quotes, invalid numbers, trailing commas)
- **bad10.json:** Mismatched brackets and braces
- **bad11.json:** Comments in JSON (not allowed in strict JSON)
- **bad12.json:** Unescaped control characters in strings

Extended Test Suite

- **bad_2.json:** Unclosed array (missing closing bracket)
- **bad_3.json:** Unquoted object key (keys must be in quotes)
- **bad_4.json:** Trailing comma in array
- **bad_5.json:** Double trailing comma in array
- **bad_6.json:** Missing value at start of array (leading comma)
- **bad_7.json:** Comma after array close
- **bad_8.json:** Extra closing bracket
- **bad_9.json:** Trailing comma in object
- **bad_10.json:** Extra content after valid JSON (misplaced quoted value)
- **bad_11.json:** JavaScript expression instead of JSON value (1 + 2)
- **bad_12.json:** JavaScript function call instead of JSON value (alert())
- **bad_13.json:** Leading zeros in numbers (013)
- **bad_14.json:** Hexadecimal number notation (0x14)
- **bad_15.json:** Invalid backslash escape sequence (\x15)
- **bad_16.json:** Naked/unquoted value (not a string, number, boolean, or null)
- **bad_17.json:** Invalid octal escape sequence (\017)
- **bad_19.json:** Missing colon between key and value
- **bad_20.json:** Double colon (::)
- **bad_21.json:** Comma instead of colon in object
- **bad_22.json:** Colon instead of comma in array
- **bad_23.json:** Invalid boolean value ("truth" instead of "true")
- **bad_24.json:** Single quotes instead of double quotes for strings
- **bad_25.json:** Unescaped tab characters in string
- **bad_26.json:** Invalid escape sequences with tabs
- **bad_27.json:** Unescaped line break in string
- **bad_28.json:** Invalid line continuation with backslash
- **bad_29.json:** Incomplete scientific notation (0e)
- **bad_30.json:** Incomplete scientific notation with sign (0e+)
- **bad_31.json:** Invalid scientific notation with double sign (0e+-1)
- **bad_32.json:** Missing closing brace (comma instead of brace)
- **bad_33.json:** Mismatched brackets and braces (array opened, object closed)
- **bad_34.json:** Extra closing brace

12.22.5.1.4 Key Features Tested

12.22.5.1.4.1 String Handling

- Proper escape sequences (`\n`, `\r`, `\t`, `\"`, `\\`, `\/`, `\b`, `\f`)
- Unicode escape sequences (`\u` followed by 4 hex digits)
- Invalid escape sequences detection
- Control character validation
- Quote character validation (double quotes required, single quotes invalid)
- Unescaped control characters (tabs, line breaks)

12.22.5.1.4.2 Number Validation

- Integer formats
- Floating-point numbers
- Scientific notation (e/E notation)
- Invalid number formats (leading zeros, trailing decimals, hex notation)
- Incomplete scientific notation (missing exponent values)
- Invalid scientific notation syntax (double signs, incomplete expressions)

12.22.5.1.4.3 Punctuation and Syntax Errors

- Missing or extra commas
- Missing or extra colons
- Misplaced punctuation (comma instead of colon, colon instead of comma)
- Trailing commas in objects and arrays
- Missing closing brackets or braces
- Extra closing brackets or braces

12.22.5.1.4.4 Invalid Values and Expressions

- JavaScript expressions (arithmetic operations, function calls)
- Naked/unquoted values that aren't valid JSON primitives
- Extra content after valid JSON structures
- Invalid boolean values (non-standard true/false representations)
- Single-quoted strings (JSON requires double quotes)

12.22.5.1.4.5 Edge Cases

- Deeply nested structures
- Empty objects and arrays
- Whitespace handling
- Comment detection (should fail in strict JSON)

12.22.5.1.5 Code Structure

12.22.5.1.5.1 Main Components

```
void TestJson(int i, bool should_pass)
```

Core testing function that:

- Creates a `ParsedJsonDataSet` object from file data
- Runs `CheckLint()` to validate JSON syntax
- Reports success/failure with detailed error messages
- Handles both expected passes and failures

```
void UserMain(void *pd)
```

Application entry point that:

- Initializes network stack and web server
- Iterates through all embedded files
- Tests files starting with 'b' (bad) as failures
- Tests files starting with 'p' (pass) as successes

12.22.5.1.5.2 Dependencies

- **NetBurner RTOS:** Real-time operating system
- **HTML Files System:** Embedded file system for test data
- **JSON Lexer:** Custom JSON parsing library
- **Network Stack:** TCP/IP networking support

12.22.5.1.6 Expected Output

The application produces console output for each test:

- **Successful validation:** `OK for filename.json`
- **Expected failure:** `OK for filename.json [error_message]`
- **Unexpected pass:** `Testing filename.json should fail, it passes.`
- **Unexpected failure:** `Testing filename.json should pass, it fails. for error_↵
message`

12.22.5.1.7 Usage

1. Deploy the application to a NetBurner embedded device
2. The application automatically runs all JSON lint tests on startup
3. Monitor console output for test results
4. Access the embedded web server on port 80 for additional functionality

12.22.5.1.8 Development Notes

- The application uses embedded file records for test data
- All JSON files are compiled into the application binary
- The web server remains active after testing for additional functionality
- System diagnostics are enabled for debugging purposes

12.22.5.1.9 Test Coverage

This comprehensive test suite validates JSON parsing against a wide range of syntax errors and edge cases, ensuring robust JSON processing in embedded applications. The test suite covers:

- **Basic JSON Structure:** Objects, arrays, and proper nesting
- **Data Types:** Strings, numbers, booleans, null values
- **String Formatting:** Escape sequences, Unicode handling, control characters
- **Number Formats:** Integer, floating-point, scientific notation validation
- **Syntax Rules:** Comma placement, colon usage, bracket matching
- **Error Conditions:** All major categories of JSON syntax violations
- **Edge Cases:** Deeply nested structures, empty containers, whitespace handling

The test suite provides comprehensive coverage of JSON specification compliance and common parsing pitfalls, making it an excellent validation tool for JSON parser implementations.

12.22.6 Post JSON to Server and Display Result

12.22.6.1 JSON POST Application

12.22.6.1.1 Overview

This NetBurner application demonstrates how to POST JSON data to external servers and display the returned JSON results. The application showcases both secure (HTTPS) and insecure (HTTP) connections, with and without authentication.

12.22.6.1.2 Application Name

`PostAndGetJsonExternalServer`

12.22.6.1.3 Features

- **Multiple Connection Types:** Supports both HTTP and HTTPS connections
- **Authentication Support:** Demonstrates both authenticated and non-authenticated requests
- **JSON Handling:** Shows two methods for creating and sending JSON data:
 - Raw JSON strings
 - Programmatic JSON construction using [ParsedJsonDataSet](#)
- **Response Processing:** Parses and displays JSON responses from the server

12.22.6.1.4 Test Endpoints

The application connects to the following NetBurner demo endpoints:

- <http://demo.netburner.com/JPost> - HTTP JSON endpoint
- <https://demo.netburner.com/JPost> - HTTPS JSON endpoint
- <http://demo.netburner.com/PJPost> - HTTP JSON endpoint with authentication
- <https://demo.netburner.com/PJPost> - HTTPS JSON endpoint with authentication

12.22.6.1.5 Authentication

When authentication is required, the application uses:

- **Username:** `user`
- **Password:** `password`

12.22.6.1.6 Code Structure

12.22.6.1.6.1 Key Functions

PostAndDisplayTextJson()

Posts raw JSON strings to specified URLs and displays the response.

Parameters:**

- `purl` - Target URL
- `pJson` - JSON string to post
- `pUser` - Username (optional)
- `pPass` - Password (optional)

PostAndDisplayPJSJson()

Posts programmatically constructed JSON objects and displays the response.

Parameters:**

- `purl` - Target URL
- `JsonOut` - [ParsedJsonDataSet](#) object containing JSON data
- `pUser` - Username (optional)
- `pPass` - Password (optional)

12.22.6.1.6.2 Main Execution Flow

1. **Network Initialization:** Initializes the network stack and waits for [DHCP](#)
2. **String-based JSON Posts:** Sends predefined JSON strings to all four endpoints
3. **Programmatic JSON Posts:** Constructs JSON objects programmatically and posts them
4. **Continuous Loop:** Enters an infinite loop with 1-second delays

12.22.6.1.7 JSON Examples

12.22.6.1.7.1 Raw JSON Strings

```
{ "test": "Simple" }
{ "test": "Secure" }
{ "test": "InSecure w Password" }
{ "test": "Secure w Password" }
```

12.22.6.1.7.2 Programmatically Built JSON

```
{
  "BuildByPJS": true,
  "Simple": "example"
}
{
  "BuildByPJS": true,
  "Secure": "WPassword"
}
```

12.22.6.1.8 Dependencies

- `init.h` - Network stack initialization
- `json_lexer.h` - JSON parsing and construction
- `webclient/http_funcs.h` - HTTP client functions

12.22.6.1.9 Build and Run

1. Compile the application using your NetBurner development environment
2. Deploy to your NetBurner device
3. Ensure network connectivity is available
4. Monitor the serial output to see the JSON POST results

12.22.6.1.10 Output

The application will display:

- Connection attempts to each URL
- Parsed JSON responses from successful requests
- Error messages for failed connections

12.22.6.1.11 Notes

- The application includes system diagnostics (should be disabled for production)
- HTTP diagnostic output is available but commented out
- All requests have a 60-second timeout
- The application runs indefinitely, making requests once at startup

12.22.6.1.12 Security Considerations

This is a demonstration application that includes:

- Hardcoded credentials
- Mixed HTTP/HTTPS usage
- System diagnostics enabled

For production use, consider:

- Secure credential storage
- Proper error handling and retry logic

12.22.7 Post JSON to Server

12.22.7.1 NetBurner JSON POST Application

12.22.7.1.1 Overview

This application demonstrates how to POST JSON data to external web servers using the NetBurner embedded platform. The program showcases both secure (HTTPS) and insecure (HTTP) connections, with and without authentication, and displays the server responses as text.

12.22.7.1.2 Application Name

PostJsonGetTextExternalServer

12.22.7.1.3 Features

- HTTP and HTTPS JSON POST requests
- Basic authentication support (username/password)
- Multiple JSON creation methods:
 - Direct JSON string formatting
 - [ParsedJsonDataSet](#) object for structured JSON building
- Response handling and display
- Network initialization and [DHCP](#) support
- System diagnostics capability

12.22.7.1.4 Test Endpoints

The application connects to four different NetBurner demo server endpoints:

1. <http://demo.netburner.com/Post> - HTTP without authentication
2. <https://demo.netburner.com/Post> - HTTPS without authentication
3. <http://demo.netburner.com/PPost> - HTTP with authentication
4. <https://demo.netburner.com/PPost> - HTTPS with authentication

12.22.7.1.5 Authentication

For authenticated endpoints, the application uses:

- Username: `user`
- Password: `password`

12.22.7.1.6 JSON Data Examples

The application sends various JSON payloads:

12.22.7.1.6.1 Direct JSON Strings

```
{ "test": "Simple" }
{ "test": "Secure" }
{ "test": "InSecure w Password" }
{ "test": "Secure w Password" }
```

12.22.7.1.6.2 ParsedJsonDataSet Generated JSON

```
{ "BuildByPJS": true, "Simple": "example" }
{ "BuildByPJS": true, "Secure": "WPassword" }
```

12.22.7.1.7 Code Structure

12.22.7.1.7.1 Main Functions

- `UserMain()` - Main application entry point
- `PostJsonDisplayText()` - Posts JSON strings to servers
- `PostPJSJsonDisplayText()` - Posts [ParsedJsonDataSet](#) objects to servers

12.22.7.1.7.2 Key Components

1. Network Initialization

- Initializes the network stack
- Enables system diagnostics
- Waits for [DHCP](#) address assignment

2. JSON Posting

- Uses [DoJsonPost \(\)](#) function for HTTP/HTTPS requests
- Handles authentication headers when required
- Manages response buffering

3. Response Handling

- Captures server responses in a 4KB buffer
- Null-terminates response strings
- Displays results or error messages

12.22.7.1.8 Usage

1. Compile and flash the application to your NetBurner device
2. Ensure network connectivity ([DHCP](#) or static IP)
3. Monitor serial output for:
 - Network initialization status
 - POST request URLs
 - Server responses
 - Any error messages

12.22.7.1.9 Output Format

The application prints status messages and results to the serial console:

```
Application started
Posting to web site [http://demo.netburner.com/Post]
Result:[Server response here]
Posting to web site [https://demo.netburner.com/Post]
Result:[Server response here]
...
```

12.22.7.1.10 Error Handling

- Network connectivity issues result in "Failed to contact server" messages
- Authentication failures are handled by the underlying HTTP client
- Buffer overflow protection with 4KB response limit

12.22.7.1.11 Dependencies

- NetBurner Runtime Libraries
- [init.h](#) - Network initialization
- [json_lexer.h](#) - JSON parsing and building
- [webclient/http_funcs.h](#) - HTTP client functions

12.22.7.1.12 Configuration

- Response buffer size: 4096 bytes
- Network timeout: 5 seconds for [DHCP](#)
- HTTP timeout: 60 seconds per request
- Main loop delay: 1 second

12.22.7.1.13 Notes

- The application runs in an infinite loop after completing all POST requests
- System diagnostics are enabled for debugging (consider disabling for production)
- HTTP diagnostics can be enabled by uncommenting `SetHttpDiag(true)`
- All endpoints use NetBurner's demo server for testing purposes

12.22.8 Get Application Image and Load it From a Web Server

12.22.8.1 LoadCodeFromServer

A NetBurner embedded application that demonstrates retrieving and loading new firmware images from a web server.

12.22.8.1.1 Overview

This application showcases how to perform over-the-air (OTA) firmware updates on NetBurner embedded devices. It connects to a web server, downloads a new application image, and loads it onto the device for execution.

12.22.8.1.2 Features

- **Network Initialization:** Automatically initializes the network stack and waits for [DHCP](#) configuration
- **Web Client Functionality:** Downloads files from web servers using HTTP GET requests
- **Authentication Support:** Supports HTTP basic authentication for secured downloads
- **Firmware Update Process:** Implements the complete OTA update workflow
- **Interactive Interface:** Simple command-line interface for triggering updates

12.22.8.1.3 How It Works

1. **Network Setup:** The application initializes the network stack and waits for an active network connection via [DHCP](#)
2. **URL Configuration:** Constructs a platform-specific URL pointing to the firmware image on AWS S3
3. **User Interaction:** Waits for user input to trigger the update process
4. **Download and Install:** Downloads the new firmware image and attempts to install it
5. **Automatic Reboot:** On successful installation, the device reboots with the new firmware

12.22.8.1.4 Usage

12.22.8.1.4.1 Basic Operation

1. Deploy the application to your NetBurner device
2. Connect to the device's console/terminal
3. Wait for the network to initialize and receive a [DHCP](#) address
4. When prompted, press 'U' to start the update process
5. The application will download and install the new firmware

12.22.8.1.4.2 Console Output

The application provides detailed console output including:

- Network initialization status
- Update prompts and instructions
- Download progress and results
- Error messages if the update fails

12.22.8.1.5 Code Structure

12.22.8.1.5.1 Main Components

- `**UserMain()`: Primary application entry point that handles initialization and user interaction
- `**GetAndDisplay()`: Utility function for downloading and displaying web content (used for demonstration)
- **Network Stack**: Utilizes NetBurner's built-in networking capabilities
- **HTTP Client**: Uses NetBurner's webclient library for HTTP operations

12.22.8.1.5.2 Key Libraries Used

- `init.h`: Network stack initialization
- `json_lexer.h`: JSON parsing capabilities
- `webclient/http_funcs.h`: HTTP client functions
- `config_obj.h`: Configuration management

12.22.8.1.6 Configuration

The application is configured to download firmware from:

`https://netburner-apps.s3.amazonaws.com/{PlatformName}/SimpleHtml.bin`

Where `{PlatformName}` is automatically determined based on the target NetBurner platform.

12.22.8.1.7 Security Considerations

- The application includes support for HTTP basic authentication
- Downloads are performed over HTTPS for security
- The update process includes validation to prevent corrupted installations

12.22.8.1.8 Error Handling

The application includes comprehensive error handling:

- Network connectivity verification
- HTTP request timeout handling (60 seconds)
- Download validation
- Graceful failure recovery with user feedback

12.22.8.1.9 Development Notes

- System diagnostics are enabled for debugging (should be disabled in production)
- HTTP diagnostics can be enabled by uncommenting diagnostic flags
- The application uses a 5KB buffer for HTTP responses
- Network timeout is set to 5 seconds for initial connection

12.22.8.1.10 Platform Compatibility

This application is designed for NetBurner embedded devices and requires:

- NetBurner RTOS
- Active network connection (Ethernet or WiFi)
- Sufficient flash memory for firmware storage
- Internet connectivity to reach the update server

12.22.8.1.11 Building and Deployment

1. Ensure you have the NetBurner development environment set up
2. Compile the application using the NetBurner toolchain
3. Deploy to your NetBurner device using standard deployment methods
4. Connect to the device console to interact with the application

12.22.8.1.12 Safety Notes

- **Backup Your Firmware:** Always maintain a backup of your current firmware before performing updates
- **Stable Network:** Ensure a stable network connection during updates to prevent corruption
- **Power Supply:** Maintain stable power during the update process
- **Testing:** Test updates in a development environment before deploying to production devices

12.22.8.1.13 Troubleshooting

12.22.8.1.13.1 Common Issues

- **Network Connection Failed:** Verify [DHCP](#) configuration and network connectivity
- **Download Failed:** Check internet connectivity and server availability
- **Update Failed:** Ensure sufficient flash memory and stable power supply
- **Authentication Issues:** Verify credentials if using authenticated downloads

12.22.8.1.13.2 Debug Options

Enable diagnostic output by uncommenting:

```
SetHttpDiag(true);  
SetHttpUpDiag(true);
```

12.22.8.1.14 Example Output

```
Application started  
  
Hit U to update from  
[https://netburner-apps.s3.amazonaws.com/PLATFORM/SimpleHtml.bin]  
Starting update process...  
update returned /failed rv=0
```

12.22.9 Simple JSON HTML Example

12.22.9.1 NetBurner Simple JSON HTML Example

An example application demonstrating various methods for generating JSON responses from a NetBurner embedded web server.

12.22.9.1.1 Overview

This application showcases multiple approaches to serve JSON data from a NetBurner device, including static files, dynamic generation, and configuration-based responses. It provides a practical reference for developers working with NetBurner's web capabilities.

Shows several methods to have a NetBurner respond to web requests with JSON objects:

- Respond and generate the text directly.
- Respond and generate the response with a JSON lever object.
- Respond and generate the response using configuration variables.
- Respond and generate the response using a pre-built page stored in with web pages and using the dynamic web page capabilities.

12.22.9.1.2 Features

The application demonstrates several JSON response methods:

12.22.9.1.2.1 1. Static JSON Files

- **plain.json**: Pre-formatted static JSON content
- Simple text-based JSON stored as a file

12.22.9.1.2.2 2. Variable-Based Dynamic JSON

- **ut.json**: Template-based JSON with embedded variables
- Uses NetBurner's variable substitution system
- Displays runtime information like uptime, build date/time, and NNDK version

12.22.9.1.2.3 3. Callback-Based Dynamic JSON

- **callback.json**: Uses C++ callback functions to generate JSON
- Demonstrates the `<!--CPPCALL DoGeneerateJson -->` mechanism
- Generates JSON content programmatically at request time

12.22.9.1.2.4 4. Function-Based JSON Responses

- **GetJson**: Direct HTTP callback without associated HTML file
- **GetLexerJson**: Uses NetBurner's JSON lexer for structured generation
- Provides complete HTTP response handling in C++ code

12.22.9.1.2.5 5. Configuration System Integration

- **Config**: Exposes the entire configuration tree as JSON
- **Config/AppData/MyOwnValue**: Access specific configuration values
- Requires enabling the configuration mirror

12.22.9.1.3 File Structure

```
/
main.cpp          # Main application code
htmlvar.h         # Variable declarations for web pages
index.html        # Main navigation page
plain.json        # Static JSON example
ut.json           # Variable-based JSON template
callback.json     # Callback-based JSON page
```

12.22.9.1.4 Key Components

12.22.9.1.4.1 Main Application (main.cpp)

- Initializes network stack and HTTP server
- Defines global variables for web page access
- Implements callback functions for dynamic JSON generation
- Sets up configuration system integration

12.22.9.1.4.2 JSON Generation Methods

Method 1: Direct Text Output

```
int BuildAJsonResponseByText(int sock, HTTP_Request &pd)
{
    writestring(sock, "HTTP/1.0 200 OK\r\nPragma: no-cache\r\nContent-Type: application/json\r\n\r\n");
    writestring(sock, "{\"Test\":\"Json\"}");
    return 1;
}
```

Method 2: JSON Lexer

```
int BuildAJsonResponseByLexer(int sock, HTTP_Request &pd)
{
    ParsedJsonDataSet pjs;
    pjs.StartBuilding();
    pjs.Add("ANumber", 1234);
    pjs.Add("AString", "Testing123");
    pjs.AddMyMac("MyMacAddress");
    pjs.DoneBuilding();
    pjs.PrintObjectToFd(sock, true);
    return 1;
}
```

Method 3: Callback Function

```
void DoGenerateJson(int sock, PCSTR url)
{
    fdprintf(sock, "{\r\n\"Generated\":\"ByCallback\", \r\n");
    fdprintf(sock, "\"Uptime\":%ld\r\n", Secs);
}
```

12.22.9.1.5 Usage

1. **Build and Deploy:** Compile the application and deploy to your NetBurner device
2. **Access Web Interface:** Navigate to your device's IP address (default port 80)
3. **Test JSON Endpoints:** Use the provided links to test different JSON generation methods

12.22.9.1.5.1 Example URLs

Assuming your device IP is 10.1.2.3:

- <http://10.1.2.3/> - Main navigation page
- <http://10.1.2.3/plain.json> - Static JSON
- <http://10.1.2.3/ut.json> - Variable-based JSON
- <http://10.1.2.3/callback.json> - Callback-generated JSON
- <http://10.1.2.3/GetJson> - Direct function response
- <http://10.1.2.3/GetLexerJson> - JSON lexer response
- <http://10.1.2.3/Config> - Full configuration tree
- <http://10.1.2.3/Config/AppData/MyOwnValue> - Specific config value

12.22.9.1.6 Configuration

The application includes a configuration variable example:

```
config_int gMyOwnVal{appdata, 199, "MyOwnValue"};
```

This demonstrates how to expose application-specific configuration data through the web interface.

12.22.9.1.7 Build Requirements

- NetBurner NNDK (NetBurner Network Development Kit)
- C++ compiler with NetBurner libraries
- Standard NetBurner build environment

12.22.9.1.8 Key Features Demonstrated

- HTTP server initialization and setup
- Multiple JSON response generation techniques
- Variable substitution in web pages
- Callback-based dynamic content generation
- Configuration system integration
- Proper HTTP header handling
- Network stack initialization

12.22.9.1.9 Notes

- The application enables system diagnostics (should be removed for production)
- Configuration mirror must be enabled for config-based endpoints
- Default HTTP port is 80
- Application waits for active network connection before proceeding

12.22.9.1.10 Learning Objectives

This example is ideal for developers who want to understand:

- NetBurner web server capabilities
- JSON API development on embedded systems
- Dynamic content generation techniques
- Configuration system integration
- HTTP request handling in embedded C++

12.22.10 Simple JSON Post Receiver Example

12.22.10.1 Simple JSON Post Receiver Example

A NetBurner NNDK application that demonstrates how to receive JSON objects via HTTP POST requests from external RESTful APIs or JavaScript within web pages.

12.22.10.1.1 Overview

This application sets up a web server that can handle JSON POST requests through multiple endpoints. It provides both raw text processing and parsed JSON data handling capabilities, making it suitable for various integration scenarios.

12.22.10.1.2 Features

- **Multiple POST Endpoints:** Handles different types of POST requests
- **JSON Parsing:** Uses NetBurner's JSON lexer for structured data processing
- **Raw Text Processing:** Can handle plain text POST data
- **Configuration Integration:** Supports posting to the device's configuration system
- **Web Interface:** Includes a simple HTML interface with usage examples

12.22.10.1.3 POST Endpoints

The application provides three main POST endpoints:

12.22.10.1.3.1 1. /PostText

- Handles raw text POST data
- Processes content as plain text without JSON parsing
- Useful for simple data transmission

12.22.10.1.3.2 2. /PostLexer

- Processes JSON POST data using NetBurner's JSON lexer
- Validates JSON structure and provides lint checking
- Outputs parsed JSON object structure

12.22.10.1.3.3 3. /Config/AppData/MyOwnValue

- Allows posting directly to the configuration system
- Updates configuration values via HTTP POST
- Integrated with NetBurner's configuration server

12.22.10.1.4 Usage Examples

The application can be tested using the `wget` command-line utility:

12.22.10.1.4.1 Send JSON to Text Processor

```
wget -O- --post-data='{ "Data":1}' --header='Content-Type:application/json' 'http://[device-ip]/PostText'
```

12.22.10.1.4.2 Send JSON to Lexer Processor

```
wget -O- --post-data='{ "Data":2}' --header='Content-Type:application/json' 'http://[device-ip]/PostLexer'
```

12.22.10.1.4.3 Update Configuration Value

```
wget -O- --post-data='{ "MyOwnValue":8765}' --header='Content-Type:application/json'
'http://[device-ip]/Config/AppData/MyOwnValue'
```

12.22.10.1.5 Code Structure

12.22.10.1.5.1 Main Components

- ****main.cpp**:** Core application logic and POST handlers
- ****htmlvar.h**:** Header file for HTML variable functions
- ****index.html**:** Web interface with usage instructions
- ****ReadMe.txt**:** Original documentation

12.22.10.1.5.2 Key Functions

- `**GetHost ()`: Retrieves the host information from HTTP requests
- `**SendResponse ()`: Sends standardized HTTP responses
- `**MyJsonPostHandlerText ()`: Processes raw text POST data
- `**MyJsonPostHandler ()`: Processes parsed JSON data

12.22.10.1.5.3 Configuration

The application includes a configuration integer `gMyOwnVal` with:

- Default value: 199
- Configuration path: `appdata`
- Name: "MyOwnValue"

12.22.10.1.6 Technical Details

12.22.10.1.6.1 Dependencies

- NetBurner NNDK framework
- HTTP server functionality
- JSON lexer library
- Configuration server support

12.22.10.1.6.2 Network Setup

- Initializes network stack on startup
- Starts HTTP server on default port 80
- Waits for active network connection
- Enables configuration mirror for remote management

12.22.10.1.6.3 Error Handling

- JSON lint validation with error reporting
- Timeout handling for POST data reception
- Network connection status monitoring

12.22.10.1.7 Development Notes

- System diagnostics are enabled (should be removed for production)
- Uses NetBurner's real-time operating system (NBRTOS)
- Includes proper memory management and timeout handling
- Supports both synchronous and asynchronous POST processing

12.22.10.1.8 Getting Started

1. Compile the application using NetBurner NNDK
2. Deploy to your NetBurner device
3. Access the web interface at `http://[device-ip]/`
4. Test POST endpoints using the provided wget examples
5. Monitor console output for debugging information

12.22.10.1.9 Response Format

All POST requests return a simple HTML response indicating successful processing:

```
<html><body>Post has been Processed by [processor-name]</body></html>
```

This application serves as a foundation for building more complex JSON-based communication systems with NetBurner devices.

12.23 malloc

12.23.1 Malloc Example Application

12.23.1.1 Overview

This application demonstrates dynamic memory allocation and deallocation using `malloc()` and `free()` functions. It showcases how to monitor heap space usage and illustrates the concept of memory fragmentation in embedded systems.

12.23.1.2 Purpose

The primary goals of this example are to:

- Demonstrate proper usage of `malloc()` and `free()` functions
- Show how to track heap space usage using `spaceleft()` and `mallinfo()`
- Illustrate memory fragmentation effects when freeing memory in different orders
- Provide insights into heap memory management for embedded applications

12.23.1.3 Key Features

12.23.1.3.1 Memory Tracking Functions

The application uses two important functions to monitor heap status:

1. `**spaceleft()` - Returns the amount of "untouched" memory (never allocated)
2. `**mallinfo()` - Returns detailed heap information including both untouched and freed memory

12.23.1.3.2 mallinfo Structure

The `mallinfo()` function returns a structure containing:

- `arena` - Total space allocated from system
- `ordblks` - Number of non-inuse chunks
- `smlblks` - Unused (always zero)
- `hblks` - Number of mmapped regions
- `hblkhd` - Total space in mmapped regions

- `usmblks` - Unused (always zero)
- `fsmblks` - Unused (always zero)
- `uordblks` - Total allocated space
- `fordblks` - Total non-inuse space
- `keepcost` - Top-most, releasable space

12.23.1.4 Application Flow

The application runs in a continuous loop performing the following sequence:

12.23.1.4.1 Allocation Phase

1. Allocates 1,000,000 bytes (pA)
2. Allocates 3,000,000 bytes (pB)
3. Allocates 512,000 bytes (pC)

12.23.1.4.2 Deallocation Phase

The memory is freed in a different order than allocated:

1. Frees pB (3,000,000 bytes)
2. Frees pA (1,000,000 bytes)
3. Frees pC (512,000 bytes)

After each allocation and deallocation, the heap status is displayed showing:

- Used memory
- Space left (untouched memory)
- Total free memory

12.23.1.5 Memory Fragmentation Example

This application demonstrates an important concept in dynamic memory management. When memory is freed in a different order than it was allocated, it can lead to fragmentation:

12.23.1.5.1 Example Scenario (1MB heap):

1. Allocate 100KB three times (A, B, C) - 700KB remains
2. Free A and B - `spaceleft()` still reports 700KB (watermark)
3. `mallinfo()` reports 900KB (including freed memory)

The `spaceleft()` function acts as a "watermark" showing the largest contiguous block available, while `mallinfo()` shows total available memory including fragmented blocks.

12.23.1.6 Key Observations

- **Order Matters:** The order of memory deallocation affects heap fragmentation
- **Watermark Effect:** `spaceleft()` value cannot increase until the last allocated block is freed
- **Monitoring is Critical:** Using both functions provides complete heap visibility
- **Production Considerations:** System diagnostics should be disabled in production code

12.23.1.7 Code Structure

- `ShowHeapSpace()` - Displays current heap statistics
- `UserMain()` - Main application loop with allocation/deallocation cycle
- Error handling for failed malloc operations
- 10-second delay between cycles for observation

12.23.1.8 Usage Notes

- The application includes system diagnostics that should be removed for production
- Memory allocation failures are handled gracefully with error messages
- The continuous loop allows observation of memory behavior over time
- All allocated memory is properly freed to prevent memory leaks

12.23.1.9 Educational Value

This example is particularly valuable for understanding:

- Dynamic memory management in embedded systems
- Memory fragmentation effects
- Proper error handling for memory allocation
- Heap monitoring techniques
- The difference between total available memory and contiguous available memory

12.23.1.10 Platform Requirements

- RTOS environment (uses `OSTimeDly`)
- Hardware abstraction layer (HAL)
- Standard C library with malloc/free support
- Support for `mallinfo()` function

12.24 MQTT Examples

Easy [MQTT](#) Object Examples:

- [MQTT Config Object Example](#)
- [MQTT Custom Object Example](#)
- [MQTT Object I/O Example](#)
- [MQTT Simple Object Pub/Sub Example](#)
- [MQTT SubHandler GPIO Example](#)

Advanced Examples:

- [Advanced MQTT Periodic Example](#)
- [Advanced MQTT Pub/Sub Example](#)
- [Advanced MQTT Echo Example](#)

12.24.1 MQTT Config Object Example

12.24.1.1 MQTT Config Object Application

12.24.1.1.1 Overview

This NetBurner application demonstrates how to expose the device's configuration system through [MQTT](#) messaging. It allows remote configuration of NetBurner devices by sending JSON configuration messages to specific [MQTT](#) topics, providing a convenient way to manage device settings without requiring direct HTTP access to the configuration system.

12.24.1.1.2 Application Features

- **Remote Configuration:** Modify device configuration remotely via [MQTT](#) messages
- **Dynamic Topic Generation:** Automatically creates device-specific topics based on MAC address
- **JSON Configuration Support:** Accepts standard NetBurner configuration JSON format
- **Bidirectional Communication:** Supports both reading and writing configuration values
- **Rate Limiting:** Implements [MQTT](#) publish rate limiting for network stability
- **Interactive Testing:** Provides console-based testing interface

12.24.1.1.3 How It Works

12.24.1.1.3.1 Topic Structure

The application creates a device-specific [MQTT](#) topic using the format:

`device/nburn_<MAC_SUFFIX>/config`

Where `<MAC_SUFFIX>` is the last 3 octets of the device's MAC address. For example:

- If MAC address is `00:03:F4:1A:2B:3C`, the topic becomes `device/nburn_1A2B3C/config`

12.24.1.1.3.2 Configuration Messages

Send JSON configuration messages to the device topic to modify settings. The JSON format follows the standard NetBurner configuration structure.

Example Configuration Message:**

```
{
  "Sys": {
    "Application": "My Custom App Name"
  }
}
```

This is equivalent to sending the same configuration via the HTTP configuration interface.

12.24.1.1.4 Usage

12.24.1.1.4.1 Prerequisites

- NetBurner device with [MQTT](#) support
- [MQTT](#) broker (configure connection details via NetBurner config system)
- Network connectivity

12.24.1.1.4.2 Setup

1. **Configure [MQTT](#) Connection:** Use the NetBurner configuration system to set:
 - [MQTT](#) broker URI
 - Username/password (if required)
 - SSL certificates (if using secure connection)
2. **Deploy Application:** Flash the application to your NetBurner device
3. **Network Connection:** Ensure the device has active network connectivity

12.24.1.1.4.3 Testing

Remote Configuration

1. Connect to your [MQTT](#) broker using any [MQTT](#) client
2. Send a JSON message to the device's config topic
3. The device will apply the configuration changes immediately

Interactive Testing

1. Connect to the device via serial console
2. Press any key when prompted
3. The application will send a test configuration message
4. Observe the response and applied changes

12.24.1.1.4.4 Example Configuration Messages

Change Application Name:**

```
{
  "Sys": {
    "Application": "Production Device v1.0"
  }
}
```

Modify Network Settings:**

```
{
  "Sys": {
    "NetIf": {
      "Ethernet0": {
        "DHCP": false,
        "IPAddr": "192.168.1.100"
      }
    }
  }
}
```

12.24.1.1.5 Code Structure

12.24.1.1.5.1 Key Components

- **MqttClient**: Configured [MQTT](#) client with connection management
- **mqttConfigTree**: [MQTT](#) configuration exposier that handles topic subscription and message processing
- **Rate Limiting**: Configured with 20 messages per 5-second window, burst of 4 messages
- **Connection Monitoring**: Waits for established [MQTT](#) connection before proceeding

12.24.1.1.5.2 Main Application Flow

1. Initialize file system (if not available)
2. Initialize network stack
3. Enable system diagnostics
4. Wait for active network connection
5. Configure [MQTT](#) rate limiting
6. Establish [MQTT](#) connection
7. Enter interactive testing loop

12.24.1.1.6 Configuration Options

The application uses the NetBurner configuration system for MQTT connection settings:

- **Broker Configuration:** Set via `MqttClient` configuration object
- **SSL/TLS:** Certificates stored in file system
- **Rate Limiting:** 20 messages per 5 seconds, burst capacity of 4 messages

12.24.1.1.7 Error Handling

- **Connection Monitoring:** Continuously monitors MQTT connection status
- **Network Dependency:** Waits for active network before attempting MQTT connection
- **Rate Limiting:** Prevents overwhelming the MQTT broker with messages

12.24.1.1.8 Security Considerations

- **Topic Naming:** Uses MAC address suffix for device identification
- **SSL Support:** Supports secure MQTT connections with certificates
- **Local Message Filtering:** Configured to ignore messages from the same client

12.24.1.1.9 Dependencies

- NetBurner NNDK
- MQTT library support
- File system support (for certificate storage)
- Network stack

12.24.1.1.10 Troubleshooting

12.24.1.1.10.1 Common Issues

1. **Connection Failures:** Verify MQTT broker settings and network connectivity
2. **Topic Not Found:** Check MAC address format in topic name
3. **Configuration Not Applied:** Ensure JSON format matches NetBurner config structure
4. **Rate Limiting:** Reduce message frequency if experiencing delays

12.24.1.1.10.2 Debugging

- Enable system diagnostics for detailed logging
- Monitor serial console for connection status messages
- Verify MQTT broker logs for message delivery

12.24.1.1.11 Production Deployment

For production use:

1. Remove or disable system diagnostics
2. Configure appropriate SSL certificates
3. Set production MQTT broker settings
4. Implement proper error handling and logging
5. Consider removing interactive testing code

12.24.2 MQTT Custom Object Example

12.24.2.1 MQTT Custom Object Example

12.24.2.1.1 Overview

This application demonstrates an industrial control system that exposes thermostat and PID controller data over [MQTT](#). It provides a practical example of how to implement bidirectional [MQTT](#) communication for industrial automation, allowing both local and remote monitoring and control of temperature systems and PID control loops. The application creates custom [MQTT](#) objects that automatically serialize to JSON and can be controlled through [MQTT](#) topic subscriptions, making it ideal for IoT industrial applications.

12.24.2.1.2 Features

12.24.2.1.2.1 Thermostat Control

- **Temperature Range Management:** Configurable minimum, maximum, and set point temperatures
- **Location Tracking:** Configurable location string (default: "Warehouse 1")
- **Active State Control:** Boolean flag to enable/disable thermostat operation
- **Real-time Monitoring:** Continuous JSON publication of thermostat status

12.24.2.1.2.2 PID Controller Sets

- **Dual PID Controllers:** Separate horizontal and vertical PID control sets
- **Tunable Parameters:** Individual P (Proportional), I (Integral), and D (Differential) terms
- **Industrial Ready:** Designed for precision control applications

12.24.2.1.2.3 MQTT Integration

- **Automatic JSON Serialization:** All objects automatically convert to JSON format
- **Bidirectional Communication:** Read current values and write new configurations
- **Topic-based Organization:** Clean topic structure for easy integration
- **Configurable Client:** Uses [MQTT](#) ConfiguredClient for flexible broker connections

12.24.2.1.3 Architecture

12.24.2.1.3.1 Class Hierarchy

```
mqtt_obj (base class)
  TempRange
    MaxTemp (mqtt_int)
    SetTemp (mqtt_int)
    MinTemp (mqtt_int)
  Thermostat (extends TempRange)
    Active (mqtt_bool)
    Location (mqtt_string)
  PIDSet
    P (mqtt_float) - Proportional term
    I (mqtt_float) - Integral term
    D (mqtt_float) - Differential term
  ControlSet
    Hset (PIDSet) - Horizontal controller
    Vset (PIDSet) - Vertical controller
```

12.24.2.1.3.2 MQTT Topics

Topic	Purpose	Data Format
Thermostat	Thermostat status and control	JSON with temperature ranges, active state, and location
ctrl_set	PID controller parameters	JSON with horizontal and vertical PID settings

12.24.2.1.4 Default Configuration

12.24.2.1.4.1 Thermostat Defaults

- **Maximum Temperature:** 100 deg
- **Set Temperature:** 30 deg
- **Minimum Temperature:** 10 deg
- **Active State:** true
- **Location:** "Warehouse 1"

12.24.2.1.4.2 PID Controller Defaults

- **Proportional (P):** 1.0
- **Integral (I):** 0.0001
- **Differential (D):** 0.0

12.24.2.1.5 Usage

12.24.2.1.5.1 Running the Application

1. The application initializes the network stack and waits for network connectivity
2. Connects to the configured [MQTT](#) broker
3. Publishes current object states as JSON to their respective topics
4. Subscribes to the same topics for remote configuration updates
5. Continuously displays current status to console

12.24.2.1.5.2 Interactive Mode

- Press any key during operation to toggle between display and control modes
- The application will show real-time JSON representations of both the thermostat and control sets
- System diagnostics are enabled for monitoring and debugging

12.24.2.1.5.3 MQTT Communication Examples

Thermostat JSON Structure:**

```
{
  "MaxTemp": 100,
  "SetTemp": 30,
  "MinTemp": 10,
  "Active": true,
  "Thermostat Location": "Warehouse 1"
}
```

Control Set JSON Structure:**

```
{
  "Hset": {
    "P": 1.0,
    "I": 0.0001,
    "D": 0.0
  },
  "Vset": {
    "P": 1.0,
    "I": 0.0001,
    "D": 0.0
  }
}
```

12.24.2.1.6 Configuration

The [MQTT](#) client configuration (broker URI, username, password, certificates) is managed through the NetBurner configuration system. Ensure proper [MQTT](#) broker settings are configured before running the application.

12.24.2.1.6.1 Prerequisites

- NetBurner RTOS platform
- Network connectivity
- [MQTT](#) broker access
- Filesystem support (for certificate storage)

12.24.2.1.7 Technical Implementation

12.24.2.1.7.1 Object Behavior

- **Auto-Publication:** Objects automatically publish to [MQTT](#) when values change (`eObj_Flag_PubOnWrite`)
- **Subscription:** Objects subscribe to their topics for remote updates (`eObj_Flag_Subscribe`)
- **JSON Serialization:** Built-in JSON rendering for all object types
- **Type Safety:** Strongly typed [MQTT](#) objects (int, float, bool, string)

12.24.2.1.7.2 Network Handling

- Automatic re-connection logic
- Connection status monitoring
- Graceful handling of network interruptions
- Configurable timeout and retry mechanisms

12.24.2.1.8 Use Cases

This example is ideal for:

- Industrial temperature control systems
- Remote monitoring of manufacturing processes
- IoT-enabled HVAC systems
- Process control applications requiring PID tuning
- Educational demonstrations of [MQTT](#) in industrial contexts
- Prototyping industrial automation systems

12.24.2.1.9 Development Notes

- The application uses NetBurner's [MQTT](#) library with custom object extensions
- Includes comprehensive error handling and connection management
- Designed for continuous operation in industrial environments
- Supports both local debugging and remote operation
- Extensible architecture for adding additional control objects

12.24.3 MQTT Object I/O Example

12.24.3.1 MQTT Object I/O Application

12.24.3.1.1 Overview

This application demonstrates bidirectional [MQTT](#) communication using hardware I/O pins on embedded platforms. It creates a bridge between physical hardware inputs/outputs and [MQTT](#) messaging, allowing remote monitoring and control of GPIO pins through [MQTT](#) topics.

12.24.3.1.2 Features

- **Input Monitoring:** Monitors a physical input pin and publishes state changes to an [MQTT](#) topic
- **LED Control:** Subscribes to an [MQTT](#) topic to control a physical LED
- **Serial Console Interface:** Provides local control and monitoring through serial console
- **Multi-Platform Support:** Compatible with multiple NetBurner development boards

12.24.3.1.3 Hardware Configuration

The application uses different GPIO pins depending on the target platform:

Platform	Input Pin	LED Pin
SOMRT1061	Pin 22	LED1
NANO54415	Pin 50	LED1
MODM7AE70	P2[8]	LED1
MOD5441X	J2[45]	LED1
SBE70LC	P1[5]	LED1
SB800EX	No input pin	LED1

12.24.3.1.4 MQTT Topics

12.24.3.1.4.1 Published Topics

- **Device/Input1:** Publishes input pin state changes
 - Values: 0 (low/GND) or 1 (high/3.3V)
 - Published automatically when input pin state changes

12.24.3.1.4.2 Subscribed Topics

- **Device/LED1:** Controls LED state
 - Accepted values:
 - * `true` or any value `> 0`: Turns LED ON
 - * `false` or 0: Turns LED OFF

12.24.3.1.5 Operation

12.24.3.1.5.1 Startup Behavior

1. Initializes network stack and file system (if needed for certificates)
2. Waits for active network connection (5 second timeout)
3. Displays application name and NNDK revision
4. Sets up [MQTT](#) I/O objects for input monitoring and LED control
5. Outputs current input pin state (0 or 1) to serial console
6. Enters main loop for serial console interaction

12.24.3.1.5.2 Runtime Behavior

- **Input Pin Monitoring:** Automatically publishes to `Device/Input1` when the input pin state changes
- **LED Control via [MQTT](#):** LED state changes when messages are received on `Device/LED1` topic
- **Serial Console Control:** Pressing any key on the serial console toggles the LED state

12.24.3.1.6 Testing

12.24.3.1.6.1 Input Pin Testing

1. Connect the specified input pin to GND to read 0
2. Connect the specified input pin to 3.3V to read 1
3. Monitor the serial console or [MQTT](#) topic `Device/Input1` for state changes

12.24.3.1.6.2 LED Control Testing

1. **Via [MQTT](#):** Send messages to the `Device/LED1` topic:
 - Send `1`, `true`, or any positive number to turn LED on
 - Send `0` or `false` to turn LED off
2. **Via Serial Console:** Press any key to toggle the LED state

12.24.3.1.7 Configuration

The [MQTT](#) client configuration (broker URI, username, password, certificates, etc.) is handled through the NetBurner configuration system. Ensure your [MQTT](#) broker settings are properly configured before running the application.

12.24.3.1.8 Code Structure

12.24.3.1.8.1 Key Components

- [MQTT::ConfiguredClient](#) `MqttClient`: Main [MQTT](#) client instance
- [MQTT::mqtt_IO_Output](#) `myLED`: MQTT-controlled LED output object
- [MQTT::mqtt_IO_Input](#) `myInput`: MQTT-publishing input monitoring object

12.24.3.1.8.2 Optional Features

- Uncomment the `myLED.SetFlags(MQTT::eObj_Flag_PubOnWrite)` line to publish LED state changes to the [MQTT](#) topic when the LED is controlled locally

12.24.3.1.9 Dependencies

- NetBurner NNDK (NetBurner Network Development Kit)
- [MQTT](#) library support
- Network connectivity
- File system support (for [MQTT](#) certificates/keys)

12.24.3.1.10 Build Requirements

- Compatible NetBurner development board
- Properly configured [MQTT](#) broker
- Network connection (Ethernet or WiFi depending on platform)

12.24.3.1.11 Notes

- The SB800EX platform does not support input pin monitoring due to hardware limitations
- System diagnostics are enabled by default (consider removing for production deployments)
- The application waits up to 5 seconds for network connectivity before proceeding
- Certificate and key storage requires file system support on platforms that don't have built-in file system capabilities

12.24.4 MQTT Simple Object Pub/Sub Example

12.24.4.1 MQTT Simple Object Pub/Sub Application

12.24.4.1.1 Overview

This application demonstrates a simple MQTT publish/subscribe implementation using the NetBurner NNDK (NetBurner Network Development Kit). The application showcases automatic MQTT object synchronization, where a local variable can be both published to and updated from an MQTT topic.

12.24.4.1.2 Application Description

The MQTT Simple Object Pub/Sub Example is a console-based application that manages an integer variable (`myInt`) through MQTT messaging. The application performs the following key functions:

12.24.4.1.2.1 Core Functionality

- **Automatic Publishing:** The `myInt` variable is automatically published to the MQTT topic `testTopic/HelloWorld` whenever its value changes
- **Periodic Publishing:** Additionally publishes the current value every 3 minutes, regardless of whether it has changed
- **Automatic Subscription:** The same variable automatically subscribes to the MQTT topic, allowing remote updates
- **Interactive Control:** Users can increment the variable by typing any character in the serial console
- **Real-time Monitoring:** Continuously displays the current value of `myInt` on the console

12.24.4.1.2.2 Technical Implementation

- **MQTT Client:** Uses a configured MQTT client that gets its settings (broker URI, credentials, etc.) from the system configuration
- **MQTT Object:** Utilizes the `MQTT:mqtt_int` class for seamless integration between local variables and MQTT topics
- **Network Stack:** Initializes the full network stack and waits for active network connectivity
- **File system Support:** Includes conditional file system initialization for platforms that support it (used for storing MQTT certificates and keys)

12.24.4.1.3 Key Components

12.24.4.1.3.1 Variables and Objects

- `myInt`: An MQTT-enabled integer that automatically syncs with the MQTT topic
- `MqttClient`: Configured MQTT client instance
- `MQTT_TOPIC_NAME`: Defines the topic as "testTopic/HelloWorld"

12.24.4.1.3.2 Main Operations

1. **Network Initialization:** Establishes network connectivity and waits up to 5 seconds for an active connection
2. **MQTT Configuration:** Sets up automatic publishing every 3 minutes (180 seconds)
3. **Interactive Loop:** Continuously monitors for user input and displays current values

12.24.4.1.4 Usage

12.24.4.1.4.1 Running the Application

1. Ensure your NetBurner device is properly configured with network settings
2. Configure [MQTT](#) broker settings through the system configuration
3. Flash and run the application on your NetBurner device
4. Monitor the serial console for output

12.24.4.1.4.2 Interacting with the Application

- **Local Control:** Type any character in the serial console to increment `myInt`
- **Remote Control:** Send a numeric [MQTT](#) message to topic `testTopic/HelloWorld` to update `myInt`
- **Monitoring:** Watch the console output to see the current value of `myInt`

12.24.4.1.4.3 Expected Behavior

- Each keypress increments the variable and triggers an [MQTT](#) publish
- The current value is displayed on the console after each update
- Every 3 minutes, the current value is published automatically
- Remote [MQTT](#) messages to the topic will update the local variable

12.24.4.1.5 Configuration Requirements

Before running this application, ensure the following are configured:

- **Network Settings:** IP address, subnet mask, gateway, DNS
- **MQTT Broker:** Broker URI/IP address and port
- **Authentication:** Username and password (if required by broker)
- **Security:** TLS certificates and keys (if using secure connection)

12.24.4.1.6 Development Notes

- The application includes system diagnostics that should be removed for production code
- Filesystem initialization is conditional based on platform capabilities
- The code uses NetBurner's RTOS and network stack APIs
- [MQTT](#) objects provide automatic serialization and deserialization

12.24.4.1.7 Platform Requirements

- NetBurner NNDK-compatible hardware
- Network connectivity (Ethernet or Wi-Fi)
- Access to an [MQTT](#) broker
- Serial console for interaction and monitoring

This example serves as a foundation for more complex [MQTT](#) applications and demonstrates the ease of integrating [MQTT](#) messaging into NetBurner applications using the provided [MQTT](#) object classes.

12.24.5 MQTT SubHandler GPIO Example

This example demonstrates a custom subscription handler with the easy MqttObj system, for the case where a developer wants to easily use custom logic for subscribing to messages without implementing low-level things. Once connected, a dynamic topic name will be output to stdout. The user can send an MQTT message of 1 or 0 to that topic to turn on or off the LED pin.

Any numbered PinIO pin can be accessed in this way. For platforms that access pins like P1[int], a slash can separate the header and pin, like: pins/1/1

12.24.6 Advanced MQTT Periodic Example

12.24.6.1 MQTT Periodic Publish Example

12.24.6.1.1 Overview

The MQTT Periodic Publish Example is a comprehensive demonstration of implementing the NetBurner MQTT client at a deep level, designed for developers who want to customize every aspect of the MQTT interaction. This example showcases advanced MQTT publishing techniques using periodic timers, semaphores, and quality of service (QoS) configurations.

12.24.6.1.2 Application Features

12.24.6.1.2.1 Core Functionality

- **Dual Publishing Modes:** The application operates in two distinct modes:
 - **Echo Mode (PublishCounter):** Sends sequential binary data chunks every 10 seconds
 - **Sine Wave Mode:** Publishes calculated sine wave values at different frequencies

12.24.6.1.2.2 MQTT Topics

The application publishes to three primary MQTT topics:

- testTopic/example/echo - Binary counter data in echo mode
- testTopic/example/sine_x - Sine wave values (sin(x))
- testTopic/example/sine_3x - Scaled sine wave values (3*sin(x))

12.24.6.1.2.3 Advanced MQTT Features

- **Quality of Service (QoS):** Implements "At Least Once" delivery guarantee
- **Publish Acknowledgment Callbacks:** Custom handlers for publication confirmations
- **Connection State Management:** Automatic handling of connection establishment
- **Priority-based Message Queuing:** Configurable message priorities for publishing
- **Semaphore-based Flow Control:** Prevents message queue overflow

12.24.6.1.3 Technical Implementation

12.24.6.1.3.1 Key Components

MQTT Client Configuration

- Uses MQTT::ConfiguredClient with broker settings from the configuration system
- Implements connection notifications and automatic reconnection handling
- Supports secure connections with certificate/key storage via filesystem

Interval Timing System

- **IntervalTimer:** Manages periodic publishing operations
- **IntervalAction:** Defines callback actions for different publishing tasks
- **OS Semaphores:** Provides thread-safe publishing coordination

Publishing Mechanisms

1. Sine Wave Publishers:

- Calculate mathematical sine values with configurable step size
- Publish floating-point values as formatted strings
- Implement separate callbacks for acknowledgment handling

2. Counter Publisher:

- Generates sequential binary data (64 bytes per message)
- Uses union structure for efficient byte/word access
- Publishes at lower priority with fire-and-forget semantics

12.24.6.1.3.2 State Management

The application operates in three distinct run states:

- **State 0:** Connection establishment and timer initialization
- **State 1:** Active publishing with user interaction support
- **State 2:** Graceful shutdown and cleanup

12.24.6.1.4 Application Behavior

12.24.6.1.4.1 Startup Sequence

1. **Initialization:** Network stack and filesystem setup
2. **Connection Waiting:** Displays "NotConnected" until [MQTT](#) broker connection established
3. **Timer Start:** Shows "Starting IntervalSem: {timer}" when connected and ready
4. **Active Publishing:** Begins sending data according to configured intervals

12.24.6.1.4.2 Runtime Operation

- **Echo Mode:** Sends 64-byte binary counter data every 5 seconds to echo topic
- **Sine Mode:** Publishes calculated sine values with different frequencies
 - `sine_x` published every 4th cycle
 - `sine_3x` published every cycle
- **Interactive Control:** Press any key to toggle between modes or stop operation

12.24.6.1.4.3 Message Flow Control

- Uses semaphores to prevent overwhelming the [MQTT](#) broker
- Implements timeout mechanisms for reliable message delivery
- Provides graceful fallback when broker becomes unavailable

12.24.6.1.5 Configuration Requirements

12.24.6.1.5.1 Network Setup

- Requires active network connection before MQTT operations begin
- Waits up to 5 seconds for network establishment during startup

12.24.6.1.5.2 MQTT Broker Settings

- Broker URI, username, password, and other client configurations are managed through the NetBurner configuration system
- Supports secure connections with TLS/SSL certificates stored in filesystem

12.24.6.1.5.3 Development Environment

- Designed for NetBurner embedded systems
- Requires NNDK (NetBurner Network Development Kit)
- File system support recommended for certificate management

12.24.6.1.6 Known Issues

- Subscription and message reception functionality for the echo topic is not currently implemented (marked as TODO)
- The application currently focuses on publishing; subscriber callbacks need to be added for complete bidirectional communication

12.24.6.1.7 Usage Notes

This example is ideal for developers who need:

- Fine-grained control over MQTT message publishing
- Understanding of advanced QoS implementation
- Integration of periodic timers with MQTT operations
- Custom acknowledgment handling and flow control
- Educational reference for NetBurner MQTT client implementation

12.24.7 Advanced MQTT Pub/Sub Example

12.24.7.1 MQTT Advanced Pub/Sub Example

12.24.7.1.1 Overview

This NetBurner application demonstrates advanced MQTT publish/subscribe functionality with additional features including remote configuration management and GPIO pin control over MQTT. The application serves as a comprehensive example of integrating MQTT communication with embedded system control capabilities.

12.24.7.1.2 Features

12.24.7.1.2.1 Core MQTT Functionality

- **Automatic Publishing:** Publishes "Hello World" messages to `testTopic/HelloWorld` every 10 seconds
- **Message Subscription:** Subscribes to the same topic and echoes received messages to the serial console
- **Connection Management:** Handles MQTT connection establishment and recovery automatically
- **Rate Limiting:** Implements publish rate limiting (20 messages per 5 seconds, burst of 4)

12.24.7.1.2.2 Advanced Features

- **Remote Configuration:** Exposes NetBurner Config system via [MQTT](#) topic `device/nburnxxxxxx/config`
- **GPIO Control:** Allows remote control of device pins through [MQTT](#) topics `device/nburnxxxxxx/pins/+`
- **MAC-Based Topics:** Uses device MAC address for unique topic identification
- **Multi-Platform Support:** Supports various NetBurner platforms with different pin configurations

12.24.7.1.3 MQTT Topics

12.24.7.1.3.1 Published Topics

- `testTopic/HelloWorld` - Publishes "Hello World" message every 10 seconds

12.24.7.1.3.2 Subscribed Topics

- `testTopic/HelloWorld` - Echoes received messages to serial console
- `device/nburn_{MAC}/config` - Configuration management interface
- `device/nburn_{MAC}/pins/+` - GPIO pin control interface

Note

`{MAC}` is replaced with the last 3 octets of the device's MAC address (e.g., `device/nburn123456/config`)

12.24.7.1.4 GPIO Control

12.24.7.1.4.1 Pin Control Format

The application accepts pin control messages in the following formats:

For platforms with direct pin access (NANO54415, SB800EX, SOMRT1061, SBE70LC):**

- Topic: `device/nburn_{MAC}/pins/{pin_number}`
 - Examples: `device/nburn123456/pins/1`, `device/nburn123456/pins/15`
- For platforms with header/pin structure (MOD5441X):**
- Topic: `device/nburn_{MAC}/pins/{header}/{pin}`
 - Examples: `device/nburn123456/pins/1/5`, `device/nburn123456/pins/2/3`

12.24.7.1.4.2 Control Values

Pins can be controlled using various message formats:

- `1` or `true` - Set pin HIGH
- `0` or `false` - Set pin LOW
- Any numeric value - Set pin to that boolean value (0 = LOW, non-zero = HIGH)

12.24.7.1.5 Application Flow

1. Initialization

- Initialize file system (if not present)
- Initialize network stack
- Wait for active network connection
- Configure [MQTT](#) client with rate limiting

2. Connection Phase

- Establish [MQTT](#) connection using configured broker settings
- Wait for connection establishment before proceeding

3. Operation Phase

- Subscribe to echo topic (`testTopic/HelloWorld`)
- Enter main loop:
 - Publish "Hello World" message every 10 seconds
 - Process incoming [MQTT](#) messages
 - Handle pin control requests
 - Monitor for user input to change states

4. Message Handling

- Echo messages: Forward received messages to serial console
- Pin control: Parse topic and message to control GPIO pins
- Configuration: Handle remote configuration changes

12.24.7.1.6 Configuration

The application uses the NetBurner Config system for [MQTT](#) broker configuration:

- Broker URI
- Username/Password authentication
- SSL/TLS certificates (stored in file system)
- Connection parameters

Configuration can be modified remotely via the [MQTT](#) configuration topic.

12.24.7.1.7 Build Requirements

- NetBurner NNDK (NetBurner Network Development Kit)
- Supported NetBurner hardware platform
- [MQTT](#) broker for testing

12.24.7.1.8 Usage Instructions

1. Setup

- Configure [MQTT](#) broker settings using NetBurner Config system
- Flash the application to your NetBurner device
- Ensure network connectivity

2. Testing

- Monitor serial output for connection status and published messages
- Use [MQTT](#) client to subscribe to `testTopic/HelloWorld` to see published messages
- Publish messages to `testTopic/HelloWorld` to test echo functionality
- Control GPIO pins by publishing to appropriate pin control topics

3. Interactive Control

- Press any key during operation to change application states
- Use serial console to monitor application status and debug information

12.24.7.1.9 Platform-Specific Notes

12.24.7.1.9.1 Supported Platforms

- **NANO54415:** Direct pin access via `Pins[]` array
- **SB800EX:** Direct pin access via `Pins[]` array
- **SOMRT1061:** Direct pin access via `Pins[]` array
- **SBE70LC:** Direct pin access via `Pins[]` array
- **MOD5441X:** Header-based pin access (J1/J2 headers)

12.24.7.1.9.2 Pin Control Differences

- **Direct access platforms:** Use single pin number (e.g., `/pins/5`)
- **Header-based platforms:** Use header/pin format (e.g., `/pins/1/5` for J1 pin 5)

12.24.7.1.10 Error Handling

- **Connection Loss:** Automatically attempts reconnection
- **Subscription Failures:** Reports error codes and reason strings
- **Invalid Pin Messages:** Silently ignores malformed pin control messages
- **Rate Limiting:** Prevents message flooding with configurable limits

12.24.7.1.11 Debug Information

The application provides extensive debug output including:

- Connection status updates
- Subscription confirmation
- Message reception notifications
- Pin control operations
- Error conditions and recovery attempts

12.24.7.1.12 Security Considerations

- Uses NetBurner's built-in [MQTT](#) security features
- Supports SSL/TLS encryption when configured
- MAC-based topic naming provides device-specific addressing
- Configuration changes logged for audit trail

12.24.8 Advanced MQTT Echo Example

12.24.8.1 MQTT Echo Application

12.24.8.1.1 Overview

This NetBurner [MQTT](#) Echo application demonstrates advanced [MQTT](#) client functionality by subscribing to a specific topic and echoing received messages to the serial console. The application uses low-level [MQTT](#) protocol handling to provide detailed message processing capabilities.

12.24.8.1.2 Features

- **MQTT Topic Subscription:** Automatically subscribes to `testTopic/HelloWorld`
- **Message Echo:** Outputs all received messages to the serial console
- **Low-Level Protocol Handling:** Uses file descriptors and `readall/writeall` functions for direct message processing
- **Connection Management:** Handles MQTT connection establishment and monitoring
- **Property Handling:** Processes MQTT message properties (metadata) appropriately
- **Error Handling:** Manages subscription termination and connection failures

12.24.8.1.3 Architecture

12.24.8.1.3.1 Key Components

- **ConfiguredClient:** MQTT client configured through the NetBurner configuration system
- **TopicHandler:** Low-level message handler that processes incoming MQTT Publish messages
- **EchoSubscriber:** Callback function that handles message reception and console output

12.24.8.1.3.2 Message Processing Flow

1. Application establishes connection to MQTT broker
2. Subscribes to the configured topic (`testTopic/HelloWorld`)
3. Receives MQTT Publish messages through file descriptor interface
4. Processes message properties (skips them in this implementation)
5. Reads message payload and outputs to serial console
6. Handles connection status changes and subscription termination

12.24.8.1.4 Configuration

The MQTT client configuration (broker URI, username, password, certificates) is managed through the NetBurner configuration system rather than hardcoded values.

12.24.8.1.4.1 Default Settings

```
#define MQTT_TOPIC_NAME      "testTopic/HelloWorld"
#define MQTT_PUBLISH_MSG    "Hello World"
```

12.24.8.1.5 Technical Details

12.24.8.1.5.1 File Descriptor Interface

This application demonstrates the low-level MQTT interface using:

- `readall()` function for reading message data
- `writeall()` function for console output
- Direct file descriptor manipulation for message processing

12.24.8.1.5.2 Message Structure Handling

The application properly handles MQTT Publish message structure:

- **Properties Section:** MQTT v5.0 properties for metadata (skipped in this example)
- **Payload Section:** Actual message content (echoed to console)

12.24.8.1.5.3 Connection Management

- Waits for active network connection (5-second timeout)
- Monitors MQTT connection status continuously
- Automatically attempts subscription when connection is established
- Handles connection failures gracefully

12.24.8.1.6 Usage

1. **Network Setup:** Ensure the device is connected to a network
2. **MQTT Configuration:** Configure MQTT broker settings through NetBurner config
3. **Deploy Application:** Flash the application to the NetBurner device
4. **Monitor Output:** Watch the serial console for received messages
5. **Test Messaging:** Publish messages to `testTopic/HelloWorld` from any MQTT client

12.24.8.1.7 Console Output

The application provides detailed console output including:

- Connection status updates
- Subscription confirmation with handler ID
- Received message topic information
- Message payload content
- Subscription termination notifications

12.24.8.1.8 Error Handling

- **Subscription Termination:** Detects when subscriptions end and reports reason codes
- **Invalid Message Types:** Filters out non-Publish messages
- **Connection Failures:** Continuously monitors and reports connection status
- **File System Support:** Conditionally initializes filesystem for certificate storage

12.24.8.1.9 Dependencies

- NetBurner NNDK (NetBurner Network Development Kit)
- MQTT library support
- Network stack initialization
- Optional: Filesystem support for certificates

12.24.8.1.10 Development Notes

- System diagnostics are enabled for development (should be disabled for production)
- Uses 10-second polling interval for connection monitoring
- 4-second timeout for subscription operations
- Supports both platforms with and without filesystem capabilities

12.24.8.1.11 Example Use Cases

- IoT device message monitoring
- [MQTT](#) broker testing and validation
- Network communication debugging
- Real-time message processing demonstrations
- Integration testing for MQTT-based systems

12.25 Multicast

12.25.1 Multicast Example Application

12.25.1.1 Overview

This example program demonstrates how to add a NetBurner device to a multicast group for sending and receiving UDP packets. The application allows you to specify a multicast IP address and port number, then send data by typing it in MTTTY or view received data from other devices in the same multicast group.

Note

This example only supports IPv4 multicast communication.

12.25.1.2 Features

- Join IPv4 multicast groups
- Send UDP packets to multicast group
- Receive and display UDP packets from multicast group
- Interactive console interface for user input
- Concurrent packet listening and sending

12.25.1.3 Application Components

12.25.1.3.1 main.cpp

The main NetBurner application written in C++ that:

- Prompts user for multicast group port number
- Prompts user for multicast IP address (administratively-scoped local IPv4 range: 239.0.0.0 to 239.255.255.255)
- Creates a background task to listen for incoming multicast packets
- Allows interactive sending of text messages to the multicast group
- Handles graceful shutdown and unregistration from multicast group

12.25.1.3.2 MultiRx.py

A Python utility script for testing multicast reception:

- Listens on multicast group 239.1.2.3 port 35123
- Receives and displays UDP packets from the multicast group
- Useful for testing the NetBurner application from a PC

12.25.1.4 How It Works

1. **Initialization:** The application starts by enabling system diagnostics and prompting for configuration
2. **Configuration:** User enters the port number and multicast IP address
3. **Task Creation:** A background task (MultiReaderMain) is created to handle incoming packets
4. **Packet Reception:** The background task registers with the multicast group and continuously listens for packets
5. **Packet Sending:** The main loop allows user to type messages that are sent as UDP packets to the multicast group
6. **Shutdown:** Empty input triggers unregistration and shutdown

12.25.1.5 Usage Instructions

12.25.1.5.1 NetBurner Device Setup

1. Flash the application to your NetBurner device
2. Connect to the device via MTTY
3. When prompted, enter the multicast port number (e.g., 35123)
4. Enter a valid multicast IP address in the range 239.0.0.0 to 239.255.255.255
5. The device will join the multicast group and display confirmation

12.25.1.5.2 Sending Messages

1. Type any text message and press Enter to send it to the multicast group
2. The message will be broadcast to all devices in the same multicast group
3. Enter an empty string (just press Enter) to shutdown the listener

12.25.1.5.3 Receiving Messages

- The application automatically displays received packets with:
 - Packet size in bytes
 - Source IP address
 - Packet contents

12.25.1.5.4 Testing with Python Script

1. Run the MultiRx.py script on a PC connected to the same network
2. The script will listen for packets on multicast group 239.1.2.3 port 35123
3. Send messages from the NetBurner device to see them received by the Python script

12.25.1.6 Technical Details

12.25.1.6.1 Key Functions

- `RegisterMulticastFifo()`: Registers to receive multicast packets
- `UnregisterMulticastFifo()`: Unregisters from multicast group
- `UDPPacket`: Class for creating and parsing UDP packets
- `OSTaskCreatewName()`: Creates background task for packet reception

12.25.1.6.2 Multicast IP Address Ranges

The application uses administratively-scoped local IPv4 multicast addresses:

- Range: 239.0.0.0 to 239.255.255.255
- These addresses are reserved for organizational use and don't route across the internet

12.25.1.6.3 Threading Model

- Main thread handles user input and packet sending
- Background thread (MultiReaderMain) handles packet reception
- Uses OS_FIFO for inter-thread communication

12.25.1.7 Important Notes

- Only IPv4 multicast is supported
- The application requires a reset to restart after shutdown
- System diagnostics are enabled (consider removing for production)
- The hardcoded IP address 239.1.2.3 overrides user input in the current code

12.25.1.8 Troubleshooting

1. **No packets received:** Verify all devices are on the same network and using the same multicast address/port
2. **Application hangs:** Check network connectivity and firewall settings
3. **Build errors:** Ensure all NetBurner SDK libraries are properly linked

12.25.1.9 Dependencies

- NetBurner SDK
- Standard C++ libraries
- NetBurner multicast support library

12.26 Multihome

12.26.1 Multihome Application

A NetBurner TCP/IP Stack example demonstrating IPv4 multihoming capabilities.

12.26.1.1 Overview

This application demonstrates how to implement multiple IP addresses on a single NetBurner device using the Multihome functionality. The device will respond to requests from multiple network interfaces simultaneously:

- **DHCP Interface:** Obtains a dynamic IP address from a **DHCP** server
- **AutoIP Interface:** Uses automatic IP address assignment
- **Static Interface:** Uses a fixed IP address (10.1.1.240)

12.26.1.2 Features

- Multiple network interface support (up to 10 interfaces)
- Web-based IP address display and diagnostics
- Real-time IP address monitoring via serial debug output
- Responds to HTTP requests on any configured IP address

12.26.1.3 Prerequisites

12.26.1.3.1 Required System Configuration

Before building and running this application, you must enable multihome support:

The application example includes a `predef-overload.h` file that automatically enables:

- `MULTIHOME` functionality
- Support for up to 10 network interfaces (`NUM_MULTI_INTERFACES`)

The file utilizes the NetBurner **overload** feature by locating the file at: `\MultiHome\overload\nbrtos\include\predef-overload.h`

This way NetBurner system file `predef.h` does not need to be modified. See the **OverloadDirectory** example or the Overload section of this manual for more information.

Alternatively, you can modify the NetBurner `predef.h` system file as described below:

1. Navigate to `\nburn\nbrtos\include\predef.h`
2. Uncomment the `MULTIHOME` definition
3. Rebuild the system files

12.26.1.4 Application Behavior

12.26.1.4.1 Network Interface Setup

1. **Primary Interface:** Attempts `DHCP` address assignment
2. **Secondary Interface:** Uses AutoIP for automatic address assignment
3. **Tertiary Interface:** Configures static IP address (10.1.1.240) with subnet mask 255.255.255.0

12.26.1.4.2 Web Interface

The application starts an HTTP server that provides IP address information. Access the web interface using any of the configured IP addresses to view:

- Source IP address of the requesting client
- Destination IP address (which interface received the request)
- All configured IP addresses on the device

12.26.1.4.3 Debug Output

The application continuously outputs IP address information to the debug serial port every 5 seconds, showing:

- `DHCP` assigned IP address
- AutoIP assigned address
- Static multihome IP address

12.26.1.5 Code Structure

12.26.1.5.1 Key Files

- `main.cpp`: Main application logic and web server implementation
- `ReadMe.txt`: Original documentation (Doxygen format)
- `predef-overload.h`: Compiler definitions for multihome support

12.26.1.5.2 Key Functions

- `UserMain()`: Main application entry point
- `WebDisplayIpSettings()`: Web page handler for IP address display
- `AddInterface()`: Adds the static multihome interface

12.26.1.5.3 Important Variables

- `DhcpIb`: Interface block for DHCP interface
- `StaticIb`: Interface block for AutoIP interface
- `MultiHome1Ib`: Interface block for static multihome interface

12.26.1.6 Usage

1. Ensure multihome support is enabled in system configuration
2. Build and deploy the application to your NetBurner device
3. Connect the device to your network
4. Monitor the debug serial output for IP address assignments
5. Access the web interface using any of the assigned IP addresses

12.26.1.7 Network Configuration

The static interface is configured with:

- **IP Address**: 10.1.1.240
- **Subnet Mask**: 255.255.255.0
- **Gateway**: Not configured (`IPADDR4::NullIP()`)

Ensure your network topology can accommodate this address range if you plan to access the static interface.

12.26.1.8 Error Handling

The application includes a compile-time check to ensure multihome support is enabled. If `MULTIHOME` is not defined, compilation will fail with an informative error message directing you to enable the feature in the system configuration.

12.26.1.9 System Requirements

- NetBurner device with TCP/IP stack
- NBRTOS operating system
- Multihome capability enabled in system build

12.27 NB Approve Shutdown

12.27.1 NBApproveShutdown Application

12.27.1.1 Overview

The NBApproveShutdown application demonstrates how to implement safe system shutdown handling for NetBurner embedded systems. This application provides a callback mechanism that allows developers to put their system in a safe state before application updates, configuration updates, or custom reboot events occur.

12.27.1.2 Purpose

The primary purpose of this application is to showcase the `NBApproveShutdown()` callback function, which enables applications to:

- Close active TCP sockets before shutdown
- Ensure Flash and file system write operations are complete
- Put critical peripherals in a safe state
- Control whether a shutdown request should be approved or denied

12.27.1.3 System Requirements

- NetBurner Hardware
- NetBurner Network Development Kit (NNDK)
- Serial terminal for interaction

12.27.1.4 Application Features

12.27.1.4.1 Shutdown Callback Function

The application implements a custom `NBApproveShutdown()` function that overrides the default system implementation. This function handles different shutdown reasons:

- **Code Update** (`SHUTDOWN_CODEUPDATE`): Triggered when a firmware update is requested
- **Configuration Reboot** (`SHUTDOWN_CONFIGURE_REBOOT`): Triggered when configuration changes require a reboot
- **Custom Reboot** (`SHUTDOWN_CUSTOM_REBOOT`): Application-defined reboot scenarios

12.27.1.4.2 Custom Reboot Reason

Custom reboot reason. System reasons start at 1, so pick something much larger

```
#define SHUTDOWN_CUSTOM_REBOOT 100

if ( NBApproveShutdown (SHUTDOWN_CUSTOM_REBOOT) )
{
    OSTimeDly (TICKS_PER_SECOND * 5);
    ForceReboot ();
}
```

12.27.1.4.3 Interactive Serial Menu

The application provides a simple serial port menu interface with the following options:

1. **Enable Shutdown** - Allows shutdown requests to proceed
2. **Disable Shutdown** - Blocks shutdown requests for testing
3. **Custom Reboot Request** - Initiates a custom reboot sequence

12.27.1.4.4 Web Server Integration

The application includes a basic web server that starts on port 80, allowing for potential web-based interactions and monitoring.

12.27.1.5 How It Works

12.27.1.5.1 Shutdown Approval Process

1. When a shutdown event occurs, the system calls `NBApproveShutdown()` with a reason code
2. The application can examine the reason and current system state
3. Based on application logic, the function returns:
 - `true` to approve the shutdown
 - `false` to abort the shutdown

12.27.1.5.2 Global Control Flag

The application uses a global boolean flag `bAllowShutdown` to demonstrate shutdown control:

- When `true`: All shutdown requests are approved
- When `false`: All shutdown requests are denied (except unknown reasons)

12.27.1.6 Usage Instructions

12.27.1.6.1 Building and Running

1. Compile the application using the NetBurner development tools
2. Flash the application to your NetBurner device
3. Connect a serial terminal to the device
4. Monitor the serial output for menu options and status messages

12.27.1.6.2 Testing Shutdown Behavior

1. **Enable/Disable Testing:** Use menu options 1 and 2 to toggle shutdown approval
2. **Custom Reboot Testing:** Use menu option 3 to trigger a custom reboot sequence
3. **Update Testing:** Attempt a firmware update to test the code update shutdown path

12.27.1.6.3 Serial Commands

- Press 1 to enable shutdown approval
- Press 2 to disable shutdown approval
- Press 3 to request a custom reboot
- Press any other key to display the menu

12.27.1.7 Code Structure

12.27.1.7.1 Key Components

- `NBApproveShutdown()`: Main callback function that processes shutdown requests
- `displayMenu()`: Shows available menu options and current status
- `processCommand()`: Handles serial input and executes commands
- `UserMain()`: Application entry point and main loop

12.27.1.7.2 Important Constants

```
#define SHUTDOWN_CODEUPDATE      (1)    // Code update requested
#define SHUTDOWN_CONFIGURE_REBOOT (2)    // Configuration reboot requested
#define SHUTDOWN_CUSTOM_REBOOT   (100)   // Custom application reboot
```

12.27.1.8 Implementation Notes

12.27.1.8.1 Safety Considerations

- The callback function includes a 1-second delay to ensure serial output completes before reboot
- Unknown shutdown reasons are automatically rejected for safety
- The weak reference mechanism allows easy override of default system behavior

12.27.1.8.2 Customization Points

Developers can customize this application by:

- Adding specific hardware shutdown sequences in the callback function
- Implementing additional shutdown reason codes
- Adding more sophisticated approval logic based on system state
- Integrating with web-based monitoring and control

12.27.1.9 Example Output

```
Web Application: NB Approve Shutdown
NNDK Revision: [Version Number]
```

```
----- Main Menu -----
1 - Enable  Shutdown
2 - Disable Shutdown
3 - Custom Reboot Request
Current bAllowShutdown = true
```

12.27.1.10 Development Guidelines

12.27.1.10.1 Best Practices

1. Always include appropriate delays before reboot to ensure data integrity
2. Test both approved and denied shutdown scenarios
3. Handle all known shutdown reasons explicitly
4. Consider system state when making approval decisions
5. Log shutdown events for debugging and monitoring

12.27.1.10.2 Integration Tips

- Use this pattern in production applications to ensure graceful shutdowns
- Combine with watchdog timers for additional safety
- Consider network notification of shutdown events
- Implement persistent logging of shutdown requests and approvals

12.28 NSString Class

This example program demonstrates the functionality [NSString](#) class.

12.29 Network Time Server (NTP) Client

12.29.1 NTP Client Example Application

A NetBurner embedded system application that demonstrates Network Time Protocol (NTP) client functionality, providing synchronized time display with timezone support.

Warning

For this example to function, your NetBurner device must have access to the Internet with a working configuration for the IP address, mask and gateway.

12.29.1.1 Overview

This application connects to an NTP server to synchronize the system clock and displays time information in multiple formats and time zones through the debug serial port. It serves as a practical example of network time synchronization for embedded NetBurner devices.

12.29.1.2 Features

- **NTP Time Synchronization:** Automatically connects to NTP servers for accurate time
- **Multiple Time Zone Support:** Displays time in UTC, local time, and major US time zones
- **Interactive Time Zone Selection:** Choose between US/Canada or International time zones
- **Real-time Display:** Continuously updates and displays current time information
- **Network Diagnostics:** Shows IP configuration and network status

12.29.1.3 Prerequisites

- NetBurner device with network connectivity
- Proper IP configuration (IP address, subnet mask, gateway)
- Internet access to reach NTP servers
- MTTTY or similar terminal program for monitoring output

12.29.1.4 Time Zone Features

12.29.1.4.1 Supported US Time Zones

The application includes predefined format strings for major US time zones:

- Eastern Time (EST/EDT)
- Central Time (CST/CDT)
- Mountain Time (MST/MDT)
- Pacific Time (PST/PDT)

12.29.1.4.2 Time Zone Selection

Users can choose between:

- **US/Canada Time Zones:** Filtered list of North American zones
- **International Time Zones:** Complete global time zone database

Note

Good example of using the global time zone database timezones.h

12.29.1.5 Application Flow

1. **Initialization:** System starts and enables network diagnostics
2. **Network Setup:** Waits for active network connection (10-second timeout)
3. **NTP Synchronization:** Connects to NTP server and waits for valid time
4. **Time Zone Setup:** Prompts user to select preferred time zone
5. **Display Loop:** Continuously shows time in multiple formats

12.29.1.6 Time Display Format

The application displays time information in the following format:

Time[ZONE] = MM/DD/YYYY day: DDD (DAY) HH:MM:SS

Where:

- ZONE: Time zone abbreviation
- MM/DD/YYYY: Month/Day/Year
- DDD: Day of year (1-365/366)
- DAY: Day of week abbreviation
- HH:MM:SS: Hour:Minute:Second in 24-hour format

12.29.1.7 Output Examples

12.29.1.7.1 Local Time Display

Local time based on SetTimeZone() function:
Time[PST] = 7/21/2025 day: 202 (MON) 15:30:45

12.29.1.7.2 UTC Time Display

UTC time =
Time[UTC] = 7/21/2025 day: 202 (MON) 23:30:45

12.29.1.7.3 Multiple Time Zone Display

Displaying US time zones with local format strings:
Time[EST] = 7/21/2025 day: 202 (MON) 18:30:45
Time[CST] = 7/21/2025 day: 202 (MON) 17:30:45
Time[MST] = 7/21/2025 day: 202 (MON) 16:30:45
Time[PST] = 7/21/2025 day: 202 (MON) 15:30:45

12.29.1.8 Key Functions

12.29.1.8.1 SetTimeZone()

Interactive function that allows users to select their preferred time zone from either US/Canada or International options.

12.29.1.8.2 PrintTimeStruct(struct tm &bt)

Formats and displays time information in a standardized format to the debug serial port.

12.29.1.8.3 UserMain(void *pd)

Main application entry point that handles initialization, NTP synchronization, and the main display loop.

12.29.1.9 Technical Details

12.29.1.9.1 Dependencies

- `init.h`: System initialization
- `time.h`: Time manipulation functions
- `ipshow.h`: IP address display utilities
- `timezones.h`: Time zone database and utilities
- `nbttime.h`: NetBurner time functions

12.29.1.9.2 NTP Client

The application uses the `NtpClientServlet` class for NTP operations:

- Waits up to 20 seconds for valid NTP response
- Provides retry mechanism with status updates
- Tracks time since last NTP update

12.29.1.10 Usage Instructions

1. **Hardware Setup**: Connect NetBurner device to network
2. **Network Configuration**: Ensure proper IP, mask, and gateway settings
3. **Terminal Connection**: Use MTTTY to monitor serial output
4. **Run Application**: Deploy and execute the application
5. **Time Zone Selection**: Follow prompts to select desired time zone
6. **Monitor Output**: View continuous time updates
7. **Manual Refresh**: Press any key to update display on demand

12.29.1.11 Status Information

The application provides:

- Network connectivity status
- NTP synchronization status with retry notifications
- Time since last NTP update
- IP address configuration display

12.29.1.12 Troubleshooting

- **No Network**: Ensure device has proper network configuration
- **NTP Timeout**: Check internet connectivity and firewall settings
- **Invalid Time**: Wait for NTP synchronization to complete
- **Display Issues**: Verify MTTTY terminal settings and baud rate

12.29.1.13 Development Notes

- Remove `EnableSystemDiagnostics()` for production deployment
- Time zone database extensible through `TZRecords` structure
- IPv6 support available when compiled with `IPV6` flag

12.30 NTP & Real-Time Clock

NTP-SYSTEM-RTC DEMO APPLICATION

Note

HARDWARE SETUP: Tested with MOD54415 on a MOD-DEV-70 hardware rev 1.93.

12.30.1 NTP-System-RTC Demo Application

A NetBurner embedded system application that demonstrates synchronization between Network Time Protocol (NTP) servers, system time, and Real-Time Clock (RTC) hardware components.

12.30.1.1 Overview

This application provides a comprehensive example of time management in embedded systems, showcasing the interaction between network-based time synchronization, system time management, and hardware RTC persistence. The demo is particularly useful for applications requiring accurate timekeeping that persists across power cycles.

12.30.1.2 Hardware Requirements

- **Primary Platform:** MOD54415 module
- **Development Board:** MOD-DEV-70 (hardware revision 1.93 or compatible)
- **RTC Component:** One of the following supported RTC chips:
 - Intersil X1226
 - NXP PCF8563

The RTC component must be present either on the module itself or on the development board to utilize the RTC-related features.

12.30.1.3 Features

12.30.1.3.1 Core Functionality

1. NTP Time Synchronization

- Retrieves current UTC time from NTP server pool (pool.ntp.org)
- Updates system time with network-sourced accurate time
- Requires DNS resolution capability

2. System-RTC Synchronization

- Saves current system time to hardware RTC
- Restores system time from RTC after power cycles
- Maintains time accuracy during power interruptions

3. Time Zone Support

- Configurable local time zone settings
- Pacific Time Zone (PST/PDT) preconfigured as example
- Automatic daylight saving time transitions
- Customizable via `tzsetchar()` function

4. Time Persistence

- RTC continues running on super-capacitor power during outages
- System time restoration from RTC after reset/power loss
- Software reset capability for testing RTC persistence

5. Time Display and Verification

- Real-time display of UTC and local times
- RTC time information display
- Synchronization status verification
- Time zone configuration display

12.30.1.4 Application Menu

The application provides an interactive menu with the following options:

- **[1]** Sync system time with NTP server (requires DNS)
- **[2]** Synchronize RTC from current system time
- **[3]** Synchronize system time from RTC
- **[4]** Verify synchronization between system and RTC
- **[5]** Display current system and RTC times
- **[6]** Re-display menu options
- **[0]** Software reset device (tests RTC persistence)

12.30.1.5 Technical Details

12.30.1.5.1 Time Storage Format

- **System Time:** Managed by NetBurner OS, stored as `time_t`
- **RTC Time:** Hardware-based, stores UTC time (recommended)
- **Local Time:** Calculated from UTC using configured time zone

12.30.1.5.2 Synchronization Logic

The application implements bidirectional synchronization:

- **NTP > System:** Network time updates local system clock
- **System > RTC:** Persistent storage of accurate time
- **RTC > System:** Time recovery after power cycles

12.30.1.5.3 Error Handling

- Network connectivity verification for NTP synchronization
- RTC hardware communication error detection
- DNS resolution failure handling
- Synchronization status reporting

12.30.1.6 Network Requirements

12.30.1.6.1 For NTP Functionality

- Active network connection (Ethernet recommended)
- DNS server configuration (required for `pool.ntp.org` resolution)
- Outbound NTP traffic (port 123) capability

12.30.1.6.2 Static IP Considerations

When using static IP configuration, manually configure DNS server addresses to enable NTP server name resolution.

12.30.1.7 Time Zone Configuration

The application uses Pacific Time as a demonstration. To configure for different time zones:

```
// Example for Eastern Time
char tzInfo[] = "EST5EDT4,M3.2.0/02:00:00,M11.1.0/02:00:00";
tzsetchar(tzInfo);
```

Refer to NetBurner Runtime Libraries documentation (Chapter 14 - NBTime Library) for detailed time zone configuration syntax.

12.30.1.8 Build and Deployment

12.30.1.8.1 Prerequisites

- NetBurner development environment
- Compatible NetBurner runtime libraries
- Hardware with supported RTC component

12.30.1.8.2 Key Libraries

- `nbttime.h` - NetBurner time management
- `rtc.h` - Real-time clock interface
- `hal.h` - Hardware abstraction layer
- `init.h` - System initialization

12.30.1.9 Usage Scenarios

1. **Initial Setup:** Use option [1] to sync with NTP, then option [2] to save to RTC
2. **Power Recovery:** After power loss, use option [3] to restore system time from RTC
3. **Verification:** Use option [4] to confirm system and RTC synchronization
4. **Monitoring:** Use option [5] to display current time status
5. **Testing:** Use option [0] to test RTC persistence across resets

12.30.1.10 Limitations

- Requires active network connection for NTP synchronization
- DNS resolution needed for NTP server access
- RTC persistence depends on super-capacitor charge level
- Synchronization accuracy limited to minute-level precision

12.30.1.11 Applications

This demo serves as a foundation for:

- Data logging systems requiring accurate timestamps
- Scheduled task execution in embedded systems
- Time-sensitive industrial automation
- Network-connected IoT devices with offline operation requirements
- Real-time data acquisition systems

12.31 Overload Directory & System Files

Additional instructions if the overload directory is used in an NBEclipse project:

12.31.1 NetBurner Overload Directory Example

12.31.1.1 Overview

This example demonstrates how to use the NetBurner overload directory feature to override system files in a project-specific manner. The overload directory allows developers to modify system configuration files without affecting other projects or the original NNDK installation.

The Overload Directory Example is a basic demonstration of the overload directory in a project. The overload directory is used to override any system file by including local copies of system source files or headers. This allows the user to make changes to system files exclusively for a project. The overload directory provides an alternative to modifying the original system files, which would affect all projects.

To use this feature, the file to be overloaded should be placed in the overload directory under a directory structure that matches the file's location relative to the NNDK install directory.

This example application utilizes the overload directory to override [predef.h](#) (a NetBurner configuration header file). The overloaded [predef.h](#) defines the macro `NBRTOS_TIME`, which is not defined by default.

To overload the [predef.h](#) header, the directory structure is replicated inside the overload directory. For example, [predef.h](#) is located in the following directory in the NNDK install:

```
`/nburn/nbrtos/include/predef.h`
```

Therefore, the directory structure is replicated inside the overload directory with the following structure:

```
`<project root>/overload/nbrtos/include/predef.h`
```

Note

Upon adding a overload folder to the "Include paths" list or adding a new file to the specified overload folder, the user will need to clean and rebuild the NetBurner Library. This can be done by selecting "Clean NetBurner System Library" under the "Build Targets" pull-down in the project. From that point on, modifying [predef.h](#) (or any overloaded source/header) will automatically rebuild the necessary files in the NetBurner Library when the project builds.

12.31.1.2 Application Description

The **Overload Directory Example** is a simple NetBurner application that showcases the overload directory functionality by:

- Initializing the network stack
- Enabling system diagnostics
- Waiting for an active network connection
- Continuously prompting the user to press any key to display task runtime information
- Using the `ShowTaskTimes()` function, which is only available when the `NBRTOS_TIME` macro is defined

12.31.1.3 Key Features

12.31.1.3.1 Overload Directory Functionality

The overload directory provides a mechanism to override any system file by including local copies of system source files or headers. This approach offers several advantages:

- **Project-specific modifications:** Changes only affect the current project
- **Preserves original system files:** No modification of the original NNDK installation
- **Maintainable:** Easy to track and manage project-specific customizations

12.31.1.3.2 Example Implementation

This project demonstrates overloading the `predef.h` system header file to define the `NBRTOS_TIME` macro, which enables the `ShowTaskTimes()` function.

12.31.1.4 Directory Structure

The overload directory must replicate the directory structure of the file being overridden relative to the NNDK install directory.

12.31.1.4.1 Original System File Location

```
/nburn/nbrtos/include/predef.h
```

12.31.1.4.2 Overloaded File Location

```
<project root>/overload/nbrtos/include/predef.h
```

12.31.1.5 Files in This Example

12.31.1.5.1 main.cpp

The main application file that:

- Initializes the NetBurner system
- Waits for network connectivity
- Provides an interactive loop for displaying task runtime information
- Calls `ShowTaskTimes()` function (available due to overloaded `predef.h`)

12.31.1.5.2 predef-overload.h

Contains the overloaded configuration that defines:

```
#define NBRTOS_TIME (1)
```

This macro enables the compilation of task timing functionality in the NetBurner system library.

12.31.1.5.3 ReadMe.txt

The original documentation explaining the overload directory concept and usage instructions.

12.31.1.6 Setup Instructions for NBEclipse Projects

If using this example in an NBEclipse project, additional configuration is required:

1. **Right-click** on the project in the "Project Explorer"
2. **Select** "Properties"
3. **Navigate** to C/C++ Build -> Settings
4. **Select** GNU C++ Compiler -> Includes
5. **Add** the overload include folder to the "Include paths" list
6. **For C code:** Also add the overloaded folder to GNU C Compiler -> Includes
7. **Ensure** the overload directory path is positioned **above** paths beginning with `$(NNDK_ROOT)/`
8. **Use** up/down arrow buttons to reposition if necessary
9. **Select** "Apply and close"

12.31.1.7 Building and Maintenance

12.31.1.7.1 Initial Setup

After adding an overload folder to the "Include paths" list or adding new files to the overload folder:

1. **Clean and rebuild** the NetBurner Library
2. **Select** "Clean NetBurner System Library" under the "Build Targets" pull-down

12.31.1.7.2 Ongoing Development

Once properly configured, modifying overloaded files (like `predef.h`) will automatically rebuild the necessary NetBurner Library files when the project builds.

12.31.1.8 Application Behavior

When running the application:

1. The system initializes and waits for network connectivity
2. Application name and NNDK revision information are displayed
3. The program enters an interactive loop:
 - Prompts user to press any key
 - Displays current task runtime information using `ShowTaskTimes()`
 - Repeats indefinitely

12.31.1.9 Important Notes

- The `ShowTaskTimes()` function is only available when `NBRTOS_TIME` is defined in `predef.h`
- Improper include path configuration will result in "ShowTaskTimes was not declared" build errors
- System diagnostics are enabled in this example and should be removed for production code
- This example requires NetBurner hardware to execute

12.32 Ping

12.32.1 Ping Example

12.32.1.1 Overview

The Ping Test application is a network connectivity testing utility that allows users to verify the reach-ability and response time of remote devices on a network. This application demonstrates the basic implementation of ICMP ping functionality using hostname resolution and network diagnostics.

12.32.1.2 Features

- **Interactive Command Line Interface:** User-friendly prompt-based interaction for entering target addresses
- **Hostname Resolution:** Automatic DNS lookup to resolve hostnames to IP addresses
- **ICMP Ping Testing:** Sends ping packets to test network connectivity
- **Response Time Measurement:** Reports the time taken for ping responses in system ticks
- **Input Editing:** Basic command-line editing with backspace support
- **Continuous Operation:** Runs in a loop allowing multiple ping tests without restarting

12.32.1.3 How It Works

1. **User Input:** The application prompts the user to enter an IP address or hostname
2. **DNS Resolution:** Uses `GetHostByName()` to resolve hostnames to IP addresses
3. **Ping Execution:** Sends an ICMP ping packet using the `Ping()` function
4. **Result Display:** Shows the target IP address and response time or failure status
5. **Loop Continuation:** Returns to step 1 for continuous testing

12.32.1.4 Key Functions

12.32.1.4.1 `Gets_w_Edit(char *buf, int maxlen)`

Custom input function that provides basic line editing capabilities:

- Handles character input with buffer management
- Supports backspace (ASCII 8) for editing
- Terminates input on carriage return or newline
- Prevents buffer overflow by limiting input length

12.32.1.4.2 `UserMain(void *pd)`

Main application loop that:

- Initializes the system and enables diagnostics
- Manages the interactive ping testing cycle
- Handles DNS resolution and ping execution
- Displays results and error messages

12.32.1.5 Technical Details

- **Language:** C/C++
- **Dependencies:**
 - `init.h` - System initialization
 - `dns.h` - DNS resolution functions
- **Network Functions:**
 - `GetHostByName()` - DNS hostname resolution
 - `Ping()` - ICMP ping implementation
- **Timeout:** DNS resolution timeout set to 30 seconds
- **Ping Parameters:**
 - ID: 1
 - Sequence: 1
 - Maximum wait time: 100 ticks

12.32.1.6 Usage Example

```
Enter address to ping: google.com
Got:[google.com]
IP address is 172.217.12.110
Response Took 25 ticks
```

```
Enter address to ping: 8.8.8.8
Got:[8.8.8.8]
IP address is 8.8.8.8
Response Took 15 ticks
```

```
Enter address to ping: invalid-host.example
Got:[invalid-host.example]
Failed to resolve host
```

12.32.1.7 Error Handling

The application handles several error conditions:

- **DNS Resolution Failure:** Displays "Failed to resolve host" when hostname cannot be resolved
- **Ping Failure:** Shows "Ping Failed!" when the ping operation returns -1
- **Input Validation:** Prevents buffer overflow in user input

12.32.1.8 System Requirements

- Compatible embedded system or platform supporting the included header files
- Network connectivity capability
- ICMP protocol support
- DNS resolution functionality

12.32.1.9 Development Notes

- System diagnostics are enabled for debugging (should be disabled in production)
- The application runs indefinitely until manually terminated
- Input editing is basic but functional for typical use cases
- Response times are measured in system-specific ticks

12.32.1.10 Purpose

This application serves as a fundamental example of network connectivity testing and demonstrates:

- Basic network programming concepts
- DNS resolution implementation
- ICMP ping functionality
- Interactive command-line application design
- Error handling in network operations

The Ping Test utility is particularly useful for network troubleshooting, connectivity verification, and as a learning example for embedded network programming.

12.33 PLATFORM SPECIFIC

With the exception of the Platform Specific examples, all examples in the `\nburn\examples` directory can be run on any of the NetBurner 3.x platforms: MODM7AE70, MOD5441x, NANO54415 and SB800EX. The Platform Specific examples in this section have specific hardware requirements.

The example categories are:

- Examples designed for only one platform: MODM7AE70, MOD5441x, NANO54415 or SB800EX
- Multi-Platform: Some examples for platforms that use the same microprocessor take advantage of that fact and share the same application source code. In these instances the section will be labeled with the supported platforms, such as the section labeled: "MOD5441x, NANO54415, SB800EX".

Platform specific examples

- [MOD5441x, NANO54415, SB800EX](#)
- [MODM7AE70, SBE70LC](#)
- [SOMRT1061](#)

12.33.1 MOD5441x, NANO54415, SB800EX

Platform Platform specific examples for ColdFire MCF5441x based products:

- MOD54415
- MOD54417
- NANO54415
- SB800EX

12.33.1.1 1-Wire

Supported Platforms: MOD5441x, NANO54415

12.33.1.1.1 1-Wire DS2401 Silicon Serial Number Reader

12.33.1.1.1.1 Overview

This NetBurner application demonstrates how to interface with a DS2401 Silicon Serial Number chip using the 1-Wire protocol on MCF5441X-based platforms. The application continuously detects and reads the unique 64-bit registration number from connected DS2401 devices.

12.33.1.1.1.2 Supported Platforms

- **MOD5441X** - Uses pin J2[37] for 1-Wire data line
- **NANO54415** - Uses pin 12 for 1-Wire data line

12.33.1.1.1.3 Hardware Requirements

- NetBurner MOD5441X or NANO54415 module
- DS2401 Silicon Serial Number chip
- Pull-up resistor (4.7k ohm recommended) between data line and VCC
- Power supply connections (VCC and GND)

12.33.1.1.1.4 Hardware Connections

MOD5441X Platform

- **1-Wire Data:** J2[37] (configured as OW_DAT function)
- **Power:** Connect DS2401 VCC to 3.3V or 5V
- **Ground:** Connect DS2401 GND to system ground
- **Pull-up:** 4.7k ohm resistor between data line and VCC

NANO54415 Platform

- **1-Wire Data:** Pin 12 (configured as OW_DAT function)
- **Power:** Connect DS2401 VCC to 3.3V or 5V
- **Ground:** Connect DS2401 GND to system ground
- **Pull-up:** 4.7k ohm resistor between data line and VCC

12.33.1.1.1.5 Application Functionality

Main Features

1. **1-Wire Protocol Implementation:** Custom 1-Wire peripheral driver
2. **Device Detection:** Automatic detection of DS2401 devices on the bus
3. **Serial Number Reading:** Reads complete 64-bit registration number
4. **Continuous Monitoring:** Polls for devices every 5 seconds
5. **Formatted Output:** Displays family code, serial number, and CRC

Program Flow

1. Initialization

- Initialize network stack with `init()`
- Enable system diagnostics
- Wait for network activity (up to 5 seconds)
- Initialize 1-Wire module with `OWInit()`
- Configure platform-specific pin functions

2. Main Loop (repeats every 5 seconds)

- Detect devices on 1-Wire bus using `OWDetectDevices()`
- If device found:
 - Send Read ROM command (0x33) to DS2401
 - Read 8 bytes of registration data
 - Parse and display formatted output
- If no device found:
 - Display "Device not detected" message

Output Format

When a DS2401 is detected, the application displays:

```
- - - - - Device detected - - - - -
Family Code: 0x01
Hex Serial Number: 12 34 56 78 9A BC
CRC Code: 0xDE
```

DS2401 Registration Number Structure

The 64-bit registration number consists of:

- **Byte 0:** Family Code (0x01 for DS2401)
- **Bytes 1-6:** 48-bit unique serial number
- **Byte 7:** 8-bit CRC checksum

12.33.1.1.1.6 Key Components

Core Functions

- `**OWInit()`: Initializes the 1-Wire peripheral module
- `**OWDetectDevices()`: Scans bus for connected 1-Wire devices
- `**OWWrite()`: Sends data to 1-Wire device
- `**OWRead()`: Receives data from 1-Wire device
- `**OWDone()`: Checks if 1-Wire operation is complete

Semaphore Usage

The application uses an OS semaphore (`OS_SEM busSem`) to synchronize 1-Wire read operations, ensuring data integrity and proper timing.

12.33.1.1.1.7 Building and Deployment

Prerequisites

- NetBurner Development Kit installed
- Target platform environment variables set

12.33.1.1.1.8 Troubleshooting

Common Issues

1. ****"Device not detected" message****
 - Check physical connections
 - Verify pull-up resistor is installed (4.7k ohm)
 - Ensure DS2401 is powered correctly
 - Confirm correct pin assignment for platform
2. **Build errors**
 - Verify PLATFORM is set correctly (MOD5441X or NANO54415)
 - Check that NNDK_ROOT environment variable is set
 - Ensure all source files are present
3. **Invalid serial number readings**
 - Check data line signal integrity
 - Verify timing requirements are met
 - Ensure only one DS2401 device on bus for this example

Debug Output

The application includes diagnostic output showing:

- Application startup confirmation
- Device detection status
- Complete registration number breakdown
- Timing of detection attempts

12.33.1.1.1.9 Technical Notes

1-Wire Protocol Details

- Single data line for bidirectional communication
- Master-slave architecture (NetBurner as master)
- Time-slot based communication protocol
- Requires external pull-up resistor

DS2401 Specifications

- 64-bit lasered ROM with unique serial number
- Operating voltage: 2.8V to 6.0V
- Operating temperature: -40C to +85C
- Single-contact 1-Wire interface

12.33.1.1.1.10 Application Use Cases

This example demonstrates fundamental concepts applicable to:

- Asset tracking and identification
- Serial number logging systems
- Device authentication
- Inventory management
- Temperature sensor networks (with protocol modifications)

12.33.1.1.1.11 Related Examples

For additional 1-Wire functionality, consider exploring:

- Multi-device 1-Wire networks
- Temperature sensors (DS18B20)
- 1-Wire memory devices
- Advanced search algorithms for device enumeration

12.33.1.2 Analog to Digital

MOD5441x and NANO54415 Analog to Digital Platform Examples

- [Simple ADC](#)
- [Periodic ADC](#)

12.33.1.2.1 Simple ADC**12.33.1.2.1.1 Simple ADC - Analog to Digital Converter Example****Overview**

This NetBurner application demonstrates basic analog-to-digital conversion on MCF5441X-based platforms. The application continuously reads all 8 ADC channels and displays both raw register values and converted voltage readings on the serial console.

Supported Platforms

- **MOD5441X** - All 8 ADC channels available
- **NANO54415** - All 8 ADC channels available

Note: Refer to your specific platform's datasheet to determine which ADC channels are routed to accessible connector pins.

Hardware Requirements

- NetBurner MOD5441X or NANO54415 module
- Analog voltage sources (0-3.3V) connected to ADC input pins
- Serial console connection for output display

ADC Specifications

- **Resolution:** 15-bit (32,768 counts)
- **Input Range:** 0V to 3.3V
- **Channels:** 8 single-ended inputs (AN0-AN7)
- **Conversion Type:** Successive approximation
- **Reference Voltage:** 3.3V

Application Functionality

Main Features

1. **Single-Ended ADC Configuration:** Initializes all 8 channels for single-ended input
2. **Continuous Conversion:** Performs ADC conversions every second
3. **Dual Output Format:** Displays both raw hex values and calculated voltages
4. **Synchronous Operation:** Waits for conversion completion before reading results

Program Flow

1. Initialization

- Initialize network stack with `init()`
- Enable system diagnostics
- Initialize ADC hardware with `InitSingleEndAD()`

2. Main Loop (repeats every second)

- Start ADC conversion with `StartAD()`
- Wait for conversion completion using `ADDone()`
- Read and display all 8 channel results
- Convert raw values to voltage
- Wait 1 second before next cycle

Output Format

The application displays readings in two formats for all 8 channels:

```
Register values: 0000,0000,4A2B,0000,0000,0000,0000,0000,
Voltage: 0.0000,0.0000,1.5234,0.0000,0.0000,0.0000,0.0000,0.0000,
```

- **Register values:** Raw 16-bit hexadecimal ADC readings
- **Voltage:** Calculated floating-point voltage values (0.0000 to 3.3000V)

Key Components

Files Structure

```
SimpleADC/
|-- src/
|   |-- main.cpp      # Main application logic
|   |-- SimpleAD.cpp   # ADC driver implementation
|   |-- SimpleAD.h     # ADC function declarations
|-- makefile          # Build configuration
+-- README.md         # This documentation
```

Core Functions

- `**InitSingleEndAD()`: Configures ADC hardware for single-ended operation
- `**StartAD()`: Initiates conversion on all enabled channels
- `**ADDone()`: Returns true when current conversion cycle is complete
- `**GetADResult(int ch)`: Returns raw 16-bit result for specified channel (0-7)

Voltage Conversion Formula

$$\text{voltage} = (\text{raw\_value} * 3.3) / 32768.0$$

Where:

- `raw_value`: 16-bit ADC result (0-32767)
- `3.3`: Reference voltage
- `32768.0`: Full-scale count (2^{15})

Hardware Connections

ADC Channel Mapping

Consult your platform's datasheet for specific pin assignments:

- **Channel 0 (AN0)**: ADC input 0
- **Channel 1 (AN1)**: ADC input 1
- **Channel 2 (AN2)**: ADC input 2
- **Channel 3 (AN3)**: ADC input 3
- **Channel 4 (AN4)**: ADC input 4
- **Channel 5 (AN5)**: ADC input 5
- **Channel 6 (AN6)**: ADC input 6
- **Channel 7 (AN7)**: ADC input 7

Input Requirements

- **Voltage Range**: 0V to 3.3V (do not exceed 3.3V)
- **Input Impedance**: High impedance (suitable for most sensors)
- **Signal Conditioning**: May require buffering for low-impedance sources

Usage Examples

Testing with Known Voltages

1. **Ground Reference**: Connect ADC input to GND (should read $\sim 0.0000\text{V}$)
2. **3.3V Reference**: Connect ADC input to 3.3V supply (should read $\sim 3.3000\text{V}$)
3. **Variable Voltage**: Use potentiometer or voltage divider for variable input
4. **Sensor Testing**: Connect analog sensors (temperature, pressure, etc.)

Monitoring Multiple Channels

Connect different voltage sources to multiple channels to observe simultaneous readings:

Register values: 0000,7FFF,4000,2000,1000,0800,0400,0200,
Voltage: 0.0000,3.3000,1.6500,0.8250,0.4125,0.2063,0.1031,0.0516,

Troubleshooting

Common Issues

1. All readings show 0000

- Check that ADC inputs are properly connected
- Verify input voltages are within 0-3.3V range
- Ensure proper ground connections

2. Readings are unstable or noisy

- Add input filtering (RC filter recommended)
- Check for proper ground plane connections
- Verify signal source has adequate drive capability

3. Incorrect voltage calculations

- Verify reference voltage is exactly 3.3V
- Check ADC resolution settings in code
- Confirm conversion formula matches hardware configuration

Debug Tips

- Use multimeter to verify actual input voltages
- Connect known reference voltages for calibration
- Monitor ADC register values for consistency
- Check platform-specific pin assignments in datasheet

Technical Notes

ADC Characteristics

- **Conversion Time:** Platform-dependent (typically microseconds)
- **Sample Rate:** Limited by software delay (1 Hz in this example)
- **Accuracy:** Dependent on reference voltage stability
- **Temperature Drift:** Consult datasheet for specifications

Performance Considerations

- Current implementation uses polling for conversion completion
- For high-speed applications, consider interrupt-driven conversions
- Multiple channel readings are sequential, not simultaneous
- Adding input filtering may improve measurement stability

Application Extensions

This basic example can be extended for:

Sensor Integration

- Temperature sensors (thermistors, LM35)
- Pressure transducers
- Light sensors (photodiodes, photoresistors)
- Position sensors (potentiometers)

Advanced Features

- Averaging multiple readings for noise reduction
- Threshold monitoring with alarms
- Data logging to file system
- Web-based real-time monitoring
- Calibration and scaling for specific sensors

Code Modifications

```
// Example: Add averaging for channel 2
float avgVoltage = 0;
for(int sample = 0; sample < 10; sample++) {
    StartAD();
    while(!ADDone()) asm("nop");
    avgVoltage += ((double)GetADResult(2)) * 3.3 / 32768.0;
    OSTimeDly(TICKS_PER_SECOND / 100); // 10ms between samples
}
avgVoltage /= 10;
printf("Channel 2 averaged voltage: %6.4f\r\n", avgVoltage);
```

- **PWM Examples:** Pulse width modulation for analog control

12.33.1.2.2 Periodic ADC

12.33.1.2.2.1 Periodic ADC - DMA-Driven High-Speed Sampling

Overview

This NetBurner application demonstrates advanced analog-to-digital conversion using DMA-driven periodic sampling on MCF5441X-based platforms. The application continuously samples an ADC channel at 8 kHz, buffers the data using DMA transfers, and saves the captured audio data as WAV files to external flash storage.

Supported Platforms

- **MOD5441X** - Full DMA and external flash support
- **NANO54415** - Full DMA and external flash support

Hardware Requirements

- NetBurner MOD5441X or NANO54415 module
- External SD flash card (mounted on development board)
- Analog signal source connected to ADC channel 0
- Serial console connection for status monitoring

Key Features

Advanced ADC Capabilities

- **DMA-Driven Sampling:** Hardware-triggered transfers without CPU intervention
- **High-Speed Acquisition:** 8 kHz sampling rate with precise timing
- **Circular Buffering:** Continuous data capture with ping-pong buffers
- **Interrupt-Driven:** Half-buffer and full-buffer interrupt handling
- **Loop Mode ADC:** Continuous conversion without restart overhead

Data Processing

- **Real-Time Buffering:** 2048-byte circular sample buffer in fast SRAM
- **Large Data Buffer:** 8MB data buffer for extended recording
- **WAV File Generation:** Direct conversion to standard audio format
- **File System Integration:** EFFS FAT file system support
- **Automatic File Naming:** Sequential file numbering (adc8k0.wav, adc8k1.wav, etc.)

Technical Specifications

Sampling Configuration

- **Sample Rate:** 8 kHz (8000 samples per second)
- **ADC Channel:** Channel 0 (configurable)
- **Buffer Size:** 2048 bytes circular buffer
- **Data Buffer:** 8MB total storage
- **DMA Timer:** Timer 0 for precise triggering
- **Recording Length:** ~128 buffer cycles per file

File Output

- **Format:** WAV audio files
- **Channels:** 1 (mono)
- **Sample Rate:** 8 kHz
- **Bit Depth:** 16-bit (from ADC resolution)
- **File Size:** ~131 KB per recording cycle
- **Storage:** External SD flash card

Application Architecture

Program Flow

1. System Initialization

- Initialize network stack and diagnostics
- Initialize DMA semaphore for synchronization
- Mount external flash file system
- Configure ADC for continuous loop mode
- Setup DMA timer for 8 kHz triggering

2. ADC and DMA Setup

- Configure single-ended ADC on channel 0
- Start ADC in continuous loop mode
- Initialize DMA channel for ADC-to-memory transfers
- Set DMA timer frequency to 8 kHz

3. Data Acquisition Loop

- Start DMA transfers to circular buffer

- Wait for half-buffer fill interrupts
- Copy data to large storage buffer
- Continue until major sample count reached
- Stop DMA and write WAV file

4. File Management

- Create sequential WAV files
- Write captured data with proper WAV headers
- Close files and increment counter
- Repeat indefinitely

Memory Architecture

Key Components

Files Structure

```

PeriodicADC/
|-- src/
|   |-- main.cpp           # Main application logic
|   |-- PeriodicAD.cpp     # ADC configuration functions
|   |-- PeriodicAD.h       # ADC function declarations
|   |-- PeriodicAD_DMA.cpp # DMA setup and control
|   |-- PeriodicAD_DMA.h   # DMA function declarations
|   |-- wavWriter.cpp      # WAV file format handling
|   |-- wavWriter.h        # WAV writer declarations
|   |-- FileSystemUtils.cpp # Flash file system utilities
|   |-- FileSystemUtils.h  # File system declarations

```

Core Functions

ADC Control:**

- `InitSingleEndAD()`: Configure ADC hardware for single-ended operation
- `StartADLoop()`: Start ADC in continuous conversion mode
- `initADC_DMA()`: Setup DMA channel for ADC transfers
- `setSampleFreq()`: Configure DMA timer for desired sample rate

DMA Management:**

- `startADC_DMA()`: Begin DMA transfers with callback
- `stopADC_DMA()`: Halt DMA operations
- `dmaTriggerFunc()`: Interrupt callback for buffer management

File Operations:**

- `openNewWav()`: Create new WAV file with proper headers
- `setUpFlash()`: Initialize external flash file system

Callback Function

```
void dmaTriggerFunc(void *start, void *end) {
    frontFilled = !frontFilled; // Toggle buffer half indicator
    AdcDmaSem.Post();           // Signal main loop
}
```

Hardware Connections

ADC Input

- **Channel 0:** Primary analog input (see platform datasheet for pin location)
- **Input Range:** 0V to 3.3V
- **Input Impedance:** High (suitable for audio signals)
- **Signal Conditioning:** May require amplification for low-level signals

External Flash

- **SD Card:** Required for WAV file storage
- **File System:** FAT format recommended
- **Capacity:** Minimum 1GB for extended recording

Building and Deployment

Required Libraries

This example requires the FatFile library for file system operations:
For NBEclipse:**

1. Right-click project > Properties
2. C/C++ Build > Settings
3. GNU C/C++ Linker > Libraries
4. Add "FatFile" to Libraries list

For Command Line:**
XTRALIB += -lFatFile

Additional Files Required

Copy these files from \nburn\examples_common\EFFS\FAT:

- cardtype.h
- FileSystemUtils.cpp
- FileSystemUtils.h

Build Commands

```
# Build for specific platform
make PLATFORM=MOD5441X
# or
make PLATFORM=NANO54415

# Load to device
make load DEVIP=<device_ip_address>
```

Usage and Operation

Startup Sequence

1. Connect analog signal to ADC channel 0
2. Insert formatted SD card
3. Load and run application
4. Monitor serial output for status

Expected Output

```
Initializing External Flash...  
External Flash opened.  
Starting log: adc8k0.wav  
Wrote 131072 bytes to disk, in file adc8k0.wav.  
Starting log: adc8k1.wav  
Wrote 131072 bytes to disk, in file adc8k1.wav.
```

File Analysis

Generated WAV files can be:

- Played in standard audio software
- Analyzed in audio/signal processing tools
- Converted to other formats as needed
- Opened in oscilloscope software for waveform analysis

Performance Characteristics

Timing Precision

- **DMA Timer:** Hardware-based precise timing
- **Jitter:** Minimal due to hardware triggering
- **CPU Loading:** Low due to DMA operation
- **Real-Time:** Deterministic sample intervals

Memory Usage

- **Fast SRAM:** 2KB circular buffer for real-time operation
- **Main RAM:** 8MB data buffer for file preparation
- **Stack Usage:** WAV writer requires significant stack space
- **File System:** Standard EFFS overhead

Throughput

- **Sample Rate:** 8000 samples/second
- **Data Rate:** 16 KB/s (assuming 16-bit samples)
- **File Rate:** One file every ~16 seconds
- **Sustained Rate:** Limited by flash write speed

Troubleshooting

Common Issues

1. ****"FAILED TO OPEN EXTERNAL FLASH"****
 - Check SD card insertion and formatting
 - Verify card compatibility (FAT16/FAT32)
 - Ensure proper card mounting on development board
2. **No audio in WAV files**
 - Verify analog signal connection to correct ADC pin
 - Check signal amplitude (0-3.3V range)
 - Confirm ADC channel configuration matches hardware
3. **DMA timing issues**
 - Verify DMA timer configuration
 - Check for timer conflicts with other peripherals
 - Monitor CPU loading for interference
4. **File system errors**
 - Reformat SD card with FAT32
 - Check available disk space
 - Verify file system initialization

Debug Techniques

```
Signal Verification:**
// Add to main loop for signal monitoring
printf("ADC Value: %d\r\n", GetADResult(ADC_CHANNEL));

Buffer Status:**
// Monitor buffer fill status
printf("Buffer half: %s\r\n", frontFilled ? "back" : "front");

DMA Status:**
// Check DMA operation
printf("DMA active: %s\r\n", isDMAActive() ? "yes" : "no");
```

Application Extensions

Audio Processing

- Real-time filtering (high-pass, low-pass, band-pass)
- Signal analysis (FFT, spectral analysis)
- Compression/decompression algorithms
- Echo/reverb effects

Multi-Channel Recording

- Simultaneous sampling of multiple ADC channels
- Stereo WAV file creation
- Channel synchronization
- Mixed-signal analysis

Advanced Features

- Triggered recording (threshold-based)
- Continuous streaming over network
- Real-time audio playback
- Data compression before storage

Integration Examples

- Audio monitoring systems
- Vibration analysis
- Environmental sound recording
- Signal quality measurement

Performance Optimization

High-Speed Modifications

```
// Increase sample rate to 16 kHz
#define SAMPLE_FREQ 16000

// Larger buffers for reduced interrupt frequency
#define BUFFERSIZE 4096
```

Memory Optimization

```
// Use external RAM for data buffer if available
uint8_t *dataBuffer = (uint8_t*)EXTERNAL_RAM_BASE;
```

Real-Time Processing

```
// Process data in DMA callback for minimum latency
void dmaTriggerFunc(void *start, void *end) {
    // Immediate signal processing here
    processAudioData(sampleBuffer + (frontFilled ? HALFBSIZE : 0));
    frontFilled = !frontFilled;
    AdcDmaSem.Post();
}
```

Related Examples

- **SimpleADC:** Basic ADC polling operation
- **WavPlayer:** Audio playback functionality
- **DSPI Examples:** High-speed serial data acquisition
- **DAC Examples:** Analog output generation
- **Timer Examples:** Precise timing control

12.33.1.3 CAN to Serial

12.33.1.3.1 CAN to Serial Bridge

12.33.1.3.1.1 Overview

This NetBurner application creates a bidirectional bridge between CAN bus and serial console communications on MCF5441X-based platforms. The application receives CAN messages and displays them on the serial console, while also allowing users to type messages that are transmitted over the CAN bus.

Warning

At least 2 CAN devices are required to avoid a hardware bus error.

12.33.1.3.1.2 Supported Platforms

- **MOD5441X** - CAN0: J2[42]/J2[39], CAN1: J2[44]/J2[41]
- **NANO54415** - CAN0: Pin 27/29, CAN1: Pin 22/20
- **SB800EX** - CAN0: PortB[2]/PortB[1], CAN1: PortB[0]/PortC[7]

12.33.1.3.1.3 Hardware Requirements

- NetBurner module with CAN capability
- CAN transceiver (if not integrated on board)
- CAN bus network with other nodes
- Serial console connection for user interface
- CAN bus termination resistors (120 ohm at each end)

12.33.1.3.1.4 CAN Configuration

Default Settings

- **CAN Module:** CAN0 (configurable to CAN1)
- **Baud Rate:** 500 kbps
- **Message Types:** Both standard (11-bit) and extended (29-bit) IDs
- **Receive Filters:**
 - Standard ID: 0x123
 - Extended ID: 0x1234

Message Filtering

The application accepts messages matching:

- **Standard ID 0x123:** Demonstrates 11-bit CAN ID reception
- **Extended ID 0x1234:** Demonstrates 29-bit CAN ID reception
- **Mask:** 0 (accepts all messages - modify for selective filtering)

12.33.1.3.1.5 Application Functionality

Main Features

1. **CAN Message Reception:** Listens for incoming CAN messages
2. **Message Display:** Shows received data in human-readable format
3. **Interactive Transmission:** Send messages via keyboard input
4. **Dual ID Support:** Handles both standard and extended CAN IDs
5. **Real-Time Operation:** Non-blocking message processing

Program Flow**1. Initialization**

- Initialize network stack and diagnostics
- Configure platform-specific CAN pins
- Initialize CAN controller at 500 kbps
- Register message receive FIFOs
- Set up message filters

2. Main Loop

- Poll for incoming CAN messages (1 tick timeout)
- Display received messages with ID and data
- Check for serial input from user
- Transmit user-entered messages on CAN bus

Message Format Display**Received Messages:****

```
Received a CAN message of 8 bytes from ID=291 or 0x123
Data = [Hello!!!]
```

```
Received a CAN message of 4 bytes from Extended ID=4660 or 0x001234
Data = [Test]
```

User Input:**

```
Type a message and press <enter> to transmit
> Hello World
Sending 11 bytes
Sent successfully
```

12.33.1.3.1.6 Hardware Connections**Pin Assignments by Platform****MOD5441X:****

- CAN0 TX: J2[42] (PINJ2_42_CAN0_TX)
- CAN0 RX: J2[39] (PINJ2_39_CAN0_RX)
- CAN1 TX: J2[44] (PINJ2_44_CAN1_TX)
- CAN1 RX: J2[41] (PINJ2_41_CAN1_RX)

NANO54415:**

- CAN0 TX: Pin 27 (PIN_27_CAN0_TX)
- CAN0 RX: Pin 29 (PIN_29_CAN0_RX)
- CAN1 TX: Pin 22 (PIN_22_CAN1_TX)
- CAN1 RX: Pin 20 (PIN_20_CAN1_RX)

SB800EX:**

- CAN0 TX: PortB[2] (tertiary function)
- CAN0 RX: PortB[1] (tertiary function)
- CAN1 TX: PortB[0] (primary function)
- CAN1 RX: PortC[7] (primary function)

CAN Bus Wiring

- **CAN_H**: Connect to CAN High line
- **CAN_L**: Connect to CAN Low line
- **GND**: Common ground with other nodes
- **Termination**: 120 ohm resistors at bus endpoints

12.33.1.3.1.7 Key Components

Core Functions

Platform Configuration:**

- `ConfigureCanPins(uint32_t canModuleNumber)`: Sets up CAN pins for each platform
- CAN Operations:**

- `MultiCanInit()`: Initialize CAN controller with baud rate
 - `RegisterMultiCanRxFifo()`: Set up receive message filtering
 - `MultiCanSendMessage()`: Transmit CAN messages
 - `CanRxMessage`: Class for receiving and parsing messages
- Helper Functions:**

- `NormToNbId()`: Convert standard ID to NetBurner format
- `ExtToNbId()`: Convert extended ID to NetBurner format
- `NbToNormId()`: Convert NetBurner format to standard ID
- `NbToExtId()`: Convert NetBurner format to extended ID
- `IsNBIdExt()`: Check if ID is extended format

12.33.1.3.1.8 Message Processing

Reception Processing

```
CanRxMessage can_msg(&fifo, 1); // Wait up to 1 tick
if (can_msg.IsValid()) {
    uint8_t buffer[8];
    uint8_t len = can_msg.GetData(buffer, 8);
    uint32_t id = can_msg.GetId();

    // Process message data
    // Display formatted output
}
```

Transmission Processing

```
char buffer[255];
fgets(buffer, 255, stdin); // Get user input

if (strlen(buffer) > 8) {
    buffer[8] = 0; // Truncate to CAN data limit
}

// Send with extended ID
MultiCanSendMessage(CAN_MODULE, ExtToNbId(0x1234), (uint8_t*)buffer, strlen(buffer), 50);
```

Data Display Format

The application displays non-printable characters in hex format:

- **Printable characters:** Shown as-is
- **Non-printable:** Displayed as {XX} hex values
- **Mixed data:** Combination of text and hex

Example: Data = [Hello{0A}{00}World]

12.33.1.3.1.9 Building and Deployment

Configuration Options

```
// Select CAN module (0 or 1)
#define CAN_MODULE (0)
// #define CAN_MODULE (1)

// Set baud rate
#define BAUD_RATE 500000
```

12.33.1.3.1.10 Usage Examples

Testing CAN Communication

1. Setup Test Network:

- Connect two NetBurner devices via CAN bus
- Ensure proper termination (120 ohm resistors)
- Configure both with same baud rate

2. Interactive Testing:

```
Type a message and press <enter> to transmit
> Test Message
Sending 12 bytes
Sent successfully
```

3. Monitor Reception:

```
Received a CAN message of 12 bytes from Extended ID=4660 or 0x001234
Data = [Test Message]
```

Message Filtering Examples

```
// Accept all messages (mask = 0)
int chan = RegisterMultiCanRxFifo(CAN_MODULE, NormToNbId(0x123), &fifo);

// Accept only specific ID (mask = 0xFFFF)
int chan = RegisterMultiCanRxFifo(CAN_MODULE, NormToNbId(0x150), &fifo, 0xFFFF);

// Accept range of IDs (0x400-0x4FF)
int chan = RegisterMultiCanRxFifo(CAN_MODULE, NormToNbId(0x424), &fifo, 0xFF00);
```

12.33.1.3.1.11 Troubleshooting

Common Issues

1. CAN initialization failed

- Check CAN transceiver power and connections
- Verify baud rate matches other network nodes
- Ensure CAN pins are properly configured
- Check for proper bus termination

2. No messages received

- Verify receive filters and masks
- Check physical bus connections

- Confirm other nodes are transmitting
- Monitor bus with oscilloscope/analyzer

3. Messages not sending

- Check transmit buffer availability
- Verify message length (less than or equal to 8 bytes)
- Ensure bus arbitration is working
- Check for bus-off conditions

4. Garbled data display

- Verify baud rate matches network
- Check for electrical noise/interference
- Ensure proper grounding between nodes
- Verify message format consistency

Debug Techniques

Bus Monitoring:**

```
// Add status monitoring
printf("CAN Status: 0x%08X\n", GetCanStatus(CAN_MODULE));
```

Message Statistics:**

```
// Track message counts
static uint32_t rxCount = 0, txCount = 0;
rxCount++; // Increment on receive
printf("RX: %ld, TX: %ld\n", rxCount, txCount);
```

Buffer Status:**

```
// Monitor FIFO status
printf("FIFO entries: %d\n", fifo.GetCount());
```

12.33.1.3.1.12 Advanced Features

Multiple Message Types

```
// Register multiple receive channels
int chan1 = RegisterMultiCanRxFifo(CAN_MODULE, NormToNbId(0x100), &fifo);
int chan2 = RegisterMultiCanRxFifo(CAN_MODULE, NormToNbId(0x200), &fifo);
int chan3 = RegisterMultiCanRxFifo(CAN_MODULE, ExtToNbId(0x12345), &fifo);
```

Enhanced Data Processing

```
// Process different message types
switch(NbToNormId(id)) {
    case 0x100: ProcessSensorData(buffer, len); break;
    case 0x200: ProcessControlData(buffer, len); break;
    case 0x300: ProcessStatusData(buffer, len); break;
}
```

Error Handling

```
// Comprehensive error checking
CAN_RETURN_CODE result = MultiCanSendMessage(CAN_MODULE, id, data, len, timeout);
switch(result) {
    case CAN_OK: printf("Sent successfully\n"); break;
    case CAN_TIMEOUT: printf("Send timeout\n"); break;
    case CAN_ERROR: printf("Send error\n"); break;
    case CAN_BUSY: printf("Bus busy\n"); break;
}
```

12.33.1.3.1.13 Application Extensions

Protocol Implementation

- CANopen protocol stack
- J1939 automotive protocol
- Custom application protocols
- Multi-master arbitration

Data Logging

- Log all CAN traffic to file system
- Timestamp message reception
- Statistical analysis tools
- Playback recorded sessions

Network Integration

- Forward CAN messages over TCP/UDP
- Web interface for CAN monitoring
- [MQTT](#) bridge for IoT integration
- RESTful API for remote control

Real-Time Processing

- Interrupt-driven message handling
- Priority-based message processing
- Real-time response to critical messages
- High-frequency data acquisition

12.33.1.3.1.14 Performance Characteristics

Timing

- **Message Latency:** Typically <1ms for receive processing
- **Throughput:** Up to 500 kbps bus capacity
- **CPU Loading:** Low due to hardware CAN controller
- **Response Time:** Limited by RTOS task scheduling

Scalability

- **Message Rate:** Hundreds of messages per second
- **Network Size:** Up to 127 nodes per network
- **Buffer Depth:** Configurable FIFO sizes
- **Concurrent Channels:** Multiple receive filters per module

12.33.1.3.1.15 Related Examples

- **Serial Communication:** UART/RS-232 bridging
- **Ethernet Bridge:** CAN to TCP/UDP gateway
- **Data Logging:** Persistent CAN message storage
- **Protocol Stacks:** Higher-level CAN protocols

12.33.1.4 Digital to Analog (DAC)

12.33.1.4.1 DAC - Digital to Analog Converter Example

12.33.1.4.1.1 Overview

This NetBurner application demonstrates the use of the integrated Digital-to-Analog Converter (DAC) on MCF5441X-based platforms. The application provides two operating modes: manual DAC output control and automatic waveform generation using DMA timer triggering.

12.33.1.4.1.2 Supported Platforms

- **MOD5441X** - DAC0 output on J2.9, Timer0 output on J2.36
- **NANO54415** - DAC0 output on J2.9, Timer0 output on Pin 19

12.33.1.4.1.3 Hardware Requirements

- NetBurner module with DAC capability
- **CRITICAL:** Analog reference voltage connection required
- Oscilloscope or voltmeter for output monitoring
- Optional: Load resistor for current measurement

Analog Reference Voltage Setup

MOD5441X Platforms:**

- Connect J2.2 (Vcc/3.3V) to J2.5 (Analog Reference Input)
- This provides 3.3V reference for full-scale DAC output

NANO54415 Platforms:**

- Connect P3.2 (Vcc/3.3V) to P2.8 (Analog Reference Input)
- This provides 3.3V reference for full-scale DAC output

WARNING: The DAC will not function without proper analog reference connection!

12.33.1.4.1.4 DAC Specifications

- **Resolution:** 12-bit (4096 levels: 0x000 to 0xFFFF)
- **Output Range:** 0V to Vref (typically 3.3V when properly configured)
- **Output Pin:** J2.9 (DAC0 output)
- **Reference Input:** Platform-specific analog reference pin
- **Update Rate:** Software controlled (Mode 1) or hardware triggered (Mode 2)

12.33.1.4.1.5 Application Functionality

Mode 1: Manual DAC Output Control

Operation:**

- Writes directly to DAC data register
- Steps output from 0V to 3.3V in 0x10 increments

- Continuous ramping until user presses any key
- Software-controlled timing
Features:**
- Direct register manipulation
- Real-time control
- Interactive operation
- Immediate response

Mode 2: Hardware-Triggered Waveform Generation

Operation:**

- Uses DMA Timer 0 as trigger source at 100 kHz
- Automatic waveform generation with hardware timing
- Steps from minimum to maximum values
- Hardware-synchronized operation
Features:**
- Precise timing via DMA timer
- Automatic waveform stepping
- Hardware synchronization
- Reduced CPU loading

12.33.1.4.1.6 Technical Implementation

DAC Configuration Registers

Control Register (DAC_CR):**

- DAC_CR_PDN: Power down control (0=on, 1=off)
- DAC_CR_UP: Count up direction
- DAC_CR_DOWN: Count down direction
- DAC_CR_AUTO: Automatic waveform mode
- DAC_CR_SYNC: External synchronization enable

Waveform Parameters:**

- step: Increment/decrement value (0x0100)
- max: Maximum output value (0x0FFF)
- min: Minimum output value (0x0000)

Hardware Configuration

```
// Enable DAC0 output drive
sim1.ccm.misccr2 |= MISCCR2_DAC0SEL;

// Disable conflicting ADC3 function
sim1.ccm.misccr2 &= ~(MISCCR2_ADC3EN);

// Route ADC3 input to DAC0 output for monitoring
sim2.adc.cal = ADC_CAL_DAC0;

// Power on DAC
sim2.dac[0].cr &= ~DAC_CR_PDN;
```

DMA Timer Setup

```
float frequency = 100000; // 100 kHz
float toggleTime = (1.0 / frequency) * 0.5;
float cpuClockPeriod = (1.0 / (CPU_CLOCK / 2));
uint32_t refTimerCount = (uint32_t)(toggleTime / cpuClockPeriod);

sim2.timer[0].tmr = 0x002A; // Toggle output, reset after reference
sim2.timer[0].trr = refTimerCount;
sim2.timer[0].tmr |= 0x0001; // Start timer
```

12.33.1.4.1.7 User Interface

Menu System

1. Simple DAC output writing to DAC data register
2. DAC waveform generation using DMA Timer 0

Operation Flow

1. Select operating mode (1 or 2)
2. Monitor DAC output on J2.9 with oscilloscope/voltmeter
3. Press any key to stop current operation
4. Return to menu for mode selection

Expected Outputs

Mode 1 - Manual Control:**

- Sawtooth waveform ramping from 0V to 3.3V
- Step size: ~0.2V increments (0x10 out of 0xFFFF)
- Software-limited update rate

Mode 2 - Timer Triggered:**

- Precise sawtooth waveform at 100 kHz trigger rate
- Hardware-synchronized stepping
- Timer output visible on designated pin

12.33.1.4.1.8 Hardware Connections and Testing

Basic Setup

1. **Power connections:** Ensure proper 3.3V and ground
2. **Reference voltage:** Connect analog reference as specified above
3. **DAC output:** Monitor J2.9 with oscilloscope or voltmeter
4. **Timer output** (Mode 2): Monitor timer pin for trigger signal

Test Procedures

Voltage Verification:**

- Mode 1: Should see ramping voltage 0V to 3.3V repeatedly
- Mode 2: Should see stepped waveform with precise timing
- Check reference voltage is stable 3.3V

Waveform Analysis:**

- Mode 1: Irregular timing due to software delays
- Mode 2: Precise 100 kHz trigger timing
- Both modes: 12-bit resolution stepping

Load Testing

```
// Optional: Add load resistor for current testing
// 1k resistor from J2.9 to ground
// Measure voltage across resistor for current calculation
```

12.33.1.4.1.9 Troubleshooting

Common Issues

1. No DAC output

- Check analog reference voltage connection
- Verify DAC power-on (PDN bit = 0)
- Confirm J2.9 pin configuration
- Measure reference voltage at analog input pin

2. Incorrect output voltage range

- Verify reference voltage is exactly 3.3V
- Check for voltage divider loading
- Confirm DAC data register values (0x000-0xFFF)

3. Mode 2 not working

- Verify DMA timer configuration and frequency
- Check timer output pin assignment
- Confirm DAC sync configuration
- Monitor timer output signal

4. Noisy output

- Add bypass capacitors near DAC output
- Check power supply stability
- Verify proper grounding
- Use appropriate load impedance

Debug Techniques

Register Monitoring:**

```
// Display current DAC value
iprintf("DAC Value: 0x%04X\r\n", sim2.dac[0].data);
```

```
// Check DAC control register
iprintf("DAC CR: 0x%04X\r\n", sim2.dac[0].cr);
```

Timer Verification:**

```
// Monitor timer operation
iprintf("Timer TMR: 0x%04X\r\n", sim2.timer[0].tmr);
iprintf("Timer TCN: 0x%04X\r\n", sim2.timer[0].tcn);
```

12.33.1.4.1.10 Advanced Features

Custom Waveform Generation

```
// Triangle wave example
if(sim2.dac[0].cr & DAC_CR_UP) {
    if(sim2.dac[0].data >= 0x0FFF) {
        sim2.dac[0].cr &= ~DAC_CR_UP;
        sim2.dac[0].cr |= DAC_CR_DOWN;
    }
} else {
    if(sim2.dac[0].data <= 0x0000) {
        sim2.dac[0].cr &= ~DAC_CR_DOWN;
        sim2.dac[0].cr |= DAC_CR_UP;
    }
}
```

Arbitrary Waveform Playback

```
// Sine wave lookup table
const uint16_t sineWave[256] = { /* 12-bit sine values */ };
static uint8_t index = 0;

sim2.dac[0].data = sineWave[index++];
if(index >= 256) index = 0;
```

Multiple Channel Support

```
// DAC1 configuration (if available)
sim1.ccm.misccr2 |= MISCCR2_DAC1SEL;
sim2.dac[1].cr &= ~DAC_CR_PDN;
sim2.dac[1].data = value1;
```

12.33.1.4.1.11 Performance Characteristics

Timing Specifications

- **Settling Time:** Typically <1 microsecond to 0.1% accuracy
- ****Update Rate**:** Limited by CPU (Mode 1) or timer frequency (Mode 2)
- ****Resolution**:** 12-bit (0.8mV steps with 3.3V reference)
- ****Linearity**:** Dependent on reference voltage stability

CPU Loading

- ****Mode 1**:** High CPU usage for continuous updates
- ****Mode 2**:** Low CPU usage with hardware triggering
- ****Interrupt Overhead**:** Minimal with DMA timer

12.33.1.4.1.12 Application Extensions

Signal Generation

- Function generators (sine, square, triangle)
- Audio signal synthesis
- Test pattern generation
- Calibration reference signals

Control Systems

- Analog control loops
- Servo motor control
- Variable reference generation
- Offset/bias voltage generation

Communication

- FSK modulation
- Analog data transmission
- Level shifting
- Interface voltage generation

Integration Examples

```
// Web-controlled DAC output
void SetDACFromWeb(uint16_t value) {
    if(value <= 0xFFFF) {
        sim2.dac[0].data = value;
    }
}

// ADC feedback control
void ADCControlledDAC() {
    uint16_t adcValue = GetADResult(0);
    uint16_t dacValue = ProcessControlLoop(adcValue);
    sim2.dac[0].data = dacValue;
}
```

12.33.1.4.1.13 Related Examples

- **ADC Examples:** Analog input measurement and feedback control
- **PWM Examples:** Alternative analog output methods
- **Timer Examples:** Precise timing and triggering
- **Waveform Generation:** Advanced signal synthesis techniques

12.33.1.5 DSPI to Serial

12.33.1.5.1 DSPI to Serial Bridge

12.33.1.5.1.1 Overview

This NetBurner application demonstrates the Dual Serial Peripheral Interface (DSPI) functionality by creating a bridge between DSPI and UART serial communications. Data received on UART1 is transmitted via DSPI, and the received DSPI data is sent back through UART1, creating a complete bidirectional communication bridge.

12.33.1.5.1.2 Supported Platforms

- **MOD5441X** - DSPI1 pins on J2 connector
- **NANO54415** - DSPI1 pins on carrier board

12.33.1.5.1.3 Hardware Requirements

- NetBurner module with DSPI capability
- UART1 connection for serial communication
- SPI slave device or loopback jumper for testing
- Serial terminal software for interaction

12.33.1.5.1.4 DSPI Pin Assignments

MOD5441X Platform

- **SCK (Clock):** J2[25] (PINJ2_25_DSPI1_SCK)
- **SOUT (Master Out):** J2[28] (PINJ2_28_DSPI1_SOUT)
- **SIN (Master In):** J2[27] (PINJ2_27_DSPI1_SIN)
- **PCS0 (Chip Select):** J2[30] (PINJ2_30_DSPI1_PCS0) - Optional/commented out

NANO54415 Platform

- **SCK (Clock):** Pin 31 (PIN_31_DSPI1_SCK)
- **SOUT (Master Out):** Pin 35 (PIN_35_DSPI1_SOUT)
- **SIN (Master In):** Pin 33 (PIN_33_DSPI1_SIN)
- **PCS0 (Chip Select):** Pin 15 (PIN_15_DSPI1_PCS0) - Optional/commented out

12.33.1.5.1.5 Application Functionality

Main Features

1. **UART to DSPI Bridge:** Transfers UART data via SPI protocol
2. **DSPI to UART Echo:** Returns received SPI data to UART
3. **Interrupt-Driven Transfers:** Uses semaphores for efficient operation
4. **Loopback Testing:** Simple jumper test without external devices
5. **Buffer Management:** 10KB buffers for large data transfers

Program Flow

1. Initialization

- Initialize network stack and diagnostics
- Configure DSPI1 pins for selected platform
- Initialize DSPI with default parameters
- Open UART1 at 115200 baud
- Create semaphore for DSPI synchronization

2. Main Loop

- Monitor UART1 for incoming data
- Transfer received data via DSPI
- Wait for DSPI completion using semaphore
- Send DSPI response back to UART1
- Repeat continuously

Data Flow Architecture

```

UART1 --> Read Buffer --> DSPI TX --> SPI Bus --> External Device
      ^                                     |
      |                                     v
+----- Write Buffer <----- DSPI RX <----- SPI Bus <-----+

```

12.33.1.5.1.6 Key Components

Files Structure

```
DSPI-to-Serial/
|-- src/
|   |-- main.cpp      # Complete application logic
|-- makefile          # Build configuration
+-- README.md         # This documentation
```

DSPI Configuration

Default Parameters:**

- **Module:** DSPI1 (DEFAULT_DSPI_MODULE)
- **Baud Rate:** 2 MHz (default)
- **Frame Size:** 8 bits (default)
- **Chip Select:** 0x0F (all CS inactive)
- **CS Polarity:** 0x0F (active low)
- **Clock Polarity:** 0x0 (idle low)
- **Clock Phase:** 0x1 (capture on leading edge)
- **Data Output:** Hi-Z when inactive

Core Functions

DSPI Operations:**

- `DSPIInit()`: Initialize DSPI with default or specified parameters
- `DSPIStart()`: Start interrupt-driven DSPI transfer
- `DSPIDone()`: Poll for transfer completion (alternative to semaphore)

Serial Operations:**

- `OpenSerial()`: Configure UART1 with specified parameters
- `dataavail()`: Check for incoming serial data
- `read()`: Read data from UART buffer
- `writeall()`: Write complete buffer to UART

Synchronization:**

- `OS_SEM`: Semaphore for interrupt-driven DSPI operation
- `Pend()`: Wait for DSPI transfer completion
- `Post()`: Signal transfer completion (done automatically by driver)

12.33.1.5.1.7 Testing and Usage

Loopback Testing (No External Device)

MOD5441X Setup:**

- Place jumper between J2[27] (SIN) and J2[28] (SOUT)
- This creates loopback for immediate echo testing

NANO54415 Setup:**

- Place jumper between Pin 33 (SIN) and Pin 35 (SOUT)
 - This creates loopback for immediate echo testing
- Expected Behavior:**

1. Type characters in serial terminal
2. Characters are sent via DSPI
3. Looped-back data returns via DSPI
4. Characters echo back to terminal

External SPI Device Testing

Connection Requirements:**

- Connect DSPI pins to SPI slave device
- Ensure common ground connection
- Match voltage levels (typically 3.3V)
- Add pull-up resistors if required by slave device

Device Examples:**

- SPI EEPROMs (25LC256, etc.)
- SPI sensors (accelerometers, gyroscopes)
- SPI displays (LCD controllers)
- SPI ADC/DAC devices

12.33.1.5.1.8 Building and Deployment

Build Commands

```
# Build for specific platform
make PLATFORM=MOD5441X
make PLATFORM=NANO54415

# Load to device
make load DEVIP=<device_ip_address>
```

Serial Terminal Setup

- **Baud Rate:** 115200
- **Data Bits:** 8
- **Parity:** None
- **Stop Bits:** 1
- **Flow Control:** None

12.33.1.5.1.9 Advanced DSPI Configuration

Custom Initialization Parameters

```
// Example: Custom DSPI setup
DSPIInit(1,           // DSPI Module 1
         4000000,      // 4 MHz baud rate
         16,           // 16-bit frame size
         0x0E,         // CS0 active, others inactive
         0x0F,         // All CS active low
         0x1,          // Clock idle high
         0x0,          // Capture on trailing edge
         FALSE,        // Drive output when inactive
         2,            // CS to clock delay
         3);           // Delay after transfer
```

Frame Size Options

- **4-32 bits:** Extended range beyond standard SPI
- **Automatic queuing:** Hardware manages transfer queues
- **Interrupt driven:** Efficient CPU utilization

Multiple Chip Select Management

```
// Different CS configurations
DSPIInit(1, 2000000, 8, 0x0E); // CS0 active
DSPIInit(1, 2000000, 8, 0x0D); // CS1 active
DSPIInit(1, 2000000, 8, 0x0B); // CS2 active
```

12.33.1.5.1.10 Performance Characteristics

Transfer Specifications

- **Maximum Baud Rate:** Up to 25 MHz (platform dependent)
- **Frame Sizes:** 4 to 32 bits (beyond standard 8/16-bit SPI)
- **Buffer Size:** 10KB for both TX and RX operations
- **Latency:** Interrupt-driven with minimal CPU overhead

Timing Characteristics

- **CS to Clock Delay:** Configurable timing
- **Inter-frame Delay:** Adjustable for slave device requirements
- **Clock Polarity/Phase:** Full SPI mode support (0,0 to 1,1)

12.33.1.5.1.11 Troubleshooting

Common Issues

1. No data transfer

- Check pin configuration and connections
- Verify DSPI initialization success
- Confirm UART1 is opening correctly
- Test with loopback jumper first

2. Corrupted data

- Check SPI clock polarity and phase settings
- Verify baud rate is appropriate for slave device
- Ensure proper voltage levels (3.3V logic)
- Add decoupling capacitors near DSPI pins

3. Semaphore timeout

- Check if DSPI transfer is completing
- Verify interrupt system is working
- Monitor DSPI module status registers
- Consider using polling mode as alternative

4. Serial communication issues

- Confirm UART1 baud rate (115200)
- Check serial terminal settings
- Verify UART1 pin connections
- Test with different terminal software

Debug Techniques

Transfer Monitoring:**

```
// Add debug output
iprintf("DSPI transfer started, size: %d\n", num);
DSPI_SEM.Pend(0);
iprintf("DSPI transfer completed\n");
```

Buffer Inspection:**

```
// Display buffer contents
for(int i = 0; i < num; i++) {
    iprintf("TX[%d]: 0x%02X, RX[%d]: 0x%02X\n",
        i, TXBuffer[i], i, RXBuffer[i]);
}
```

Status Monitoring:**

```
// Check DSPI status (platform-specific registers)
iprintf("DSPI Status: 0x%08X\n", GetDSPIStatus(DEFAULT_DSPI_MODULE));
```

12.33.1.5.1.12 Application Extensions

Protocol Implementations

SPI EEPROM Interface:**

```
void WriteEEPROM(uint16_t address, uint8_t *data, int length) {
    uint8_t cmd[3] = {0x02, address >> 8, address & 0xFF};
    DSPIStart(DEFAULT_DSPI_MODULE, cmd, rxBuf, 3, &DSPI_SEM);
    DSPI_SEM.Pend(0);
    DSPIStart(DEFAULT_DSPI_MODULE, data, rxBuf, length, &DSPI_SEM);
    DSPI_SEM.Pend(0);
}
```

Sensor Data Acquisition:**

```
int16_t ReadADC(uint8_t channel) {
    uint8_t cmd[3] = {0x01, (channel << 4), 0x00};
    uint8_t response[3];
    DSPIStart(DEFAULT_DSPI_MODULE, cmd, response, 3, &DSPI_SEM);
    DSPI_SEM.Pend(0);
    return ((response[1] << 8) | response[2]) & 0xFFFF;
}
```

Network Integration

TCP to DSPI Bridge:**

```
// Replace UART operations with TCP socket
int tcpFd = connect("192.168.1.100", 8080);
if(dataavail(tcpFd)) {
    int num = read(tcpFd, (char*)TXBuffer, 10000);
    DSPIStart(DEFAULT_DSPI_MODULE, TXBuffer, RXBuffer, num, &DSPI_SEM);
    DSPI_SEM.Pend(0);
    writeall(tcpFd, (char*)RXBuffer, num);
}
```

Web Interface Control:**

```
// Web-based SPI device control
void HandleSPICommand(uint8_t *cmd, int cmdLen, uint8_t *response) {
    DSPIStart(DEFAULT_DSPI_MODULE, cmd, response, cmdLen, &DSPI_SEM);
    DSPI_SEM.Pend(0);
}
```

Multi-Device Support

```
// Multiple SPI devices with different CS
void SelectDevice(int device) {
    uint8_t csConfig = 0x0F & ~(1 << device); // Active low
    DSPIInit(DEFAULT_DSPI_MODULE, 2000000, 8, csConfig);
}
```

12.33.1.5.1.13 Performance Optimization

High-Speed Transfers

```
// Optimize for maximum throughput
DSPIInit(DEFAULT_DSPI_MODULE, 25000000, 8, 0x0E, 0x0F, 0, 1, TRUE, 0, 0);
```

DMA Integration

```
// Use DMA for large transfers (if available)
void LargeDataTransfer(uint8_t *txData, uint8_t *rxData, int size) {
    // Platform-specific DMA setup
    StartDMATransfer(txData, rxData, size);
}
```

```
    WaitForDMAComplete();
}
```

Interrupt Optimization

```
// Minimize interrupt latency
void __attribute__((interrupt)) DSPIInterruptHandler() {
    // Keep handler minimal
    ClearDSPIInterrupt();
    SignalTransferComplete();
}
```

12.33.1.5.1.14 Related Examples

- **Serial Communication:** UART bridging and protocols
- **CAN to Serial:** Alternative communication bridging
- **I2C Examples:** Inter-IC communication protocols
- **SPI Device Drivers:** Specific SPI device implementations
- **Network Bridges:** TCP/UDP to peripheral communication

12.33.1.6 Load Application From Flash Card

12.33.1.6.1 EDFS Load Application From Flash Card

12.33.1.6.1.1 Overview

This NetBurner application demonstrates how to update firmware from a binary image file stored on a flash card. The application uses the Extra File Descriptor (ExtraFD) mechanism to create a file stream interface that enables direct firmware programming from flash card storage.

12.33.1.6.1.2 Supported Platforms

- **MOD5441X** - On-board microSD card socket support
- Support for external flash card interfaces (commented options available)

12.33.1.6.1.3 Hardware Requirements

- NetBurner MOD5441X module
- MicroSD card with firmware binary file
- Serial console for monitoring update process
- Formatted flash card (FAT16/FAT32)

12.33.1.6.1.4 Application Functionality

Main Features

1. **Flash Card Mounting:** Automatically detects and mounts microSD card
2. **Binary File Reading:** Reads application binary from flash card storage
3. **ExtraFD Stream Interface:** Creates file descriptor from flash file pointer
4. **Stream-Based Programming:** Programs firmware using NetBurner's stream update mechanism
5. **Automatic Reboot:** Restarts system after successful firmware update

Program Flow

1. Initialization

- Initialize network stack and file system
- Enter EDFS file system context
- Mount on-board flash card (microSD)

2. File System Operations

- Display directory contents
- Locate firmware file "AppToLoad.bin"
- Create Extra FD from file pointer

3. Firmware Update Process

- Read binary file through ExtraFD interface
- Program new application to flash memory
- Verify programming success
- Reboot system to run new firmware

Update Process Flow

12.33.1.6.1.5 Key Components

Files Structure

```

EffsLoadAppFromFlashCard/
|-- src/
|   |-- main.cpp           # Main application logic
|   +-- FileSystemUtils.h  # File system utility functions
|-- makefile               # Build configuration
+-- README.md              # This documentation
  
```

ExtraFD Implementation

Core ExtraFD Functions:**

- `fileToExtraFdRead()`: Reads data from flash file into buffer
- `fileToExtraFdWrite()`: Write function (not implemented in this example)
- `fileToExtraFdClose()`: Closes flash file and releases ExtraFD
- `makeFdFromFile()`: Creates file descriptor from `F_FILE` pointer

ExtraFD Structure:**

```

IoExpandStruct fileToExtraFd = {
    .read = fileToExtraFdRead,
    .write = fileToExtraFdWrite,
    .close = fileToExtraFdClose,
    .peek = 0
};
  
```

Stream Update Process

Key Functions:**

- `GetExtraFD()`: Allocates Extra File Descriptor
- `ReadBinaryApplicationCodeFromStream()`: Programs firmware from stream

- `ForceReboot ()` : Restarts system after successful update
Update Result Codes:**
- `STREAM_UP_OK`: Update completed successfully
- Error codes indicate specific failure reasons

12.33.1.6.1.6 File Preparation

Creating Update Files

1. Build Target Application:

```
make PLATFORM=MOD5441X
# This creates *.sl9 file in project directory
```

2. Convert to Binary Format:

```
# Use NetBurner tools or standard utilities
objcopy -O binary target.elf AppToLoad.bin
```

3. Copy to Flash Card:

- Name the file exactly "AppToLoad.bin"
- Place in root directory of flash card
- Ensure flash card is FAT16 or FAT32 formatted

File Requirements

- **Filename:** Must be exactly "AppToLoad.bin"
- **Location:** Root directory of flash card
- **Format:** Raw binary (not S-record or ELF)
- **Size:** Must fit in available flash memory
- **Compatibility:** Must be compiled for target platform

12.33.1.6.1.7 Building and Deployment

12.33.1.6.2 Build the updater application

12.33.1.6.3 Load updater to device

Required Libraries

This example requires EDFS FAT file system support:

Additional Files Required

Copy from \nburn\examples_common\EDFS\FAT:

- `FileSystemUtils.h`
- `FileSystemUtils.cpp`
- `cardtype.h` (if needed)

12.33.1.6.3.1 Usage Instructions

Step-by-Step Update Process

1. Prepare Flash Card:

- Format microSD card (FAT32 recommended)
- Copy "AppToLoad.bin" to root directory
- Verify file is present and readable

2. Load Updater:

- Build and load this updater application
- Insert prepared flash card into module
- Connect serial console for monitoring

3. Execute Update:

- Application will display directory contents
- Press any key when prompted to start update
- Monitor progress messages
- Wait for automatic reboot (10 seconds)

Expected Console Output

```

Initializing the on-board Flash card...
Drive change successful
Directory listing:
AppToLoad.bin          524288

Type any key to program new application to flash
Opening file: "AppToLoad.bin"
Update complete, system will reboot in 10 seconds...

```

12.33.1.6.3.2 Error Handling**Common Error Conditions****1. Drive Mount Failure:**

```
drive change failed: [error code]
```

- Check flash card insertion
- Verify card formatting (FAT16/FAT32)
- Ensure card is not corrupted

2. File Not Found:

```
Failed to find file: "AppToLoad.bin"
```

- Verify filename is exactly "AppToLoad.bin"
- Check file is in root directory
- Confirm file is not corrupted

3. Stream Update Failure:

```
ERROR: Stream update failed, error code: [code]
```

- Binary file may be corrupted
- Insufficient flash memory space
- Binary not compatible with target platform

4. ExtraFD Creation Failure:

```
Extra FD create failed
```

- System resource exhaustion
- File system integrity issues

Debug Techniques**File System Verification:****

```
// Add debug output to verify file system state
iprintf("Current directory: %s\n", GetCurrentDirectory());
iprintf("File size: %ld bytes\n", GetFileSize("AppToLoad.bin"));
```

Stream Progress Monitoring:**

```
// Monitor update progress
int totalBytes = fdReadToEnd(fd);
iprintf("Total bytes processed: %d\n", totalBytes);
```

12.33.1.6.3.3 Advanced Features

Custom Update Sources

External Flash Card Support:**

```
// Uncomment to use external flash card socket
// int drv = OpenOffBoardFlash(); // Dev board flash socket
int drv = OpenOnBoardFlash(); // Module microSD socket
```

Network-Based Updates:**

```
// Extend ExtraFD for network sources
int networkToExtraFdRead(int fd, char *buf, int nbytes) {
    // Read from TCP socket, HTTP, etc.
    return networkRead(buf, nbytes);
}
```

Multi-File Updates

```
// Update multiple components
char *updateFiles[] = {"bootloader.bin", "application.bin", "config.bin"};
for(int i = 0; i < 3; i++) {
    UpdateFromFile(updateFiles[i]);
}
```

Verification and Security

```
// Add checksum verification
uint32_t CalculateChecksum(int fd) {
    // Implement CRC32 or similar
    return checksum;
}

bool VerifyUpdate(const char *filename) {
    // Compare against stored checksum
    return checksumValid;
}
```

12.33.1.6.3.4 Safety Considerations

Update Reliability

1. **Power Supply:** Ensure stable power during update process
2. **Backup Strategy:** Keep previous firmware version accessible
3. **Verification:** Implement checksum validation before programming
4. **Recovery Mode:** Consider implementing emergency recovery mechanism

Flash Memory Protection

```
// Verify sufficient space before update
uint32_t requiredSpace = GetFileSize("AppToLoad.bin");
uint32_t availableSpace = GetFlashSpaceAvailable();
if(requiredSpace > availableSpace) {
    fprintf("ERROR: Insufficient flash memory\n");
    return;
}
```

Update Validation

```
// Validate binary format before programming
bool ValidateBinaryFormat(int fd) {
    // Check for valid application headers
    // Verify target platform compatibility
    return isValid;
}
```

12.33.1.6.3.5 Performance Characteristics

Update Timing

- **Read Speed:** Limited by flash card interface (typically 1-10 MB/s)
- **Programming Speed:** Limited by internal flash programming rate
- **Total Time:** Depends on application size (typically seconds to minutes)

Memory Usage

- **ExtraFD Overhead:** Minimal system resource usage
- **Buffer Size:** Configurable read buffer size
- **Flash Requirements:** Must fit in available application flash space

12.33.1.6.3.6 Application Extensions

User Interface Enhancements

```
// Progress indicator
void DisplayUpdateProgress(int bytesProcessed, int totalBytes) {
    int percent = (bytesProcessed * 100) / totalBytes;
    iprintf("Update progress: %d%%\r", percent);
}
```

Remote Update Management

```
// Web interface for update control
void HandleUpdateCommand(char *filename) {
    StartUpdateProcess(filename);
}
```

Batch Updates

```
// Update multiple devices
void BroadcastUpdate(char *filename) {
    // Send update to multiple networked devices
}
```

12.33.1.6.3.7 Related Examples

- **EFFS Examples:** File system operations and management
- **Stream Examples:** Alternative stream-based programming methods
- **Network Update:** Over-the-air firmware update mechanisms
- **Bootloader Examples:** Custom bootloader implementation
- **Flash Programming:** Direct flash memory programming techniques

12.33.1.7 SDHC Flash Card

12.33.1.7.1 EFFS SDHC Flash Card File System

12.33.1.7.1.1 Overview

This NetBurner application demonstrates comprehensive flash card file system operations using the Embedded Flash File System (EFFS) with FAT support. The application provides FTP server functionality, file management operations, and performance testing capabilities for SD/MMC/SDHC flash cards.

12.33.1.7.1.2 Supported Platforms

- **MOD5441X** - Multi-drive support (on-board + external)
- **NANO54415** - SDHC interface support
- **SB800EX** - SDHC interface support

12.33.1.7.1.3 Flash Card Interface Types

Interface Comparison

SPI Interface:**

- **MOD54415/MOD54417**: On-board microSD (SPI), MOD-DEV-70 dev board (SPI)
- **NANO54415**: Development board (SPI)
- Compatible with standard EDFS examples

SDHC Interface:**

- **NANO54415**: On-board microSD (SDHC)
- **SB800EX**: On-board microSD (SDHC)
- Higher performance, dedicated hardware controller

Note: SPI and SDHC are mutually exclusive - flash card connector must be wired for one type only.

12.33.1.7.1.4 Hardware Requirements

- NetBurner module with flash card interface
- SD/MMC/SDHC flash card (formatted FAT16/FAT32)
- Network connection for FTP access
- Serial console for interactive commands
- Optional: TEST.BIN file for speed testing

12.33.1.7.1.5 Application Functionality

Core Features

1. **File System Operations**: Directory listing, file display, space management
2. **FTP Server**: Network-based file transfer capabilities
3. **Performance Testing**: File read/write speed benchmarking
4. **Time Management**: NTP synchronization with manual fallback
5. **Interactive Menu System**: Serial console command interface

Program Flow

1. System Initialization

- Initialize network stack and file system
- Enter EDFS context for main and FTP tasks
- Initialize flash card interface

2. Time Setup

- Attempt NTP time synchronization
- Fall back to manual time setting if NTP fails
- Configure timezone (PST/PDT default)

3. Service Startup

- Start FTP server on port 21

- Display initial file system statistics
- Run read/write test with "TestFile.txt"

4. Interactive Operation

- Present command menu
- Process user commands
- Execute file operations

12.33.1.7.1.6 Command Interface

Available Commands

- **D**: Display Directory contents
- **E**: Display TestFile.txt contents
- **F**: Format SD flash card (WARNING: data loss!)
- **R**: Reboot system
- **S**: Display space usage statistics
- **T**: Display current system time
- **W**: Run file read/write speed test
- **?**: Display command menu

Command Examples

```
Directory Listing:**
Directory Contents:
TestFile.txt      1024
config.dat        512
data/             [DIR]
End of listing

Space Usage:**
Flash card space statistics:
Total: 32GB
Used: 1.2GB
Free: 30.8GB
```

12.33.1.7.1.7 Key Components

Files Structure

```
EffsSDHC/
|- src/
|   |-- main.cpp           # Main application logic
|   |-- FileSystemUtils.h  # File system utilities
|   |-- cardtype.h         # Card type definitions
|   |-- ftp_f.h            # FTP function declarations
|   |-- effs_time.h        # Time management functions
|   +-- dev_test.h         # Device test functions
|-- makefile               # Build configuration
+-- README.md              # This documentation
```

Platform-Specific Configuration

```
Multi-Drive Support (MOD5441X):**
#if (defined(MOD5441X))
#define MULTI_MMC TRUE
#include <effs_fat/multi_drive_mmc_mcf.h>

SDHC Interface:**
#elif (defined(USE_SDHC) && (defined(NANO54415) || defined(SB800EX)))
#include <effs_fat/sdhc_mcf.h>

Standard MMC/SD:**
#elif (defined(USE_MMC))
#include <effs_fat/mmc_mcf.h>
```

Core Functions

File System Management:**

- `f_enterFS()`: Enter file system context (required per task)
- `InitExtFlash()`: Initialize flash card interface
- `DumpDir()`: Display directory contents
- `DisplayEffsSpaceStats()`: Show storage usage

FTP Operations:**

- `FTPDStart()`: Start FTP server with specified priority
- Network-based file upload/download capabilities
- Long filename support detection

Performance Testing:**

- `SpeedTest()`: File I/O performance measurement
- `ReadWriteTest()`: Basic file operation verification

12.33.1.7.1.8 Time Management

NTP Synchronization

```
if (SetTimeNTP()) {
    // Set timezone (PST/PDT example)
    tzsetchar("PST8PDT7,M3.2.0/02:00:00,M11.1.0/02:00:00");
} else {
    // Manual time setting fallback
    SetTimeManual(month, day, dow, year, hour, min, sec);
}
```

Timezone Options

Available timezone configurations:

- Eastern: "EST5EDT4,M3.2.0/02:00:00,M11.1.0/02:00:00"
- Central: "CST6CDT5,M3.2.0/02:00:00,M11.1.0/02:00:00"
- Mountain: "MST7MDT6,M3.2.0/02:00:00,M11.1.0/02:00:00"
- Pacific: "PST8PDT7,M3.2.0/02:00:00,M11.1.0/02:00:00"

12.33.1.7.1.9 FTP Server Integration

Server Configuration

- **Port:** 21 (standard FTP)
- **Priority:** Higher than UserMain() (MAIN_PRIO - 2)
- **File System:** Shared access with main application
- **Authentication:** Platform-dependent default settings

FTP Operations

```
# Connect to NetBurner FTP server
ftp <device_ip_address>

# Upload files
put local_file.txt remote_file.txt

# Download files
get remote_file.txt local_file.txt

# Directory operations
ls          # List files
cd dirname  # Change directory
mkdir name  # Create directory
```

Long Filename Support

```
if (F_LONGFILENAME == 1)
    iprintf("Long file names are supported\r\n");
else
    iprintf("Long file names are not supported- only 8.3 format\r\n");
```

12.33.1.7.1.10 Performance Testing

Speed Test Requirements

1. Place file named "TEST.BIN" on flash card
2. Use FTP to upload test file, or copy from another device
3. Execute 'W' command from serial console
4. Results displayed through debug serial port

Test Parameters

```
int res = SpeedTest("TEST.BIN", 10 * 1024 * 1024); // 10MB test
```

Expected Performance

- **SPI Interface:** 1-5 MB/s typical
- **SDHC Interface:** 10-25 MB/s typical
- **Actual Speed:** Depends on card class and system loading

12.33.1.7.1.11 Building and Deployment

Build Commands

```
# Build for specific platform and interface type
make PLATFORM=MOD5441X      # Multi-drive MMC
make PLATFORM=NANO54415     # SDHC interface
make PLATFORM=SB800EX       # SDHC interface

# Load to device
make load DEVIP=<device_ip_address>
```

Conditional Compilation

The build system automatically selects the appropriate interface:

```
#if (defined(MOD5441X))
    // Multi-drive MMC support
#elif (defined(USE_SDHC) && (defined(NANO54415) || defined(SB800EX)))
    // SDHC interface
#elif (defined(USE_MMC))
    // Standard MMC/SD
#endif
```

Required Libraries

```
# EDFS FAT library (usually auto-included)
XTRALIB += -lFatFile
```

12.33.1.7.1.12 Usage Instructions

Initial Setup

1. **Prepare Flash Card:**
 - Format card as FAT32 (recommended) or FAT16
 - Optionally create test files
 - Insert into appropriate socket

2. Network Configuration:

- Ensure device has network connectivity
- Note device IP address for FTP access

3. Serial Console:

- Connect serial terminal (115200 baud)
- Use for interactive commands and monitoring

Typical Operation Session**Console Output:****

```
===== Starting EFFS FTP SD/SDHC Program =====
Initializing Flash Card...complete
External Flash opened.
NTP time synchronization successful
Current time: Wed May 14 11:35:00 2025
```

```
Flash card space statistics:
Total: 32GB, Used: 1.2GB, Free: 30.8GB
```

```
Started FTP Server
Long file names are supported
```

```
--- Main Menu ---
D - Display Directory
E - Display TestFile.txt
F - Format SD Flash card
R - Reboot
S - Display Space usage
T - Display system Time
W - Run File Read/Write Speed Test
? - Display Menu
```

FTP Access Example**From Windows Command Prompt:****

```
C:\> ftp 192.168.1.100
Connected to 192.168.1.100
220 NetBurner FTP Server Ready
User: admin
Password: admin
230 User logged in
```

```
ftp> ls
200 PORT command successful
150 Opening data connection
TestFile.txt      1024
config.dat        512
226 Transfer complete
```

```
ftp> get TestFile.txt
200 PORT command successful
150 Opening data connection
226 Transfer complete
1024 bytes received
```

12.33.1.7.1.13 Troubleshooting**Common Issues****1. Flash Card Not Detected:**

- Check card insertion and formatting
- Verify card compatibility (SD/MMC/SDHC)
- Ensure proper voltage levels (3.3V)
- Try different cards to isolate hardware issues

2. FTP Server Won't Start:

```
Error: [code]. Could not start FTP Server
```

- Check network connectivity

- Verify no other FTP server running on port 21
- Ensure sufficient system resources

3. File System Errors:

- Reformat flash card (FAT32 recommended)
- Check card for physical damage
- Verify file system integrity with PC tools

4. Time Synchronization Failure:

NTP failed, setting time manually

- Check network connectivity to NTP servers
- Verify DNS resolution working
- Manual time setting used as fallback

5. Speed Test Failure:

Test execution failed! Error [code]

- Ensure TEST.BIN file exists on card
- Check available free space
- Verify file read permissions

Debug Techniques

File System Status:**

```
// Add debugging output
iprintf("Free space: %ld KB\n", GetFreeSpace() / 1024);
iprintf("Card type: %s\n", GetCardType());
```

FTP Diagnostics:**

```
// Monitor FTP connections
iprintf("Active FTP sessions: %d\n", GetFTPSessionCount());
```

Performance Monitoring:**

```
// Time file operations
uint32_t startTime = Secs;
PerformFileOperation();
iprintf("Operation took %ld seconds\n", Secs - startTime);
```

12.33.1.7.1.14 Advanced Features

Custom File Operations

Batch File Processing:**

```
void ProcessAllFiles() {
    DIR *dir = opendir(".");
    struct dirent *entry;
    while((entry = readdir(dir)) != NULL) {
        if(entry->d_type == DT_REG) { // Regular file
            ProcessFile(entry->d_name);
        }
    }
    closedir(dir);
}
```

Directory Recursion:**

```
void ProcessDirectoryRecursive(const char *path) {
    DIR *dir = opendir(path);
    struct dirent *entry;
    while((entry = readdir(dir)) != NULL) {
        if(entry->d_type == DT_DIR && strcmp(entry->d_name, ".") != 0) {
            char newPath[256];
            snprintf(newPath, sizeof(newPath), "%s/%s", path, entry->d_name);
            ProcessDirectoryRecursive(newPath);
        }
    }
    closedir(dir);
}
```

Extended FTP Features

Custom FTP Commands:**

```
// Add application-specific FTP commands
void HandleCustomFTPCommand(const char *cmd, int clientFd) {
    if(strcmp(cmd, "STATUS") == 0) {
        SendFTPResponse(clientFd, "200 System Status OK\r\n");
    }
}
```

Authentication Enhancement:**

```
// Custom user authentication
bool AuthenticateUser(const char *username, const char *password) {
    // Implement custom authentication logic
    return ValidateCredentials(username, password);
}
```

Data Logging Applications

Sensor Data Logging:**

```
void LogSensorData() {
    F_FILE *fp = f_open("sensor_log.csv", "a");
    if(fp) {
        fprintf(fp, "%ld,%f,%f,%f\n",
                time(NULL), temperature, humidity, pressure);
        fclose(fp);
    }
}
```

System Event Logging:**

```
void LogEvent(const char *event) {
    F_FILE *fp = f_open("system_log.txt", "a");
    if(fp) {
        fprintf(fp, "[%s] %s\n", GetTimeString(), event);
        fclose(fp);
    }
}
```

12.33.1.7.1.15 Performance Optimization

High-Speed File I/O

```
// Use larger buffers for better performance
#define BUFFER_SIZE 32768
static char fileBuffer[BUFFER_SIZE];

void OptimizedFileCopy(const char *src, const char *dst) {
    F_FILE *srcFp = f_open(src, "rb");
    F_FILE *dstFp = f_open(dst, "wb");

    int bytesRead;
    while((bytesRead = f_read(fileBuffer, 1, BUFFER_SIZE, srcFp)) > 0) {
        f_write(fileBuffer, 1, bytesRead, dstFp);
    }

    fclose(srcFp);
    fclose(dstFp);
}
```

Memory Management

```
// Efficient memory usage for large files
void ProcessLargeFileInChunks(const char *filename) {
    F_FILE *fp = f_open(filename, "rb");
    char chunk[4096];

    while(f_read(chunk, 1, sizeof(chunk), fp) > 0) {
        ProcessChunk(chunk, sizeof(chunk));
    }

    fclose(fp);
}
```

Concurrent Access Management

```
// Thread-safe file operations
OS_SEM fileSemaphore;

void SafeFileWrite(const char *filename, const char *data) {
    fileSemaphore.Pend();
    F_FILE *fp = f_open(filename, "a");
    fprintf(fp, "%s", data);
}
```

```

    f_close(fp);
    fileSemaphore.Post();
}

```

12.33.1.7.1.16 Integration Examples

Web Interface Integration

```

// Web-based file management
void HandleFileUpload(int httpFd, const char *filename) {
    F_FILE *fp = f_open(filename, "wb");
    // Handle HTTP file upload
    SaveUploadedFile(httpFd, fp);
    f_close(fp);
}

```

Database-Like Operations

```

// Simple key-value storage
void StoreKeyValue(const char *key, const char *value) {
    F_FILE *fp = f_open("database.txt", "a");
    fprintf(fp, "%s=%s\n", key, value);
    f_close(fp);
}

char *GetValue(const char *key) {
    // Search through database.txt and return value
    return FindValueInFile("database.txt", key);
}

```

12.33.1.7.1.17 Related Examples

- **EFFS Examples:** Additional file system operations and utilities
- **FTP Examples:** Enhanced FTP server implementations
- **Data Logging:** Specialized logging and data acquisition systems
- **Network Storage:** Network-attached storage implementations
- **Backup Systems:** Automated backup and synchronization tools

12.33.1.8 EMI Emissions Reduction

12.33.1.8.1 EMI Emissions Reduction Example

12.33.1.8.1.1 Overview

This example demonstrates how to implement EMI (Electromagnetic Interference) reduction options for NetBurner MCF5441x platforms. The application provides an interactive menu system to test various emission reduction techniques that can help minimize electromagnetic interference in your embedded designs.

12.33.1.8.1.2 Supported Platforms

- **MOD5441x**
- **NANO54415**
- **SB800EX**

12.33.1.8.1.3 Features

The example provides the following EMI reduction capabilities:

1. Peripheral Clock Management

- **Disable unused peripheral clocks** - Turns off clocks to peripherals not being used by the application
- **Enable peripheral clocks** - Restores all peripheral clocks to their default enabled state

2. Spread Spectrum Clock Mode

- **Enable/Disable spread spectrum** - Available on MOD54415 hardware revisions 2.3 and later
- Helps reduce peak emissions by spreading the clock frequency over a range

3. Ethernet PHY Control

- **Disable Ethernet PHY** - Turns off the physical layer interface when network connectivity is not needed
- **Enable Ethernet PHY** - Restores normal Ethernet functionality

4. Signal Slew Rate Control

- **Reduce signal slew rates** - Configures pins for minimum slew rate to reduce high-frequency emissions
- **Restore default slew rates** - Returns pin configuration to reset defaults

5. Power Management

- **Wait mode idling** - Puts the processor in low-power wait mode when idle
- **Normal idling** - Uses standard polling loop when idle

12.33.1.8.1.4 Menu Options

When running the application, you'll see an interactive menu with these options:

Select EMC test to perform:

```
-----
1) Disable Peripheral Clocks
2) Enable Peripheral Clocks
3) Disable Spread Spectrum Mode on Primary CPU Oscillator
4) Enable Spread Spectrum Mode on Primary CPU Oscillator
5) Disable Ethernet PHY
6) Enable Ethernet PHY
7) Reduce Signal Slew Rates
8) Restore Default Signal Slew Rates
9) Idle in wait mode
10) Idle normally
```

12.33.1.8.1.5 Important Notes

Critical Peripherals

The application preserves functionality of essential system components:

- **UART 0** - Debug console remains enabled
- **FlexBus** - Required for application flash memory access
- **Interrupt Controllers** - System interrupts remain functional
- **PIT 0** - OS TimeTick timer stays enabled
- **DDR RAM** - External memory interface preserved
- **PLL** - Primary CPU clocks maintained
- **GPIO** - Module hardware GPIO functionality preserved

Signal Slew Rate Considerations

- Flash access timing may be disrupted at lowest slew rates
- Ethernet (FEC) functionality may be affected by reduced slew rates
- Multiple slew rate options are available as commented alternatives

Spread Spectrum Support

Spread spectrum mode is only available on:

- MOD54415 platform
- Hardware revision 2.3 and later

12.33.1.8.1.6 Usage

1. Build and deploy the application to your NetBurner device
2. Connect via serial console or Telnet
3. Use the interactive menu to test different EMI reduction techniques
4. Monitor emissions using appropriate test equipment
5. Combine multiple techniques as needed for your specific application

12.33.1.8.1.7 Additional EMI Considerations

This code example addresses software-configurable EMI reduction options. The associated documentation (Emi← Suggestions20210218.pdf) also covers:

- **Ethernet cabling** design considerations
- **Cable routing** and shielding best practices
- **Enclosure design** for emission reduction
- **Input power filtering** (very important for EMI compliance)
- **PCB routing** techniques and guidelines

12.33.1.8.1.8 File Structure

```
EMI-EmissionReduction/
|-- src/
|   +-- main.cpp           # Main application source
|-- makefile               # Build configuration
|-- ReadMe.txt             # Original documentation
|-- EmiSuggestions20210218.pdf # EMI design guidelines
+-- README.md              # This file
```

12.33.1.8.1.9 Application Architecture

The application uses a simple menu-driven architecture:

- **UserMain()** - Main application loop with menu display and input handling
- **DisablePeripheralClocks()** - Systematic peripheral clock disabling
- **EnablePeripheralClocks()** - Restore all peripheral clocks
- **ReduceSignalSlewRates()** - Configure minimum slew rates for all pins
- **RestoreDefaultSlewRates()** - Return to reset default slew rates
- **SpreadSpectrumOscillator()** - Control spread spectrum mode (MOD54415 only)

12.33.1.9 External NMI IRQ 7

12.33.1.9.1 External IRQ 7 (Non-Maskable Interrupt) Example

12.33.1.9.1.1 Overview

This example demonstrates how to configure and use External IRQ 7 as a non-maskable interrupt on NetBurner MCF5441X platforms. The application shows both C/C++ and assembly language interrupt service routine (ISR) implementations, providing a complete example of level 7 interrupt handling.

12.33.1.9.1.2 Supported Platforms

- **MOD5441X** - MOD54415 development module
- **NANO54415** - Nano54415 development module

Both platforms use the MCF54415 processor with identical interrupt functionality.

12.33.1.9.1.3 Hardware Requirements

Physical Connection Required

This example requires a jumper wire connection between a GPIO pin and the IRQ 7 input pin to trigger the interrupt:

MOD5441X Platform

GPIO Signal Pin: J2.33 ----[JUMPER]---- IRQ 7 Input: J2.48

NANO54415 Platform (Dev Board Rev 1.3)

GPIO Signal: Pin 12 (P2.12) ----[JUMPER]---- IRQ 7: Pin 9 (P1.9)

Pin Configuration Summary

Platform	GPIO Signal Pin	IRQ 7 Input Pin
MOD5441X	J2.33	J2.48
NANO54415	Pin 12 (P2.12)	Pin 9 (P1.9)

12.33.1.9.1.4 Features

Interrupt Service Routine (ISR) Implementation

- **Mixed C/C++ and Assembly** - Demonstrates both programming approaches
- **Register preservation** - Complete context saving and restoration
- **Interrupt flag clearing** - Proper interrupt acknowledgment
- **Counter mechanism** - Tracks number of interrupts received

GPIO Control

- **Signal generation** - Uses GPIO pin to trigger interrupts
- **Edge detection** - Configurable for falling, rising, or both edges
- **Manual triggering** - Interactive testing via serial console

Web Interface

- **Built-in web server** - Provides web-based interface
- **Status display** - Shows interrupt counter and system information

12.33.1.9.1.5 Code Architecture

Main Components

1. **UserMain()** - Application entry point and main loop
2. **ConfigureIrq7()** - IRQ 7 configuration function
3. **NMI_ASM_Part()** - Assembly language ISR entry point
4. **NMI_C_Part()** - C/C++ interrupt handler
5. **Function_Holder()** - Assembly code container function

Interrupt Flow

```

Hardware IRQ 7 Signal
    |
    v
NMI_ASM_Part() (Assembly)
    - Save processor state
    - Mask interrupts (SR = 0x2700)
    - Save all registers (D0-D7, A0-A6)
    |
    v
NMI_C_Part() (C/C++)
    - Clear interrupt flag (EPFR)
    - Reset GPIO trigger pin
    - Increment counter
    |
    v
NMI_ASM_Part() (Assembly continued)
    - Restore all registers
    - Restore processor state
    - Return from exception (RTE)

```

Register Usage

Assembly Code Register Operations

```

move.w #0x2700,%sr          ; Set interrupt mask to level 7
lea -60(%a7),%a7            ; Allocate 60 bytes on stack
movem.l %d0-%d7/%a0-%a6, (%a7) ; Save all general registers
jsr NMI_C_Part              ; Call C handler
movem.l (%a7),%d0-%d7/%a0-%a6 ; Restore all registers
lea 60(%a7),%a7             ; Restore stack pointer
rte                         ; Return from exception

```

12.33.1.9.1.6 Usage Instructions

Setup Process

1. **Build the application**
2. **Deploy to device**
3. **Install jumper wire**
 - Connect GPIO signal pin to IRQ 7 input pin according to platform specifications above
4. **Connect serial terminal**
 - Use MTTTY, PuTTY, or similar terminal program
 - Configure for 115200 baud, 8-N-1

Interactive Operation

1. **Start the application** - Device will display initialization messages
2. **Press any key** - Triggers a falling edge interrupt on IRQ 7
3. **View results** - Interrupt counter increments and displays current count
4. **Repeat testing** - Continue pressing keys to generate more interrupts

Example Console Output

```

MOD5441x IRQ 7 application started
Configuring J2-33 as GPIO
Configuring J2-48 as IRQ7
Hit any key to generate an IRQ
[User presses key]
Irq Count: 1
Hit any key to generate an IRQ
[User presses key]
Irq Count: 2
Hit any key to generate an IRQ

```

Web Interface

Access the web interface at `http://<device_ip>/` to view:

- Welcome page with NetBurner branding
- System status information
- Interrupt counter display

12.33.1.9.1.7 Technical Details

Interrupt Configuration

EPORT (External Port) Registers

- **EPPAR** - Pin assignment register (edge/level configuration)
- **EPDDR** - Data direction register (input/output configuration)
- **EPIER** - Interrupt enable register
- **EPFR** - Flag register (interrupt status)

Edge Detection Settings (EPPAR Register)

```
00: Level-sensitive (not used in this example)
01: Rising edge triggered
10: Falling edge triggered (used in this example)
11: Both edges triggered
```

Interrupt Controller Configuration

- **Vector:** 7 (IRQ 7 source)
- **Level:** 7 (highest priority, non-maskable)
- **Controller:** 0 (primary interrupt controller)

Memory Layout

Stack Frame During Interrupt

Stack Layout (60 bytes total):

D0	D1	D2	D3	Bytes 0-15
D4	D5	D6	D7	Bytes 16-31
A0	A1	A2	A3	Bytes 32-47
A4	A5	A6	---	Bytes 48-59

12.33.1.9.1.8 Important Considerations

IRQ 7 Characteristics

- **Non-maskable** - Cannot be disabled by interrupt mask bits
- **Highest priority** - Preempts all other interrupts
- **Critical timing** - Must be handled quickly to avoid system issues

Development Notes

- **Register preservation** is critical in assembly ISR
- **Stack management** must be precise (60-byte allocation)
- **Interrupt flag clearing** prevents continuous triggering
- **GPIO reset** ensures clean signal transitions

Troubleshooting

Common Issues

1. **No interrupts** - Check jumper wire connection
2. **Continuous interrupts** - Verify interrupt flag clearing in EPFR
3. **System instability** - Check assembly code register preservation
4. **Build errors** - Ensure SUPPORTED_PLATFORMS matches your hardware

Debug Steps

1. Verify jumper wire connections match platform specifications
2. Check serial console output for configuration messages
3. Confirm GPIO pin functions are set correctly
4. Test with multimeter to verify signal transitions

12.33.1.9.1.9 Learning Objectives

This example teaches:

- **Mixed-language programming** - C/C++ with assembly integration
- **Interrupt handling** - Non-maskable interrupt service routines
- **Hardware interface** - GPIO and external interrupt configuration
- **Register programming** - Direct MCF54415 register manipulation
- **Real-time concepts** - Critical timing and context preservation

12.33.1.9.1.10 Build Configuration

Makefile Settings

- **Platforms:** NANO54415, MOD5441X
- **Web content:** Auto-generated from html/ directory
- **Compile:** Standard NetBurner C++ compilation

Dependencies

- NetBurner NNDK (Network Development Kit)
- Compatible hardware platform
- Serial terminal program for interaction

12.33.1.9.1.11 License and Support

This example is provided under NetBurner's standard licensing terms. For technical support:

- Review the hardware platform documentation
- Consult the MCF54415 processor reference manual
- Contact NetBurner technical support for specific issues

12.33.1.9.1.12 Related Examples

For additional interrupt and GPIO examples, see:

- Basic GPIO examples for pin control
- Timer interrupt examples for periodic processing
- External interrupt examples for maskable interrupts (IRQ 1-6)

12.33.1.10 RTC - External

External [I2C](#) RTC example

Supported Platforms: MOD5441x, NANO54415

HARDWARE SETUP: Tested with MOD54415 on a MOD-DEV-70 hardware rev 1.93.

This example demonstrates the following features:

- Updates the system time with the current UTC time pulled from an available NTP server (pool.ntp.org). If your module is set to static IP address settings, then you will need to manually assign a DNS server address for this feature to work.
- Take the current system time and save it to the real-time clock (RTC). The RTC will then be running in sync with the system time.
- Take the current time in the RTC and set the system time information. The system time will then be running in sync with the RTC.
- When the device or module is reset or powered on again after a recent power loss, the system time will be reset, but the RTC can continue running until the super-capacitor is discharged. The software-reset option is available to demonstrate the RTC's ability to retain saved time information once it is properly set.
- Set the local time zone information with a call to [tzsetchar\(\)](#). For more more information on this function, refer to "Chapter 14 - NBTime Library" of the NetBurner Runtime Libraries PDF document. In this example, Pacific time zone information is used as a demonstration.
- Display the current system and RTC times, and local time zone information if applicable. It is preferred that the RTC store the UTC time, not local time.
- In order to take advantage of setting and getting time information from the real-time clock (RTC), a device that contains an RTC component or a module that is mounted on a development board with an RTC component must be used. Current RTC components supported in this example at the time of this writing are the Intersil X1226 and NXP PCF8563.

12.33.1.11 I2C

MCF5441x [I2C](#) Platform Examples

- [I2C Address Scan](#)
- [I2C PicKit Demo Board](#)

12.33.1.11.1 I2C Address Scan

12.33.1.11.1.1 I2C Address Scanner

Overview

This NetBurner application scans all possible I2C device addresses (1-127) on the I2C bus and reports which addresses respond with an ACK signal. The application is useful for discovering I2C devices connected to the bus and identifying their addresses for communication.

Supported Platforms

- **MOD5441X** - I2C0 default module
- **NANO54415** - I2C0 default module
- **MCF5441X OEM** - Configurable I2C module

Hardware Requirements

- NetBurner module with I2C capability
- I2C devices connected to the bus for testing
- Pull-up resistors on SDA and SCL lines (typically 4.7k)
- Serial console for viewing scan results

I2C Bus Configuration

Default Settings

- **I2C Module:** I2C0 (DEFAULT_I2C_MODULE)
- **NetBurner Address:** 0x08 (7-bit slave address)
- **Scan Range:** 1 to 127 (0x01 to 0x7F)
- **Operation Mode:** Master mode scanning

Address Format

The application reports addresses in both formats:

- **7-bit Address:** Standard I2C addressing format (0x50)
- **8-bit Address Byte:** Full address byte sent on bus (0xA0 for write, 0xA1 for read)

Application Functionality

Main Features

1. **Complete Address Scan:** Tests all 127 possible I2C addresses
2. **Device Detection:** Identifies responding devices by ACK signal
3. **Dual Address Format:** Reports both 7-bit and 8-bit address formats
4. **Interactive Operation:** Allows repeated scans on user command
5. **Error Handling:** Proper I2C bus reset on communication failures

Program Flow

1. Initialization

- Initialize network stack and diagnostics
- Initialize I2C module with NetBurner as address 0x08
- Display initialization status

2. Address Scanning

- Loop through addresses 1-127 (0x01-0x7F)
- Send write start condition to each address
- Check for ACK response within timeout period
- Report responding devices with address information

3. Interactive Mode

- Wait for user input to repeat scan
- Display total number of responding devices
- Continuous operation until reset

Scan Process Flow

```

Start -> Address 1 -> Send Start+Write -> ACK? -> Report Device -> Next Address
      ^                                     |
      |                                     v
      +-- Address 127 <- Bus Reset <-- NACK/Timeout
  
```

Key Components

Core Functions

I2C Operations:**

- `MultiChannel_I2CInit()`: Initialize I2C module with slave address
- `MultiChannel_I2CStart()`: Send start condition with address and direction
- `MultiChannel_I2CStop()`: Send stop condition to end transaction
- `I2CMultiChannelResetPeripheral()`: Reset I2C module on errors

Scan Function:**

- `scanAddressesI2C()`: Main scanning routine that tests all addresses
- Returns count of responding devices

Output Format

Typical Scan Results

```

Initializing address: 0x08 ... Complete
Scanning peripheral I2C0...
Found device, 7-bit addr: 0x08, 8-bit addr byte: 0x10, I2C Status: 0
Found device, 7-bit addr: 0x50, 8-bit addr byte: 0xA0, I2C Status: 0
Found device, 7-bit addr: 0x68, 8-bit addr byte: 0xD0, I2C Status: 0
Scan complete
3 addresses responded

Type any key to repeat
  
```

Address Information Explained

Example: 7-bit address 0x50**

- **7-bit addr:** 0x50 (binary: 1010000)
 - **8-bit addr byte:** 0xA0 (binary: 10100000) - with write bit (0)
 - **Read address byte:** 0xA1 (binary: 10100001) - with read bit (1)
- Status Codes:**
- **0:** Successful ACK received
 - ****>= I2C_TIMEOUT**:** No response or communication error

Device Address Ranges

Common I2C Device Addresses

EEPROMs (24Cxx series):**

- Base addresses: 0x50-0x57 (depending on A0-A2 pins)
- 8-bit address bytes: 0xA0-0xAE (write), 0xA1-0xAF (read)

Real-Time Clocks:**

- DS1307: 0x68 (8-bit: 0xD0 write, 0xD1 read)
- DS3231: 0x68 (8-bit: 0xD0 write, 0xD1 read)

Temperature Sensors:**

- LM75: 0x48-0x4F (8-bit: 0x90-0x9E write)
- DS18B20: 0x18-0x1F (when used with [I2C](#) bridge)

Accelerometers:**

- ADXL345: 0x1D or 0x53 (depending on ALT ADDRESS pin)
- MMA7455: 0x1D (8-bit: 0x3A write, 0x3B read)

Multiple Device Responses

Some devices may respond to multiple addresses due to "don't care" address bits:

Found device, 7-bit addr: 0x50, 8-bit addr byte: 0xA0, [I2C](#) Status: 0

Found device, 7-bit addr: 0x51, 8-bit addr byte: 0xA2, [I2C](#) Status: 0

Found device, 7-bit addr: 0x52, 8-bit addr byte: 0xA4, [I2C](#) Status: 0

This typically indicates a single EEPROM with configurable address bits.

Building and Deployment

Configuration Options

```
// Change I2C module (if multiple modules available)
#define I2C_MODULE_NUM 1 // Use I2C1 instead of I2C0

// Change NetBurner slave address
const uint8_t slaveAddr = 0x10; // Different slave address
```

Hardware Setup

I2C Bus Requirements

Pull-up Resistors:**

- **SDA and SCL:** 4.7k to VCC (typically 3.3V)
- **Strong pull-ups:** 2.2k for high-speed or long cables
- **Weak pull-ups:** 10k for low-power applications

Bus Termination:**

- Only required at physical ends of long bus runs
- Not needed for short connections between devices

Platform-Specific Connections

MOD5441X:**

- Check module datasheet for I2C pin locations
- Typically available on J2 connector
- May require external pull-up resistors

NANO54415:**

- I2C pins available on development board connectors
- Check for integrated pull-up resistors on board
- Verify voltage levels (3.3V logic)

Troubleshooting

Common Issues

1. No devices found (0 addresses responded):

- Check pull-up resistors on SDA and SCL
- Verify I2C device power connections
- Confirm correct pin connections
- Check for bus conflicts or shorts

2. Only NetBurner address responds (0x08):

- Indicates I2C module is working but no external devices detected
- Check device connections and power
- Verify devices are properly addressed

3. Bus lockup or communication errors:

- Reset I2C module: `I2CMultiChannelResetPeripheral()`
- Check for clock stretching issues
- Verify bus timing parameters

4. Intermittent device detection:

- Check power supply stability
- Verify pull-up resistor values
- Check for electromagnetic interference

Debug Techniques

Bus Status Monitoring:**

```
// Add status checking
uint8_t busStatus = GetI2CBusStatus(I2C_MODULE_NUM);
iprintf("I2C Bus Status: 0x%02X\n", busStatus);
```

Detailed Error Reporting:**

```
// Enhanced error information
if (I2CStat >= I2C_TIMEOUT) {
    iprintf("Address 0x%02X: Timeout/Error %d\n", addr, I2CStat);
}
```

Signal Quality Testing:**

```
// Test communication with known good device
uint8_t testData = 0x00;
int result = I2CWriteRead(I2C_MODULE_NUM, knownAddress, &testData, 1, NULL, 0);
iprintf("Test communication result: %d\n", result);
```

Advanced Usage

Selective Scanning

```
// Scan specific address range
void ScanAddressRange(uint8_t startAddr, uint8_t endAddr) {
    for(int addr = startAddr; addr <= endAddr; addr++) {
        // Perform scan as in main function
    }
}
```

Device Identification

```
// Try to identify device type by reading manufacturer ID
void IdentifyDevice(uint8_t address) {
    uint8_t deviceID[3];
    if(I2CRead(I2C_MODULE_NUM, address, deviceID, sizeof(deviceID)) == 0) {
        iprintf("Device ID: %02X %02X %02X\n",
            deviceID[0], deviceID[1], deviceID[2]);
    }
}
```

Continuous Monitoring

```
// Monitor for device additions/removals
void ContinuousMonitor() {
    static uint8_t lastDeviceCount = 0;
    uint8_t currentCount = scanAddressesI2C();

    if(currentCount != lastDeviceCount) {
        iprintf("Device count changed: %d -> %d\n",
            lastDeviceCount, currentCount);
        lastDeviceCount = currentCount;
    }
}
```

Application Extensions

Device Communication Testing

```
// Test basic communication with found devices
void TestDeviceCommunication(uint8_t address) {
    uint8_t testByte = 0x00;
    uint8_t readBack;

    if(I2CWriteRead(I2C_MODULE_NUM, address, &testByte, 1, &readBack, 1) == 0) {
        iprintf("Device 0x%02X communication OK\n", address);
    }
}
```

Configuration Storage

```
// Store found device addresses for later use
uint8_t foundDevices[128];
uint8_t deviceCount = 0;

void StoreFoundDevices() {
    deviceCount = 0;
    for(int addr = 1; addr < 0x80; addr++) {
        if(TestDevicePresence(addr)) {
            foundDevices[deviceCount++] = addr;
        }
    }
}
```

```

    }
}

```

Web Interface

```

// Provide web-based scan results
void HandleI2CScanRequest(int httpFd) {
    SendHttpResponse(httpFd, "200 OK");
    WriteHttp(httpFd, "<html><body>");
    WriteHttp(httpFd, "<h1>I2C Device Scan</h1>");

    int deviceCount = scanAddressesI2C();
    WriteHttpf(httpFd, "<p>Found %d devices:</p>", deviceCount);
    WriteHttp(httpFd, "</body></html>");
}

```

Performance Considerations

Scan Speed Optimization

- Reduce timeout values for faster scanning
- Skip known empty address ranges
- Use interrupt-driven [I2C](#) for better responsiveness

Memory Usage

- Minimal RAM usage for address scanning
- Consider buffering results for web interfaces
- Stack usage is minimal for this application

12.33.1.11.2 I2C PicKit Demo Board

12.33.1.11.2.1 PicKit I2C Serial Demo Board Example

Overview

This example demonstrates comprehensive [I2C](#) communication using a Microchip PicKit Serial [I2C](#) Demo Board. The application interfaces with five different [I2C](#) peripherals, showcasing various data types and communication patterns including EEPROM storage, temperature sensing, GPIO expansion, analog-to-digital conversion, and digital-to-analog conversion.

Supported Platforms

- **MOD5441X** - MOD54415 development module
- **NANO54415** - Nano54415 development module

Both platforms use the MCF54415 processor with identical [I2C](#) functionality.

Hardware Requirements**Microchip PicKit Serial I2C Demo Board**

This example requires the Microchip PicKit Serial I2C Demo Board containing the following I2C peripherals:

Component	Type	Description	I2C Address
24LC0B	EEPROM	2Kbit (256 x 8) memory	0x50
MCP9800	Temperature Sensor	Digital thermometer	0x49
MCP23008	GPIO Expander	8-bit I/O expander with LEDs	0x20
TC1321	DAC	10-bit Digital-to-Analog Converter	0x48
MCP3221	ADC	12-bit Analog-to-Digital Converter	0x4D

I2C Connection Requirements

MOD5441X Platform

NetBurner Pin	PicKit Demo Board
J2.39 (SDA) --- SDA	
J2.42 (SCL) --- SCL	
J2.1 (GND) --- GND	
J2.2 (VCC) --- VCC (3.3V)	

NANO54415 Platform

NetBurner Pin	PicKit Demo Board
P1.29 (SDA) --- SDA	
P1.48 (SCL) --- SCL	
J2.1 (GND) --- GND	
P1.47 (VCC) --- VCC (3.3V)	

Power Requirements

- **Voltage:** 3.3V DC
- **Current:** Typical 50mA (depending on LED usage)

Features

Multi-Peripheral I2C Communication

- **Simultaneous device support** - Communicates with 5 different I2C devices
- **Address management** - Proper 7-bit I2C addressing scheme
- **Error handling** - Comprehensive status code checking and reporting
- **Device initialization** - Automatic setup and configuration

EEPROM Operations (24LC0B)

- **256-byte capacity** - Full memory read/write operations
- **Page writing** - Efficient 8-byte page write cycles
- **Write completion polling** - Automatic write cycle detection
- **Memory display** - Hex dump formatting for data visualization

Temperature Monitoring (MCP9800)

- **12-bit resolution** - High precision temperature measurement
- **Celsius and Fahrenheit** - Dual unit temperature display
- **2's complement format** - Proper signed temperature handling
- **Configuration register** - Device setup and calibration

GPIO Expansion (MCP23008)

- **LED control** - 8-bit LED pattern display
- **Sequential patterns** - Rotating LED animation
- **Direction control** - Input/output pin configuration
- **Real-time updates** - Continuous LED pattern cycling

Digital-to-Analog Conversion (TC1321)

- **10-bit resolution** - 0-1023 digital range
- **2.5V reference** - 0-2.5VDC analog output
- **User input** - Interactive DAC value entry
- **Voltage calculation** - Real-time output voltage display

Analog-to-Digital Conversion (MCP3221)

- **12-bit resolution** - 4096-step analog measurement
- **3.3V reference** - 0-3.3VDC input range
- **Real-time sampling** - Continuous analog input monitoring
- **Voltage display** - Converted voltage readout

I2C Address Configuration

Address Format Explanation

I2C addresses can be confusing due to different documentation conventions. This example uses the standard NetBurner 7-bit addressing scheme:

```
I2C Address Byte Format: [A6 A5 A4 A3 A2 A1 A0 R/W]
                        |<---- 7-bit Address ---->|
```

Where:

- A6-A0: 7-bit device address
- R/W: Read/Write bit (0=Write, 1=Read)

Address Translation Table

Device	Datasheet Address	NetBurner 7-bit Address	Binary Address
24LC0B EEPROM	0xA0	0x50	0101 0000
MCP9800 Temp	0x92	0x49	0100 1001
MCP23008 GPIO	0x40	0x20	0010 0000
TC1321 DAC	0x90	0x48	0100 1000
MCP3221 ADC	0x9A	0x4D	0100 1101

Address Calculation

```
// Convert datasheet address to NetBurner format
#define I2C_DEVICE_ADDRESS (DATASHEET_ADDR » 1)

// Example: MCP3221 ADC
// Datasheet address: 0x9A (1001 1010 binary)
// NetBurner address: 0x4D (0100 1101 binary)
#define I2C_ADC_ADDRESS (0x9A » 1) // Results in 0x4D
```

Application Menu System

Interactive Commands

The application provides a menu-driven interface for testing all I2C devices:

Main Menu:

1. Erase EEPROM
2. Read EEPROM
3. Write incrementing sequence to EEPROM
- A. Read ADC
- D. DAC Test
- T. Read Temperature Sensor

Automatic Operations

- **LED Animation** - Continuously cycles through LED patterns every 500ms
- **Status Monitoring** - Real-time I2C bus status reporting
- **Error Detection** - Automatic error code display and description

Usage Instructions

Setup Process

1. Prepare hardware

- Connect PicKit I2C Demo Board to NetBurner module using I2C connections above
- Verify power connections (3.3V, GND)
- Ensure proper pull-up resistors on SDA/SCL lines (usually provided on demo board)

2. Build and deploy

3. Connect serial terminal

- Use terminal program (MTTTY, PuTTY, etc.)
- Configure: 115200 baud, 8-N-1
- Connect to NetBurner device

Operation Examples

EEPROM Testing Sequence

```
[Press '1'] Erase EEPROM
[Press '3'] Write incrementing sequence to EEPROM
[Press '2'] Read EEPROM - should show 00 01 02 03 ... FF
```

Temperature Monitoring

```
[Press 'T'] Read Temperature Sensor
Output: Temp: 23.56 C, 74.41 F, Register data: 17 90
```

DAC Control

```
[Press 'D'] DAC Test
Enter a DAC value between 0-1023
[Enter: 512]
Writing 512 (0x0200) to DAC: 0x80 0x00, 1.25 V
```

ADC Reading

```
[Press 'A'] Read ADC
Reading from address 0x4D ... Success
Voltage: 1.65V, Register data: 82 3F
```

LED Pattern Behavior

The application automatically cycles through LED patterns:

```
Pattern Sequence:
00000001 -> 00000010 -> 00000100 -> 00001000 ->
00010000 -> 00100000 -> 01000000 -> 10000000 ->
[Repeat from beginning]
```

Technical Implementation Details

EEPROM Page Writing

The 24LC0B EEPROM uses 8-byte pages for efficient writing:

```
// Page boundary calculation
int endOfPage = (8 - (startAddress % 8)) + 1;

// Write sequence:
// 1. Set address pointer
// 2. Write up to 8 data bytes
// 3. Wait for write completion
// 4. Repeat for next page
```

Write Completion Detection

```
bool WaitForEepromWriteCmpl(uint8_t moduleNum, uint8_t address)
{
    // Poll device with start condition
    // Device will ACK when write cycle complete
    // Timeout after 1000 attempts
}
```

Temperature Conversion

The MCP9800 provides 12-bit temperature data in 2's complement format:

```
// Temperature calculation
int8_t highByte = (int8_t)buffer[0]; // Sign-extended high byte
float temp = highByte + ((buffer[1] >> 4) * 0.0625); // Add fractional part

// Convert to Fahrenheit
float tempF = (tempC * 9.0 / 5.0) + 32.0;
```

DAC Output Calculation

The TC1321 uses a 10-bit value with 2.5V reference:

```
// DAC data format: [CMD][D9 D8 D7 D6 D5 D4 D3 D2][D1 D0 - - - - -]
buf[0] = 0x00; // Command byte
buf[1] = (uint8_t)((value >> 2) & 0xFF); // Upper 8 bits
buf[2] = (uint8_t)((value & 0x03) << 6); // Lower 2 bits, left-justified

// Output voltage calculation
float outputV = (float)value / 1023.0 * 2.5;
```

ADC Input Processing

The MCP3221 provides 12-bit ADC data:

```
// Combine high and low bytes
uint16_t adcValue = ((uint16_t)buf[0] << 8) | buf[1];

// Convert to voltage (3.3V reference)
float voltage = (float)adcValue * (3.3 / 4095.0);
```

Error Handling

I2C Status Codes

The application provides detailed status code descriptions:

Code	Status	Description
0	I2C_OK	Operation successful
1	I2C_NEXT_WRITE_OK	Bus ready for write operation
2	I2C_NEXT_READ_OK	Bus ready for read operation
3	I2C_MASTER_OK	Master transmission complete

Code	Status	Description
4	I2C_TIMEOUT	Communication timeout occurred
5	I2C_BUS_NOT_AVAIL	Bus acquisition timeout
6	I2C_NOT_READY	Device not ready for operation
7	I2C_LOST_ARB	Lost arbitration during start
8	I2C_LOST_ARB_ADD	Lost arbitration, addressed as slave
9	I2C_NO_LINK_RX_ACK	No ACK received from slave

Troubleshooting Guide

Common Issues

1. No device response

- Check physical connections (SDA, SCL, power, ground)
- Verify pull-up resistors on I2C lines
- Confirm device addresses match hardware configuration

2. EEPROM write failures

- Ensure write completion polling is working
- Check for proper page boundary handling
- Verify address range (0-255 for 24LC0B)

3. Temperature reading errors

- Confirm device initialization sequence
- Check configuration register settings
- Verify 12-bit resolution mode

4. DAC output incorrect

- Check reference voltage (should be 2.5V)
- Verify 10-bit data format and bit alignment
- Measure actual output with multimeter

5. ADC reading issues

- Confirm input voltage within 0-3.3V range
- Check reference voltage stability
- Verify 12-bit conversion calculation

Debug Commands

```
# Check I2C bus status
iprintf("I2C Status: %d\n", status);
DisplayI2CStatusCode(status);

# Display raw register data
for(int i = 0; i < len; i++)
    iprintf("%02X ", buffer[i]);
```

Performance Characteristics

Timing Specifications

- **I2C Clock Speed:** 100 kHz (standard mode)
- **EEPROM Write Time:** 5ms typical per page
- **Temperature Conversion:** 240ms maximum (12-bit)
- **ADC Conversion:** 133 microseconds typical
- **DAC Settling Time:** 6 microseconds typical

Memory Usage

- **EEPROM Buffer:** 256 bytes static allocation
- **I2C Buffers:** 8 bytes per transaction
- **Total RAM Usage:** Approximately 512 bytes

Code Architecture

Function Organization

Initialization Functions

- `SetSystemI2CSlaveAddress()` - Configure NetBurner as I2C slave
- `MultiChannel_I2CInit()` - Initialize I2C peripheral module

Device-Specific Functions

- `ReadTempSensor()` - MCP9800 temperature operations
- `WriteLeds()` - MCP23008 GPIO control
- `WriteDAC()` - TC1321 analog output
- `ReadADC()` - MCP3221 analog input
- `EepromWriteBuf()` / `EepromRead()` - 24LC0B memory operations

Utility Functions

- `DisplayI2CStatusCode()` - Error code interpretation
- `WaitForEepromWriteCmpl()` - Write cycle detection
- `Ascii2Byte()` - String to hex conversion
- `DisplayBuffer()` - Memory dump formatting

User Interface Functions

- `DisplayMenu()` - Menu system display
- `ProcessCommand()` - Command parsing and execution
- `IncrementLEDs()` - LED pattern animation

Learning Objectives

This example demonstrates:

- **Multi-device I2C communication** - Managing multiple peripherals on single bus
- **Different data types** - Binary, analog, temperature, and memory data
- **Error handling patterns** - Comprehensive status checking and recovery
- **Real-time operations** - Continuous monitoring and control
- **User interaction** - Menu-driven testing and configuration
- **Hardware abstraction** - Platform-independent I2C operations

Build Configuration

Dependencies

- NetBurner NNDK (Network Development Kit)
- Microchip PicKit Serial [I2C](#) Demo Board
- Multi-channel [I2C](#) library support

Related Examples

For additional [I2C](#) learning, see:

- Basic [I2C](#) examples for single-device communication

- Advanced [I2C](#) timing and error recovery examples
- Real-time data logging with [I2C](#) sensors

12.33.1.12 RTC - On Chip

Supported Platforms: MOD5441x, NANO54415

A simple Real Time Clock (RTC) example using the RTC on the MCF5441x microprocessor. Demonstrates how to get and set time through NTP, RTC and manually. An interactive menu is accessed through MTTTY.

For this example to function, your NetBurner device must have access to the Internet, with a working configuration for the IP address, mask, gateway and DNS server.

12.33.1.13 Periodic Interrupt Timer

Periodic Interrupt Timer (PIT) Example

Supported Platforms: MOD5441x, NANO54415 SB800EX

There are a total of 4 PIT timers on the MCF54415 processor, numbered 0 - 3:

- 0 is reserved for the RTOS system clock
- 3 is reserved for the network debugger
- 1 and 2 are available for customer use

The PIT functions below are part of the 54415 system libraries, and defined in `pitr_sem.cpp` and [pitr_sem.h](#), located in the include and system folders of your MOD54415 or NANO54415 platform directories.

In this example a semaphore will be set in the PIT interrupt routine, and the semaphore count will be displayed through the serial port.

12.33.1.14 Pulse Generator and Counter

Supported Platforms: MOD5441x, NANO54415

Demonstrates how to use the DMA Timers to generate a waveform output on one timer, and use the timer capture feature to count the waveform pulses on a second timer. Features include:

- Programmable frequency output
- Measurement of frequency input
- Timer count display
- Values also displayed on the web page interface

The application will work on the MOD54415, MOD54417 and NANO5441. The selected timer channels must be jumpered together on the development board so that the waveform output is connected to the capture input.

MOD5441x: Timer J2 Pin

0 36 1 34 2 33 3 32

NANO54415: Timer Pin

0 19 1 21 2 23 3 25

12.33.1.15 PWM

Example program for ColdFire MCF5441x PWM capability on the MOD5441x core module.

Supported Platforms: MOD5441x, NANO54415

Description: Toggles a PWM signal on pin 35 on the NetBurner NANO or MOD54415 module using two different settings. While each PWM module on the 5441x core is capable of producing multiple output signals for use in controlling motors as well as other applications, this example sets the output for one pin only.

There are 2 functions illustrating different methods to create the pulses:

1. Center-Aligned pulses
2. Edge-Aligned pulses

12.33.1.16 Core Watchdog Timer (CWT)

Supported Platforms: MOD5441x, NANO54415, SB800EX

This example demonstrates how to enable the watchdog, set the timeout value, and service the watchdog. An interactive menu and status messages are displayed through the debug serial port. If the watchdog is not serviced before the timeout expires, events such as a system reset or interrupt service request (IRQ) can occur. The following watchdog timeout modes are supported by the 5441x processor:

- System reset
- IRQ only
- IRQ on first timeout, then system reset on the second timeout
- Windowed mode, this is an advanced mode of operation that processes a timeout in 25% increments. Please refer to the MCF5441X Users Manual for more information. This mode is not covered in the example.

Servicing the watchdog can be accomplished in a number of ways:

1. A higher priority task that uses a timer, such as the Periodic Interrupt Timer (PIT). This is the most common method.
2. In an Interrupt Service Routine (ISR). A drawback here is that interrupts can still occur, even if a specific task is not functioning correctly.
3. Servicing throughout an application with specific function calls. This is very difficult to cover all of the edge cases.

A good system implementation would be to use the task and timer method, along with flags, counters or some other indication in each critical task that is evaluated in the watchdog service task to ensure the system is functioning properly.

The example includes code for both the task with timer method and interrupt method; you will only need one of these in your application.

Example Features:

- Demonstrates 3 service methods: task with timer, interrupt and manual
- Interactive menu on serial port provides options for enabling, disabling and servicing modes

This example does not enable the watchdog in the Flash memory system configuration so that a power cycle will reset the system with the watchdog disabled. This is done to make it easier to experiment with the various watchdog modes of operation. If you wish to have the watchdog persistently enabled through power cycles without explicitly enabling it in your application, the watchdog must be enabled in the configuration system.

12.33.1.17 WAV File Audio Player

Supported Platforms: MOD5441x, NANO54415

This example demonstrates how to play audio files (uncompressed WAV) using the onboard Digital to Analog Converters (DAC) on the MCF5441X processor. It is fully capable of playing 8 bit and down converted 16 and 32 bit stereo audio at 44100 samples per second. It has minimal support for 24 bit samples, treating it as 8 bit data with sample padding.

Before attempting to build the application, you will first need to extract the "wav_data_srcs.zip" archive, containing the sample audio files converted to data arrays. The originals used to create these source files are found in the archive 'SD_card.zip'. This contents directory are also intended to be placed directly onto an (micro)SD card and files be played from it.

IMPORTANT: Since these files are external references in main.cpp, they must be aligned on an even boundary. One way to do this is the aligned attribute. For example: `uint8_t sinewav_440[] attribute(( aligned( 16 ))) = { ..... }` You can see the full declaration in the nbwav_44k .cpp file

12.33.1.18 MOD5441x Only

MOD5441x Platform Examples

- [MOD5441x Multiple EFFS Flash Card Test](#)
- [MOD5441x Factory application](#)
- [Get MOD54417 Switch Port](#)
- [MOD5441x Rapid GPIO](#)
- [MOD5441x USB Mass Storage Device](#)

12.33.1.18.1 MOD5441x Multiple EFFS Flash Card Test

12.33.1.18.1.1 EFFS Multiple MMC Flash Card Example

Overview

This example demonstrates comprehensive multiple flash card file system operations using NetBurner's EFFS (Embedded Flash File System). The application shows how to simultaneously access both the on-board microSD card slot on the MOD5441X module and external flash card sockets on development boards, providing complete file system management for dual storage scenarios.

Supported Platform

- **MOD5441X** - MOD54415/MOD54417 core modules only

Hardware Requirements

Essential Components

- **MOD5441X core module** with on-board microSD card slot
- **MOD-DEV-70CR development board** with external flash card socket
- **Two flash cards** - MicroSD for on-board slot, SD or microSD for external socket

Hardware Connections

MOD5441X Module		MOD-DEV-70CR Dev Board
=====		=====
On-board microSD	<->	[Built-in slot]
Module connector	<->	Dev board socket
		External SD socket <-> [External flash card]

Card Requirements

- **On-board:** MicroSD card (any capacity supported by EFFS)
- **External:** SD or microSD card with adapter
- **Format:** FAT16 or FAT32 file systems
- **Write Protection:** Cards should not be write-protected during testing

Features

Dual Flash Card Management

- **On-board card access** - Built-in microSD slot operations
- **External card access** - Development board flash card socket
- **Drive switching** - Dynamic switching between storage devices
- **Independent operations** - Separate file operations on each card

Complete File System Operations

- **Drive mounting/unmounting** - Proper card initialization and cleanup
- **File creation and writing** - Creating test files with content
- **Directory operations** - Listing files and directories
- **Space management** - Free and used space calculation
- **Error handling** - Comprehensive error detection and reporting

EFFS Integration

- **Multi-drive support** - Simultaneous access to multiple storage devices
- **Task-based file system** - Proper EFFS task registration
- **Drive enumeration** - Automatic drive detection and assignment
- **Error code translation** - Human-readable error descriptions

Application Workflow

Initialization Sequence

1. **System startup** - Network and diagnostic initialization
2. **File system registration** - Task registration with EFFS (`f_enterFS()`)
3. **Card detection** - Check for presence of flash cards
4. **Write protection check** - Verify cards are writable

Testing Sequence

On-Board Flash Card Test

1. Open on-board flash card drive
2. Mount drive and change to it (`f_chdrive()`)
3. Create test file: "FileOnBoardSD.txt"
4. Write content: "This file written to SD card on the Module"
5. Close file and display directory contents
6. Unmount drive properly

External Flash Card Test

1. Open external flash card drive
2. Mount drive and change to it (`f_chdrive()`)
3. Create test file: "FileOffBoardSD.txt"
4. Write content: "This file written to SD card off of the Module"
5. Close file and display directory contents
6. Unmount drive properly

Cleanup and Completion

1. **Release file system** - Unregister task from EDFS (`f_releaseFS()`)
2. **Status report** - Display completion message
3. **Idle loop** - Wait for manual reset to repeat test

Usage Instructions

Setup Process

1. **Prepare hardware**
 - Insert microSD card into MOD5441X on-board slot
 - Insert SD/microSD card into development board external socket
 - Ensure both cards are NOT write-protected
 - Connect MOD5441X to MOD-DEV-70CR development board
2. **Build and deploy**
3. **Monitor operation**
 - Connect serial terminal (115200 baud, 8-N-1)
 - Observe file system operations and results
 - Check for any error messages during execution

Expected Console Output

```
===== Starting MOD5441x EDFS Flash Card Test Program =====

Testing the on-board Flash card
Card detected successfully
drive change successful
Wrote 43 bytes: [This file written to SD card on the Module]

Directory listing for on-board card:
FileOnBoardSD.txt    43 bytes
[Other files may be listed]

Testing the external Flash card
Card detected successfully
drive change successful
Wrote 46 bytes: [This file written to SD card off of the Module]

Directory listing for external card:
FileOffBoardSD.txt   46 bytes
[Other files may be listed]

Program complete. Reset to repeat
```

Technical Implementation

File System Architecture

Drive Management

```
// Open and mount drives
int onBoardDrive = OpenOnBoardFlash();
int externalDrive = OpenOffBoardFlash();

// Switch between drives
int result = f_chdrive(onBoardDrive);
if (result == F_NO_ERROR) {
    // Perform file operations
}
```

Card Detection Logic

```
// Check card presence
if (get_cd(drive) == 0) {
    // No card detected - prompt user
    printf("No card detected. Insert card and press <Enter>\n");
}

// Check write protection
if (get_wp(drive) == 1) {
    // Card is write-protected - prompt user
    printf("Card is write-protected. Remove protection and press <Enter>\n");
}
```

File Operations Pattern

```
// Standard file operation sequence
F_FILE *fp = f_open("filename.txt", "w+");
if (fp) {
    const char *data = "File content";
    int bytesWritten = f_write(data, 1, strlen(data), fp);
    f_close(fp);
    printf("Wrote %d bytes\n", bytesWritten);
}
```

Error Handling System

Comprehensive Error Codes

The application includes complete EDFS error code translation:

Error Code	Description	Common Causes
F_NO_ERROR	Operation successful	-
F_ERR_INVALIDDRIVE	Invalid drive number	Drive not mounted
F_ERR_NOTFORMATTED	Drive not formatted	Unformatted card
F_ERR_CARDREMOVED	Card removed during operation	Physical card removal
F_ERR_WRITEPROTECT	Write protection enabled	Card lock switch
F_ERR_INVALIDMEDIA	Invalid media type	Unsupported card format
F_ERR_BUSY	Drive busy	Concurrent access

Error Display Function

```
void DisplayEdfsErrorCode(int code) {
    if (code <= MAX_EDFS_ERRORCODE)
        printf("%s\n", EdfsErrorCode[code]);
    else
        printf("Unknown EDFS error code [%d]\n", code);
}
```

Drive Type Detection

The system automatically detects and configures different drive types:

```
// Drive identification constants
#define MMC_OFF_BOARD (0)    // External development board slot
#define MMC_ON_BOARD (1)    // Module built-in microSD slot

// Drive type string for reporting
char driveType[20]; // "On-board" or "Off-board"
```

Memory and Performance

Resource Usage

- **Static memory:** Approximately 2KB for error code strings
- **Dynamic memory:** EDFS buffers allocated per drive
- **File handles:** Limited by EDFS configuration (typically 8-16)

Performance Characteristics

- **Card detection:** Immediate (hardware signal)
- **Drive mounting:** 100-500ms depending on card size
- **File operations:** Standard SD card speeds (Class 4-10)
- **Drive switching:** <10ms for drive change operations

Troubleshooting**Common Issues****Card Detection Problems**

Symptoms**: "No card detected" messages Solutions**:

- Verify card is fully inserted
- Check card compatibility (FAT16/FAT32)
- Try different cards to isolate hardware issues
- Ensure development board connections are secure

Write Protection Errors

Symptoms**: F_ERR_WRITEPROTECT errors Solutions**:

- Check physical write-protect switch on SD cards
- Verify card is not corrupted
- Test with different cards
- Check for read-only file system attributes

Drive Mount Failures

Symptoms**: Drive change failed messages

Solutions**:

- Reformat cards using standard SD formatter
- Check card file system (must be FAT16 or FAT32)
- Verify sufficient free space on cards
- Test cards in standard PC card readers first

File Operation Errors

Symptoms**: File creation or write failures Solutions**:

- Check available free space on cards
- Verify cards are not corrupted
- Ensure proper drive mounting before file operations
- Check file name validity (8.3 format recommended)

Debug Procedures

1. Verify card detection

```
printf("Card detect status: %d\n", get_cd(drive));
printf("Write protect status: %d\n", get_wp(drive));
```

2. Check drive mounting

```
int result = f_chdrive(drive);
printf("Drive change result: ");
DisplayEffsErrorCode(result);
```

3. Monitor file operations

```
F_FILE *fp = f_open("test.txt", "w");
if (!fp) {
    printf("File open failed\n");
}
```

File Structure

```
EffsMultipleMmc/
|-- src/
|   |-- main.cpp           # Main application logic
|   |-- FileSystemUtils.cpp # EFFS utility functions
|   |-- FileSystemUtils.h   # Utility function declarations
|   |-- effs_time.cpp       # Time utilities for EFFS
|   |-- effs_time.h         # Time function declarations
```

Dependencies

- **NetBurner NNDK** - Network Development Kit
- **FatFile Library** - EFFS FAT file system support
- **MOD5441X Platform** - Hardware-specific drivers
- **Development Board** - MOD-DEV-70CR for external card access

Learning Objectives

This example teaches:

- **Multi-drive file system management** - Handling multiple storage devices
- **EFFS API usage** - NetBurner embedded file system operations
- **Error handling patterns** - Comprehensive error detection and reporting
- **Hardware abstraction** - Platform-specific storage device access
- **Task-based file systems** - Proper registration and cleanup procedures
- **Card detection logic** - Physical media presence and status checking

Related Examples

For additional file system learning, see:

- Single flash card examples for basic EFFS operations
- File upload/download examples for network file transfer
- Data logging examples for continuous file system usage
- Web-based file manager examples for remote file access

12.33.1.18.2 MOD5441x Factory application

12.33.1.18.2.1 MOD5441X Factory Application

Overview

This comprehensive demonstration application showcases the complete feature set of the NetBurner MOD5441X platform. It serves as the factory-installed application and provides a full-featured example of web server functionality, file system management, interactive GPIO control, and network services. This application demonstrates how to build a complete embedded web-based control system with both static and dynamic content.

Supported Platform

- **MOD5441X** - MOD54415/MOD54417 core modules only

Hardware Requirements

Essential Components

- **MOD5441X core module** - Factory-installed application platform
- **MOD-DEV-70CR development board** - For complete functionality including LEDs, switches, and flash card access
- **Network connection** - Ethernet for web server access
- **Flash card** - SD or microSD for file system demonstrations (optional)

Development Board Features Utilized

- **8 LEDs** - Interactive web-controlled indicators on J2 pins
- **8 DIP switches** - Analog switch reading on J2 pins
- **Flash card socket** - External storage for FTP and file operations
- **Serial debugging** - Console interface for system monitoring

LED and Switch Pin Mapping

MOD-DEV-70 Board GPIO Assignments:
LEDs (J2 pins): 15, 16, 31, 23, 37, 19, 20, 24
Switches (A/D pins): 8, 6, 7, 10, 9, 11, 12, 13

Features

Comprehensive Web Server

- **Multi-page website** - Complete navigation structure with header/footer
- **Static content** - HTML, CSS, JavaScript, and image resources
- **Dynamic content** - Real-time data generation using CPPCALL tags
- **Interactive controls** - Web-based LED control and switch monitoring
- **Modern web support** - jQuery integration and responsive design
- **WebSocket communication** - Real-time bidirectional data exchange

File System Services

- **FTP Server** - Full FTP daemon for file transfer operations
- **EFFS Integration** - Flash card file system access
- **Multi-drive support** - On-board and external flash card management
- **File operations** - Create, read, write, delete file operations
- **Directory navigation** - Complete directory structure management

Network Services

- **HTTP Server** - Full-featured web server on port 80
- **FTP Server** - File Transfer Protocol server on port 21
- **WebSocket Server** - Real-time communication support
- **Network diagnostics** - [ARP](#) cache, IP addresses, counters display

Interactive Hardware Control

- **LED Control** - Web-based LED pattern control and display
- **Switch Reading** - Real-time DIP switch position monitoring
- **Analog-to-Digital** - Switch position detection via ADC
- **GPIO Management** - Direct hardware pin control and configuration

Entertainment and Testing

- **Tic-Tac-Toe Game** - Interactive game demonstrating AI algorithms
- **System Diagnostics** - Memory usage, task status, network statistics
- **Test Functions** - Manufacturing test routines and validation
- **Debug Interface** - Serial console command system

Web Interface Structure

Main Navigation Pages

Home Page (`index.html`)

- **Welcome interface** - Introduction to MOD5441X capabilities
- **Feature overview** - Description of available demonstrations
- **Hardware images** - Visual representation of module and development board
- **Getting started guide** - Basic usage instructions

LED Control (`led.html`)

- **Interactive LED grid** - 8 LEDs with clickable on/off control
- **Visual indicators** - Green (ON) and red (OFF) LED status images
- **URL encoding** - LED state encoded in URL parameters
- **Instant feedback** - Immediate hardware response to web clicks
- **DIP switch display** - Real-time switch position indicators

Dynamic Web (dynamicweb.html)

- **Real-time data** - Live system information display
- **Switch status** - Current DIP switch positions
- **System uptime** - Elapsed time since boot
- **Memory usage** - Available RAM and system resources
- **Network statistics** - Traffic counters and connection status

FTP Access (ftp.html)

- **File transfer** - Instructions for FTP client connection
- **Directory listing** - Flash card file and folder display
- **Upload/download** - Bidirectional file transfer capabilities
- **File management** - Create, delete, rename file operations

Tic-Tac-Toe Game (tt.html)

- **Interactive game** - Play against embedded AI opponent
- **Game logic** - Complete tic-tac-toe rule implementation
- **AI opponent** - Intelligent move selection algorithm
- **Score tracking** - Win/loss statistics maintenance

Technical Support (support.html)

- **Contact information** - NetBurner support resources
- **Documentation links** - Additional learning resources
- **Troubleshooting** - Common issue resolution guides
- **Community forums** - User support community access

Technical Implementation**Web Server Architecture****Dynamic Content Generation**

```
// Example CPPCALL function for LED display
void WebLeds(int sock, PCSTR url) {
    int32_t urlEncodeOffset = 9;
    int v;

    // Parse LED state from URL parameter
    if ((*url + urlEncodeOffset) == '?') {
        v = atoi((char *) (url + urlEncodeOffset + 1));
    } else {
        v = 0xAA; // Default pattern
    }

    WriteLeds((uint8_t)v & 0xFF);

    // Generate HTML for each LED with toggle links
    for (int i = 1; i < 256; i = i << 1) {
        char buffer[80];
        if (v & i) {
            // LED is ON - generate link to turn OFF
            snprintf(buffer, 80,
                "<td><A href=\"LED.HTML?%d\"><img src=\"images/ON.GIF\"></a></td>",
                v & (~i));
        } else {
            // LED is OFF - generate link to turn ON
            snprintf(buffer, 80,
```

```

        "<td><A href=\"LED.HTML?%d\"><img src=\"images/OFF.GIF\"></a></td>",
        v | i);
    }
    writestring(sock, buffer);
}
}

```

LED Hardware Control

```

void WriteLeds(uint8_t LedMask) {
    static BOOL bLedGpioInit = FALSE;
    const uint8_t PinNumber[8] = {15, 16, 31, 23, 37, 19, 20, 24};

    // Initialize GPIO pins on first use
    if (!bLedGpioInit) {
        for (int i = 0; i < 8; i++) {
            J2[PinNumber[i]].function(PIN_GPIO);
        }
        bLedGpioInit = TRUE;
    }

    // Set LED states (LEDs are active low)
    uint8_t BitMask = 0x01;
    for (int i = 0; i < 8; i++) {
        if ((LedMask & BitMask) == 0) {
            J2[PinNumber[i]] = 1; // LED OFF
        } else {
            J2[PinNumber[i]] = 0; // LED ON
        }
        BitMask <<= 1;
    }
}

```

Switch Reading via ADC

```

uint8_t ReadSwitch() {
    static bool bReadSwitchInit = FALSE;
    const uint8_t PinNumber[8] = {7, 6, 5, 3, 4, 1, 0, 2};
    uint8_t BitMask = 0;

    if (!bReadSwitchInit) {
        InitSingleEndAD(); // Initialize ADC system
        bReadSwitchInit = TRUE;
    }

    // Read each switch via ADC and determine position
    for (int i = 0; i < 8; i++) {
        uint16_t adcValue = GetADResult(PinNumber[i]);
        if (adcValue > SWITCH_THRESHOLD) {
            BitMask |= (1 << i);
        }
    }

    return BitMask;
}

```

File System Integration

Multi-Drive Flash Card Support

```

void doSingleMemCardTest(int mmc_drive) {
    const char *driveLabel;
    int rv;

    // Determine drive type
    if (mmc_drive == MMC_OFF_BOARD) {
        driveLabel = "Off-board Card Reader";
        rv = f_mountfat(mmc_drive, mmc_initfunc, F_MMC_DRIVE0);
    } else {
        driveLabel = "On-board Card Reader";
        rv = f_mountfat(mmc_drive, mmc_initfunc, F_MMC_DRIVE1);
    }

    if (rv == F_NO_ERROR) {
        rv = f_chdrive(mmc_drive);

        if (rv == F_NO_ERROR) {
            // Create test file
            F_FILE *fp = f_open("TestFile.txt", "w+");
            if (fp) {
                const char *content = "Hello Memory Card!";
                f_write(content, 1, strlen(content), fp);
                f_close(fp);
            }
        }
    }
}

```

```

        printf("PASS - %s test successful\n", driveLabel);
    }
}
}
}

```

Network Services

Main Application Loop

```

void UserMain(void *pd) {
    init();
    EnableSystemDiagnostics();
    WaitForActiveNetwork(TICKS_PER_SECOND * 5);

    // Display network configuration
    showIpAddressesSerial();

    // Start web server
    StartHttp();
    RegisterWebFuncs();

    // Initialize file system
    f_enterFS();

    // Start FTP server with priority below main task
    FTPDStart(21, MAIN_PRIO - 2);

    printf("%s\n", FirmwareVersion);
    displayMenu();

    // Main command processing loop
    char buffer[255];
    while (1) {
        SendWebSocketData(); // Handle WebSocket communication

        if (charavail()) {
            fgets(buffer, 255, stdin);
            processCommand(buffer);
        }

        OSTimeDly(2);
    }
}

```

WebSocket Communication

```

void SendWebSocketData() {
    static uint32_t lastSendTime = 0;

    if (TimeTick > (lastSendTime + TICKS_PER_SECOND)) {
        // Prepare JSON data for WebSocket clients
        snprintf(ReportBuffer, ReportBufSize,
            "{\n"
            "  \"uptime\":%lu,\n"
            "  \"switches\":%d,\n"
            "  \"freemem\":%lu\n"
            "}",
            Secs, ReadSwitch(), GetFreeRam());

        // Send to all connected WebSocket clients
        for (int i = 0; i < WS_MAX_SOCKS; i++) {
            if (wsFdList[i] != -1) {
                ws_send(wsFdList[i], ReportBuffer, strlen(ReportBuffer));
            }
        }

        lastSendTime = TimeTick;
    }
}

```

Usage Instructions

Initial Setup

1. Hardware assembly

- Mount MOD5441X on MOD-DEV-70CR development board
- Connect Ethernet cable to network
- Insert flash card in external card socket (optional)

- Power up system
2. **Network configuration**
 - Note IP address from serial console output
 - Verify network connectivity with ping test
 - Configure firewall if necessary for HTTP/FTP access
 3. **Web browser access**
 - Open web browser to `http://<device_ip>`
 - Navigate through demonstration pages
 - Test interactive features (LEDs, switches)

Web Interface Operations

LED Control Testing

1. **Access LED page** - Navigate to LED control page from main menu
2. **Click LEDs** - Click individual LED images to toggle state
3. **Observe hardware** - Watch physical LEDs change on development board
4. **Pattern testing** - Create different LED patterns using web interface
5. **Switch monitoring** - Observe DIP switch positions update automatically

Dynamic Content Monitoring

1. **Access dynamic page** - Navigate to dynamic web content
2. **Real-time updates** - Page displays live system information
3. **Switch changes** - Move DIP switches on development board
4. **System statistics** - Monitor uptime, memory usage, network counters

FTP File Operations

1. **FTP client connection**

```
Host: <device_ip>
Port: 21
Username: (none required)
Password: (none required)
```
2. **File operations**
 - **Upload files** - Transfer files from PC to flash card
 - **Download files** - Retrieve files from flash card to PC
 - **Directory navigation** - Browse folder structure
 - **File management** - Create, delete, rename operations

Tic-Tac-Toe Game

1. **Start game** - Navigate to tic-tac-toe page
2. **Make moves** - Click squares to place X marks
3. **AI response** - System automatically makes O moves
4. **Game completion** - Play until win, loss, or draw
5. **Reset game** - Start new game after completion

Serial Console Interface

Debug Commands

```
----- Main Menu -----
A - Show ARP Cache
B - Show IP Addresses
C - Show Counters
E - Show Ethernet Registers
W - Show OS Seconds Counter
? - Display Menu
```

Network Diagnostics

- **ARP Cache** - Display Address Resolution Protocol table
- **IP Addresses** - Show current network configuration
- **Counters** - Network traffic and error statistics
- **Ethernet Registers** - Low-level hardware status
- **System Uptime** - OS tick counter and elapsed time

Manufacturing Test Commands

```
Special Commands:
~ - Manufacturing Test Sequence
\ - Dual Memory Card Test
```

Expected Console Output

Startup Sequence

```
MOD54415 Factory Demo
IP Address: 192.168.1.100
Subnet Mask: 255.255.255.0
Gateway: 192.168.1.1
DNS Server: 192.168.1.1

NetBurner Release Version: 3.x.x
----- Main Menu -----
A - Show ARP Cache
B - Show IP Addresses
C - Show Counters
E - Show Ethernet Registers
W - Show OS Seconds Counter
? - Display Menu
Link Status: Connected at 100 Mbps Full Duplex
```

LED Control Feedback

```
[Web browser LED click generates URL with parameter]
LED Pattern: 0xAA (binary: 10101010)
Hardware LEDs updated to match web interface
```

Advanced Features

WebSocket Real-Time Communication

Client-Side JavaScript

```
// Example WebSocket connection for real-time updates
var ws = new WebSocket('ws://' + window.location.host + '/ws');

ws.onmessage = function(event) {
    var data = JSON.parse(event.data);

    // Update switch display
    updateSwitchDisplay(data.switches);

    // Update system information
    document.getElementById('uptime').innerHTML = data.uptime + ' seconds';
    document.getElementById('freemem').innerHTML = data.freemem + ' bytes';
};

function updateSwitchDisplay(switchValue) {
```

```

    for (var i = 0; i < 8; i++) {
        var checkbox = document.getElementById('cbox' + (i + 1));
        checkbox.checked = (switchValue & (1 << i)) != 0;
    }
}

```

Server-Side WebSocket Handler

```

void RegisterWebFuncs() {
    // Register CPPCALL functions for dynamic content
    SetNewWSCallback(WSCallback);
    SetNewWSCallback(WSUpgrade);

    // Register standard web functions
    RegisterPost("LED.HTML", WebLeds);
    RegisterGet("dynamicweb.html", WebDynamicContent);
}

```

Manufacturing Test System

Comprehensive Hardware Testing

```

void doManfTest() {
    printf("Starting Manufacturing Test Sequence...\n");

    // Test 1: LED functionality
    printf("Testing LEDs... ");
    for (int i = 0; i < 8; i++) {
        WriteLeds(1 << i);
        OSTimeDly(TICKS_PER_SECOND / 10);
    }
    printf("PASS\n");

    // Test 2: Switch reading
    printf("Testing switches... ");
    uint8_t switches = ReadSwitch();
    printf("Switch pattern: 0x%02X - ", switches);
    printf("PASS\n");

    // Test 3: Network connectivity
    printf("Testing network... ");
    if (GetInterfaceStatus() == INTERFACE_UP) {
        printf("PASS\n");
    } else {
        printf("FAIL\n");
    }

    printf("Manufacturing test complete.\n");
}

```

Dual Memory Card Testing

```

void doDualMemCardTest() {
    printf("Testing both memory card slots...\n");

    // Test on-board microSD slot
    doSingleMemCardTest(MMC_ON_BOARD);

    // Test external SD card slot
    doSingleMemCardTest(MMC_OFF_BOARD);

    printf("Memory card testing complete.\n");
}

```

Performance and Scalability

Web Server Performance

- **Concurrent connections** - Supports multiple simultaneous users
- **Page load times** - <1 second for static content
- **Dynamic content** - Real-time generation with minimal delay
- **Image serving** - Efficient binary content delivery

Memory Usage

- **Static allocation** - ~64KB for web content and resources
- **Dynamic buffers** - 512 bytes for JSON WebSocket data
- **File system** - EDFS buffers scale with flash card usage
- **Network stacks** - Standard NetBurner TCP/IP overhead

Network Throughput

- **HTTP traffic** - 10+ Mbps sustained throughput
- **FTP transfers** - Limited by flash card write speed
- **WebSocket updates** - 1 Hz real-time data refresh
- **Concurrent users** - 5-10 simultaneous web browsers supported

Troubleshooting

Common Issues

Web Page Not Loading

Symptoms**: Browser cannot connect to device Solutions**:

- Verify IP address from serial console
- Check network connectivity with ping
- Confirm firewall settings allow HTTP traffic
- Verify Ethernet cable connection
- Check power supply stability

LEDs Not Responding

Symptoms**: Web clicks don't change hardware LEDs Solutions**:

- Verify MOD5441X is properly seated on development board
- Check development board power connections
- Confirm LED functionality with manual GPIO test
- Verify web page URL encoding is working
- Check GPIO pin configuration in code

FTP Connection Failures

Symptoms**: FTP client cannot connect Solutions**:

- Verify FTP server is running (check serial console)
- Confirm port 21 is not blocked by firewall
- Try passive mode in FTP client
- Check flash card insertion and formatting
- Verify file system initialization

Switch Reading Errors

Symptoms*: DIP switches not reading correctly Solutions*:

- Verify ADC initialization completed successfully
- Check switch physical connections to development board
- Adjust ADC threshold values if necessary
- Test with different switch positions
- Verify power supply voltage stability

Debug Procedures

Network Diagnostics

```
// Check network interface status
if (GetInterfaceStatus() == INTERFACE_UP) {
    printf("Network interface is UP\n");
    printf("IP: %s\n", GetCurrentIP().AsString());
    printf("Netmask: %s\n", GetCurrentNetmask().AsString());
    printf("Gateway: %s\n", GetCurrentGateway().AsString());
} else {
    printf("Network interface is DOWN\n");
}
```

GPIO Testing

```
// Manual LED test sequence
void TestLEDs() {
    const uint8_t PinNumber[8] = {15, 16, 31, 23, 37, 19, 20, 24};

    for (int i = 0; i < 8; i++) {
        J2[PinNumber[i]].function(PIN_GPIO);
        J2[PinNumber[i]] = 0; // Turn on LED
        OSTimeDly(TICKS_PER_SECOND / 4);
        J2[PinNumber[i]] = 1; // Turn off LED
    }
}
```

File System Verification

```
// Check flash card status
if (get_cd(MMC_OFF_BOARD)) {
    printf("External flash card detected\n");
    if (!get_wp(MMC_OFF_BOARD)) {
        printf("Card is writable\n");
    } else {
        printf("Card is write-protected\n");
    }
} else {
    printf("No external flash card detected\n");
}
```

Dependencies

- **NetBurner NNDK** - Network Development Kit with full web server support
- **FatFile Library** - EFFS FAT file system support for flash cards
- **jQuery Library** - Modern web interface functionality
- **Development Board** - MOD-DEV-70CR for complete hardware feature access

Learning Objectives

This comprehensive example demonstrates:

- **Complete web application development** - Full-stack embedded web development
- **Multi-service architecture** - HTTP, FTP, and WebSocket servers
- **Hardware abstraction patterns** - GPIO, ADC, and file system integration
- **Real-time web interfaces** - WebSocket communication and dynamic content
- **Production application structure** - Modular code organization and scalability
- **Manufacturing test integration** - Automated hardware validation procedures
- **Network service coordination** - Multiple simultaneous network protocols

Related Examples

For additional learning and development, see:

- Individual MOD5441X examples for focused feature demonstrations
- Web server examples for advanced HTTP functionality
- File system examples for EFFS and storage management
- Network protocol examples for custom service development

12.33.1.18.3 Get MOD54417 Switch Port

12.33.1.18.3.1 GetSwitchPort Application

Overview

The GetSwitchPort application is a network monitoring utility designed for the MOD54417 platform that demonstrates how to determine which physical Ethernet port received a specific MAC address. This application listens for UDP Multicast traffic and identifies the source switch port for each received packet.

Purpose

This example demonstrates how to use the `GetSwitchSourcePort()` function to determine which physical interface an Ethernet MAC address was last received by. This is particularly useful for network topology discovery, device location tracking, and network diagnostics in switched environments.

Features

- **Multicast UDP Listening:** Listens for UDP packets on Multicast address 224.1.2.3:23456
- **Switch Port Detection:** Identifies which physical Ethernet port received each packet
- **MAC Address Tracking:** Maps Ethernet MAC addresses to their source ports
- **Real-time Monitoring:** Continuously monitors and reports network traffic
- **Data Display:** Shows received packet data in a readable format

Technical Details

Network Configuration

- **Multicast Address:** 224.1.2.3
- **UDP Port:** 23456
- **Timeout:** 1 second per packet receive attempt

Port Mapping

The application maps bit flags returned by `GetSwitchSourcePort()` to physical port numbers:

Bit Flag	Physical Port
0x1	Port 0
0x2	Port 1
0x4	Port 2
0x8	Port 3
0x10	Port 4
0x20	Port 5
0x40	Port 6
0x80	Port 7

Dependencies

The application requires the following NetBurner libraries:

- `init.h` - Network stack initialization
- `nbrtos.h` - NetBurner RTOS functions
- `system.h` - System utilities
- `sim.h` - Simulation support
- `udp.h` - UDP networking
- `multicast.h` - Multicast support
- `etherswitch.h` - Ethernet switch functions
- `utils.h` - Utility functions

Operation

1. **Initialization:** The application initializes the network stack and enables system diagnostics
2. **Network Wait:** Waits up to 5 seconds for an active network connection
3. **Multicast Registration:** Registers to receive UDP packets on the specified multicast address and port
4. **Packet Processing:** Continuously processes incoming UDP packets:
 - Validates each received packet
 - Extracts the source MAC address
 - Determines the source switch port using `GetSwitchSourcePort()`
 - Displays packet information including size, source IP, and switch port
 - Shows the packet data in hexadecimal format

Output Format

For each received packet, the application displays:

```
Rxd [bytes] Bytes From [source_ip] on port [port_number]
[hexadecimal data dump]
```

Example:

```
Rxd 64 Bytes From 192.168.1.100 on port 2
[packet data in hex format]
```

Use Cases

- **Network Topology Mapping:** Identify which devices are connected to which switch ports
- **Device Location:** Locate specific devices in a switched network
- **Network Diagnostics:** Troubleshoot connectivity and switching issues
- **Security Monitoring:** Track device movement between ports
- **Asset Management:** Maintain inventory of connected devices and their locations

Platform Requirements

- NetBurner MOD54417 development board
- NetBurner Development Kit (NNDK)
- Switched Ethernet network environment
- Multicast-capable network infrastructure

Build Instructions

Compile using the NetBurner tool chain with the standard NNDK build process. Ensure all required libraries are linked and the target platform is set to MOD54417.

Notes

- System diagnostics are enabled for development purposes and should be disabled in production code
- The application runs indefinitely until manually stopped
- Port numbering is zero-based (0-7 for an 8-port switch)
- Unknown or invalid port mappings return -1

12.33.1.18.4 MOD5441x Rapid GPIO

12.33.1.18.4.1 Rapid GPIO (RGPIO) Example

Overview

This example demonstrates the high-speed Rapid GPIO functionality unique to the NetBurner MOD5441X platform. The application showcases three different methods to generate extremely fast GPIO pulses, achieving toggle rates up to 62.5 MHz (16ns edge-to-edge timing) using the MCF54415's dedicated Rapid GPIO module connected directly to the processor's local bus.

Supported Platform

- **MOD5441X** - MOD54415/MOD54417 core modules only

Hardware Requirements

Essential Components

- **MOD5441X core module** - Hardware with MCF54415/MCF54417 processor
- **High-speed oscilloscope** - Bandwidth >100MHz recommended for timing measurements
- **High-frequency probe** - With very short ground connection (<1 inch)
- ****Connection point**** - Access to module pin J2.37

Signal Output Location

- ****Primary test pin****: J2.37 (RGPIO_0 signal)
- ****Processor pin****: N11 (OW_DAT/DACK0 alternate functions)
- ****Ground reference****: Any nearby ground pin on J2 connector

Oscilloscope Setup Requirements

Probe Settings:

- Bandwidth: >200 MHz (for 16ns pulse measurement)
- Coupling: DC
- Ground lead: <1 inch length (critical for accuracy)
- Probe impedance: 10:1 recommended

Trigger Settings:

- Mode: Edge trigger on rising edge
- Level: 1.65V (mid-point of 3.3V logic)
- Time base: 50ns/div (for initial setup)

Features

Rapid GPIO Module Capabilities

- ****16-bit high-speed GPIO**** - Connected to processor's 32-bit local bus
- ****Zero wait-state response**** - Single data phase cycle completion
- ****Multiple access sizes**** - Byte, word, and longword operations supported
- ****Direct register access**** - Set, clear, and toggle operations without read-modify-write
- ****Maximum performance**** - 1.5-3.5x faster than standard peripheral bus GPIO

Three Performance Implementation Methods

Method 1: Pure Assembly Code (Fastest - 16ns)

- ****Direct register addressing**** - Assembly language register manipulation
- ****Unrolled loops**** - 50 consecutive toggle operations
- ****Critical section protection**** - Interrupt-free execution
- ****Performance****: 62.5 MHz toggle rate

Method 2: Assembly + C Hybrid (Medium - 68ns)

- ****Assembly register setup**** - Optimized register addressing
- ****C loop control**** - Standard loop structure with assembly toggle
- ****Cache considerations**** - NOP instruction for consistent timing
- ****Performance****: ~14.7 MHz toggle rate

Method 3: Pure C Code (Slowest - 94ns)

- ****C pointer access**** - Volatile pointer-based register access
- ****Loop-based control**** - Standard for-loop implementation
- **Compiler optimization** - Relies on compiler efficiency
- **Performance**: ~10.6 MHz toggle rate

RGPIO Pin Mapping

RGPIO Bit	Module Pin	Processor Pin	Primary Function	Alternate Function
RGPIO_0	J2.37	N11	GPIO	OW_DAT/DACK0
RGPIO_1	J2.32	G13	GPIO	T3IN/PWM_EXT A3
RGPIO_2	J2.33	H14	GPIO	T2IN/PWM_EXT A2
RGPIO_3	J2.34	H13	GPIO	T1IN/PWM_EXT A1
RGPIO_4	J2.36	H15	GPIO	T0IN/PWM_EXT A0
RGPIO_5	J2.29	E13	GPIO	UART0_CTS
RGPIO_6	J2.38	D10	GPIO	UART1_RTS
RGPIO_7	J2.24	C10	GPIO	UART1_CTS
RGPIO_8	J2.23	B11	GPIO	UART0_RTS

Technical Implementation

RGPIO Module Architecture

Memory-Mapped Register Layout

Base Address: 0x8C000000 (RGPIO_BAR)

Register Offsets (16-bit word access):

- +0x00: Direction Register (RGPIO_DIR) - Input/Output control
- +0x02: Data Register (RGPIO_DAT) - Pin state [read/write](#)
- +0x04: Enable Register (RGPIO_ENB) - Pin enable control
- +0x06: Clear Register (RGPIO_CLR) - Atomic bit clear
- +0x0A: Set Register (RGPIO_SET) - Atomic bit set
- +0x0E: Toggle Register (RGPIO_TOG) - Atomic bit toggle

Register Bit Mapping

```

Bit Position:  15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
RGPIO Signal:  -  -  -  -  -  -  -  8  7  6  5  4  3  2  1  0
Module Pin:    -  -  -  -  -  -  - 23 24 38 29 36 34 33 32 37
  
```

Processor Setup Requirements

RGPIO Module Activation

```
// Enable RGPIO module access via control register
asm(" move.l #0x8C000035,%d0"); // Base address + enable bit
asm(" movec %d0,#0x009");      // Write to control register
```

Pin Configuration Sequence

```
volatile uint16_t *pRGPIO_BAR = (uint16_t *)RGPIO_BAR;

pRGPIO_BAR[RGPIO_DIR] = RGPIO_0; // Configure as output
pRGPIO_BAR[RGPIO_ENB] = RGPIO_0; // Enable pin functionality
```

Maximum Slew Rate Configuration

```
// Set all relevant slew rate registers to maximum frequency
siml.gpio.scrs_dspiow = 0x33; // DSPI0 & One-Wire pins
siml.gpio.scrs_timer |= 0xFF; // Timer pins
siml.gpio.scrs_uart |= 0x0F;  // UART0/1 pins
siml.gpio.scrs_sdhc |= 0x03;  // SDHC pins
```

Performance Implementation Details

Method 1: Pure Assembly (16ns edge-to-edge)

```
void Pulse50() {
    USER_ENTER_CRITICAL();

    asm(" move.l #0x8C00000E,%d0"); // Toggle register address
    asm(" move.l %d0,%a5");        // Load into address register
    asm(" move.l #0x01,%d5");      // RGPIO_0 bit mask

    // Unrolled 50 toggle operations
    asm(" move.w %d5,%a5@");      // Toggle #1
    asm(" move.w %d5,%a5@");      // Toggle #2
    // ... [48 more identical operations]

    USER_EXIT_CRITICAL();
}
```

Method 2: Assembly + C Hybrid (68ns edge-to-edge)

```
void Pulse50LoopAsm() {
    USER_ENTER_CRITICAL();

    asm(" move.l #0x8C00000E,%d0");
    asm(" move.l %d0,%a5");
    asm(" move.l #0x01,%d5");

    for (int i = 0; i < 50; i++) {
        asm(" nop"); // Cache consistency
        asm(" move.w %d5,%a5@"); // Single toggle
    }

    USER_EXIT_CRITICAL();
}
```

Method 3: Pure C Code (94ns edge-to-edge)

```
void Pulse50LoopC() {
    volatile uint16_t *pRGPIO_BAR = (uint16_t *)RGPIO_BAR;

    USER_ENTER_CRITICAL();

    for (int i = 0; i < 50; i++) {
        asm(" nop"); // Cache consistency
        pRGPIO_BAR[RGPIO_TOG] = RGPIO_0;
    }

    USER_EXIT_CRITICAL();
}
```

Usage Instructions

Setup Process

1. Hardware connections

- Connect oscilloscope probe to J2.37 on MOD5441X
- Use very short ground connection (<1 inch) to nearby J2 ground pin
- Configure oscilloscope for high-frequency measurements

2. ****Build and deploy****

```
make clean
make
make load DEVICE_IP=<your_device_ip>
```

3. **Initial signal verification**

- Application generates slow GPIO toggles during startup
- Use these to verify correct pin connection
- Look for clear logic level transitions (0V to 3.3V)

Operation and Measurement

Console Output

Running Rapid GPIO example on Pin J2-37

```
RB at [8C000000] = 0001    // Direction register
RB at [8C000002] = 0000    // Data register
RB at [8C000004] = 0001    // Enable register
RB at [8C000006] = 0000    // Clear register
RB at [8C00000A] = 0000    // Set register
RB at [8C00000E] = 0000    // Toggle register
```

Oscilloscope Measurements

Method 1 (Assembly): Expected Waveform**

Timing: 16ns edge-to-edge
 Frequency: 62.5 MHz **for** 800ns burst duration
 Pattern: 50 pulses every 1 second
 Amplitude: 0V to 3.3V logic levels
 Rise **time**: <2ns (limited by probe/scope bandwidth)

Method 2 (Hybrid): Expected Waveform**

Timing: 68ns edge-to-edge
 Frequency: ~14.7 MHz **for** 3.4us burst duration
 Pattern: 50 pulses every 1 second
 Amplitude: 0V to 3.3V logic levels

Method 3 (C Code): Expected Waveform**

Timing: 94ns edge-to-edge
 Frequency: ~10.6 MHz **for** 4.7us burst duration
 Pattern: 50 pulses every 1 second
 Amplitude: 0V to 3.3V logic levels

Performance Measurement Techniques

Oscilloscope Settings for 16ns Pulses

Time Base: 10ns/div (to see individual edges)
 Vertical: 500mV/div (**for** 3.3V logic)
 Trigger: Edge, rising, 1.65V level
 Bandwidth: Maximum available (>200MHz)
 Sampling Rate: >1GSa/s minimum

Measurement Procedures

1. **Single pulse timing**: Measure rising edge to rising edge
2. **Burst duration**: Time for complete 50-pulse sequence
3. **Amplitude verification**: Confirm 0V to 3.3V swings
4. **Rise/fall times**: Limited by oscilloscope/probe bandwidth
5. **Jitter analysis**: Use persistence display mode

Performance Comparison

Speed Analysis

Method	Implementation	Edge Timing	Frequency	Burst Duration
Assembly	Unrolled ASM	16ns	62.5 MHz	800ns
Hybrid	ASM + C Loop	68ns	14.7 MHz	3.4us
C Code	Volatile Pointer	94ns	10.6 MHz	4.7us
Standard GPIO	Pin Class	>1us	<1 MHz	>50us

Performance Factors

Speed Advantages of Assembly Method

- **No loop overhead** - Unrolled operations eliminate branch instructions
- **Register pre-loading** - Address and data values loaded once
- **No compiler optimization** - Direct control over instruction sequence
- **Critical section** - No interrupt latency during pulse generation

Hybrid Method Considerations

- **Loop overhead** - Branch instruction every cycle adds ~52ns
- **Register reuse** - Address register loaded once, data register per cycle
- **Cache effects** - NOP instruction ensures consistent timing
- **Interrupt protection** - Critical section maintains timing accuracy

C Method Limitations

- **Pointer dereferencing** - Additional memory access overhead
- **Compiler optimization** - Dependent on compiler efficiency
- **Volatile access** - Required for memory-mapped registers
- **Loop processing** - Standard C loop with increment and comparison

Troubleshooting

Common Measurement Issues

No Signal Observed

Symptoms**: Flat line on oscilloscope Solutions**:

- Verify connection to correct pin (J2.37)
- Check ground connection quality (<1 inch)
- Confirm oscilloscope trigger settings
- Verify probe compensation
- Check for proper module power-up

Incorrect Timing Measurements

Symptoms**: Wrong edge-to-edge timing values Solutions**:

- Increase oscilloscope bandwidth setting
- Reduce time base to 5-10ns/div
- Verify probe impedance setting (10:1)
- Check for ground loop issues
- Use shortest possible probe ground lead

Inconsistent Pulse Timing

Symptoms**: Variable pulse spacing Solutions**:

- Verify critical section implementation
- Check for interrupt activity during measurement
- Use oscilloscope infinite persistence mode
- Increase sample rate on oscilloscope
- Verify stable power supply to module

Amplitude Issues

Symptoms**: Wrong voltage levels Solutions**:

- Confirm 3.3V logic levels (not 5V)
- Check probe attenuation setting
- Verify oscilloscope vertical scale
- Test with known reference voltage
- Check for probe loading effects

Debug Procedures

Register Verification

```
// Display RGPIO register contents
volatile uint16_t *pRGPIO_BAR = (uint16_t *)RGPIO_BAR;
for (int i = 0; i < 8; i++) {
    printf("RGPIO[%d] at [%p] = %04X\n", i, pRGPIO_BAR + i, pRGPIO_BAR[i]);
}
```

Pin Function Verification

```
// Use slow GPIO to verify correct pin
J2[37].function(PINJ2_37_GPIO);
for (int i = 0; i < 10; i++) {
    J2[37] = 1;
    OSTimeDly(TICKS_PER_SECOND/10); // 100ms
    J2[37] = 0;
    OSTimeDly(TICKS_PER_SECOND/10); // 100ms
}
```

RGPIO Module Status Check

```
// Verify RGPIO module is properly enabled
printf("RGPIO Direction: 0x%04X\n", pRGPIO_BAR[RGPIO_DIR]);
printf("RGPIO Enable:    0x%04X\n", pRGPIO_BAR[RGPIO_ENB]);
printf("RGPIO Data:      0x%04X\n", pRGPIO_BAR[RGPIO_DAT]);
```

Learning Objectives

This example demonstrates:

- **High-speed GPIO techniques** - Achieving maximum toggle rates
- **Assembly language integration** - Inline assembly with C/C++
- **Memory-mapped register access** - Direct hardware manipulation
- **Performance optimization** - Different implementation approaches
- **Critical section usage** - Interrupt-free timing-critical code
- **Hardware-specific features** - Platform-unique capabilities

12.33.1.18.5 MOD5441x USB Mass Storage Device

12.33.1.18.5.1 USB Mass Storage Device (MSD) Simple Example

Overview

This example demonstrates USB Mass Storage Device Host functionality on the NetBurner MOD5441X platform. The application acts as a USB host, allowing connection to external USB flash drives for file operations including reading, writing, and directory management. This provides embedded systems with the ability to interface with standard USB storage devices for data logging, file transfer, and storage expansion.

Supported Platform

- **MOD5441X** - MOD54415/MOD54417 core modules only

Hardware Requirements

Essential Components

- **MOD5441X core module** - MOD54415 or MOD54417 with USB OTG support
- **NBUSB-ADPT-100R** - NetBurner USB development adapter
- **MOD-DEV-70CR** - Development board for USB connector access
- **USB flash drives** - Standard USB 2.0 flash drives (FAT16/FAT32 formatted)

Hardware Assembly

Assembly Stack (bottom to top):

1. MOD-DEV-70CR development board (base)
2. MOD5441X core module (mounted on dev board)
3. NBUSB-ADPT-100R adapter (plugged into USB connector)
4. USB flash drive (plugged into adapter)

Power Requirements

- **USB Host Power:** 5V supply to USB port (controlled by VBUS_ENABLE)
- **Flash Drive Power:** Supplied through USB host port
- **Current Budget:** Up to 500mA for USB device power

Features

USB Host Stack Functionality

- **USB 2.0 Host Support** - Full-speed and high-speed device support
- **Mass Storage Class** - Standard USB MSD device compatibility
- **Hot-plug Detection** - Automatic device insertion and removal detection
- **VBUS Power Control** - Programmable 5V power supply to USB devices

File System Operations

- **FFFS Integration** - NetBurner Embedded Flash File System support
- **FAT16/FAT32 Support** - Standard PC-compatible file systems
- **Directory Operations** - File and folder listing, navigation
- **File I/O Operations** - Create, read, write, delete operations
- **Space Management** - Free space calculation and monitoring

Interactive Menu System

- **Menu-driven Interface** - Simple command-based operations
- **Real-time Status** - Device connection and operation feedback
- **Error Handling** - Comprehensive error reporting and recovery
- **Test File Operations** - Built-in test file creation and verification

Application Menu System

Menu Options (when USB drive connected)

MSD driver version: 1.0

```
1 = Attach file system to USB drive
2 = Display current directory
3 = Create test file: "testnb.txt"
4 = Read "testnb.txt"
5 = Delete "testnb.txt"
```

Menu Command Functions

Command 1: Attach File System

- **Purpose:** Initialize file system access to USB drive
- **Operation:** Mount USB drive and prepare for file operations
- **Result:** File system ready for read/write operations

Command 2: Display Directory

- **Purpose:** List all files and directories on USB drive
- **Output Format:** Filename and file size display
- **Navigation:** Recursive directory traversal and display

Command 3: Create Test File

- **Purpose:** Create and write test content to "testnb.txt"
- **Content:** Multiple test lines and character patterns
- **Verification:** File creation confirmation and size reporting

Command 4: Read Test File

- **Purpose:** Read and display contents of "testnb.txt"
- **Output:** Character-by-character file content display
- **Validation:** File integrity and readability verification

Command 5: Delete Test File

- **Purpose:** Remove "testnb.txt" from USB drive
- **Confirmation:** Delete operation success/failure reporting
- **Cleanup:** File system space recovery

Technical Implementation**USB Host Stack Architecture****Initialization Sequence**

```
// Initialize USB host stack and MSD driver
if (MSDOpen(&ossFileCommander, &iMSDAppVolume) == 0) {
    StartMSDTask();
    VBUSEnable(1); // Enable 5V power to USB port
} else {
    printf("MSD initialization failed\n");
}
```

Device Detection and Mounting

```
// USB device insertion detection
if (device_connected) {
    // Mount file system on detected device
    int result = f_chdrive(msdDriveNum);
    if (result == F_NO_ERROR) {
        driveOpen = true;
        printf("USB drive mounted successfully\n");
    }
}
```

File System Operations**Directory Listing Implementation**

```
int Dir(void) {
    F_FIND find;
    int result = f_findfirst("*.*", &find);

    if (result == F_NO_ERROR) {
        printf("%s\n", find.filename);

        while ((result = f_findnext(&find)) == F_NO_ERROR) {
            printf("%s\n", find.filename);
        }
    }

    return result;
}
```

File Writing Operations

```
int WriteFileTest(const char *fileName) {
    F_FILE *file = f_open(fileName, "w+");

    if (file) {
        // Write test content
        f_write("testline1 \r\n", 12, 1, file);
        f_write("testline2 \r\n", 12, 1, file);
        f_write("testline3 \r\n", 12, 1, file);
        f_write("testline4 \r\n", 12, 1, file);
        f_write("testline5 \r\n", 12, 1, file);

        // Write character patterns
        for (int i = 0; i < 40; i++) {
            f_putc(' \r', file);
            f_putc(' \n', file);
            for (int j = 48; j < 91; j++) {
                f_putc(j, file); // ASCII characters 0-9, A-Z
            }
        }

        f_flush(file);
        f_close(file);
        printf("Created file: %s\n", fileName);
        return 0;
    }

    printf("Error: could not create file: %s\n", fileName);
    return 1;
}
```

File Reading Operations

```
int ReadFileTest(const char *fileName) {
    F_FILE *file = f_open(fileName, "r");
    char character;

    if (file) {
        printf("File Opened OK\n");

        while (f_read(&character, 1, 1, file) > 0) {
            printf("%c", character);
        }

        printf("Done reading file\n");
        f_close(file);
        return 0;
    }

    printf("Error: could not open %s\n", fileName);
    return 1;
}
```

USB Power Management

VBUS Control

```
// Enable USB host power (5V to connected devices)
VBUSEnable(1); // Turn on VBUS power
VBUSEnable(0); // Turn off VBUS power
```

Power Sequencing

1. **System Initialization** - Core module and USB stack startup
2. **VBUS Enable** - Provide 5V power to USB connector
3. **Device Detection** - Wait for USB device insertion
4. **Enumeration** - USB host identifies connected device
5. **MSD Recognition** - Verify device is Mass Storage Class
6. **File System Mount** - Initialize EDFS access to device

Usage Instructions

Setup Process

1. Hardware assembly

- Mount MOD5441X on MOD-DEV-70CR development board
- Install NBUSB-ADPT-100R USB adapter
- Prepare USB flash drive (FAT16 or FAT32 formatted)

2. Build and deploy

```
make clean
make
make load DEVICE_IP=<your_device_ip>
```

3. Connect terminal

- Serial terminal: 115200 baud, 8-N-1
- Connect to NetBurner debug port

Operation Procedure

Initial Startup

```
Application MOD54415_USB_MSD_2 started
MSD driver version: 1.0
[Menu appears when USB drive is detected]
```

USB Drive Connection

1. **Insert USB flash drive** into NBUSB-ADPT-100R adapter
2. **Wait for detection** - System will automatically detect device
3. **Menu activation** - Interactive menu becomes available
4. **File system access** - Ready for file operations

Testing Sequence

```
[Press '1'] - Attach file system to USB drive
[Press '3'] - Create test file: "testnb.txt"
[Press '2'] - Display current directory (should show testnb.txt)
[Press '4'] - Read "testnb.txt" (displays file contents)
[Press '5'] - Delete "testnb.txt"
[Press '2'] - Display directory again (file should be gone)
```

Expected Output Example

```
[Command 3] Created file: testnb.txt

[Command 4] File Opened OK
testline1
testline2
testline3
testline4
testline5

0123456789;.<=>?@ABCDEFGHIJKLMNQRSTUvwxyz
[Pattern repeats 40 times]
Done reading file

[Command 5] Deleted file: testnb.txt
```

USB Drive Disconnection

1. **Safe removal** - Complete all file operations before removal
2. **File system unmount** - System automatically handles disconnection
3. **Menu deactivation** - Menu disappears until next device insertion
4. **VBUS power** - Remains active for next device connection

File System Utilities

Directory Display Features

Recursive Directory Traversal

```
uint8_t displayDirectory() {
    F_FIND finder;
    int rc = f_findfirst("*.*", &finder);

    if (rc == F_NO_ERROR) {
        do {
            if (finder.attr & F_ATTR_DIR) {
                printf("Directory [%s]\n", finder.filename);
                if (finder.filename[0] != '.') {
                    f_chdir(finder.filename);
                    displayDirectory(); // Recursive call
                    f_chdir("..");
                }
            } else {
                printf("File [%s] : %lu Bytes\n",
                    finder.filename, finder.filesize);
            }
        } while (!f_findnext(&finder));
    }

    return rc;
}
```

Space Usage Reporting

```
uint8_t DisplayEfsSpaceStats(int32_t driveNumber) {
    F_SPACE space;
    int rv = f_getfreespace(driveNumber, &space);

    if (rv == F_NO_ERROR) {
        long long totalSize = ((long long)space.total_high << 32) + space.total;
        long long freeSize = ((long long)space.free_high << 32) + space.free;
        long long usedSize = ((long long)space.used_high << 32) + space.used;
        long long badSize = ((long long)space.bad_high << 32) + space.bad;

        printf("%llu total, %llu free, %llu used, %llu bad\n",
            totalSize, freeSize, usedSize, badSize);
    }

    return rv;
}
```

Error Handling and Troubleshooting

Common Issues

USB Device Not Detected

Symptoms**: No menu appears, device not recognized Solutions**:

- Verify USB flash drive is functional in PC
- Check NUSB-ADPT-100R connection to development board
- Confirm 5V power supply is adequate (>500mA capacity)
- Try different USB flash drives (some may not be compatible)
- Verify VBUS power is enabled (VBUSEnable(1))

File System Mount Failures

Symptoms**: "Attach file system" fails Solutions**:

- Reformat USB drive with standard FAT32 formatter
- Check for file system corruption on USB drive
- Verify drive is not write-protected
- Try smaller capacity drives (<32GB often more compatible)
- Check for proper USB enumeration in debug output

File Operation Errors

Symptoms*: File create, read, or write failures Solutions*:

- Verify sufficient free space on USB drive
- Check file name validity (avoid special characters)
- Ensure file system is properly mounted before operations
- Test with different file sizes and content types
- Monitor EDFS error codes for specific failure reasons

Power-Related Issues

Symptoms*: Device detected but operations fail Solutions*:

- Check development board power supply capacity
- Verify USB cable quality and connections
- Monitor current consumption during operations
- Try powered USB hub for high-current devices
- Check for voltage drop under load conditions

Debug Procedures

USB Stack Status Checking

```
// Monitor USB host controller status
void SeePortSC1Status() {
    // Display USB host controller register status
    // Implementation depends on specific debugging needs
    printf("USB Host Status: [register values]\n");
}
```

EDFS Error Code Translation

```
void DisplayEdfsErrorCode(int code) {
    if (code <= MAX_EDFS_ERRORCODE) {
        printf("%s\n", EdfsErrorCode[code]);
    } else {
        printf("Unknown EDFS error code [%d]\n", code);
    }
}
```

File System Verification

```
// Verify file system integrity
int result = f_checkdisk(driveNumber);
if (result != F_NO_ERROR) {
    printf("File system check failed: ");
    DisplayEdfsErrorCode(result);
}
```

Performance Characteristics

USB Transfer Rates

- **USB 2.0 Full Speed:** Up to 12 Mbps theoretical
- **Practical throughput:** 500KB/s - 2MB/s depending on device
- **File system overhead:** 10-20% reduction from raw transfer rates
- **Small file operations:** Overhead dominates transfer time

Memory Usage

- **USB Host Stack:** ~8KB RAM for buffers and control structures
- **EFFS Buffers:** ~4KB per mounted drive
- **File Handles:** Limited by EFFS configuration (typically 8-16)
- **Application Data:** <2KB for menu system and variables

Device Compatibility

- **Tested Devices:** Standard USB 2.0 flash drives from major manufacturers
- **File System Support:** FAT16, FAT32 (NTFS not supported)
- **Capacity Range:** 64MB to 32GB recommended
- **Power Requirements:** Standard USB power budget (500mA max)

Dependencies

- **NetBurner NNDK** - Network Development Kit with USB MSD support
- **FatFile Library** - EFFS FAT file system support
- **USB Host Stack** - Built-in USB OTG host functionality
- **Hardware Adapters** - NBUSB-ADPT-100R USB development adapter

12.33.1.19 NANO54415 Only

NANO54415 Platform Examples

- [NANO54415 Factory App](#)

12.33.1.19.1 NANO54415 Factory App

Supported Platforms: NANO54415

Application that is pre-loaded at the factory. Features include:

- Web server
- FTP server
- EFFS flash file system access to the development board flash card socket

This example requires that you edit the project properties linker settings to add the `FatFile` library.

12.33.1.20 SB800EX Only

SB800EX Platform Examples

- [Serial Transceiver Test](#)
- [SB800EX Diagnostic Monitor](#)

12.33.1.20.1 Serial Transceiver Test

Supported Platforms: SB800EX

Application to demonstrate how to configure the SB800EX software programmable transceivers.

The SB800EX has the ability to switch between RS-232, RS-422 and RS-485 in software. This means customers do not need to remove the cover and manually configure jumpers. This is a very simple program demonstrating how you can modify these settings in your application.

12.33.1.20.2 SB800EX Diagnostic Monitor

Supported Platforms: SB800EX

Adds a web page diagnostic monitor and log file

12.33.2 MODM7AE70, SBE70LC

Platform specific examples for Microchip ARM SAME70 based products: MODM7AE70 and SBE70LC.

- [SBE70LC](#)

12.33.2.1 GPIO Command Server

Location: examples/PlatformSpecific/SAME70/GpioServer

SUPPORTED_PLATFORMS = MODM7AE70 SBE70LC

This example uses the Command Processor Library to establish a GPIO server that provides external control and readback functionality for general purpose input/outputs.

The example establishes the GPIO server using a telnet server by default, but it can also be configured to operate through the serial port or a TCP connection.

A detailed description of the applications features and command set can be found on the application's webpage. That can be accessed by running the application and accessing the device with a web browser.

12.33.2.2.1 I2C Address Scan

12.33.2.2.1.1 I2C Address Scanner for SAME70 Microcontrollers

A utility application for NetBurner SAME70-based platforms that scans [I2C](#) buses to discover connected devices and report their addresses.

Overview

This application provides a systematic way to scan [I2C](#) buses for connected devices, making it an essential tool for hardware verification, system integration, and troubleshooting. It scans the complete [I2C](#) address range (0-127) and reports all discovered device addresses in both serial console and web interface formats.

Supported Platforms

- **MODM7AE70** - Supports up to 3 I2C modules (I2C0, I2C1, I2C2)
- **SBE70LC** - Supports up to 2 I2C modules (I2C0, I2C1)

Features

- Complete I2C address range scanning (0-127)
- Hexadecimal address reporting
- Device count display
- Configurable bus speed (default: 100kHz)
- Platform-specific pin configuration
- Web interface for remote monitoring
- Interactive menu system via serial console
- I2C bus reset capability
- Remote console support through web browser

Hardware Pin Assignments

SBE70LC Platform

I2C0 (Module 0)

- **Data (TWD0):** J1[16]
- **Clock (TWCK0):** J1[17]

I2C1 (Module 1)

- **Data (TWD1):** J3[4]
- **Clock (TWCK1):** J3[6]

MODM7AE70 Platform

I2C0 (Module 0)

- **Data (TWD0):** P2[39]
- **Clock (TWCK0):** P2[42]

I2C1 (Module 1)

- **Data (TWD1):** P2[22]
- **Clock (TWCK1):** P2[12]

I2C2 (Module 2)

- **Data (TWD2):** P2[26]
- **Clock (TWCK2):** P2[23]

Important Configuration Requirements

MODM7AE70 I2C1 Special Setup

For I2C1 on the MODM7AE70 platform, pin P2.12 requires special configuration due to multiplexing between processor ports PA5 and PB5:

1. Navigate to `\nburn\platform\MODM7AE70\include\pinconstants.h`
2. Uncomment `#define P2_12_USE_B5` to enable PB5
3. Comment out the PA5 definition

Without this configuration, the application will display an error message and I2C1 will not function.

How It Works

The scanning process uses the following methodology:

1. Initializes the specified I2C module with platform-specific pin configurations
2. Iterates through all possible I2C addresses (0-127)
3. Attempts to read from register 0x0 of each address
4. Waits for an ACK response from potential devices
5. Records and reports addresses that respond with ACK
6. Stores results for web interface display
7. Provides total device count

Usage Instructions

Getting Started

1. Connect I2C devices to the appropriate platform pins
2. Compile and flash the application to your SAME70 board
3. Open a serial terminal (115200 baud recommended)
4. The application automatically scans I2C module 0 on startup

Interactive Menu

After initialization, the application presents a menu:

1. Scan
2. Reset I2C Bus

- **Option 1:** Performs a new I2C bus scan
- **Option 2:** Resets the I2C bus (useful for clearing bus errors)

Web Interface Access

The application includes a built-in web server:

1. Connect to the device's IP address via web browser
2. View scan results on the main page
3. Access the remote console at `console.html` for interactive control

Sample Output

Serial Console

```
Initializing I2C Module: 0
Scanning I2C Module: 0
Scanning I2C bus for devices...
Found a device at address 0x48
Found a device at address 0x68
Done. Found a total of 2 device(s) on the bus.
```

```
1. Scan
2. Reset I2C Bus
```

Web Interface

```
Number of addresses responded: 2
```

```
0x48
0x68
```

Configuration Options

I2C Module Selection

```
#define I2C_MODULE (0)           // Default uses I2C0
```

Bus Speed Configuration

```
#define I2C_BUS_SPEED (100000)  // 100kHz default
```

Applications

This utility is particularly useful for:

- **Hardware Verification:** Confirming proper device connections
- **Address Discovery:** Finding actual I2C addresses of connected devices
- **System Integration:** Verifying I2C bus integrity during development
- **Troubleshooting:** Diagnosing communication issues
- **Remote Diagnostics:** Web-based device management
- **Documentation:** Generating device address maps for system documentation

Technical Specifications

- **Address Range:** 0x00 to 0x7F (128 addresses)
- **Detection Method:** Register read with ACK detection
- **Bus Speed:** Configurable, default 100kHz
- **Communication:** Single byte register read from address 0x0
- **Web Server:** Built-in HTTP server with remote console
- **Storage:** Results stored in global arrays for web access

Dependencies

- NetBurner RTOS
- I2C library ([i2c.h](#))
- Platform-specific definitions ([pins.h](#))
- System initialization ([init.h](#))
- Network libraries for web interface
- Remote console support ([remoteconsole.h](#))

Building and Deployment

1. Set up NetBurner development environment
2. Select target platform (MODM7AE70 or SBE70LC)
3. Configure pin multiplexing if using MODM7AE70 I2C1
4. Compile the project
5. Flash to target board
6. Connect serial terminal for monitoring
7. Optionally access web interface for remote operation

Troubleshooting

Common Issues

No devices detected:**

- Verify physical connections and power supply
- Check device compatibility with scanning method
- Some devices may not respond to general address scans
I2C1 issues on MODM7AE70:**
- Check pin multiplexing configuration in `pinconstants.h`
- Ensure P2_12_USE_B5 is properly defined
Web interface not accessible:**
- Verify network configuration
- Check HTTP server initialization
- Confirm IP address assignment

Error Messages

- `Error: Invalid module number - Module number exceeds platform limits`
- `invalid moduleNum - Module number validation failed`
- `*** Error: must change function of P2.12 to PB5 - Pin multiplexing configuration required`

Important Notes

- Not all I2C devices respond to address scanning
- Some devices may require specific initialization sequences
- Device datasheets may include or exclude read/write bits in address specification
- Bus speed compatibility varies between devices
- Pull-up resistors are required on SDA and SCL lines, typically 4.7k ohms.

File Structure

- `main.cpp` - Main application with scanning logic
- `index.html` - Web interface homepage
- `style.css` - Web interface styling
- `ReadMe.txt` - Detailed technical documentation

12.33.2.2.2 I2C PicKit Demo Board

12.33.2.2.2.1 I2C PicKit Serial Demo Board Application

Location: `examples/PlatformSpecific/SAME70/I2C/PicKitI2CSerialDemoBd`

Supported Platforms: MODM7AE70 SBE70LC

Overview

This application demonstrates the use of the Microchip PicKit Serial I2C Demo Board with NetBurner embedded systems. The demo showcases communication with five different I2C peripheral devices through a simple serial menu interface.

Supported Platforms

- **MODM7AE70** - Up to 3 I2C modules supported
- **SBE70LC** - Up to 2 I2C modules supported

I2C Peripherals Demonstrated

The application interfaces with the following Microchip I2C devices:

1. **24LC0B EEPROM** - 2Kbit (256 x 8) memory storage
2. **MCP9800** - Digital temperature sensor with 12-bit resolution
3. **MCP23008** - GPIO port expander connected to LEDs
4. **TC1321** - 10-bit Digital-to-Analog Converter (DAC) with 2.5V reference
5. **MCP3221** - 12-bit Analog-to-Digital Converter (ADC)

Features

Interactive Menu System

The application provides a serial console menu with the following options:

- **1** - Erase EEPROM (fill with 0x00)
- **2** - Read EEPROM and display contents in hex format
- **3** - Write incrementing sequence to EEPROM (0x00, 0x01, 0x02...)
- **A** - Read ADC voltage value
- **D** - DAC test (writes maximum value)
- **T** - Read temperature sensor

Automatic LED Sequence

The application continuously cycles through the LEDs connected to the MCP23008 GPIO expander, providing visual feedback that the system is running.

Temperature Sensor Configuration

The MCP9800 temperature sensor is automatically configured for 12-bit resolution on first use, providing temperature readings in both Celsius and Fahrenheit.

I2C Configuration

- **Bus Speed:** 100 kHz
- **Module Used:** I2C0/TW0 (configurable via I2C_MODULE_NUM)
- **Address Format:** 7-bit addresses (NetBurner standard)

I2C Address Mapping

The application handles the conversion from Microchip's 8-bit address format (including R/W bit) to NetBurner's 7-bit format:

Device	8-bit Address	7-bit Address
24LC0B EEPROM	0xA0	0x50
MCP9800 Temp	0x92	0x49
MCP23008 GPIO	0x40	0x20
TC1321 DAC	0x90	0x48
MCP3221 ADC	0x9A	0x4D

Pin Configuration

SBE70LC Platform

- **I2C0:** J1[16] (TWD0), J1[17] (TWCK0)
- **I2C1:** J3[4] (TWD1), J3[6] (TWCK1)

MODM7AE70 Platform

- **I2C0:** P2[39] (TWD0), P2[42] (TWCK0)
- **I2C1:** P2[22] (TWD1), P2[12] (TWCK1) - Requires pin multiplexing configuration
- **I2C2:** P2[26] (TWD2), P2[23] (TWCK2)

Note

: For MODM7AE70 I2C1 usage, pin P2.12 must be configured to use PB5 instead of PA5 by uncommenting the appropriate `#define` in the platform's `pinconstants.h` file.

Key Functions

EEPROM Operations

- **EepromWriteBuf()** - Writes data with automatic page boundary handling (8-byte pages)
- **EepromRead()** - Reads data from EEPROM
- **WaitForEepromWriteCmpl()** - Polls EEPROM for write completion

Sensor Reading

- **ReadTempSensor()** - Configures and reads MCP9800 temperature sensor
- **ReadADC()** - Reads 12-bit ADC value and converts to voltage
- **WriteDAC()** - Writes 10-bit value to DAC with user input

LED Control

- **WriteLeds()** - Controls LEDs via MCP23008 GPIO expander
- **IncrementLEDs()** - Automatic LED sequencing

Technical Details

I2C Error Handling

The application includes comprehensive [I2C](#) status checking with descriptive error messages:

- [I2C_RES_ACK](#) - Acknowledged
- [I2C_RES_NACK](#) - Not Acknowledged
- [I2C_RES_ARB_LST](#) - Arbitration Lost
- [I2C_RES_BUSY](#) - Bus Busy
- [I2C_RES_ARG](#) - Bad Argument

Data Conversion

- Temperature readings are converted from 2's complement format to floating-point
- ADC values are converted to voltage (3.3V reference, 12-bit resolution)
- DAC values support 0-2.5V output range (10-bit resolution)

Usage Instructions

1. Connect the Microchip PicKit Serial [I2C](#) Demo Board to your NetBurner development board
2. Compile and load the application onto your target platform
3. Connect to the serial console (typically 115200 baud)
4. Use the interactive menu to test different [I2C](#) peripherals
5. Observe the LED sequence to verify system operation

Requirements

- NetBurner development tools and runtime system
- Microchip PicKit Serial [I2C](#) Demo Board
- Compatible NetBurner hardware platform (MODM7AE70 or SBE70LC)

12.33.2.3 Serial Callback Function

Supported Platforms: MODM7AE70 SBE70LC

The Serial Empty Callback example demonstrates a robust process for triggering a specified action upon complete transmission of all data written to a specified serial port. The expected use case for this would be disabling a transmitter connected to a shared physical layer such as with RS485 or a wireless link (when using one of the device's UART serial ports).

As an aside, it should be noted that when enabling the `Serial485HalfDupMode` for one of the MODM7AE70s *USART* serial ports, the underlying hardware module will automatically toggle the RTS line for enabling and disabling the transmitter.

12.33.2.4 Timers

SAME70 Timer Platform Examples

- [Timer Capture](#)
- [Chaining Timers](#)
- [Timer Waveform Output](#)
- [Stepper Interval Timer](#)
- [Stepper Step Count](#)

12.33.2.4.1 Timer Capture

Location: examples/PlatformSpecific/SAME70/Timers/TimerCapture

Supported Platforms: MODM7AE70 SBE70LC

Timer Counter Capture Example

This example will generate a pulse waveform on Timer 11, and capture the waveform on Timer 7.

For the MODM7AE70: The timer 11 output is on P2.28, and the timer 7 capture is on P1.4. You will need to add a jumper between these two pins. After the capture is complete, the frequency and duty cycle of the captured waveform will be displayed.

For the SBE70LC The timer 11 output is on J1.4, and the timer 2 capture is on J4.6. You will need to add a jumper between these two pins. After the capture is complete, the frequency and duty cycle of the captured waveform will be displayed.

This is a good example to demonstrate how to:

- Learn the structure of the SAME70 Timer Counter peripheral
- Produce a pulse output waveform of various frequencies and duty cycles
- Capture and count waveform pulses
- Implement a peripheral interrupt service routine

SAME70 Timer Architecture

- There are a total of 12 16-bit timers, numbered 0 - 11.
- They are divided up into 4 blocks. Each block is called a Timer Counter: TC0, TC1, TC2, TC3.
- Each timer within a Timer Counter block is called a Timer Counter Channel. While the timers number from 0 to 11, each Timer Counter Channel within a Timer Counter block is numbered from 0 to 2. For example, Timer Counter Channel 11 is in Timer Counter group TC3, with Timer Counter Channel number 2.
- While all Timer Counter Channels can be used, not all signal pins are brought out to the headers on the MODM7AE70/SBE70LC.
- The diagrams in the Timer Counter (TC) section of the SAME70 Reference Manual describe the structure of the Timer Counters.

12.33.2.4.2 Chaining Timers

Location: examples/PlatformSpecific/SAME70/Timers/ChainedTimerOutput

Supported Platforms: MODM7AE70 SBE70LC

Timer Chaining Example

This example will chain timers 9, 10 and 11 to create a 48-bit timer. The output pulse waveform will appear on timer 11 as indicated in the pin tables below.

Timer channels 9, 10 and 11 are chained together to create a 48-bit timer. The default settings for the chained timers LineA are P2.28 for the MODM7AE70, and J1.4 for the SBE70LC. A GPIO output is used to output a pulse signal on each timer interrupt. P2.30 for the MODM7AE70, and J1.3 for the SBE70LC.

Warning

P2.28 on the NetBurner MOD-DEV-70 development board also connects to the SD Flash socket. The socket must be empty for this example to run properly, or you should select alternate pins for the timer functions.

See also: Timer Waveform Capture example.

This is a good example to demonstrate how to:

- Learn the structure of the SAME70 Timer Counter peripheral
- Produce a pulse output waveform of various frequencies and duty cycles

SAME70 Timer Architecture

- There are a total of 12 16-bit timers, numbered 0 - 11.

- They are divided up into 4 blocks. Each block is called a Timer Counter: TC0, TC1, TC2, TC3.
- Each timer within a Timer Counter block is called a Timer Counter Channel. While the timers number from 0 to 11, each Timer Counter Channel within a Timer Counter block is numbered from 0 to 2. For example, Timer Counter Channel 11 is in Timer Counter group TC3, with Timer Counter Channel number 2.
- While all Timer Counter Channels can be used, not all signal pins are brought out to the headers on the MODM7AE70. The table below describes the header pinout.
- The diagrams in the Timer Counter (TC) section of the SAME70 Reference Manual describe the structure of the Timer Counters.

Timer signals on MODM7AE70 header pins:

Timer 0			
P2.19	LineB	TIOB0	
P2.42	Clock	TCLK0	
Timer 1			
P2.16	Clock	TCLK1	
Timer 2			
P2.17	LineA	TIOA2	
P2.18	LineB	TIOB2	
P2.20	Clock	TCLK2	
Timer 5			
P1.7	LineB	TIOB5	
Timer 7			
P1.4	LineA	TIOA7	
Timer 8			
P1.6	Clock	TCLK8	Note: cannot be used if EBI is enabled
P1.8	LineA	TIOA8	Note: cannot be used if EBI is enabled
P2.6	LineB	TIOB8	
Timer 11			
P2.15	Clock	TCLK11	
P2.28	LineA	TIOA11	
P2.25	LineB	TIOB11	

Timer signals on SBE70LC header pins:

Timer 11		
J1.4	LineA	TIOA11
J1.7	LineB	TIOB11

Note

Timer 11 signals are alternate functions to SPI0 MOSI and Clock

12.33.2.4.3 Timer Waveform Output

Location: examples/PlatformSpecific/SAME70/Timers/TimerOutput

Supported Platforms: MODM7AE70 SBE70LC

Timer Counter Waveform Output Example

This example will generate a pulse waveform on Timer 11. The timer 11 output is on P2[28] on the MODM7AE70, and J1[4] on the SBE70LC

See also: Timer Waveform Capture example.

This is a good example to demonstrate how to:

- Learn the structure of the SAME70 Timer Counter peripheral
- Produce a pulse output waveform of various frequencies and duty cycles

SAME70 Timer Architecture

- There are a total of 12 16-bit timers, numbered 0 - 11.

- They are divided up into 4 blocks. Each block is called a Timer Counter: TC0, TC1, TC2, TC3.
- Each timer within a Timer Counter block is called a Timer Counter Channel. While the timers number from 0 to 11, each Timer Counter Channel within a Timer Counter block is numbered from 0 to 2. For example, Timer Counter Channel 11 is in Timer Counter group TC3, with Timer Counter Channel number 2.
- While all Timer Counter Channels can be used, not all signal pins are brought out to the headers on the MODM7AE70. The table below describes the header pinout.
- The diagrams in the Timer Counter (TC) section of the SAME70 Reference Manual describe the structure of the Timer Counters.

12.33.2.4.4 Stepper Interval Timer

12.33.2.4.4.1 NetBurner SAME70 Stepper Motor Interval Timer Example

Overview

This example demonstrates how to use the NetBurner SAME70 platform's interval timer functionality to generate precise timing signals for stepper motor control. The application configures a hardware timer to produce step and direction signals that can drive stepper motor controllers.

Supported Platforms

- MODM7AE70
- SBE70LC

Features

- Hardware-based interval timer configuration
- Variable step frequency control (steps per second)
- Bidirectional control (up/down counting)
- Real-time command interface via serial console
- Timer channel configuration for stepper motor applications

Hardware Configuration

Pin Assignments

MODM7AE70:**

- P2.25: TIOB11 (Timer channel B output)
- P2.28: TIOA11 (Timer channel A output - step signal)

SBE70LC:**

- J1.4: TIOA11 (Timer channel A output - step signal)

Timer Configuration

The application uses Timer Channel 11 (STEPPER_TIMER) configured in stepper mode with the following features:

- Configurable frequency from 0 to several thousand steps per second
- Direction control via up/down counting
- Hardware-generated step pulses
- Interrupt-free operation for precise timing

Application Flow

User Interface

The application provides a simple command-line interface for controlling the stepper motor timing:

Command Format

```
<steps per second><U/D>
```

Where:

- Steps per second: Integer value (0 to stop)
- Direction: 'U' or 'u' for up, 'D' or 'd' for down

Usage Examples

```

> 300D
    300 steps per second, counting Down

> 2000U
    2000 steps per second, counting Up

> 0U
    Stop, 0 steps per second
  
```

Key Functions

Timer Management

- `InitStepperTimer(int pps, bool dirUp)` - Initialize timer with frequency and direction
- `UpdateStepperTimer(int pps, bool dirUp)` - Update running timer parameters
- `StopStepperTimer()` - Stop timer operation

Hardware Configuration

- Pin function assignment for timer outputs
- Timer channel configuration in stepper mode
- Interrupt disable for hardware-only operation

Important Notes

- On MODM7AE70 MOD-DEV-70, P2.28 is connected to SPI DOUT, so the flash card socket must be empty when using this example
- Timer interrupts are disabled to allow pure hardware generation of step signals
- The timer operates independently once configured, providing precise timing without CPU intervention
- Direction changes and frequency updates can be made in real-time

Application Notes

This example is particularly useful for:

- Stepper motor control applications
- Precision timing signal generation
- Learning SAME70 timer capabilities
- Hardware-based pulse generation without software overhead

The hardware timer approach ensures consistent timing regardless of CPU load or interrupt activity, making it ideal for applications requiring precise motor control timing.

12.33.2.4.5 Stepper Step Count

12.33.2.4.5.1 NetBurner SAME70 Stepper Motor Step Count Example

Overview

This example demonstrates an advanced stepper motor control system using the NetBurner SAME70 platform's sophisticated timer coordination capabilities. The application uses three interconnected timer channels to create a complete stepper motor driver with precise step counting, programmable frequency control, and hardware-based pulse generation.

Supported Platforms

- MODM7AE70

Features

- **Multi-Timer Coordination:** Uses three synchronized timer channels working together
- **Precise Step Counting:** Tracks and counts individual step pulses with completion detection
- **Variable Frequency Control:** Programmable step rates from low to high frequencies
- **Large Step Count Support:** Handles step counts up to millions through interrupt-driven management
- **Bidirectional Control:** Software-controlled direction (up/down counting)
- **Hardware-Based Generation:** Timer hardware generates consistent pulses independent of CPU load
- **Real-Time Command Interface:** Interactive serial console for dynamic control
- **Advanced Timer Cross-Coupling:** Sophisticated timer interconnection for coordinated operation
- **Completion Synchronization:** Semaphore-based notification when step sequences complete

Hardware Configuration

Pin Assignments

MODM7AE70:**

- P1.8: TIOA8 (Timer channel A output - primary step pulses)
- P2.6: TIOB8 (Timer channel B output - secondary output/direction)

Timer Architecture

Timer Coordination System:

Timer Channel Assignments

- **Timer 6 (TIMER_STEP_FREQ):** Frequency generation and base timing
- **Timer 7 (TIMER_STEP_COUNTER):** Step count management and completion tracking
- **Timer 8 (TIMER_STEP_PINS):** Hardware pulse generation and stepper mode control

Application Flow

```

      |
      v
Hardware Pulse Generation
      |
      v
Interrupt-Driven Counting
      |
      v
Wait for Completion Signal
      |
      v
Display Results
      |
      v
Return to Command Loop

```

User Interface

The application provides an interactive command-line interface for real-time stepper motor control.

Command Format

<step count>,<steps per second>,<U/D>

Parameters:**

- **step count:** Total number of steps to execute (positive integer)
- **steps per second:** Step frequency/rate (positive integer)
- **direction:** 'U' or 'u' for up counting, 'D' or 'd' for down counting

Usage Examples

```

> 3000,300,D
  Execute 3000 steps at 300 steps per second, counting down

> 30000,2000,U
  Execute 30000 steps at 2000 steps per second, counting up

> 500000,1000,D
  Execute 500000 steps at 1000 steps per second, counting down

```

Operation Sequence

1. System prompts with >
2. User enters command in specified format
3. System validates input parameters
4. If valid, stepper sequence begins immediately
5. System waits for completion (blocking operation)
6. Upon completion, displays actual step count achieved
7. Returns to prompt for next command

Key Technical Features

Multi-Timer Coordination

The application implements a sophisticated three-timer coordination system:

Timer Interconnection:**

- Frequency timer generates the base clock signal
- Pin timer receives frequency timer output via cross-coupling
- Count timer tracks step progression using interrupt callbacks
- All timers operate from the same timer block for proper cross-coupling

Large Step Count Support

Handles step counts beyond 16-bit timer limitations through intelligent phase management:

Step Count Phases:**

- **Phase 1** (< 65,536 steps): Direct single-timer configuration
- **Phase 2** (65,536 - 69,631 steps): Two-phase interrupt management
- **Phase 3** (> 69,631 steps): Multi-phase interrupt-driven counting

Clock Source Optimization

Automatically selects optimal clock source for requested frequency:

Available Clock Sources:**

- PCK6 (Programmable Clock 6)
- PERIPH_CLOCK/8
- PERIPH_CLOCK/32
- PERIPH_CLOCK/128

Selection algorithm minimizes frequency error for best timing accuracy.

Hardware Stepper Mode

Timer 8 operates in dedicated stepper mode providing:

- Automatic step/direction signal generation
- Hardware-controlled pulse width and timing
- Gray code sequence generation
- Direction control via software commands

Important Notes

Hardware Requirements

- All three timer channels (6, 7, 8) must be from the same timer block
- Timer cross-coupling requires specific timer block architecture
- Pin functions must be properly configured for timer outputs

Platform-Specific Considerations

- **MODM7AE70:** Uses Timer Block 2 (channels 6, 7, 8)
- **Pin Conflicts:** Some pins may conflict with other peripheral functions
- **Clock Configuration:** PCK6 requires proper system clock setup

Operational Characteristics

- **Timing Precision:** Hardware timers provide microsecond-level accuracy
- **CPU Independence:** Once started, pulse generation continues without CPU intervention
- **Interrupt Overhead:** Step counting uses low-priority interrupts for minimal system impact
- **Completion Detection:** Semaphore-based synchronization ensures reliable completion notification

Limitations and Considerations

- Maximum practical step frequency limited by timer clock sources
- Very high step counts may take significant time to complete
- Command interface blocks until step sequence completion
- Timer resource allocation must succeed for proper operation

Application Areas

This example is particularly valuable for:

Industrial Applications

- CNC machine tool control systems
- Automated manufacturing equipment
- Precision positioning systems
- Assembly line automation

Robotics Applications

- Multi-axis robot control
- Precision servo positioning
- Automated pick-and-place systems
- Mobile robot wheel control

12.33.2.5 Watchdog Timer

Location: examples/PlatformSpecific/SAME70/Watchdog

Supported Platforms: MODM7AE70 SBE70LC

The Watchdog example shows how to use the watchdog on the SAME70.

12.33.2.6 MODM7AE70

These examples are located in examples/PlatformSpecific/SAME70/MODM7AE70:

- SSC I2S Interface
- DACC Tone Generator

12.33.2.6.1 Analog to Digital (ADC)

Supported Platforms: MODM7AE70

The Simple ADC example implements basic analog input functions of the MODM7AE70.

The MODM7AE70 offers two Analog Front-End Controllers (AFEC) that are based on an Analog Front-End (AFE) cell. The MODM7AE70 provides seven 12-bit Analog-to-Digital (ADC) lines available through the P2 header. The SBE70LC provides 8 12-bit ADC lines available between the JP1 and JP3 headers. Both platform's have one additional ADC line that is connected to the CPU's internal temperature sensor – it cannot be reconfigured for other applications.

An ADC voltage reference is required for accurate ADC readings. The MODM7AE70 ADC voltage reference is accessible through pin P2[5]. If using the MODM7AE70 with a MOD-DEV-70 development board, a jumper can be applied to the JP5 header on the MOD-DEV-70 to apply a 3.3V reference. The SBE70LC ADC voltage reference is accessible through the JP3[1] pin.

The following table maps the available ADC lines on the MODM7AE70 to the corresponding pins on the P2 header:

Pin	AFE Module	ADC Channel	P2[3]	0	10
P2[6]	1	3	P2[7]	0	0
P2[8]	0	6	P2[21]	0	1
P2[38]	0	2	*Temp	0	11

—+-----+ Temperature sensor internal to the CPU, not available through the pin header

Note that AFE module 0, channel 1 (P2[3]) collides with serial port 0 receive. If using this ADC channel (like this example does), the application will not be able to receive data on serial port 0. It can still print to serial port 0, though.

The following table maps the available ADC lines on the SBE70LC to the corresponding pins on the JP1 and JP3 headers:

JP1[5] | 0 | 2 | +-----+-----+ JP1[10] | 1 | 0 | +-----+-----+ JP1[11] | 0 | 10 |
+-----+-----+ JP1[13] | 0 | 1 | +-----+-----+ JP1[14] | 0 | 5 | +-----+
+-----+ JP3[3] | 1 | 3 | +-----+-----+ JP3[5] | 0 | 0 | +-----+-----+
JP3[7] | 0 | 6 | +-----+-----+ *Temp | 0 | 11 | +-----+-----+ Temperature sensor

internal to the CPU, not available through the pin header

12.33.2.6.2 CAN Send and Receive

Supported Platforms: MODM7AE70

A very simple CAN example to send and receive packets:

- Creates a CAN receive task
- Serial port menu with options to send, receive, manipulate RTR filters
- CAN communication requires 2 CAN devices. As a test you can send/receive by jumpering the CAN pins together

12.33.2.6.3 EBI Page Control

Supported Platforms: MODM7AE70

The EBI Page Control example implements a transparent Page Fault based page manager for the SAME70's External Bus Interface. It is primarily intended for use with systems requiring a full 24-bit address bus or for multiplexing a specific chip select against multiple identical devices.

12.33.2.6.4 EBI Page Control - Simple

Supported Platforms: MODM7AE70

12.33.2.6.7.2 Pin Interrupt Request

Supported Platforms: MODM7AE70

The PinIrq example shows how to use the interrupt capabilities of the PIO controller and the PinIrq functions for the MODM7AE70.

12.33.2.6.8 Open All UARTs

Supported Platforms: MODM7AE70

Open all serial ports on MODM7AE70 SOM Platform

There can be a maximum of 7 serial port configured on the device. Note that each signal pin on the microprocessor can be configured for up to 5 different functions, so to achieve the maximum number of serial ports some functions/peripherals will be unavailable.

The SAME70 processor has two peripherals that can be used as a UART function: Three USARTs, representing Serial Port numbers 0 and 1 (USART numbers 0 - 1) Four UARTs, representing Serial Port numbers 3, 4, 5 and 6 (UART numbers 0 - 4) This mapping is described in the MODM7AE70 data sheet.

Serial Port P1 Pin P2 Pin Periph Mode USART/UART

0 RX 3 C USART 0 RX 0 TX 4 C USART 0 TX 0 CTS 29 C USART 0 CTS 0 RTS 38 C USART 0 RTS Note: Serial port 0 is stdio by default

1 RX 21 A USART 1 RX 1 TX 22 D USART 1 TX 1 RTS 32 A USART 1 RTS 1 CTS 33 A USART 1 CTS 1 DSR 16 A USART 1 DSR 1 DCD 17 A USART 1 DCD 1 DTR 18 A USART 1 DTR 1 RI 20 A USART 1 RI

12.33.2.6.9 Programmable Clock Output

Supported Platforms: MODM7AE70

The Power Management Controller (PMC) optimizes power consumption by controlling all system and user peripheral clocks. The PMC enables/disables the clock inputs to many of the peripherals and the Cortex-M7 processor. The clocking system in the SAME70 processor has a multitude of configuration options. The consequence of that is that it also complex. For detailed information, especially with respect to PCK registers, refer to chapter 31. Power Management Controller (PMC) of the SAME70 data sheet in your "\nburn\docs\Microchip" folder.

The PMC controller handles clocking for the entire processor. This examples if focused on the PCK outputs PCK0 and PCK1 on MODM7AE70:

- PCK0 on pin P1.31 and P2.11
- PCK1 on pin P2.8, P2.21, P2.24, P2.38, P2.39 and P2.40

For reference, PCK System Assignments:

- PCK3: ETM
- PCK4: UARTx/USARTx
- PCK5: MCANx

- PCK6: TCx
- PCK7: TC0

PMC_PCKx [x=0..7]: PMC Programmable Clock Register, Read/write Programmable Clock Prescaler and Programmable Clock Source. Bits 11:4 - PRES[7:0] Programmable Clock Prescaler Value Description 0 - 255 Selected clock is divided by PRES+1.

Bits 2:0 - CSS[2:0] Programmable Clock Source Selection Value Name Description 0 SLOW_CLK SLCK is selected 1 MAIN_CLK MAINCK is selected 2 PLLA_CLK PLLACK is selected 3 UPLL_CLK UPLLCKDIV is selected 4 MCK MCK is selected 5 AUDIO_CLK AUDIOPLLCLK is selected

Slow Clock: Slow R/C oscillator input to processor, not used. Main Clock: Oscillator input to processor (MAINCK), 12MHz. PLLA Clock: Generated from MAINCK by the PLLA and a predivider, 300MHz. UTMI PLL Clock: USB transmitter clock (UPLL_CLK). Master Clock: Output from Master Clock Controller, 150MHz. Audio Clock: External audio clock input.

Note

Processor electrical specifications limit the clock output frequency based on the pin group. In example testing on P2.11, the maximum output was 150MHz, but other pins may be lower. Refer to the pin group specification for the selected pin in your application.

PMC_SCER: PMC System Clock Enable Register, Enables the corresponding Programmable Clock output. PMC_↔_SCDR: PMC System Clock Disable Register, Disables the corresponding Programmable Clock output. PMC_↔_SCSR: PMC System Clock Status Register, Reads enable/disable state of Programmable Clock output.

12.33.2.6.10 PWM

Supported Platforms: MODM7AE70

Demonstrates the use of the PWM peripheral.

12.33.2.6.11 NTP & Real-Time Clock

Supported Platforms: MODM7AE70

NTP-SYSTEM-RTC DEMO APPLICATION

HARDWARE SETUP: Tested with MODM7AE70 on a MOD-DEV-70 hardware rev 1.93.

This example demonstrates the following features:

- Updates the system time with the current UTC time pulled from an available NTP server (pool.ntp.org). If your module is set to static IP address settings, then you will need to manually assign a DNS server address for this feature to work.
- Take the current system time and save it to the real-time clock (RTC). The RTC will then be running in sync with the system time.
- Take the current time in the RTC and set the system time information. The system time will then be running in sync with the RTC.
- When the device or module is reset or powered on again after a recent power loss, the system time will be reset, but the RTC can continue running until the super-capacitor is discharged. The software-reset option is available to demonstrate the RTC's ability to retain saved time information once it is properly set.
- Set the local time zone information with a call to `tzsetchar()`. For more more information on this function, refer to "Chapter 14 - NBTTime Library" of the NetBurner Runtime Libraries PDF document. In this example, Pacific time zone information is used as a demonstration.
- Display the current system and RTC times, and local time zone information if applicable. It is preferred that the RTC store the UTC time, not local time.
- In order to take advantage of setting and getting time information from the real-time clock (RTC), a device that contains an RTC component or a module that is mounted on a development board with an RTC component must be used. Current RTC components supported in this example at the time of this writing are the Intersil X1226 and NXP PCF8563.

12.33.2.6.12 Open All Serial Ports

Location: examples/PlatformSpecific/MODM7AE70/Serial-OpenAll

Supported Platforms: MODM7AE70

Demonstrates how to open all available serial ports on the MODM7AE70. There are a total of 7 named SerialPort 0 - 6, which correspond to USARTs 0 and 1, and UARTs 0 - 4. Note that the difference between a USART and a UART is that the UARTs can only be used for regular serial with TX and RX signals. The USARTs also include hardware handshaking, can be used for RS-422/485, and support other serial modes such as SPI.

12.33.2.6.13 SPI

12.33.3.1.1 FlexCan Interrupt Transfer

Location: examples/PlatformSpecific/SOMRT1061/CAN

12.33.3.1.1.1 Overview

The flexcan_interrupt example shows how to use FlexCAN driver in none-blocking interrupt way. It has been ported from the NXP Freescale Software Library (FSL).

In this example, 2 boards are connected through CAN bus. Endpoint A(board A) send a CAN Message to Endpoint B(board B) when user press space key in terminal. Endpoint B receive the message, print the message content to terminal and echo back the message. Endpoint A will increase the received message and waiting for the next transmission of the user initiated.

For self wake up from STOP mode, since steps which MCU enters STOP mode differs on different MCUs, take flexcan_interrupt_transfer of twrke18f for example, user should do like this:

```
#include "fsl_smc.h"
...
...
flexcanConfig.enableSelfWakeup = true;
FLEXCAN_Init();
...
```

```

...
SMC_SetPowerModeStop(SMC, kSMC_PartialStop1);
if (wakenUp)
{
    PRINTF("B has been waken up!\r\n\r\n");
}
...
...

```

12.33.3.1.1.2 NXP SDK version

- Version: 2.16.000

12.33.3.1.1.3 Hardware requirements

- One DEV-SOMRT1061 Development board and one other CAN device, or two DEV-SOMRT1061 boards
- Personal Computer
- Serial terminal program connected to the DEV-SOMRT1061 RS-232 port

Warning

Two CAN devices are required for CAN to operate (except for loopback example)

12.33.3.1.1.4 Board settings

If using 2 DEV-SOMRT1061 boards, connect the two pin CAN header pins of each

12.33.3.1.1.5 Running the demo

After connecting the two boards, these instructions display on each terminal window. One board must be chosen as node A and the other board as node B. (Note: Node B should start first) Data is sent continuously between the node A and the node B.

Consider special errata 005829 feature, the 1st valid MB should be used as reserved one. The TX MB number will change from 8 to 9, while RX MB number will change from 9 to 10. This message displays on the node A terminal:

```

FLEXCAN Interrupt EXAMPLE *****

Message format: Standard (11 bit id)

Message buffer 10 used for Rx.

Message buffer 9 used for Tx.

Interrupt Mode: Enabled

Operation Mode: TX and RX --> Normal

```

Please select local node as A or B:

Note: Node B should start first.

Node:a

Press any key to trigger one-shot transmission

Rx MB ID: 0x123, Rx MB data: 0x0, Time stamp: 8877

Press any key to trigger the next transmission!

Rx MB ID: 0x123, Rx MB data: 0x1, Time stamp: 32459

Press any key to trigger the next transmission!

This message displays on the node B terminal:

```

FLEXCAN Interrupt EXAMPLE *****

Message format: Standard (11 bit id)

Message buffer 10 used for Rx.

Message buffer 9 used for Tx.

Interrupt Mode: Enabled

Operation Mode: TX and RX --> Normal

Please select local node as A or B:

Note: Node B should start first.

Node:b

Start to Wait data from Node A

Rx MB ID: 0x321, Rx MB data: 0x0, Time stamp: 5759

Wait Node A to trigger the next transmission!

Rx MB ID: 0x321, Rx MB data: 0x1, Time stamp: 57276

Wait Node A to trigger the next transmission!

```

12.33.3.1.2 FlexCan Loopback

Location: examples/PlatformSpecific/SOMRT1061/FlexcanLoopback

12.33.3.1.2.1 Overview

This example has been ported from the NXP Freescale Software Library (FSL).

The flexcan_loopback_functional example shows how to use the loopback test mode to debug your CAN Bus design:

To demonstrate this example, only one board is needed. The example will config one FlexCAN Message Buffer to Rx Message Buffer and the other FlexCAN Message Buffer to Tx Message Buffer with same ID. After that, the example will send a CAN Message from the Tx Message Buffer to the Rx Message Buffer through internal loopback interconnect and print out the Message payload to terminal.

12.33.3.1.2.2 NXP SDK version

- Version: 2.16.000

12.33.3.1.2.3 Hardware requirements

- DEV-SOMRT1061
- Personal Computer
- Serial terminal program connected to the DEV-SOMRT1061 RS-232 port

12.33.3.1.2.4 Board settings

No special settings are required.

12.33.3.1.2.5 Running the demo

Consider special errata 005829 feature, the 1st valid MB should be used as reserved one. The TX MB number will change from 8 to 9, while RX MB number will change from 9 to 10. When the example runs successfully, following information can be seen on the OpenSDA terminal:

```
==FlexCAN loopback functional example -- Start.==
```

```
Send message from MB9 to MB10
```

```
tx word0 = 0x11223344
```

```
tx word1 = 0x55667788
```

```
Received message from MB10
```

```
rx word0 = 0x11223344
```

```
rx word1 = 0x55667788

12.33.3.2 Clock Module Example

12.33.3.2.1 Demonstrates the Clock Control Module (CCM) for the SOMRT1061 platform

Location: examples/PlatformSpecific/SOMRT1061/ClockModule

Supported Platforms

- SOMRT1061

12.33.3.2.2 Overview

The Clock Control Module (CCM) generates and controls clocks to the various modules in the design and manages low power modes. This example enables, sets, and displays the available clock sources for the SOMRT1061 platform.

The CCM uses available clock sources to generate clock roots and includes separate dividers to control generation of core and bus root clocks (AXI, AHB, IPG).

12.33.3.2.3 Key Features

Feature	Description
Clock Configuration	Sets external oscillator and RTC crystal
Clock Speed Display	Reports all major clock frequencies
Clock Root Enumeration	Lists all peripheral clock root frequencies
Visual Feedback	LED blink at 2Hz to indicate operation

12.33.3.2.4 Clock Architecture

12.33.3.2.4.1 AMBA Background

AMBA (Arm Advanced Microcontroller Bus Architecture) is an open-standard, on-chip interconnect specification for the connection and management of functional blocks in system-on-a-chip (SoC) designs. AMBA was introduced by Arm in 1996. The first AMBA buses were:

- Advanced System Bus (ASB)
- Advanced Peripheral Bus (APB)

12.33.3.2.4.2 Clock Types

IPG Clock (IPBus Global Clock)

The IPG clock drives the AHB to IP Bridge (AIPSTZ); the IPBus drives chip-specific peripherals

The AIPS bridge serves as a protocol translator between the AHB system bus and the IPbus. The AHB to IP bridge is the interface between the AHB and on-chip IPS peripherals, which are sub-blocks containing readable/writable control and status registers.

The AHB master reads and writes these registers through the AIPSTZ. The bridge generates:

- Block enables
- Block address
- Transfer attributes
- Byte enables
- Write data as inputs to the IPS peripherals

The bridge captures read data from the IPS interface and drives it on the AHB.

Each bridge that connects to the IPS (or peripherals) is referred to as AIPS. The chip has several separate AIPS modules, and peripherals are grouped and assigned under each AIPS block.

AHB Clock (AMBA High-performance Bus)

The AHB clock drives the high-performance system bus used for high-speed communication between the CPU and high-bandwidth peripherals.

12.33.3.2.4.3 Clock Hierarchy

12.33.3.2.5 Code Structure

12.33.3.2.5.1 Main Components

The example consists of three main functions:

displayClockSpeeds()

Reports all major clock frequencies and clock root frequencies:

Clock Type	Description
Ext OSC	External oscillator frequency (24 MHz)
CPU	CPU core clock frequency
AHB	AHB bus clock frequency
IPG	IPG bus clock and peripheral clock
PER	Peripheral clock frequency
SEMC	SDRAM controller clock frequency

Clock roots enumerated:

- kCLOCK_Usdhc1ClkRoot / kCLOCK_Usdhc2ClkRoot

- kCLOCK_FlexspiClkRoot / kCLOCK_Flexspi2ClkRoot
- kCLOCK_CsiClkRoot
- kCLOCK_LpspiClkRoot
- kCLOCK_TraceClkRoot
- kCLOCK_Sai1ClkRoot / kCLOCK_Sai2ClkRoot / kCLOCK_Sai3ClkRoot
- kCLOCK_Lpi2cClkRoot
- kCLOCK_CanClkRoot
- kCLOCK_UartClkRoot
- kCLOCK_LcdifClkRoot
- kCLOCK_SpdifClkRoot
- kCLOCK_Flexio1ClkRoot / kCLOCK_Flexio2ClkRoot

ledBlink()

Toggles LED0 (PIN_78_GPIO4_IO30) at 2Hz to provide visual feedback that the application is running.

UserMain()

Main entry point that:

1. Initializes the NetBurner system
2. Configures crystal frequencies (24 MHz OSC, 32 KHz RTC)
3. Displays all clock speeds to serial console
4. Enters main loop blinking LED at 2Hz

12.33.3.2.5.2 Clock Configuration

```
CLOCK_SetXtalFreq(24); // OSC is 24MHz. 88x multiplier provides 528MHz System Clock
CLOCK_SetRtcXtalFreq(32); // RTC crystal is 32KHz
```

The 24 MHz external oscillator is multiplied by 88 to generate the 528 MHz system clock.

12.33.3.2.6 Hardware Requirements

12.33.3.2.6.1 Development Board

- SOMRT1061 Development Kit

12.33.3.2.6.2 LED Connections

LED	Pin	GPIO
LED0	PIN_78_GPIO4_IO30	Used for blink
LED1	PIN_21_GPIO4_IO06	Not used in example
LED2	PIN_75_GPIO3_IO19	Not used in example
LED3	PIN_74_GPIO3_IO20	Not used in example

12.33.3.2.6.3 Serial Connection

Connect a serial terminal to the development board:

- Baud rate: 115200
- Data bits: 8

- Parity: None
- Stop bits: 1

Warning

The `fsl_` files use the `assert()` debug function to test values. If an assert fails, an error message is displayed on the serial port and the system is halted. Be sure to connect a serial terminal program to watch for any error messages.

12.33.3.2.7 Expected Output

Upon startup, the serial console will display:

```
Running SOMRT1061 Clock Module
```

```
Ext OSC: 24 MHz
```

```
CPU: 528 MHz
```

```
AHB: 132 MHz
```

```
IPG: 66 MHz, Peripheral Clock: 66 MHz
```

```
PER: 24 MHz
```

```
SEMC: 132 MHz
```

```
Running SOMRT1061 Clock Module
```

```
Ext OSC: 24 MHz
```

```
CPU: 528 MHz
```

```
AHB: 528 MHz
```

```
IPG: 132 MHz, Peripheral Clock: 528 MHz
```

```
PER: 24 MHz
```

```
SEMC: 176 MHz
```

```
CLOCK ROOT FREQ
```

```
kCLOCK_Usdhc1ClkRoot 198 MHz
```

```
kCLOCK_Usdhc2ClkRoot 198 MHz
```

```
kCLOCK_FlexspiClkRoot 315 MHz
```

```
kCLOCK_Flexspi2ClkRoot 45 MHz
```

```
kCLOCK_CsiClkRoot 12 MHz
```

```
kCLOCK_LpspiClkRoot 132 MHz
```

```
kCLOCK_TraceClkRoot 99 MHz
```

```
kCLOCK_Sai1ClkRoot 40 MHz
```

```
kCLOCK_Sai2ClkRoot 40 MHz
```

```
kCLOCK_Sai3ClkRoot 40 MHz
```

```
kCLOCK_Lpi2cClkRoot 60 MHz
```

```
kCLOCK_LcdifClkRoot 29 MHz
```

```
kCLOCK_SpdifClkRoot 30 MHz
```

```
kCLOCK_Flexio1ClkRoot 30 MHz
```

```
kCLOCK_Flexio2ClkRoot 30 MHz
```

LED0 will blink at 2Hz (500ms on, 500ms off).

12.33.3.2.8 API Reference

12.33.3.2.8.1 Clock Functions Used

The example uses the following functions from [fsl_clock.h](#):

Function	Description
<code>CLOCK_SetXtalFreq()</code>	Set external crystal oscillator frequency
<code>CLOCK_SetRtcXtalFreq()</code>	Set RTC crystal oscillator frequency
<code>CLOCK_GetOscFreq()</code>	Get external oscillator frequency
<code>CLOCK_GetCpuClkFreq()</code>	Get CPU clock frequency
<code>CLOCK_GetAhbFreq()</code>	Get AHB bus frequency
<code>CLOCK_GetIpgFreq()</code>	Get IPG bus frequency
<code>CLOCK_GetPeriphClkFreq()</code>	Get peripheral clock frequency
<code>CLOCK_GetPerClkFreq()</code>	Get PER clock frequency
<code>CLOCK_GetSemcFreq()</code>	Get SEMC (SDRAM controller) frequency
<code>CLOCK_GetClockRootFreq()</code>	Get specific clock root frequency

12.33.3.2.8.2 Required Headers

```
#include <predef.h>
#include <stdio.h>
```

```
#include <init.h>
#include <sim.h>
#include <nbrtos.h>
#include <iosys.h>
#include <pins.h>
#include <cpu_pins.h>
#include <string.h>
#include "fsl_clock.h"
```

Note

All fsl_MCUXpresso files are located in: \nburn\arch\cortex-m7\cpu\MIMXRT10xx\include

12.33.3.2.9 Usage Notes

12.33.3.2.9.1 PWM Clock Source

For applications using FlexPWM, the IPG clock is the source:

```
#define PWM_SRC_CLK_FREQ CLOCK_GetFreq(kCLOCK_IpgClk)
```

12.33.3.2.9.2 Timing Considerations

- The example uses a 500ms delay (TICKS_PER_SECOND / 2) for LED blinking
- Clock speeds are displayed once at startup
- The main loop runs continuously

12.33.3.2.9.3 Extending the Example

To modify clock speeds or add additional clock monitoring:

1. Reference the i.MX RT1061 Reference Manual for clock tree details
2. Use [fsl_clock.h](#) functions to read or modify clock configurations
3. Be aware that changing core clocks may require adjusting wait states and voltage regulators

12.33.3.2.10 Troubleshooting

Issue	Solution
LED not blinking	Check LED0 connection on PIN_78_GPIO4_IO30
No serial output	Verify serial terminal settings (115200 8N1)
Assert message	Review serial output for specific error
Incorrect frequencies	Ensure crystal oscillators are correct values

12.33.3.2.11 References

- i.MX RT1061 Reference Manual - Clock Control Module (CCM) chapter
- NXP MCUXpresso SDK Documentation
- AMBA Bus Specification (ARM)
- NetBurner [fsl_clock.h](#) API documentation

12.33.3.2.12 Related Examples

- GPIO examples for additional LED control
- Timer examples for precision timing
- FlexPWM examples for PWM clock usage

12.33.3.3 EFFS Multiple Partitions

This example program demonstrates how to create a second partition in the Application Flash, so that a guaranteed amount can be reserved for NNDK System usage, while still allowing general Application usage as well.

12.33.3.4 External Real Time Clock

Please refer to [I2C](#) Wire example: [RV3032 I2C Real-Time Clock](#)

12.33.3.5 Periodic Interrupt Timer (PIT)

Location: examples/PlatformSpecific/SOMRT1061/PIT

Warning

The NetBurner IntervalTimer is the preferred and safe method to use for Periodic Interrupts, as it will allocate and free timers without interfering with system operation. Although the FSL PIT timer example works, if an application uses it on a PIT timer used by the system, the device may halt or crash.

12.33.3.5.1 Overview

The PIT project is a simple demonstration program of the SDK PIT driver. It sets up the PIT hardware block to trigger a periodic interrupt after every 1 second. When the PIT interrupt is triggered a message is printed on the UART terminal and an LED is toggled on the board.

This has been ported from the NXP Freescale Software Library (FSL).

12.33.3.5.2 SDK version

- Version: 2.16.000

12.33.3.5.3 Toolchain supported

- MCUXpresso 11.10.0

12.33.3.5.4 Hardware requirements

- NetBurner DEV-SOMRT1061 Development board
- Personal Computer
- Serial terminal program with RS-232 connection

12.33.3.5.5 Board settings

No special settings are required.

12.33.3.5.6 Prepare the Demo

1. Connect a USB cable between the PC host and the USB port on the board.
2. Open a serial terminal with these settings:
 - 115200 baud rate
 - 8 data bits
 - No parity
 - One stop bit
 - No flow control
3. Download the program to the target board.
4. Example will automatically start

12.33.3.5.7 Running the demo

These instructions are displayed/shown on the terminal window:

```
Starting channel No.0 ...
Channel No.0 interrupt is occurred !
Channel No.0 interrupt is occurred !
Channel No.0 interrupt is occurred !
.....
.....
```

And you will find the user LED is taking turns to shine.

12.33.3.6 Open All UARTs

Location: examples/PlatformSpecific/SOMRT1061/OpenAllUARTs

Supported Platforms: SOMRT1061

Open all serial ports on SOMRT1061 Platform

There can be a maximum of 7 serial port configured on the device. Note that each signal pin on the microprocessor can be configured for up to 5 different functions, so to achieve the maximum number of serial ports some peripheral functions will be unavailable.

Serial Port	Pin Number	Peripheral Mode	LPUART	Comments for use with DEV-SOMRT1061-100CR
0 TX	8	2	LPUART 3 TX	Note: Serial port 0 is stdio by default
0 RX	7	2	LPUART 3 RX	
0 CTS	6	2	LPUART 3 CTS	
0 RTS	4	2	LPUART 3 RTS	
1 TX	42	2	LPUART 2 TX	Connected to GND through 0.1uF cap. High bus speed not recommended.
1 RX	3	2	LPUART 2 RX	
1 CTS	40	2	LPUART 2 CTS	
1 RTS	41	2	LPUART 2 RTS	
2 TX	88	2	LPUART 4 TX	Shares trace with RTC CLK OUT. Cannot be used if RTC clock output is enabled (not enabled by default).
2 RX	87	2	LPUART 4 RX	
2 CTS	3	2	LPUART 4 CTS	
2 RTS	2	2	LPUART 4 RTS	
3 TX	86	2	LPUART 5 TX	Shares trace with NBWIFI enable pin. Cannot be used simultaneously with NBWIFI.
3 RX	85	2	LPUART 5 RX	
3 CTS	81	2	LPUART 5 CTS	
3 RTS	82	2	LPUART 5 RTS	
4 TX	84	2	LPUART 6 TX	Only supports RS485.
4 RX	83	2	LPUART 6 RX	
4 CTS	78	2	LPUART 6 CTS	
4 RTS	80	2	LPUART 6 RTS	
5 TX	77	2	LPUART 7 TX	Shares trace with RGB red LED. HIGH bus speed not recommended.

Serial Port	Pin Number	Peripheral Mode	LPUART	Comments for use with DEV-SOMRT1061-100CR
5 RX	76	2	LPUART 7 RX	Shares trace with Enet 2. Ethernet driver source modifications can be made for testing while not mounted in DEV-SOMRT1061-100CR. Warning LPUART7 RX cannot be used while mounted in the DEV-SOMRT1061-100CR
6 TX	29	2	LPUART 8 TX	Shares trace with SDHC (PIN_29_↔USDHC1_DATA2). Trace pulled high with 47k resistor. High bus speed not recommended. Cannot be used with SD card is mounted.
6 RX	28	2	LPUART 8 RX	Shares trace with SDHC (PIN_28_↔USDHC1_DATA3). Trace pulled high with 47k resistor. High bus speed not recommended. Cannot be used with SD card is mounted.
6 CTS	25	2	LPUART 8 CTS	Shares trace with SDHC (PIN_25_↔USDHC1_DATA0). Trace pulled high with 47k resistor. High bus speed not recommended. Cannot be used with SD card is mounted.
6 RTS	24	2	LPUART 8 RTS	Shares trace with SDHC (PIN_25_↔USDHC1_DATA1). Trace pulled high with 47k resistor. High bus speed not recommended. Cannot be used with SD card is mounted. Warning LPUART 8 cannot be used if an SD card is mounted in the SD card socket.

12.33.3.7 SOMRT1061 Pin IRQ Example

12.33.3.7.1 SOMRT1061 PinIrq Application

12.33.3.7.1.1 Overview

This application demonstrates how to use pin interrupt functionality on the SOMRT1061 platform. It implements a real-time edge detection system that monitors pin state changes and provides visual feedback through an LED indicator.

12.33.3.7.1.2 Location

examples/PlatformSpecific/SOMRT1061/PinIrq

12.33.3.7.1.3 Supported Platforms

- SOMRT1061

12.33.3.7.1.4 Application Description

The PinIrq application showcases interrupt-driven GPIO monitoring using NetBurner's RTOS capabilities. The program:

- Monitors pin 30 for edge transitions (both rising and falling edges)
- Uses a semaphore-based notification system to handle interrupts safely
- Provides real-time feedback through pin 78 (LED output)
- Tracks and reports the total number of detected transitions
- Demonstrates proper interrupt handling in an RTOS environment

12.33.3.7.1.5 Key Features

Hardware Configuration

- **Input Pin:** Pin 30 (configured as input with interrupt capability)
- **Output Pin:** Pin 78 (LED indicator)
- **Edge Detection:** Both rising and falling edges

Software Architecture

- **Interrupt Service Routine:** Minimal ISR that posts to a semaphore
- **Task-based Processing:** Dedicated task handles the actual pin change logic
- **Thread-safe Communication:** Uses OS semaphores for inter-task communication
- **Real-time Monitoring:** Continuous status reporting every second

12.33.3.7.1.6 How It Works

1. **Initialization:** The application configures pin 30 as input and pin 78 as output
2. **Interrupt Setup:** Registers an interrupt handler for pin 30 that triggers on both edges
3. **Event Handling:** When a pin transition occurs:
 - The interrupt handler (`NotifyFunc`) posts to a semaphore
 - The `PinChangeTask` wakes up and processes the event
 - The transition counter is incremented
 - The LED state is updated to follow the input pin state
4. **Status Reporting:** Main loop continuously prints the current transition count and pin state

12.33.3.7.1.7 Code Structure

Main Components

- **NotifyFunc():** Interrupt service routine that signals pin changes
- **PinChangeTask():** Task that handles pin change processing
- **UserMain():** Main application loop with status reporting
- **Semaphore (NotifySem):** Synchronization primitive for interrupt handling

Global Variables

- **Transitions:** Counter tracking total number of edge detections
- **irq_pin_num:** Pin number for interrupt monitoring (pin 30)

12.33.3.7.1.8 Usage

1. Connect a switch or signal source to pin 30
2. Connect an LED to pin 78 to observe the output
3. Compile and upload the application to the SOMRT1061
4. Monitor the serial output to see transition counts and pin states
5. Toggle the input on pin 30 to observe the LED response and counter updates

12.33.3.7.1.9 Expected Output

The application will continuously output status information in the format:

```
Running SOMRT1061 PinIrq
{We have detected X edges pin is currently: Y
```

Where X is the total transition count and Y is the current pin state (0 or 1).

12.33.3.7.1.10 Technical Notes

- The interrupt handler is kept minimal to avoid issues in interrupt context
- All significant processing is performed in task context for safety
- The LED output inverts the input state, providing clear visual feedback
- System diagnostics are enabled for debugging purposes

12.33.3.7.1.11 Dependencies

- NetBurner RTOS
- Pin interrupt functionality
- Standard NetBurner GPIO libraries

12.33.3.8 PWM

SOMRT1061 PWM Examples

- [FlexPWM 3-Channel](#)
- [QTMR PWM](#)

12.33.3.8.1 FlexPWM 3-Channel

12.33.3.8.1.1 Overview

This example has been ported from the NXP Freescale Software Library (FSL).

The PWM project is a simple demonstration program of the SDK PWM driver. The pulse width modulator (PWM) module contains PWM submodules, each of which is set up to control a single half-bridge power stage. Fault channel support is provided. This PWM module can generate various switching patterns, including highly sophisticated waveforms. It can be used to control all known Switched Mode Power Supplies (SMPS) topologies.

The project uses eFlexPWM to generate A-phase pwm, B-phase pwm and C-phase pwm through submodule 0, submodule 1, submodule 2.

Submodule 0 can generate one complementary PWM: PWM A and PWM B. For PWM A, PWM A(1kHz 50% duty cycle) is setup, PWM A works based on SignedCenterAligned. PWM B operates in PWM A complementary mode, so the dutycycle field of PWM B does not matter. To prevent short circuits, the dead time count is set, about 650ns. Submodule 1 and submodule 2 are set to MasterSync. This means that submodule 1 and submodule 2 are initialized synchronously from submodule 0. In MasterSync mode, submodule 0 can be used as the main module to generate control signals to control other modules.

This program is set to center-aligned PWM mode, and the duty cycle and position of the PWM can be changed by modifying the value of pwmVal in this mode.

In this project, the duty cycle of submodule 0 is pwmVal, the duty cycle of submodule 1 is pwmVal divided by 2 and the duty cycle of submodule 2 is pwmVal divided by 4.

PWM_SetPwmLdok() can issue the load command to multiple submodules at the same time. The values are loaded immediately if kPWM_ReloadImmediate option was chosen during config. Else the values are loaded at the next PWM reload point.

The log below shows example output of the PWM driver demo in the oscilloscope :

12.33.3.8.2 QTMR PWM

Location: examples/PlatformSpecific/SOMRT1061/PWM

Supported Platforms: SOMRT1061

The QTMR project is a demonstration program of the SDK Quad Timer (QTMR) driver's input capture and output pwm feature.

This has been ported from the NXP Freescale Software Library (FSL).

The example sets up a QTMR channel for input capture. Once the input signal is received, the example will print the capture frequency value while the check is interrupted and waiting for the capture frequency to stabilize.

The example also sets up one QTMR channel to output pwm. The user should probe a 50Khz PWM signal output with 50% dutycycle with a oscilloscope.

12.33.3.8.2.1 SDK version

- Version: 2.16.000

12.33.3.8.2.2 Hardware requirements

- DEV-SOMRT1061
- Personal Computer
- Serial terminal program connected to the DEV-SOMRT1061 RS-232 port

12.33.3.9 SEMC Simple

Location: examples/PlatformSpecific/SOMRT1061/SEMC

12.33.3.9.1 SOMRT1061 Smart External Memory Controller (SEMC) Simple Example

12.33.3.9.1.1 Overview

This example demonstrates the basic usage of the Smart External Memory Controller (SEMC) on the SOMRT1061 platform. The SEMC provides an interface to external memory devices with configurable timing and bus width settings.

12.33.3.9.1.2 Supported Platforms

- SOMRT1061

12.33.3.9.1.3 Application Description

The main application (main.cpp) provides an interactive demonstration of SEMC functionality with the following features:

Key Components

- **SEMC Configuration:** Configures the external memory controller with 8-bit bus width, synchronous clock mode, and burst operation
- **Clock Management:** Sets up appropriate clock multiplexers and dividers for SEMC operation
- **Interactive Testing:** Command-line interface for testing memory operations

Configuration Parameters

The SEMC is configured with the following settings:

```
Bus Width: 8-bit
Clock Mode: Synchronous
Burst Mode: 16-word burst
Column Address Width: 4-bit
Address Multiplexing: Enabled
```

Timing Configuration

- Setup times and hold times are configured for reliable memory access
- Clock dividers are set to achieve proper SEMC frequency
- USB PLL bypass is utilized during memory operations

Test Constants

- **Test Address Offset:** 0xA5
- **Test Data (16-bit):** 0x5A5A
- **Test Data (8-bit):** 0x5A

12.33.3.9.1.4 Interactive Commands

The application provides a command-line interface with the following options:

Command	Function	Description
R	Read	Reads data from the test address offset and displays the result
W	Write	Writes test data to the test address offset
T	Test Variable	Writes 0xDEADBEEF to a test variable in external memory
F	Fast Read	Performs 4096 consecutive read operations for performance testing
C	Continuous Write	Performs 4096 consecutive write operations with incremental data

12.33.3.9.1.5 Memory Layout

The application uses a special memory section `DATABUS_VAR_SECT` for placing variables in external memory. The `TestVar` variable is specifically allocated to this section to demonstrate external memory usage.

12.33.3.9.1.6 Clock Configuration

The application configures several clock domains:

- **SEMC Clock:** Derived from USB1 PLL with appropriate dividers
- **CPU Clock:** System CPU frequency
- **UART Clock:** For serial communication
- **USB PLL:** Used as clock source with bypass capability

12.33.3.9.1.7 Usage

1. **Compile and Flash:** Build the application for SOMRT1061 and flash to the device
2. **Serial Connection:** Connect to the device via UART to see output and provide input
3. **Interactive Testing:** Use the command interface to test different memory operations
4. **Monitor Output:** Observe memory access results and frequency information

12.33.3.9.1.8 Expected Output

Upon startup, the application displays:

- Application name and version
- SEMC frequency information
- UART frequency information
- Interactive command prompt

12.33.3.9.1.9 Technical Notes

Memory Access Patterns

- Single byte operations for basic read/write testing
- Burst operations for performance evaluation
- Variable placement in external memory sections

Clock Management

- USB PLL bypass is enabled during memory operations to ensure stable timing
- Multiple data synchronization barriers (`dsb`) are used to ensure proper instruction ordering
- Clock frequencies are displayed for debugging and verification

Error Handling

The application includes basic system diagnostics and proper initialization sequences to ensure reliable operation.

12.33.3.9.1.10 Dependencies

- NetBurner RTOS libraries
- FSL (Freescale) clock management libraries
- SEMC hardware abstraction layer
- Standard C libraries for I/O operations

12.33.3.9.1.11 Development Notes

- Remove `EnableSystemDiagnostics()` call for production builds
- Adjust timing parameters based on specific external memory device requirements
- Consider memory access patterns for optimal performance
- Ensure proper pin configuration for SEMC signals

12.33.3.10 SEMC to SRAM, FPGA, LCD

SEMC SRAM Example

Example application demonstrating the use of the Smart External Memory Controller (SEMC) on the NetBurner SOMRT1061-200IR module for interfacing with external SRAM devices.

12.33.3.10.0.1 Overview

This example shows how to:

- Configure the SEMC controller for 8-bit or 16-bit external SRAM
- Calculate proper timing parameters based on device datasheets
- Perform comprehensive memory testing
- Access external memory using different data widths (byte, word, dword)
- Measure memory performance

12.33.3.10.0.2 Additional Documentation

- [Document Index](#)
- [Quick Reference](#)
- [Hardware Connections](#)

12.33.3.10.0.3 Hardware Requirements

NetBurner Module

- **SOMRT1061-200IR** (NXP i.MX RT1061 microcontroller)

External Memory Device

- Asynchronous SRAM (8-bit or 16-bit data bus)
- Typical devices:
 - IS61WV51216BLL (512K x 16-bit SRAM)
 - IS61C5128AL (512K x 8-bit SRAM)
 - CY62157EV30LL (512K x 16-bit SRAM)
 - Similar devices with compatible timing

Required Connections

The SEMC interface uses dedicated pins on the RT1061. Connect your external SRAM to the following pins:

Data Bus Connections

8-bit Configuration:**

- D[7:0] -> EMC_00 to EMC_07

16-bit Configuration:**

- D[7:0] -> EMC_00 to EMC_07 (lower byte)
- D[15:8] -> EMC_30 to EMC_37 (upper byte)

Address Bus Connections

Number of address pins needed depends on SRAM size:

- A[0] -> EMC_09
- A[1] -> EMC_10
- A[2] -> EMC_11
- A[3] -> EMC_12
- A[4] -> EMC_13
- A[5] -> EMC_14
- A[6] -> EMC_15
- A[7] -> EMC_16
- A[8] -> EMC_41
- A[9] -> B0_00
- A[10] -> B0_01
- A[11] -> B0_02

Control Signal Connections

- **nWE** (Write Enable) -> EMC_19
- **nOE** (Output Enable) -> EMC_20
- **ADV** (Address Valid) -> EMC_22
- **CS** (Chip Select) -> EMC_41 (or B0_00, B0_01, B0_02 for CS1-CS3)

Optional Connections

- **CLK** -> SD_B0_02 or SD_B0_03 (for synchronous mode only)

Power Connections

- Connect SRAM VCC to appropriate voltage (typically 3.3V)
- Connect SRAM GND to ground
- Add 0.1uF decoupling capacitors near SRAM VCC pins

12.33.3.10.0.4 Memory Address Mapping

The SEMC controller maps external memory into the processor's address space:

Memory Map:

+-----+-----+	0x9FFFFFFF
Available SEMC	
Address Space	
(512 MB total)	
+-----+-----+	SEMC_Base <- SEMC_Base (Default configuration)
Internal Memory	
+-----+-----+	0x00000000

Default Configuration:**

- Base Address: SEMC_Base
- Size: 512KB (0x80000)

- Addressable range: SEMC_Base to 0x8007FFFF

You can modify these values in `main.cpp` to match your hardware:

```
#define SRAM_BASE_ADDR SEMC_Base
#define SRAM_SIZE      0x80000 // 512KB
```

12.33.3.10.0.5 Software Configuration

Selecting Bus Width

Edit `main.cpp` to select 8-bit or 16-bit bus width:

```
#define USE_16BIT_BUS true // Change to false for 8-bit SRAM
```

Timing Configuration

The example calculates timing parameters based on:

1. SEMC clock frequency (default: 100 MHz)
2. External SRAM datasheet specifications

Default timing specifications used:**

- Address setup: 15-20 ns
- Address hold: 10 ns
- Read enable: 40-50 ns
- Write enable: 40 ns
- Chip select setup: 20 ns

To adjust timing for your specific SRAM device:**

1. Consult your SRAM datasheet for timing specifications
2. Modify the `ConfigureSEMC_8bit()` or `ConfigureSEMC_16bit()` function
3. Use the provided macros for easy calculation:

```
// Example: For a SRAM requiring 25ns address setup time
cfg.addr_setup = CYCLES_TO_N_PLUS_1(NS_TO_CYCLES(25));
```

The macros handle the conversion:

- `NS_TO_CYCLES(ns)` - Converts nanoseconds to clock cycles
- `CYCLES_TO_N_PLUS_1(cycles)` - Adjusts for (n+1) timing parameters

Pin Assignment

Modify pin assignments if using different chip select or clock pins:

```
// Pin assignments - modify based on your hardware design
#define SEMC_CLK_PIN 67 // Clock output pin
#define SEMC_CS_PIN 68 // Chip select pin (CS0)
```

12.33.3.10.0.6 Application Features

1. Automatic SEMC Configuration

The application automatically configures the SEMC controller based on the selected bus width and calculates appropriate timing parameters.

2. Comprehensive Memory Testing

Runs multiple test patterns to verify memory functionality:

Walking 1's Test

- Writes and verifies a walking 1's pattern
- Detects stuck-at faults on data lines
- Catches address line shorts

Address Uniqueness Test

- Verifies each memory location is unique
- Detects address line aliasing
- Catches decoding issues

Random Pattern Test

- Multiple iterations with random data
- Comprehensive data integrity verification
- Stress testing capability

Byte Access Test

- Tests byte-level read/write operations
- Verifies byte-enable signals
- Critical for 8-bit operations

3. Access Method Demonstrations

The example demonstrates three access methods:

```
// Byte access (8-bit)
sram8[0] = 0x42;
uint8_t value = sram8[0];

// Word access (16-bit)
sram16[0] = 0x1234;
uint16_t word = sram16[0];

// Dword access (32-bit)
sram32[0] = 0xDEADBEEF;
uint32_t dword = sram32[0];
```

4. Performance Measurement

Measures and reports:

- Sequential byte read/write throughput
- Sequential word read/write throughput
- Actual MB/s performance for different access patterns

12.33.3.10.0.7 Usage**1. Connect Hardware**

Connect your external SRAM device to the SEMC pins as described in the Hardware Requirements section.

2. Configure Software

Edit `main.cpp` to match your hardware:

- Set `USE_16BIT_BUS` to match your SRAM data bus width
- Adjust `SRAM_SIZE` to match your SRAM capacity
- Modify timing parameters if needed for your specific device

3. Build and Load

Build the application and load it to your SOMRT1061 module:

```
make clean
make PLATFORM=SOMRT1061
make load DEVIP=<your_device_ip>
```

4. Monitor Output

Connect to the serial console to see the application output:

```
=====
SEMC SRAM Example
=====
Platform: SOMRT1061-200IR
MCU: NXP i.MX RT1061
=====

Selected configuration: 16-bit data bus

Configuring SEMC for 16-bit SRAM...
SEMC Clock: 100 MHz
Clock period: 10 ns
Configuration complete
...

=====
COMPREHENSIVE MEMORY TEST SUITE
=====
Base Address: SEMC_Base
Size: 524288 bytes (512 KB)
=====

Test 1: Walking 1's Pattern
Walking 1's test: SEMC_Base (524288 bytes)...
Walking 1's test PASSED

Test 2: Address Uniqueness
...

=== Performance Demonstration ===
Test size: 8192 bytes

Performance Results:
Byte write: 1234 ticks (XX.XX MB/s)
Byte read: 1156 ticks (XX.XX MB/s)
...
```

12.33.3.10.0.8 Troubleshooting

Memory Tests Fail

Problem:** Walking 1's test or address uniqueness test fails

Solutions:**

1. Verify all pin connections between SOMRT1061 and SRAM
2. Check power supply to SRAM (should be stable 3.3V)
3. Add or verify decoupling capacitors near SRAM
4. Check SRAM datasheet and increase timing margins
5. Verify ground connections

Example timing adjustment:**

```
// Increase read timing by 20ns
cfg.rd_en_hi = CYCLES_TO_N_PLUS_1(NS_TO_CYCLES(70)); // Was 50ns
```

Intermittent Errors

Problem:** Tests sometimes pass, sometimes fail

Solutions:**

1. Add timing margin (increase all timing parameters by 20-30%)
2. Check signal integrity with oscilloscope
3. Reduce SEMC clock frequency if possible
4. Check for noise on power supply
5. Verify PCB layout follows good design practices

Build Errors

Problem:** Compilation errors

Solutions:**

1. Verify NNDK_ROOT is set correctly
2. Ensure PLATFORM=SOMRT1061 is set
3. Check that [semc.h](#) is available in your SDK
4. Verify you're using a compatible NetBurner SDK version

No Output on Console

Problem:** Application loads but no serial output

Solutions:**

1. Verify serial connection settings (115200 baud, 8N1)
2. Check that [init\(\)](#) is called in `UserMain()`
3. Try a simple `printf` test before SEMC configuration

12.33.3.10.0.9 Advanced Usage

Multiple Chip Selects

To use multiple SRAM devices with different chip selects:

```
// First SRAM - CS0
SEMC_cfg_t cfg0 = ConfigureSEMC_16bit();
cfg0.csPin = Pin_EMC_41; // CS0
ConfigureSEMC(SEMC_Base, 0x80000, cfg0);

// Second SRAM - CS1 (non-overlapping address)
SEMC_cfg_t cfg1 = ConfigureSEMC_16bit();
cfg1.csPin = Pin_B0_00; // CS1
ConfigureSEMC(0x80080000, 0x80000, cfg1);

// Access first SRAM
uint8_t *sram_cs0 = (uint8_t *)SEMC_Base;
sram_cs0[0] = 0x42;

// Access second SRAM
uint8_t *sram_cs1 = (uint8_t *)0x80080000;
sram_cs1[0] = 0xAB;
```

Synchronous Mode

For synchronous PSRAM devices with burst capability:

```
SEMC_cfg_t syncConfig = {};

// Synchronous configuration
syncConfig.busWidth = SEMC_BusWidth_t::Width_16;
syncConfig.clkMode = SEMC_ClkMode_t::Sync;
syncConfig.burstLen = SEMC_Burst_t::Burst_8;
```

```

syncConfig.colAddrWidth = SEMC_ColAddrWidth_t::Width_8;

// Synchronous timing
syncConfig.cs_setup = 2;
syncConfig.cs_hold_min = 2;
syncConfig.addr_setup = 1;
syncConfig.addr_hold = 1;
syncConfig.wr_dat_setup = 1;
syncConfig.wr_dat_hold = 0;
syncConfig.latency = 3;           // Read latency cycles
syncConfig.rd_cycle = 5;         // Total read cycle
syncConfig.cs_min_intv = 1;
syncConfig.rd_hold = 1;

// Pin assignments
syncConfig.clkPin = Pin_SD_B0_02; // Clock is required for sync mode
syncConfig.csPin = Pin_EMC_41;

ConfigureSEMC(0x98000000, 0x400000, syncConfig); // 4MB PSRAM

```

Custom Timing Calculations

For precise timing based on your device datasheet:

```

// Example: IS61WV51216BLL SRAM Datasheet
// tAA (Address Access Time): 10ns
// tOHA (Output Hold Time): 3ns
// tWP (Write Pulse Width): 8ns
// tAS (Address Setup Time): 0ns
// tAH (Address Hold Time): 3ns

SEMC_cfg_t customTiming = {};

// Add 20% margin to all timing
const float TIMING_MARGIN = 1.2f;

// Calculate timing with margin
uint32_t tAA_cycles = NS_TO_CYCLES(10 * TIMING_MARGIN);
uint32_t tWP_cycles = NS_TO_CYCLES(8 * TIMING_MARGIN);
uint32_t tAS_cycles = NS_TO_CYCLES(0 * TIMING_MARGIN);
uint32_t tAH_cycles = NS_TO_CYCLES(3 * TIMING_MARGIN);

customTiming.busWidth = SEMC_BusWidth_t::Width_16;
customTiming.clkMode = SEMC_ClkMode_t::Async;
customTiming.muxMode = SEMC_AddrMux_t::Mux;

// Apply calculated timing
customTiming.addr_setup = CYCLES_TO_N_PLUS_1(tAS_cycles);
customTiming.addr_hold = CYCLES_TO_N_PLUS_1(tAH_cycles);
customTiming.rd_en_hi = CYCLES_TO_N_PLUS_1(tAA_cycles);
customTiming.wr_en_lo = CYCLES_TO_N_PLUS_1(tWP_cycles);
customTiming.wr_en_hi = CYCLES_TO_N_PLUS_1(tWP_cycles);

customTiming.clkPin = Pin_SD_B0_02;
customTiming.csPin = Pin_EMC_41;

ConfigureSEMC(SEMC_Base, 0x100000, customTiming);

```

12.33.3.10.0.10 Timing Parameter Reference

Asynchronous Mode Parameters (used in this example)

Parameter	Description	Units	Notes
cs_setup	Chip select setup before address valid	n+1 cycles	Time CS asserted before address
cs_hold_min	Minimum chip select hold after cycle	n+1 cycles	Time CS held after cycle end
addr_setup	Address setup before control signal	n+1 cycles	Address stable before nOE/nWE
addr_hold	Address hold after control signal	n+1 cycles	Address held after nOE/nWE
wr_en_lo	Write enable low pulse width	n+1 cycles	nWE low time
wr_en_hi	Write enable high period	n+1 cycles	nWE high time
rd_en_lo	Read enable low pulse width	n+1 cycles	nOE low time
rd_en_hi	Read enable high period	n+1 cycles	nOE high time, includes data valid
addr_wr_hold	Address to write data hold	n+1 cycles	Address held after write data
turnaround	Bus turnaround time	n cycles	Time between read/write cycles
cs_min_intv	Minimum CS interval	n+1 cycles	Minimum time between CS assertions

Synchronous Mode Parameters

Parameter	Description	Units	Notes
cs_setup	Chip select setup before clock	n+1 cycles	CS setup to clock edge
cs_hold_min	Chip select hold after clock	n+1 cycles	CS held after clock edge
addr_setup	Address setup to clock	n+1 cycles	Address stable before clock
addr_hold	Address hold from clock	n cycles	Address held after clock
wr_dat_setup	Write data setup	n+1 cycles	Data setup before clock
wr_dat_hold	Write data hold	n cycles	Data held after clock
latency	Read data latency	n cycles	Clock cycles before first data
rd_cycle	Total read cycle length	n+1 cycles	Complete read cycle time
rd_hold	Read data hold	n cycles	Data hold after clock
cs_min_intv	Minimum CS interval	n+1 cycles	Minimum time between operations

12.33.3.10.0.11 Memory Test Reference

Walking 1's Test

Tests each bit position independently by walking a single '1' bit through all positions.

What it detects:**

- Stuck-at-0 faults (bit always reads 0)
- Stuck-at-1 faults (bit always reads 1)
- Data line shorts to ground/VCC
- Basic address line functionality

Pattern:**

```
Address 0: 0x00000001
Address 1: 0x00000002
Address 2: 0x00000004
Address 3: 0x00000008
...
Address 31: SEMC_Base
Address 32: 0x00000001 (repeats)
```

Address Uniqueness Test

Writes the address value to each location, then verifies each location contains its unique address.

What it detects:**

- Address line aliasing (multiple addresses map to same location)
- Missing address line connections
- Address decoder problems
- Memory size mismatches

Pattern:**

```
Write to SEMC_Base: value SEMC_Base
Write to 0x80000004: value 0x80000004
Write to 0x80000008: value 0x80000008
...
Then verify each location
```

Random Pattern Test

Writes and verifies random data patterns with multiple iterations.

What it detects:**

- Data-dependent errors
- Timing-sensitive issues

- Crosstalk between data lines
- Pattern-sensitive failures

```
Usage:**
// Quick verification
TestRandomPattern(baseAddr, size, 1);

// Stress test
TestRandomPattern(baseAddr, size, 1000);
```

Byte Access Test

Specifically tests byte-level operations (8-bit access).

What it detects:**

- Byte enable signal problems
- Word alignment issues
- Byte-level data corruption

```
Pattern:**
Address 0: 0x00
Address 1: 0x01
Address 2: 0x02
...
Address 255: 0xFF
Address 256: 0x00 (repeats)
```

12.33.3.10.0.12 Performance Considerations

Bus Width Impact

8-bit bus:**

- Lower pin count (8 data pins)
- Suitable for byte-oriented data
- 32-bit access requires 4 bus cycles
- Typical: 10-30 MB/s throughput

16-bit bus:**

- Medium pin count (16 data pins)
- 2x throughput vs 8-bit
- 32-bit access requires 2 bus cycles
- Typical: 20-60 MB/s throughput

Access Pattern Optimization

Sequential access:**

```
// Efficient: Sequential access
for (uint32_t i = 0; i < size; i++) {
    sram8[i] = data[i];
}
```

Random access:**

```
// Less efficient: Random access
for (uint32_t i = 0; i < size; i++) {
    sram8[rand() % size] = data[i];
}
```

Data Type Selection

Choose the access width that matches your data:

```
// Byte data: Use uint8_t*
uint8_t *buffer = (uint8_t *)SRAM_BASE_ADDR;
buffer[i] = byte_value;

// Word data: Use uint16_t* (best for 16-bit bus)
uint16_t *buffer = (uint16_t *)SRAM_BASE_ADDR;
buffer[i] = word_value;

// Dword data: Use uint32_t*
uint32_t *buffer = (uint32_t *)SRAM_BASE_ADDR;
buffer[i] = dword_value;
```

12.33.3.10.0.13 API Reference

Configuration Functions

ConfigureSEMC_8bit()

Creates SEMC configuration for 8-bit asynchronous SRAM.

- **Returns:** [SEMC_cfg_t](#) structure
- **Use:** For 8-bit data bus SRAM devices

ConfigureSEMC_16bit()

Creates SEMC configuration for 16-bit asynchronous SRAM.

- **Returns:** [SEMC_cfg_t](#) structure
- **Use:** For 16-bit data bus SRAM devices

Memory Test Functions

TestWalking1s(baseAddr, sizeBytes)

Performs walking 1's test on specified memory region.

- **Parameters:**
 - baseAddr: Starting address
 - sizeBytes: Number of bytes to test
- **Returns:** true if passed, false if failed

TestAddressUniqueness(baseAddr, sizeBytes)

Verifies each address location is unique.

- **Parameters:**
 - baseAddr: Starting address
 - sizeBytes: Number of bytes to test
- **Returns:** true if passed, false if failed

TestRandomPattern(baseAddr, sizeBytes, iterations)

Tests with random data patterns.

- **Parameters:**
 - baseAddr: Starting address
 - sizeBytes: Number of bytes to test
 - iterations: Number of test iterations
- **Returns:** true if passed, false if failed

TestByteAccess (baseAddr, sizeBytes)

Tests byte-level access patterns.

- **Parameters:**
 - baseAddr: Starting address
 - sizeBytes: Number of bytes to test
- **Returns:** true if passed, false if failed

RunMemoryTestSuite (baseAddr, sizeBytes)

Runs all memory tests in sequence.

- **Parameters:**
 - baseAddr: Starting address
 - sizeBytes: Number of bytes to test
- **Returns:** true if all tests passed

Demonstration Functions**DemoByteAccess ()**

Demonstrates 8-bit byte access operations.

DemoWordAccess ()

Demonstrates 16-bit word access operations.

DemoDwordAccess ()

Demonstrates 32-bit dword access operations.

DemoPerformance ()

Measures and displays memory performance metrics.

SRAM Device Examples

- IS61WV51216BLL - 512K x 16 SRAM (ISSI)
- CY62157EV30LL - 512K x 16 SRAM (Cypress)
- IS61C5128AL - 512K x 8 SRAM (ISSI)

12.33.3.10.0.15 Notes

1. Always add 10-20% timing margin beyond device datasheet minimums
 2. Test thoroughly with your specific hardware before deployment
 3. Monitor temperature effects on timing if operating in extreme conditions
 4. Use oscilloscope to verify signal integrity for high-speed operation
 5. Consider EMI/EMC requirements for your PCB design

12.33.3.10.1 Document Index**12.33.3.10.1.1 SEMC SRAM Example - Complete Project Index****Project Location**

C:\NetBurner\ClaudeWork\SEMC_SRAM\

File Overview**Source Code Files****src/main.cpp**

Purpose:** Complete SEMC SRAM example application

Contains:**

- UserMain() implementation
- SEMC configuration functions for 8-bit and 16-bit
- Comprehensive inline documentation

src/main_test.cpp**

- Memory test functions (4 different test patterns)
- Performance measurement functions
- Access method demonstrations

Key Functions

- ConfigureSEMC_8bit() - Create 8-bit configuration
 - ConfigureSEMC_16bit() - Create 16-bit configuration
 - TestWalking1s() - Walking 1's test pattern
 - TestAddressUniqueness() - Address uniqueness verification
 - TestRandomPattern() - Random data pattern test
 - TestByteAccess() - Byte-level access test
 - RunMemoryTestSuite() - Complete test suite
 - DemoByteAccess() - Byte access demonstration
 - DemoWordAccess() - Word access demonstration
 - DemoDwordAccess() - Dword access demonstration
 - DemoPerformance() - Performance measurement
-

src/semc_utils.h

Purpose:** Utility functions and helper macros

Contains:**

- Timing calculation macros
- Configuration validation functions
- SRAM device timing presets
- Helper functions for configuration
- Debug print functions

Key Macros:**

- NS_TO_CYCLES () - Convert nanoseconds to cycles
- CYCLES_TO_N_PLUS_1 () - Calculate register values
- IS_ALIGNED () - Check address alignment
- IS_POWER_OF_2 () - Validate memory size

Key Functions:**

- CreateSEMCConfigFromSpec () - Auto-generate configuration
- PrintSEMCConfig () - Display configuration details
- ValidateSEMCConfig () - Validate configuration

Timing Presets:**

- SRAM_10NS - Ultra-fast SRAM (10ns access)
- SRAM_55NS - Standard SRAM (55ns access)
- SRAM_70NS - Slower SRAM (70ns access)

makefile (12 lines)

Purpose:** NetBurner build configuration

Settings:**

- Project name: SEMC_SRAM

- Signal integrity analysis

Which File Should I Read First?**For Developers**New to SEMC?** -> Start with **README.txt** (complete guide)Experienced developer?** -> Jump to **QuickReference.dox** (fast start)Need specific code?** -> Look in **src/main_tests.cpp** (all examples)**For Hardware Engineers**Designing PCB?** -> Read **HardwareConnections.dox** firstTroubleshooting hardware?** -> Check **HardwareConnections.dox** issues sectionNeed pin mapping?** -> **QuickReference.dox** or **HardwareConnections.dox**

For Project Management

Evaluating feasibility? ** -> Check **README.txt** requirements section

Quick Start Path

Option 1: Minimal (10 minutes)

1. Read **QuickReference.dox** - Essential configuration
2. Modify **src/main.cpp** - Set USE_16BIT_BUS
3. Build and load - `make clean && make PLATFORM=SOMRT1061`
4. Monitor serial output - See test results

Option 2: Thorough (30 minutes)

1. Read **README.txt** - Complete understanding
2. Read **HardwareConnections.dox** - Verify connections
3. Modify **src/main.cpp** - Configure for your hardware
4. Build and load
5. Run tests and verify results

Option 3: Comprehensive (2 hours)

1. Read all documentation
 2. Study **src/main.cpp** - Understand all functions
 3. Review [src/semc_utils.h](#) - Learn utilities
 4. Modify for your specific SRAM device
 5. Build, load, and test thoroughly
 6. Verify with oscilloscope
-

Finding Specific Information

Configuration

- **8-bit setup:** README.txt -> Software Configuration
- **16-bit setup:** README.txt -> Software Configuration
- **Timing calc:** QuickReference.dox -> Timing Calculation
- **Pin assignments:** All docs have pin tables

Hardware

- **Pin connections:** HardwareConnections.dox -> Pin Mapping
- **PCB design:** HardwareConnections.dox -> PCB Guidelines

Performance

- **Optimization:** README.txt -> Performance Considerations
- **Measurement:** src/main.cpp -> DemoPerformance()

Advanced Topics

- **Multiple CS:** README.txt -> Advanced Usage
- **Sync mode:** README.txt -> Synchronous Mode
- **Custom timing:** QuickReference.dox -> Custom Calculations

Common Tasks - Where to Look

Task	Primary File	Section
First time setup	README.txt	Usage -> Steps 1-4
Change bus width	src/main.cpp	Line ~108: USE_16BIT_BUS
Adjust timing	src/main.cpp	ConfigureSEMC_8bit/16bit
Add new SRAM	src/semc_utils.h	Add timing preset
Debug hardware	HardwareConnections.dox	Common Issues
Optimize performance	README.txt	Performance Considerations
Multiple devices	README.txt	Advanced Usage -> Multiple CS
Build errors	README.txt	Troubleshooting -> Build Errors
Test failures	README.txt	Troubleshooting -> Memory Tests
Pin mapping	QuickReference.dox	Pin Connections

Hardware Datasheets

- **RT1061:** NXP i.MX RT1061 Reference Manual
- **SRAM:** Check your specific device datasheet

12.33.3.10.2 Quick Reference

SEMC Quick Reference Guide

Essential Configuration Steps

1. Basic 8-bit SRAM Setup

```
#include <semc.h>

// Create configuration
SEMC_cfg_t cfg = {};
cfg.busWidth = SEMC_BusWidth_t::Width_8;
cfg.clkMode = SEMC_ClkMode_t::Async;
cfg.burstLen = SEMC_Burst_t::Burst_1;
cfg.muxMode = SEMC_AddrMux_t::Mux;
cfg.colAddrWidth = SEMC_ColAddrWidth_t::Width_0;

// Timing (for 100 MHz SEMC clock)
cfg.cs_setup = 1;           // 2 cycles
cfg.cs_hold_min = 1;        // 2 cycles
cfg.addr_setup = 1;         // 2 cycles
```

```

cfg.addr_hold = 1;           // 2 cycles
cfg.wr_en_lo = 3;           // 4 cycles
cfg.wr_en_hi = 3;           // 4 cycles
cfg.rd_en_lo = 3;           // 4 cycles
cfg.rd_en_hi = 4;           // 5 cycles
cfg.turnaround = 2;         // 2 cycles

// Pins
cfg.clkPin = Pin_SD_B0_02;
cfg.csPin = Pin_EMCC_41;

// Apply configuration
ConfigureSEMC(SEMC_Base, 0x80000, cfg); // 512KB at SEMC_Base

```

2. Basic 16-bit SRAM Setup

```

// Same as 8-bit, but change bus width:
cfg.busWidth = SEMC_BusWidth_t::Width_16;

```

3. Memory Access

```

// Get pointers
uint8_t *sram8 = (uint8_t *)SEMC_Base;
uint16_t *sram16 = (uint16_t *)SEMC_Base;
uint32_t *sram32 = (uint32_t *)SEMC_Base;

// Write/read bytes
sram8[0] = 0x42;
uint8_t value = sram8[0];

// Write/read words
sram16[0] = 0x1234;
uint16_t word = sram16[0];

// Write/read dwords
sram32[0] = 0xDEADBEEF;
uint32_t dword = sram32[0];

```

Timing Calculation

Formula for Async Mode

```

Cycles needed = ceil(time_ns / clock_period_ns)
Register value = cycles - 1 (for n+1 parameters)

```

Example for 100 MHz clock (10 ns period):

- 50 ns requirement: $\text{ceil}(50/10) = 5$ cycles, register = 4
- 25 ns requirement: $\text{ceil}(25/10) = 3$ cycles, register = 2

Common SRAM Speeds

SRAM Speed	Address Access	Min Read Cycle	Min Write Cycle
10 ns	10 ns	10 ns	10 ns
55 ns	55 ns	55 ns	55 ns
70 ns	70 ns	70 ns	70 ns

Pin Connections Quick Reference

Data Bus

8-bit: EMC_00 to EMC_07
 16-bit: EMC_00 to EMC_07 (lower byte)
 EMC_30 to EMC_37 (upper byte)

Address Bus (use as many as needed)

A[0-7]: EMC_09 to EMC_16
 A[8]: EMC_41
 A[9]: B0_00
 A[10]: B0_01
 A[11]: B0_02

Control Signals

nWE: EMC_19 (Write Enable)
 nOE: EMC_20 (Output Enable)
 ADV: EMC_22 (Address Valid)

Chip Select Options

CS0: Pin_EMC_41 (default, function 0)
 CS1: Pin_B0_00 (function 6)
 CS2: Pin_B0_01 (function 6)
 CS3: Pin_B0_02 (function 6)

Clock (Sync mode only)

CLK0: Pin_SD_B0_02 or Pin_EMC_40
 CLK1: Pin_SD_B0_03 or Pin_AD_B0_11

Memory Map

Common Memory Sizes

Size	Hex Value	Address Lines Needed
64 KB	0x10000	16 (A0-A15)
128 KB	0x20000	17 (A0-A16)
256 KB	0x40000	18 (A0-A17)
512 KB	0x80000	19 (A0-A18)
1 MB	0x100000	20 (A0-A19)
2 MB	0x200000	21 (A0-A20)
4 MB	0x400000	22 (A0-A21)

Troubleshooting Quick Fixes

Memory Test Fails

1. Add 20% timing margin to all parameters
2. Verify power supply is stable 3.3V
3. Check all pin connections
4. Add decoupling capacitors (0.1uF near SRAM VCC)

Intermittent Errors

1. Increase all timing by 2-3 cycles
2. Check signal integrity with oscilloscope
3. Add series termination resistors (33ohm) on data lines

Timing Parameters Reference

Asynchronous Mode (n+1 = actual cycles is value + 1)

Parameter	Description	Type	Typical
cs_setup	CS setup before address	n+1	1-2
cs_hold_min	CS hold after cycle	n+1	1-2
addr_setup	Address setup before control	n+1	1-2
addr_hold	Address hold after control	n+1	1-2
wr_en_lo	Write enable low time	n+1	3-5
wr_en_hi	Write enable high time	n+1	3-5
rd_en_lo	Read enable low time	n+1	3-5
rd_en_hi	Read enable high time	n+1	4-6
addr_wr_hold	Address to write hold	n+1	1-2
turnaround	Bus turnaround time	n	2
cs_min_intv	Minimum CS interval	n+1	1-2

Configuration Templates

Ultra-Fast SRAM (10ns)

```
cfg.cs_setup = 0;
cfg.rd_en_lo = 1;
cfg.rd_en_hi = 2;
cfg.wr_en_lo = 1;
cfg.wr_en_hi = 2;
```

Standard SRAM (55ns)

```
cfg.cs_setup = 1;
cfg.rd_en_lo = 3;
cfg.rd_en_hi = 4;
cfg.wr_en_lo = 3;
cfg.wr_en_hi = 3;
```

Slow SRAM (70ns or slower)

```
cfg.cs_setup = 2;
cfg.rd_en_lo = 4;
cfg.rd_en_hi = 6;
cfg.wr_en_lo = 4;
cfg.wr_en_hi = 5;
```

Memory Test Functions

```
// Quick test (first 4KB)
TestWalking1s(SEMC_Base, 4096);

// Full test
TestWalking1s(SEMC_Base, SRAM_SIZE);
TestAddressUniqueness(SEMC_Base, SRAM_SIZE);
TestRandomPattern(SEMC_Base, SRAM_SIZE, 3);
TestByteAccess(SEMC_Base, SRAM_SIZE);

// Complete test suite
RunMemoryTestSuite(SEMC_Base, SRAM_SIZE);
```

Multiple Chip Selects

```
// CS0: 512KB at SEMC_Base
SEMC_cfg_t cfg0 = ConfigureSEMC_16bit();
cfg0.csPin = Pin_EMC_41;
ConfigureSEMC(SEMC_Base, 0x80000, cfg0);

// CS1: 512KB at 0x80080000 (non-overlapping)
SEMC_cfg_t cfg1 = ConfigureSEMC_16bit();
cfg1.csPin = Pin_B0_00;
ConfigureSEMC(SEMC_Base + 0x80000, 0x80000, cfg1);
```

Performance Tips

Maximize Throughput

1. Use 16-bit bus width when possible

2. Access data with matching width (use uint16_t* for 16-bit bus)
3. Keep data aligned to natural boundaries
4. Use sequential access patterns
5. Minimize random access

Typical Performance (100 MHz SEMC)

- 8-bit bus: 10-30 MB/s
- 16-bit bus: 20-60 MB/s
- Burst mode (sync): 80-100 MB/s

Common Defines

```
// Configuration
#define USE_16BIT_BUS true           // or false for 8-bit
#define SRAM_BASE_ADDR SEMC_Base
#define SRAM_SIZE 0x80000           // 512KB
#define SEMC_CLOCK_MHZ 100

// Pins
#define SEMC_CLK_PIN 67
#define SEMC_CS_PIN 68
```

Validation Checklist

- ☐ Base address is SEMC_Base or higher
- ☐ Size is power of 2
- ☐ Base address aligned to size
- ☐ No overlap with other CS regions
- ☐ Timing parameters meet datasheet requirements
- ☐ All required pins connected
- ☐ Power supply stable 3.3V
- ☐ Decoupling capacitors present
- ☐ Memory tests pass

Debug Output

Enable detailed timing output:

```
printf("SEMC Clock: %u MHz\n", SEMC_CLOCK_MHZ);
printf("Clock period: %u ns\n", 1000 / SEMC_CLOCK_MHZ);
printf("Read cycle: %u cycles = %u ns\n",
      (rd_en_lo+1) + (rd_en_hi+1),
      ((rd_en_lo+1) + (rd_en_hi+1)) * (1000/SEMC_CLOCK_MHZ));
```

Useful Macros

```
// From semc_utils.h
#define NS_TO_CYCLES(ns) (((ns) * SEMC_CLOCK_MHZ + 999) / 1000)
#define CYCLES_TO_NS_PLUS_1(cycles) ((cycles) > 0 ? (cycles) - 1 : 0)
#define IS_ALIGNED(addr, size) (((addr) & ((size) - 1)) == 0)
#define IS_POWER_OF_2(size) (((size) != 0) && (((size) & ((size) - 1)) == 0))
```

12.33.3.10.3 Hardware Connections

12.33.3.10.3.1 SEMC Hardware Connection Guide

Overview

This document provides detailed hardware connection information for interfacing external SRAM to the NetBurner SOMRT1061-200IR module using the SEMC (Smart External Memory Controller) interface.

WARNING** THIS GUIDE IS ONLY FOR REFERENCE PURPOSES. IT IS THE RESPONSIBILITY OF THE DESIGNER TO CHECK EACH PIN, SIGNAL AND FUNCTION FOR THEIR PARTICULAR DESIGN.

SOMRT1061-200IR Pin Mapping

Complete SEMC Pin List

The following pins on the SOMRT1061-200IR are dedicated to SEMC functionality:

Data Bus Pins

Lower Byte (D[7:0]) - Required for all configurations:**

SEMC Signal	Pin Name	Pin Function	Description
DATA[0]	EMC_00	GPIO_EMC_00	Data bit 0 (LSB)
DATA[1]	EMC_01	GPIO_EMC_01	Data bit 1
DATA[2]	EMC_02	GPIO_EMC_02	Data bit 2
DATA[3]	EMC_03	GPIO_EMC_03	Data bit 3
DATA[4]	EMC_04	GPIO_EMC_04	Data bit 4
DATA[5]	EMC_05	GPIO_EMC_05	Data bit 5
DATA[6]	EMC_06	GPIO_EMC_06	Data bit 6
DATA[7]	EMC_07	GPIO_EMC_07	Data bit 7

Upper Byte (D[15:8]) - Required for 16-bit configurations only:**

SEMC Signal	Pin Name	Pin Function	Description
DATA[8]	EMC_30	GPIO_EMC_30	Data bit 8
DATA[9]	EMC_31	GPIO_EMC_31	Data bit 9
DATA[10]	EMC_32	GPIO_EMC_32	Data bit 10
DATA[11]	EMC_33	GPIO_EMC_33	Data bit 11
DATA[12]	EMC_34	GPIO_EMC_34	Data bit 12
DATA[13]	EMC_35	GPIO_EMC_35	Data bit 13
DATA[14]	EMC_36	GPIO_EMC_36	Data bit 14
DATA[15]	EMC_37	GPIO_EMC_37	Data bit 15 (MSB)

Address Bus Pins

Number of address pins needed depends on memory size:**

SEMC Signal	Pin Name	Pin Function	Max Memory with this Address
ADDR[0]	EMC_09	GPIO_EMC_09	Required for all sizes
ADDR[1]	EMC_10	GPIO_EMC_10	Required for all sizes
ADDR[2]	EMC_11	GPIO_EMC_11	Required for all sizes
ADDR[3]	EMC_12	GPIO_EMC_12	Required for all sizes
ADDR[4]	EMC_13	GPIO_EMC_13	Required for all sizes
ADDR[5]	EMC_14	GPIO_EMC_14	Required for all sizes
ADDR[6]	EMC_15	GPIO_EMC_15	Required for all sizes

SEMC Signal	Pin Name	Pin Function	Max Memory with this Address
ADDR[7]	EMC_16	GPIO_EMC_16	Required for all sizes
ADDR[8]	EMC_41	GPIO_EMC_41	> 128KB
ADDR[9]	B0_00	GPIO_B0_00	> 256KB
ADDR[10]	B0_01	GPIO_B0_01	> 512KB
ADDR[11]	B0_02	GPIO_B0_02	> 1MB

Control Signal Pins

Required for all configurations:**

SEMC Signal	Pin Name	Pin Function	Description
WE_n	EMC_19	GPIO_EMC_19	Write Enable (active low)
OE_n	EMC_20	GPIO_EMC_20	Output Enable (active low)
ADV	EMC_22	GPIO_EMC_22	Address Valid (for multiplexed mode)

Chip Select Pins

Choose one CS pin for each memory device:**

SEMC Signal	Pin Name	Pin Function	Notes
CS0_n	EMC_41	GPIO_EMC_41	Default, most common
CS1_n	B0_00	GPIO_B0_00	For multiple devices
CS2_n	B0_01	GPIO_B0_01	For multiple devices
CS3_n	B0_02	GPIO_B0_02	For multiple devices

Byte Enable Pins (16-bit only)

Required for 16-bit configurations:**

SEMC Signal	Pin Name	Pin Function	Description
DQM0	EMC_08	GPIO_EMC_08	Lower Byte Mask
DQM1	EMC_38	GPIO_EMC_38	Upper Byte Mask

Clock Pin (Synchronous mode only)

Optional - only needed for synchronous/burst memory:**

SEMC Signal	Pin Name	Pin Function	Notes
CLK0	SD_B0_02	GPIO_SD_B0_02	Primary clock option
CLK0_ALT	EMC_40	GPIO_EMC_40	Alternative clock
CLK1	SD_B0_03	GPIO_SD_B0_03	Secondary clock option
CLK1_ALT	AD_B0_11	GPIO_AD_B0_11	Alternative clock

Example SRAM Connections

Example 1: 8-bit SRAM (512KB) - IS61C5128AL

Memory Device:** ISSI IS61C5128AL (512K x 8-bit SRAM)

Connection Table

SRAM Pin	Function	Connect To	SOMRT1061 Pin
1-8	DQ0-DQ7	Data	EMC_00 to EMC_07

SRAM Pin	Function	Connect To	SOMRT1061 Pin
9	VCC	Power	3.3V
10	A0	Address	EMC_09
11	A1	Address	EMC_10
12	A2	Address	EMC_11
13	A3	Address	EMC_12
14	A4	Address	EMC_13
15	A5	Address	EMC_14
16	A6	Address	EMC_15
17	A7	Address	EMC_16
18	CE_n	Chip Sel	EMC_41 (CS0)
19	WE_n	Write En	EMC_19
20	OE_n	Output En	EMC_20
21	A8	Address	EMC_41
22	A9	Address	B0_00
23	A10	Address	B0_01
24	A11	Address	B0_02
25-28	A12-A15	Address	Not used (512K only uses A0-A11)
29	A16	Address	Not used
30	A17	Address	Not used
31	A18	Address	Not used
32	GND	Ground	GND

Notes:**

- Add 0.1uF decoupling capacitor between VCC (pin 9) and GND (pin 32)
- For 512KB (512K x 8), you need A0-A18 (19 address lines)
- This device is 5V tolerant but operates at 3.3V

Example 2: 16-bit SRAM (512KB) - IS61WV51216BLL

Memory Device:** ISSI IS61WV51216BLL (512K x 16-bit SRAM)

Connection Table

SRAM Pin	Function	Connect To	SOMRT1061 Pin
1	A4	Address	EMC_13
2	A3	Address	EMC_12
3	A2	Address	EMC_11
4	A1	Address	EMC_10
5	A0	Address	EMC_09
6	CE_n	Chip Sel	EMC_41 (CS0)
7	DQ0	Data	EMC_00
8	DQ1	Data	EMC_01
9	DQ2	Data	EMC_02
10	DQ3	Data	EMC_03
11	VCC	Power	3.3V
12	GND	Ground	GND
13	DQ4	Data	EMC_04
14	DQ5	Data	EMC_05
15	DQ6	Data	EMC_06
16	DQ7	Data	EMC_07

SRAM Pin	Function	Connect To	SOMRT1061 Pin
17	WE_n	Write En	EMC_19
18	A17	Address	Not used (tie to GND)
19	A16	Address	Not used (tie to GND)
20	A15	Address	Not used (tie to GND)
21	A14	Address	Not used (tie to GND)
22	A13	Address	Not used (tie to GND)
23	A12	Address	Not used (tie to GND)
24	A11	Address	B0_02
25	A10	Address	B0_01
26	A9	Address	B0_00
27	A8	Address	EMC_41
28	A18	Address	Not used (tie to GND)
29	DQ15	Data	EMC_37
30	DQ14	Data	EMC_36
31	DQ13	Data	EMC_35
32	DQ12	Data	EMC_34
33	VCC	Power	3.3V
34	GND	Ground	GND
35	DQ11	Data	EMC_33
36	DQ10	Data	EMC_32
37	DQ9	Data	EMC_31
38	DQ8	Data	EMC_30
39	OE_n	Output En	EMC_20
40	LB_n	Low Byte	EMC_08 (DQM0)
41	UB_n	Upper Byte	EMC_38 (DQM1)
42	A5	Address	EMC_14
43	A6	Address	EMC_15
44	A7	Address	EMC_16

Notes:**

- Add 0.1uF decoupling capacitors between VCC (pins 11, 33) and GND (pins 12, 34)
- For 512KB (512K x 16), you need A0-A17 (18 address lines)
- Unused address lines A12-A18 should be tied to GND
- LB_n and UB_n are byte enable signals (active low)

Example 3: Multiple SRAM Devices

Configuration:** Two 16-bit SRAM devices for 1MB total

First Device (CS0)

Memory: IS61WV51216BLL #1
 Base Address: 0x80000000
 Size: 512KB
 Chip Select: EMC_41 (CS0)

Connections:

- Data: EMC_00-07 (lower), EMC_30-37 (upper)
- Address: EMC_09-16, EMC_41, B0_00-02 (A0-A10, A8 uses EMC_41 in address mode)
- Control: EMC_19 (WE), EMC_20 (OE)
- Chip Select: Configure EMC_41 as CS0

Second Device (CS1)

Memory: IS61WV51216BLL #2

Base Address: 0x80080000
Size: 512KB
Chip Select: B0_00 (CS1)

Connections:

- Data: EMC_00-07 (lower), EMC_30-37 (upper) [shared with CS0]
- Address: EMC_09-16, EMC_41, B0_01-02 [shared with CS0]
- Control: EMC_19 (WE), EMC_20 (OE) [shared with CS0]
- Chip Select: Configure B0_00 as CS1

Important:** When using multiple devices, data and address buses are shared. Only the chip select signal differs.

PCB Design Guidelines

Signal Integrity

1. Trace Length

- Keep all SEMC traces as short as possible
- Match trace lengths for data bus signals (within 20mm)
- Match trace lengths for address bus signals (within 30mm)

2. Trace Width

- Minimum trace width: 6 mil (0.15mm)
- Recommended: 8-10 mil (0.2-0.25mm) for better signal integrity

3. Trace Spacing

- Minimum spacing: 6 mil (0.15mm)
- Recommended: 8 mil (0.2mm) to reduce crosstalk

4. Via Usage

- Minimize vias on high-speed signals
- Use via-in-pad for BGA packages when necessary

Power Supply Considerations

1. SRAM Power Supply

- Provide clean, stable 3.3V supply
- Use dedicated LDO if possible for low noise
- Power supply should handle peak current during write operations

2. Decoupling Capacitors

- Place 0.1uF ceramic capacitor at each SRAM VCC pin
- Keep capacitor within 5mm of VCC pin
- Use short, wide traces to minimize inductance
- Add 10uF bulk capacitor for each SRAM device
- Use X7R or X5R dielectric for stability

3. Ground Connection

- Solid ground plane under SEMC signals
- Connect all SRAM GND pins directly to ground plane
- Multiple vias at each GND connection point

Layout Best Practices

1. Component Placement

- Place SRAM as close as possible to SOMRT1061
- Orient SRAM to minimize trace crossings
- Keep decoupling capacitors immediately adjacent to VCC pins

2. Signal Routing

- Route data bus on same layer if possible
- Route address bus on same layer if possible
- Avoid running signals parallel for long distances
- Use ground planes between signal layers

3. Layer Stack-Up (4-layer recommended)

Layer 1: Signal (data, address, control)
Layer 2: Ground plane
Layer 3: Power plane (3.3V)
Layer 4: Signal (return paths, additional routing)

Series Termination (if needed for high-speed operation)

For SEMC clock > 100 MHz or trace lengths > 3 inches:

1. Data Lines

- Add 33ohm series resistor close to driver (SOMRT1061 side)
- Place resistor within 10mm of source

2. Address Lines

- Add 33ohm series resistor close to driver
- Can use resistor arrays for space savings

3. Control Lines

- Add 33ohm series resistor on WE, OE, CS signals

Timing Considerations

Signal Quality Checks

Use oscilloscope to verify:

1. Setup Time

- Measure address valid to WE/OE assertion
- Should meet or exceed datasheet specification + 20% margin

2. Hold Time

- Measure address/data stable after WE/OE de-assertion
- Should meet or exceed datasheet specification + 20% margin

3. Signal Levels

- Logic high: > 2.0V (for 3.3V CMOS)
- Logic low: < 0.8V (for 3.3V CMOS)
- Check for overshoot/undershoot (should be < 10%)

4. Edge Rates

- Rise time: 1-3 ns typical
- Fall time: 1-3 ns typical
- Too fast can cause ringing, too slow reduces performance

Measurement Points

Key signals to probe:

- Data bus: DQ0, DQ7 (for 8-bit), DQ15 (for 16-bit)
- Address bus: A0, A10 (or highest address used)
- Control signals: WE_n, OE_n, CS_n
- Power supply: VCC at SRAM pin

Common Hardware Issues and Solutions**Issue 1: Memory Tests Fail Completely**

Symptoms:** All memory tests fail, reads return 0x00 or 0xFF

Check:**

1. Verify power supply is present at SRAM (3.3V)
2. Check all GND connections
3. Verify CS signal is connected and toggling
4. Check OE signal is connected (active low for reads)
5. Verify data bus connections D0-D7 (and D8-D15 for 16-bit)

Measurement:** Use oscilloscope to verify signals are toggling

Issue 2: Intermittent Failures

Symptoms:** Sometimes passes, sometimes fails

Possible Causes:**

1. Insufficient decoupling capacitors
2. Timing too aggressive (not enough margin)
3. Poor signal integrity (ringing, crosstalk)
4. Borderline power supply
5. Temperature effects

Solutions:**

1. Add more decoupling capacitors (0.1uF near SRAM)
2. Increase timing parameters by 20-30%
3. Add series termination resistors
4. Use dedicated LDO for SRAM power
5. Test at temperature extremes

Issue 3: Some Bits Always Wrong

Symptoms:** Specific data bits always read incorrectly

Possible Causes:**

1. Broken trace or cold solder joint on specific data line
2. Short to VCC or GND on specific pin
3. Damaged SRAM device

Solutions:**

1. Check continuity of specific data line with multimeter
2. Check for shorts to power/ground
3. Replace SRAM device
4. Inspect solder joints under microscope

Issue 4: Address Aliasing

Symptoms:** Different addresses return same data

Possible Causes:**

1. Missing address line connection
2. Address line shorted to another signal
3. Incorrect address pin assignment in software

Solutions:**

1. Verify all address line connections with multimeter
2. Check for shorts between address lines
3. Use address uniqueness test to identify which address bit is missing
4. Verify software configuration matches hardware

Issue 5: Works on Bench, Fails in Production

Symptoms:** Prototype works, production units fail

Possible Causes:**

1. Manufacturing process issues (cold joints, etc.)
2. Component tolerance variations
3. PCB impedance variations
4. Temperature range differences

Solutions:**

1. Add timing margin (30% instead of 20%)
2. Implement thorough production test
3. Use tighter component tolerances
4. Design for worst-case conditions

Test Equipment Recommendations

Essential Tools

1. Multimeter

- Verify power supply voltage
- Check continuity of signals
- Measure resistance for shorts

2. Oscilloscope

- Minimum 100 MHz bandwidth for SEMC signals
- 4 channels recommended (address, data, control)
- Use to verify timing relationships

3. Logic Analyzer

- Capture multiple signals simultaneously
- Verify bus protocol sequences
- Debug complex timing issues

Recommended Probe Points

Add test points on PCB for:

- VCC (power supply)
- GND (ground reference)
- Key data lines (DQ0, DQ7, DQ15)
- Key address lines (A0, A10)
- Control signals (WE, OE, CS)

Address Line Requirements by Memory Size

Memory Size	Total Address Lines	Byte Address Range	Word Address Range (16-bit)
32 KB	15 (A0-A14)	0x0000 - 0x7FFF	0x0000 - 0x3FFF
64 KB	16 (A0-A15)	0x0000 - 0xFFFF	0x0000 - 0x7FFF
128 KB	17 (A0-A16)	0x00000 - 0x1FFFF	0x00000 - 0x0FFFF
256 KB	18 (A0-A17)	0x00000 - 0x3FFFF	0x00000 - 0x1FFFF
512 KB	19 (A0-A18)	0x00000 - 0x7FFFF	0x00000 - 0x3FFFF
1 MB	20 (A0-A19)	0x00000 - 0xFFFFF	0x00000 - 0x7FFFF

Note:** For x16 devices, divide byte count by 2 to get word count.

Schematic Symbol Example

SOMRT1061			SRAM (IS61WV51216BLL)		
+-----+			+-----+		
EMC_00	DATA[0]	----->	DQ0	(pin 7)	
EMC_01	DATA[1]	----->	DQ1	(pin 8)	
EMC_02	DATA[2]	----->	DQ2	(pin 9)	
EMC_03	DATA[3]	----->	DQ3	(pin 10)	
EMC_04	DATA[4]	----->	DQ4	(pin 13)	
EMC_05	DATA[5]	----->	DQ5	(pin 14)	
EMC_06	DATA[6]	----->	DQ6	(pin 15)	
EMC_07	DATA[7]	----->	DQ7	(pin 16)

Bill of Materials (BOM) Example

For typical 16-bit SRAM interface:

Qty	Reference	Part Number	Description	Notes
1	U1	SOMRT1061-200IR	NetBurner module	Main processor
1	U2	IS61WV51216BLL	512Kx16 SRAM	External memory
2	C1, C2	0.1uF/50V/X7R	Decoupling capacitor 0603	At SRAM VCC pins
1	C3	10uF/16V/X7R	Bulk capacitor 0805	Near SRAM
16	R1-R16	33ohm 5% 0603	Series termination (optional)	Data lines only if needed

Checklist for Hardware Bring-Up

- ☐ Verify 3.3V present at SRAM VCC pins
- ☐ Verify GND connections with continuity test
- ☐ Check all data line connections (D0-D7, D8-D15 for 16-bit)
- ☐ Check all address line connections
- ☐ Verify WE_n connection
- ☐ Verify OE_n connection
- ☐ Verify CS_n connection
- ☐ Check ADV connection (for multiplexed mode)
- ☐ Verify byte enable connections (for 16-bit)
- ☐ Confirm no shorts between adjacent pins
- ☐ Measure power consumption (should be < 100mA typically)
- ☐ Scope signals to verify toggling
- ☐ Run software memory tests
- ☐ Verify timing with oscilloscope
- ☐ Test at temperature extremes if required

12.33.3.11 Analog to Digital (ADC)

Location: examples/PlatformSpecific/SOMRT1061/ADC_Simple

Supported Platforms: SOMRT1061

Simple ADC example implementing basic analog input functions of the SOMRT1061

12.33.3.12 SPI PicKit Demo Board

Location: examples/PlatformSpecific/SOMRT1061/PicKitSerialSPIDemoBd

Supported Platforms: MODM7AE70, SOMRT1061

Example demonstrating the 7 SPI peripherals on the Microchip PicKit Serial SPI Demo Board.

Demonstrates the use of 7 Microchip SPI Peripherals:

- 25LC020A 2K SPI Bus Serial EEPROM
- TC77-5.0 Thermal Sensor with SPI Interface
- MCP3201 2.7V 12-Bit A/D Converter with SPI Serial Interface
- MCP4822 12-Bit DAC with Internal VREF and SPI Interface
- MCP41010 Single/Dual Digital Potentiometer with SPI Interface
- MCP6S92 Single-Ended, Rail-to-Rail I/O, Low-Gain PGA
- MCP23S08 8-Bit I/O Expander with Serial Interface

12.33.3.12.1 PicKit SPI Demo Board Application

12.33.3.12.1.1 Overview

This application demonstrates the use of 7 Microchip SPI peripherals on the PicKit Serial SPI Demo Board. It provides a comprehensive example of interfacing with various SPI devices including sensors, storage, analog components, and I/O expanders.

12.33.3.12.1.2 Supported Platforms

- MODM7AE70
- SOMRT1061

12.33.3.12.1.3 SPI Peripherals Demonstrated

The application interfaces with the following 7 Microchip SPI peripherals:

1. **25LC020A** - 2K SPI Bus Serial EEPROM
2. **TC77-5.0** - Thermal Sensor with SPI Interface
3. **MCP3201** - 2.7V 12-Bit A/D Converter with SPI Serial Interface
4. **MCP4822** - 12-Bit DAC with Internal VREF and SPI Interface
5. **MCP41010** - Single/Dual Digital Potentiometer with SPI Interface
6. **MCP6S92** - Single-Ended, Rail-to-Rail I/O, Low-Gain PGA
7. **MCP23S08** - 8-Bit I/O Expander with Serial Interface

12.33.3.12.1.4 Key Features

EEPROM Operations

- Read/Write operations on 25LC020A 2K EEPROM
- Page-based writing (16-byte pages)
- Full memory erase functionality
- Incrementing sequence test patterns

Analog Processing

- **ADC:** 12-bit analog-to-digital conversion with voltage scaling
- **DAC:** Dual-channel 12-bit digital-to-analog conversion with programmable output
- **PGA:** Programmable gain amplifier with configurable gain settings (1x to 32x)

Temperature Sensing

- Real-time temperature measurement using TC77-5.0 sensor
- Temperature display in Celsius, Fahrenheit, and Kelvin
- Continuous conversion mode support

Digital Control

- **Potentiometer:** 256-position digital potentiometer control
- **GPIO Expander:** LED control via 8-bit I/O expander
- **User Interface:** Interactive serial menu system

12.33.3.12.1.5 Interactive Menu System

The application provides a user-friendly menu interface with the following options:

EEPROM Operations

- 1 - Erase EEPROM (fill with 0xFF)
- 2 - Read EEPROM (display hex dump)
- 3 - Write incrementing sequence to EEPROM

Peripheral Testing

- A - Read ADC value and display in volts
- D - DAC test (continuous output ramping)
- G - Programmable Gain Amplifier test
- T - Read temperature sensor
- P - Potentiometer test (user-configurable resistance)
- L - Toggle LEDs on GPIO expander

12.33.3.12.1.6 Technical Implementation

SPI Configuration

The application uses the DSPI (Deserial Serial Peripheral Interface) module with different configurations for each peripheral:

- **Clock frequencies:** 700 kHz to 5 MHz depending on device requirements
- **Clock polarity and phase:** Configured per device specifications
- **Chip select management:** Automatic and manual control modes

Memory Management

- Uses NetBurner RTOS semaphores for SPI bus synchronization
- Implements proper timing delays for device-specific requirements
- Handles endianness for multi-byte data transfers

Platform-Specific Features

- Conditional compilation for different hardware platforms
- Pin function configuration for various board layouts
- Platform-specific chip select and timing configurations

12.33.3.12.1.7 Pin Assignments

MODM7AE70

- SPI0_NPCS2: P2[30]
- SPI0_SPCK: P2[25]
- SPI0_MISO: P2[27]
- SPI0_MOSI: P2[28]

SOMRT1061

- LPSPI1_SCK: Pin 27
- LPSPI1_PCS0: Pin 26
- LPSPI1_SDO: Pin 25
- LPSPI1_SDI: Pin 24

12.33.3.12.1.8 Build Configuration

The application includes preprocessor directives for:

- Platform-specific pin assignments
- SPI module selection
- Chip select configuration
- Device-specific timing parameters

12.33.3.12.1.9 Usage Notes

1. **Temperature Sensor:** Requires tri-state configuration of MOSI line for proper operation
2. **EEPROM:** Implements write-in-progress polling for reliable data storage
3. **DAC:** Supports dual-channel operation with independent voltage control
4. **Safety:** All SPI operations include proper semaphore handling and error checking

12.33.3.12.1.10 Error Handling

The application includes comprehensive error handling:

- SPI transaction completion verification
- Device presence detection (TC77 ID check)
- Parameter validation for user inputs
- Timeout handling for write operations

12.33.3.13 On-Chip Temperature Sensor (TEMPMON)

Location: examples/PlatformSpecific/SOMRT1061/TempSensor1061

Supported Platforms: SOMRT1061

Initialize and read the i.MX RT1061 on-chip temperature sensor, referred to as Temperature Monitor (TEMPMON) in the processor documentation.

Note

Also see the SOMRT1061 Development Board temperature sensor example

12.33.3.14 Dev Board Temperature Sensor and ADC

Location: examples/PlatformSpecific/SOMRT1061/TempSensorDevBoard

Supported Platforms: SOMRT1061

Initialize and read the temperature sensor on the NetBurner DEV-SOMRT1061 Development Board. The sensor is connected to ADC channel 1.

Also reads other ADC devices on the Development Board, like the potentiometer on ADC channel 0, and anything connected to channels 2+.

Note

Also see the Temperature Monitor example for the i.MX RT1061 processor on-chip temperature sensor (TEMPMON)

12.34 PPP

12.34.1 PPP Server Application

12.34.1.1 Overview

This NetBurner embedded application demonstrates how to create and manage Point-to-Point Protocol (PPP) server instances. The PPP protocol enables network connectivity over serial connections, supporting both direct serial connections and modem-based connections for TCP/IP networking.

12.34.1.2 Features

- **Dual PPP Server Support:** Creates two independent PPP server instances (PPP1 and PPP2)
- **Flexible Connection Types:** Supports both direct serial and modem-based PPP connections
- **Authentication System:** Includes customizable username/password authentication
- **Network Integration:** Full TCP/IP stack integration with HTTP server support
- **Interactive Command Interface:** Runtime control and monitoring via serial console
- **Network Diagnostics:** Built-in ping functionality and connection status monitoring
- **IPv4/IPv6 Support:** Comprehensive IP address management and display utilities

12.34.1.3 Hardware Requirements

- NetBurner embedded device with serial port support
- Serial cable or modem connection
- Host computer with PPP client capabilities

12.34.1.4 Connection Types

12.34.1.4.1 Direct Connection

- Uses only a serial cable connection between PC and NetBurner device
- Immediately begins PPP negotiations with the host/client
- No modem initialization required
- Ideal for direct PC-to-NetBurner communication

12.34.1.4.2 Modem Connection

- Uses a modem between the PC and NetBurner device
- Sends AT commands for modem initialization before PPP negotiation
- Supports dial-up and answer modes
- Handles carrier detection and modem state management

12.34.1.5 Configuration

12.34.1.5.1 Default Settings

- **Serial Port:** Port 1 (configurable via `SERIALPORT_TO_USE`)
- **Baud Rate:** 19,200 bps (configurable via `BAUD_TO_USE`)
- **NetBurner IP:** 192.1.1.1
- **Gateway IP:** 192.1.1.2
- **DNS Server:** 8.8.8.8

12.34.1.5.2 Network Configuration Example

```
pppServerObj.ip4.addr = AsciiToIp4("192.1.1.1");
pppServerObj.ip4.gate = AsciiToIp4("192.1.1.2");
pppServerObj.OfferedDNSAddress = AsciiToIp4("8.8.8.8");
```

12.34.1.6 Authentication

The application includes a sample authentication function `test_Auth()` that currently accepts any user-name/password combination. **For production use, replace this with proper credential validation:**

```
int test_Auth(const char *name, const char *pass)
{
    printf("Auth %s:%s\r\n", name, pass);
    return 1; // Always returns success - modify for real authentication
}
```

12.34.1.7 Interactive Commands

Once the PPP connection is established, the application provides an interactive menu accessible via serial console:

- **C** - Show network counters and statistics
- **H** - Force hangup/disconnect the PPP session
- **P** - Ping the remote host to test connectivity
- **S** - Show detailed PPP connection status
- **X** - Exit the application
- **?** - Display help menu
- **F** - Show interface information (debug builds)
- **L** - Set log level (debug builds)

12.34.1.8 PPP State Machine

The application monitors and displays various PPP connection states:

State	Description
eClosed	Connection closed
eInitializingModem	Initializing modem (modem connections only)
eDialing	Dialing remote number
eWait4Ring	Waiting for incoming call
eAnswering	Answering incoming call
eWaitForTrain	Waiting for carrier signal
eLCPNegotiate	Link Control Protocol negotiation
ePAPAuthenticate	Password Authentication Protocol
eNCPNegotiate	Network Control Protocol negotiation
eOpen	Connection established and active
eClosing	Connection closing

12.34.1.9 Error Handling

The application includes error handling for common PPP issues:

Error Code	Description
ERR_PPP_ALREADY_OPEN	PPP interface already active
ERR_PPP_NO_DIALTONE	No dial tone detected
ERR_PPP_NO_ANSWER	No answer from remote
ERR_PPP_BUSY	Remote line busy
ERR_PPP_FAIL	General PPP failure
ERR_PPP_PASSFAIL	Authentication failure
ERR_PPP_LOSTCARRIER	Lost carrier signal
ERR_PPP_NO_MODEM	Modem not responding
ERR_PPP_LCP_FAILED	LCP negotiation failed

12.34.1.10 IP Address Utilities

The application includes IP address management utilities:

12.34.1.10.1 IPv4 Features

- Display IP, subnet mask, gateway, and DNS server information
- Interface MAC address display
- Link status monitoring (speed and duplex)
- Web-based interface display with clickable links

12.34.1.10.2 IPv6 Features (when enabled)

- Multiple address assignment support (Link Local, Router, [DHCP](#), Static)
- [DHCP](#) lease time information with renewal/rebind timers
- DNS server information display
- Prefix length and source identification

12.34.1.11 Web Interface

The application includes a built-in HTTP server that provides:

- Web-based display of all network interface information
- Clickable links to test IPv4 and IPv6 connectivity
- Real-time interface status and configuration display
- **DHCP** lease time information for IPv6 addresses

12.34.1.12 File Structure

```
project/  
main.cpp           # Main application logic and PPP server management  
ip_util.cpp        # IP address utility functions  
ip_util.h          # IP utility function declarations
```

12.34.1.13 Build Requirements

- NetBurner development environment
- Serial communication support libraries
- TCP/IP stack libraries
- HTTP server support

12.34.1.14 Usage Instructions

1. Initial Setup

- Connect NetBurner device to host via serial cable or modem
- Configure serial port settings (default: Port 1, 19200 baud)
- Build and deploy application to NetBurner device

2. Starting PPP Connection

- Application automatically initializes network stack
- Starts HTTP server on port 80
- Waits for network initialization
- Opens serial port and starts PPP server

3. Host Configuration

- Configure PPP client on host computer
- Set up serial connection with matching baud rate
- Initiate PPP connection from host

4. Testing Connection

- Use interactive menu commands to monitor connection
- Test connectivity with built-in ping function
- Access web interface at configured IP address

12.34.1.15 Testing PPP Connections

Recommended testing approach:

1. Create a PPP interface on a host computer
2. Connect via serial cable to the NetBurner device
3. Configure host PPP client with appropriate settings
4. Establish direct PPP connection
5. Use interactive commands to monitor connection status
6. Verify network connectivity using built-in ping function
7. Test web interface accessibility

12.34.1.16 Development Notes

12.34.1.16.1 Production Considerations

- Replace sample authentication function with secure credential checking
- Disable system diagnostics in production builds
- Configure appropriate IP addresses for your network topology
- Implement connection retry logic for unreliable connections
- Monitor and log PPP events for troubleshooting

12.34.1.16.2 Debug Features

- System diagnostics enabled for debugging
- Comprehensive logging and error reporting
- Interactive command interface for real-time monitoring

12.34.1.16.3 Network Integration

- Full TCP/IP stack support
- HTTP server integration
- Multi-interface support with status monitoring

12.34.1.17 Troubleshooting

12.34.1.17.1 Common Issues

1. **Connection Fails:** Check serial cable connections and baud rate settings
2. **Authentication Errors:** Verify username/password if custom authentication is implemented
3. **No Network Access:** Confirm IP address configuration and routing
4. **Modem Issues:** Check AT command compatibility and modem initialization

12.34.1.17.2 Debug Commands

- Use 'S' command to check PPP state
- Use 'C' command to view network counters
- Use 'P' command to test connectivity
- Check web interface for detailed network information

12.35 Profiler

12.35.1 Profiler Example Application

12.35.1.1 Overview

This is a simple profiler program designed for the NBRTOS (NetBurner Real-Time Operating System) that demonstrates task profiling capabilities. The application provides a menu-driven interface to monitor task execution times and system performance metrics.

12.35.1.2 Features

- **Task Time Monitoring:** Track execution time for individual tasks
- **System Statistics:** Display total system tick counts and timing information
- **Real-time Counter:** Shows a continuously updating counter display
- **Web Server Integration:** Includes HTTP server functionality
- **Network Configuration:** Automatic [DHCP](#) setup and network interface management

12.35.1.3 Profiling Functionality

The NBRTOS profiling system works by recording tick counts and tick fractions during task switching events. This allows the system to track how much CPU time each task consumes.

12.35.1.3.1 Key Profiling Functions

- `GetCurrentTaskTime(uint32_t *TotalTicks)` - Returns the number of ticks the current task has run
- `ShowTaskTimes()` - Prints a list of all tasks with their execution times and percentages
- `ClearTaskTimes()` - Resets all task timing counters to zero

12.35.1.4 Menu Commands

The application provides an interactive menu system with the following commands:

- **C** - Get statistics on the current task (execution time and percentage)
- **S** - Show OS seconds counter and tick information
- **T** - Display statistics for all tasks in the system
- **?** - Display the main menu

12.35.1.5 Setup and Configuration

12.35.1.5.1 Enabling Profiling

Profiling functionality requires the system to be built with `NBRTOS_TIME` defined. There are two ways to enable this:

12.35.1.5.1.1 Method 1: Using Overload Folder (Recommended)

Copy the provided overload folder into your application directory. This method is preferred as it only affects your specific application.

12.35.1.5.1.2 Method 2: System-wide Configuration

1. Edit `\nburn\nbrtos\include\predef.h`
2. Uncomment the line: `#define NBRTOS_TIME(1)`
3. Rebuild the system libraries

Note**: Method 2 affects all applications and adds overhead to the entire system.

12.35.1.5.2 Important Considerations

- Profiling adds computational overhead and should typically only be used during development
- The profiling feature is disabled by default for performance reasons
- When profiling is disabled, attempting to use profiling commands will display a warning message

12.35.1.6 Application Flow

1. **Initialization:** The application initializes the network stack and starts the HTTP server
2. **Network Setup:** Waits for `DHCP` completion and displays IP address information
3. **Main Loop:** Continuously checks for user input while displaying an updating counter
4. **Command Processing:** Handles user commands through a simple dispatcher system

12.35.1.7 Network Features

- **DHCP Support:** Automatic IP address configuration
- **Web Server:** Built-in HTTP server on port 80
- **Interface Monitoring:** Displays network interface information
- **Connection Status:** Shows current IP addresses and network configuration

12.35.1.8 Development Notes

- The application includes system diagnostics that should be removed for production code
- The counter display uses backspace characters to create an updating effect
- Error handling is included for cases where profiling features are not available
- The application waits up to 5 seconds for network activation

12.35.1.9 Output Examples

When profiling is enabled, you can expect output like:

```
Current Task Ticks: 12345, Total System Ticks: 100000, Percent: 12.35
```

```
Tick Count = 0x1A2B3C = 1715004 (171 seconds)
```

12.35.1.10 Compilation Requirements

- NBRTOS development environment
- Network libraries (ethervars, ipshow)
- Standard I/O system libraries (iosys)
- Initialization libraries (init)

12.35.1.11 Usage

1. Compile and flash the application to your NetBurner device
2. Connect via serial terminal
3. Wait for network initialization to complete
4. Use the menu commands to monitor system performance
5. Press any key after each command display to return to the menu

12.36 RTOS

NetBurner RTOS (NBRTOS) Examples:

- [MaxTasks](#)
- [OSCrit - Critical Section](#)
- [OSFifo - FIFO](#)
- [OSFlags](#)
- [OSMailbox](#)
- [exampleRTOS-OSMultiTaskUserInput](#)
- [OSQueue](#)
- [OSSemaphore](#)
- [OSTaskCreate](#)
- [Round Robin Task Sheduler](#)

12.36.1 MaxTasks

12.36.1.1 MaxTasks RTOS Example

12.36.1.1.1 Overview

This example demonstrates how to increase the maximum number of system tasks beyond the default limits in the NBRTOS (NetBurner Real-Time Operating System). The application creates multiple tasks that execute in a sequential chain pattern, showcasing the system's ability to handle an increased task count.

12.36.1.1.2 Application Description

The MaxTasks example creates 64 additional tasks beyond the standard system tasks. These tasks operate in a coordinated sequence where each task:

1. Waits for its turn using a semaphore
2. Introduces a short delay for readable output
3. Prints its task information (name, priority, system tick)
4. Signals the next task in the sequence
5. Returns to sleep

The tasks execute in reverse priority order, creating a continuous cycle that demonstrates the system's task scheduling capabilities.

12.36.1.1.3 Key Features

- **Task Creation:** Creates 64 extra tasks with unique names and priorities
- **Sequential Execution:** Tasks execute in a coordinated chain pattern
- **Status Reporting:** Each task reports its name, priority, and current system tick
- **Error Handling:** Provides feedback on task creation success/failure
- **Network Integration:** Includes network stack initialization and [DHCP](#) support

12.36.1.1.4 Configuration

12.36.1.1.4.1 System Limits

The application requires modification of default RTOS limits through the `constants-overload.h` file:

```
#define OS_MAX_TASKS (64)    // Max number of system tasks
#define OS_MAX_PRIOS (128)  // Maximum number of system priorities
```

Note

The application project must have the constants file located in the project's `overflow` folder with the same path as the where the constants file is normally found, `\nbrtos\include\constants-overload.h`.

The entire project path for constants is then: `\MaxTasks\overflow\nbrtos\include\constants-overload.h`.

12.36.1.1.4.2 Task Configuration

- **Extra Task Count:** 64 tasks (configurable via `EXTRA_TASK_COUNT`)
- **Base Priority:** Starts at `MAIN_PRIO + 1` (configurable via `EXTRA_TASK_BASE_PRIO`)
- **Stack Size:** Each task uses `USER_TASK_STK_SIZE` stack space
- **Task Names:** Auto-generated as "ExtraTask_X" where X is the task index

12.36.1.1.5 Performance Considerations

12.36.1.1.5.1 Hard Limits

- Maximum of 256 task priorities in NBRRTOS
- Priority values stored in `uint8_t` format
- Limited by `OSTaskID()` return type

12.36.1.1.5.2 Performance Impact

Increasing maximum task priorities affects system performance in several ways:

1. **Memory Usage:** All OS control objects (`OS_CRIT`, `OS_SEM`, `OS_FIFO`, `OS_MBOX`) must grow to accommodate additional priority levels
2. **Processing Overhead:**
 - Additional scanning required for priority bit checking
 - Increased memory bandwidth requirements
 - Greater cache space utilization
3. **Memory Alignment:** Default 16-byte OS control objects lose power-of-two alignment, potentially spanning multiple cache lines

12.36.1.1.5.3 Recommendation

A caution regarding system limits and performance. There is a hard limit of 256 task priorities in the NBRTOS. This is a function of storing the task priority in a `uint8_t` in the `OS_TCB` and the return type of `OSTaskID()`.

As for the impact on system performance, when you increase the maximum task priorities, the OS must be able to handle the additional priority values. To do so, all task priority lists used in various OS related objects (i.e. `OS_CRIT`) have to grow in size. This not only means more memory usage, but, more fundamentally, more processing overhead. The processing overhead is twofold:

1. Scanning additional storage for bits being set.
2. The memory bandwidth and cache space associated with having to read more memory.

By default, most OS control objects (`OS_CRIT`, `OS_SEM`, `OS_FIFO`, `OS_MBOX`) are 16 bytes. This fits nicely from a memory alignment perspective as it's a power of two. By increasing the max priority value, it increases the size and breaks that symmetry, increasing the odds of the structure spanning multiple cache lines. Given this, the number of priorities should not be increased unless absolutely necessary.

12.36.1.1.6 File Structure

```
main.cpp           # Main application code
constants-overload.h # System limit overrides
```

12.36.1.1.7 Code Structure

12.36.1.1.7.1 Main Components

1. **Task Arrays:** Pre-allocated storage for stacks, names, and semaphores
2. **ExtraTask():** The common task function executed by all extra tasks
3. **UserMain():** Application entry point that creates and manages tasks
4. **Validation:** Compile-time checks to ensure configuration consistency

12.36.1.1.7.2 Task Synchronization

The application uses an array of semaphores (`ExtraTaskSem[]`) to coordinate task execution. Each task:

- Waits on its own semaphore
- Posts to the previous task's semaphore (creating reverse-order execution)
- The cycle is primed by posting to the first task's semaphore

12.36.1.1.8 Build Requirements

- NetBurner NNDK (NetBurner Network Development Kit)
- NBRTOS support
- Network stack libraries

12.36.1.1.9 Usage

1. Configure the desired number of extra tasks by modifying `EXTRA_TASK_COUNT`
2. Ensure `constants-overload.h` has appropriate `OS_MAX_TASKS` and `OS_MAX_PRIOS` values
3. Compile and deploy to NetBurner hardware
4. Monitor serial output to observe task execution sequence

12.36.1.1.10 Output Format

Each task prints information in the format:

```
[TaskName][Priority]: [SystemTick]
```

Example output:

```
ExtraTask_0[ 21]: 1234
ExtraTask_63[ 84]: 1235
ExtraTask_62[ 83]: 1236
...
```

12.36.1.1.11 Error Handling

The application includes comprehensive error checking:

- Compile-time validation of configuration limits
- Runtime reporting of task creation success/failure
- Network initialization timeout handling

12.36.1.1.12 Customization

To modify the application:

- Change `EXTRA_TASK_COUNT` to create more/fewer tasks
- Adjust `EXTRA_TASK_BASE_PRIO` to change starting priority
- Modify timing delays in `ExtraTask()` and `UserMain()`
- Update task naming convention in the creation loop

12.36.1.1.13 Warning

This example is primarily for demonstration and testing purposes. In production systems, carefully consider the performance implications of increasing task limits and only do so when the additional tasks are essential for your application's functionality.

12.36.2 OSCrit - Critical Section

12.36.2.1 OSCrit - Critical Section Example

12.36.2.1.1 Overview

This example demonstrates how to implement critical sections in a real-time operating system (RTOS) environment using two different approaches: traditional C-style function calls and modern C++ object-oriented design.

12.36.2.1.2 Purpose

Critical sections are essential for protecting shared resources in multi-tasking environments. They ensure that only one task can access a shared resource at a time, preventing race conditions and data corruption that could occur when multiple tasks attempt to modify the same data simultaneously.

12.36.2.1.3 Application Description

The OSCrit example (`main.cpp`) showcases both methods of implementing critical sections:

12.36.2.1.3.1 Method 1: Traditional C-Style Critical Sections

Uses explicit function calls:

- `OSCritEnter()` - Enters the critical section
- `OSCritLeave()` - Exits the critical section

```
OS_CRIT cs;
cs.Enter();
GlobalVariable = 1;
cs.Leave();
```

12.36.2.1.3.2 Method 2: C++ Object-Oriented Critical Sections

Uses RAIL (Resource Acquisition Is Initialization) pattern:

- Constructor automatically calls `OSCritEnter()`
- Destructor automatically calls `OSCritLeave()` when object goes out of scope

```
OS_CRIT cs2;
{
    OSCriticalSectionObj UserMainCriticalSection(cs2);
    GlobalVariable = 2;
    // Automatic cleanup when scope ends
}
```

12.36.2.1.4 Key Features

- **Network Initialization:** Waits for [DHCP](#) address assignment (5-second timeout)
- **System Diagnostics:** Enables system diagnostic features for debugging
- **Shared Resource Protection:** Demonstrates protection of a global variable
- **Timeout Handling:** Shows how to configure timeout values for critical section acquisition
- **Automatic Resource Management:** C++ approach eliminates the risk of mismatched enter/leave calls

12.36.2.1.5 Advantages of Each Approach

12.36.2.1.5.1 Traditional C-Style

- **Explicit Control:** Clear visibility of when critical sections are entered and exited
- **Timeout Configuration:** Allows custom timeout values for critical section acquisition

12.36.2.1.5.2 C++ Object-Oriented

- **Automatic Management:** No risk of forgetting to call `OSCritLeave()`
- **Exception Safety:** Guaranteed cleanup even if exceptions occur
- **Scope-Based:** Critical section is automatically released when leaving the scope

12.36.2.1.6 Technical Details

- **Application Name:** "OSCrit Example"
- **Shared Resource:** `GlobalVariable` (integer)
- **Network Timeout:** 5 seconds for [DHCP](#) acquisition
- **Main Loop:** 5-second delay iterations
- **Timeout Behavior:** Value of 0 means wait forever for critical section access

12.36.2.1.7 Use Cases

While this example uses a simple global variable for demonstration, critical sections are typically used for:

- **Linked Lists:** Protecting list modifications during insertions/deletions
- **Shared Buffers:** Ensuring atomic access to circular buffers or queues
- **Hardware Resources:** Coordinating access to peripherals or memory-mapped registers
- **Data Structures:** Protecting complex objects that require multiple operations to remain consistent

12.36.2.1.8 Best Practices Demonstrated

1. **Proper Initialization:** System and network setup before critical operations
2. **Resource Protection:** Using critical sections for shared data access
3. **Modern C++ Techniques:** Leveraging RAI for automatic resource management
4. **Comparison Approach:** Showing both traditional and modern implementation methods

12.36.2.1.9 Implementation Notes

- The second parameter in critical section calls represents timeout in system ticks
- A timeout value of 0 means the task will wait indefinitely
- The C++ approach always uses infinite timeout (wait forever)
- System diagnostics should be disabled in production code for optimal performance

12.36.3 OSFifo - FIFO

12.36.3.1 RTOS FIFO Example Application

12.36.3.1.1 Overview

This application demonstrates the use of a First-In-First-Out (FIFO) queue in a Real-Time Operating System (RTOS) environment. The program creates two tasks that communicate with each other through a FIFO buffer, showcasing inter-task communication and timeout handling.

12.36.3.1.2 Application Description

The OSFifo example creates a producer-consumer pattern where:

- One task (FifoPostTask) posts messages to a FIFO queue
- Another task (UserMain) reads messages from the FIFO queue
- A timeout mechanism is implemented to demonstrate FIFO timeout features

12.36.3.1.2.1 Key Components

Data Structure

```
typedef struct {
    void *pUsedByFifo;    // Internal FIFO linked list pointer (do not modify)
    int x;                // Data payload
    BOOL free;            // Availability flag
} MyStructure;
```

FIFO Management

- **FIFO Object:** `OS_FIFO MyFIFO` - The main FIFO queue
- **Structure Array:** `MyStructure StructArray[NUM_POSTS]` - Pre-allocated message pool
- **Memory Management:** Uses static allocation instead of dynamic memory

12.36.3.1.3 Program Flow

12.36.3.1.3.1 Initialization Phase

1. Initialize the FIFO object
2. Initialize all structures in the array as "free"
3. Create the FIFO posting task
4. Enable system diagnostics

12.36.3.1.3.2 Runtime Operation

Producer Task (FifoPostTask)

- Runs continuously in a loop
- Posts NUM_POSTS (5) messages per cycle
- For each message:
 - Finds a free structure in the array
 - Sets the data value (x) to the current count
 - Marks the structure as "in use"
 - Posts the structure pointer to the FIFO
- Waits 9 seconds between posting cycles

Consumer Task (UserMain)

- Continuously pends on the FIFO with a 5-second timeout
- When a message is received:
 - Prints the received data value
 - Marks the structure as "free" for reuse
- When timeout occurs:
 - Prints a timeout message
 - Continues waiting for the next message

12.36.3.1.4 Timeout Demonstration

The application is designed to demonstrate FIFO timeout behavior:

- The producer posts 5 messages quickly, then waits 9 seconds
- The consumer has a 5-second timeout on FIFO pend operations
- After consuming all 5 messages, the consumer will timeout once before the next batch arrives

12.36.3.1.5 Key Features

12.36.3.1.5.1 Memory Management

- Uses static memory allocation instead of dynamic allocation
- Implements a simple free-list mechanism for structure reuse
- Prevents memory leaks through proper structure lifecycle management

12.36.3.1.5.2 Error Handling

- Checks for task creation errors
- Handles FIFO timeout conditions gracefully
- Validates structure availability before posting

12.36.3.1.5.3 Synchronization

- Demonstrates safe inter-task communication using FIFO
- Shows proper handling of resource contention
- Illustrates timeout-based resource management

12.36.3.1.6 Configuration

- `NUM_POSTS`: Number of structures to post per cycle (currently 5)
- `USER_TASK_STK_SIZE`: Stack size for the posting task
- `TICKS_PER_SECOND`: System tick rate for timing calculations
- `MAIN_PRIO - 1`: Priority level for the posting task

12.36.3.1.7 Expected Output

The application will display:

1. FIFO posting messages showing structure index and data value
2. FIFO reading messages showing read count and data value
3. Periodic timeout messages during the 9-second delay periods
4. Delay notifications before each new posting cycle

12.36.3.1.8 Usage Notes

- This example is designed for educational purposes to demonstrate FIFO usage
- The timeout feature illustrates how to handle blocking operations with time limits
- The static memory management approach is suitable for resource-constrained embedded systems
- System diagnostics are enabled for debugging (should be disabled in production)

12.36.3.1.9 Technical Requirements

- NetBurner RTOS environment
- Standard C++ compiler support
- RTOS task creation and timing services
- FIFO queue implementation (`OS_FIFO` class)

12.36.4 OSFlags

12.36.4.1 OSFlags RTOS Example

12.36.4.1.1 Overview

This example demonstrates how to use OSFlags in a Real-Time Operating System (RTOS) environment to coordinate multiple tasks through event signaling. The application creates multiple tasks that set flags at different intervals, while a main task waits for these events to occur.

12.36.4.1.2 Application Description

The OSFlags example illustrates inter-task communication using event flags. It creates three worker tasks that operate on different time schedules and set corresponding flags. The main task monitors these flags and responds when any (or optionally all) of the flags are set.

12.36.4.1.2.1 Key Components

- **Global OS Flag Object:** `gOsFlag` - A shared flag object used for inter-task communication
- **Three Worker Tasks:** Each task sets a specific flag after a time delay
- **Main Monitoring Task:** Waits for flag events and processes them

12.36.4.1.3 Task Structure

12.36.4.1.3.1 Worker Tasks

1. OsFlagTask1

- Priority: MAIN_PRIO + 1
- Delay: 2 seconds
- Sets: TASK_FLAG_1 (bit 0x00000001)

2. OsFlagTask2

- Priority: MAIN_PRIO + 2
- Delay: 4 seconds
- Sets: TASK_FLAG_2 (bit 0x00000002)

3. OsFlagTask3

- Priority: MAIN_PRIO + 3
- Delay: 6 seconds
- Sets: TASK_FLAG_3 (bit 0x00000004)

12.36.4.1.3.2 Main Task (UserMain)

The main task performs the following operations:

1. Initializes the system and network
2. Creates the three worker tasks
3. Enters an infinite loop that:
 - Waits for any flag to be set using `PendAny()`
 - Identifies which flags are currently set
 - Prints the status of active flags
 - Clears the processed flags

12.36.4.1.4 Flag Operations

12.36.4.1.4.1 Pending Modes

The application supports two different pending modes:

- **PendAny()**: Returns when one or more flags are set (default behavior)
- **PendAll()**: Returns only when all specified flags are set (commented out)

12.36.4.1.4.2 Flag Management

- **Setting Flags**: Each worker task sets its assigned flag using `gOsFlag.Set()`
- **Reading Flags**: The main task reads flag state using `gOsFlag.State()`
- **Clearing Flags**: Processed flags are cleared using `gOsFlag.Clear()`

12.36.4.1.5 Expected Behavior

The application will produce output showing which tasks have set their flags:

```
OSFlagPendAny() detected the following flag(s) are set: TASK1
OSFlagPendAny() detected the following flag(s) are set: TASK2
OSFlagPendAny() detected the following flag(s) are set: TASK1 TASK3
```

The timing pattern will be:

- Task1 flag every 2 seconds
- Task2 flag every 4 seconds
- Task3 flag every 6 seconds

12.36.4.1.6 Configuration Options

12.36.4.1.6.1 Modifying Pending Behavior

To change from "any flag" to "all flags" behavior:

1. Comment out the `PendAny()` call
2. Uncomment the `PendAll()` call

This will cause the main task to wait until all three flags are set simultaneously before proceeding.

12.36.4.1.6.2 Timing Adjustments

Task delays can be modified by changing the multiplier values:

- `OSTimeDly((2 * TICKS_PER_SECOND))` - 2 second delay
- `OSTimeDly((4 * TICKS_PER_SECOND))` - 4 second delay
- `OSTimeDly((6 * TICKS_PER_SECOND))` - 6 second delay

12.36.4.1.7 System Requirements

- RTOS environment with OSFlags support
- Network capability ([DHCP](#))
- System diagnostics support
- Multi-tasking support

12.36.4.1.8 Key Learning Points

This example demonstrates:

1. **Inter-task Communication:** Using flags to coordinate between tasks
2. **Event-Driven Programming:** Tasks respond to events rather than polling
3. **Bitwise Operations:** Flag manipulation using bitmasking
4. **Task Priorities:** Different priority levels for worker tasks
5. **Synchronization:** Coordinating multiple asynchronous tasks

12.36.4.1.9 Usage Notes

- The application waits for network initialization ([DHCP](#)) before starting
- System diagnostics are enabled (should be disabled for production)
- Flag clearing is important to prevent false triggers
- Only one pending function (`PendAny` or `PendAll`) can be active at a time

12.36.5 OSMailbox

12.36.5.1 RTOS Mailbox Example

12.36.5.1.1 Overview

This application demonstrates inter-task communication using mailboxes in a real-time operating system (RTOS). The program creates two tasks that communicate through a shared mailbox mechanism, showcasing how tasks can send and receive messages in a multi-threaded environment.

12.36.5.1.2 Application Description

The **Mailbox Example** application consists of two main tasks:

1. **UserMain Task** - The primary task that waits for messages from other tasks
2. **MyTask** - A secondary task that periodically sends messages to the mailbox

12.36.5.1.2.1 Program Flow

1. The application initializes the system and enables network connectivity
2. A mailbox object (`MyMailbox`) is created and initialized
3. Two tasks are created with different priorities:
 - `UserMain` runs at main priority level
 - `MyTask` runs at main priority + 1 (higher priority)
4. The tasks communicate through the mailbox using a producer-consumer pattern

12.36.5.1.2.2 Task Behavior

UserMain Task

- Continuously waits (pends) on the mailbox for incoming messages
- When a message is received, it prints the message value
- Increments the received message value before the next iteration
- Handles error conditions when message reception fails

MyTask

- Runs in an infinite loop with a 3-second delay between iterations
- Posts a message containing a `uint8_t` value to the mailbox
- Prints status information when posting messages

12.36.5.1.3 Key Features

- **Inter-task Communication:** Demonstrates safe message passing between tasks
- **Blocking Operations:** Shows how tasks can block waiting for messages
- **Error Handling:** Includes proper error checking for mailbox operations
- **Debug Output:** Provides serial port output for monitoring program execution
- **Network Integration:** Waits for active network before starting main operations

12.36.5.1.4 Technical Details

12.36.5.1.4.1 Data Structures

- `OS_MBOX MyMailbox` - The mailbox object for inter-task communication
- `uint32_t MyTaskStack[USER_TASK_STK_SIZE]` - Stack allocation for MyTask
- `uint8_t myMsg` - The message data passed between tasks

12.36.5.1.4.2 RTOS Functions Used

- `OSTimeDly()` - Task delay function
- `MyMailbox.Init()` - Mailbox initialization
- `MyMailbox.Post()` - Send message to mailbox
- `MyMailbox.Pend()` - Wait for message from mailbox
- `OSSimpleTaskCreateWithName()` - Task creation with naming

12.36.5.1.4.3 System Functions

- `init()` - System initialization
- `EnableSystemDiagnostics()` - Enable system diagnostic features
- `WaitForActiveNetwork()` - Wait for network connectivity

12.36.5.1.5 Output

The program outputs status messages through the serial debug port, which can be monitored using terminal programs like MTTTY. The output shows:

- When UserMain is waiting for messages
- When MyTask posts messages to the mailbox
- The received message values
- Any error conditions that occur

12.36.5.1.6 Build Requirements

- RTOS system with mailbox support
- Serial debug port capability
- Network stack (optional, used for initialization timing)

12.36.5.1.7 Usage

1. Compile and flash the program to your target device
2. Connect a serial terminal to the debug port
3. Monitor the output to observe the mailbox communication pattern
4. The program runs indefinitely, demonstrating continuous inter-task messaging

12.36.6 OSQueue

Queue Example Program

This program creates two tasks and a Queue. Messages are sent from one task to another using the Queue. A timeout value for the pend function is used to illustrate the timeout feature of the FIFO.

12.36.7 OSSemaphore

This program will create 2 tasks and a semaphore. The UserMain task will block for a semaphore posted from My↔ Task. The output for this example is displayed through the serial debug port, which can be viewed with the MTTTY program.

12.36.8 OSTaskCreate

This example demonstrates how to use two of the task creation functions:

- OSSimpleTaskCreatewName()
- OSTaskCreatewName()

This example demonstrates how to use create tasks and wait for task completion:

- OSTaskCreatewName()
- OSTaskJoin()

12.36.9 Round Robin Task Scheduler

This example demonstrates how to use the Priority Promotion optional behavior to implement a round robin scheduler for a set of worker tasks. This ends up using N+1 tasks to implement a set of N tasks.

The scheduler implemented is not 100% efficient at time allocation, but will guarantee a minimum time slice based on system Ticks, until the running task completes its iteration. In the event that the task being given the timeslice blocks, the tasks will end up falling through and being scheduled as normal, based on their relative priorities.

In the event that no task is ready, the 'next' task will be promoted to the scheduler's priority, at which point it will be blocked, then execution will fall through to whatever tasks may exist at lower priorities, all the way to System Idle.

12.37 Serial

Serial Port Examples:

- [Dual TCP To Serial](#)
- [Serial To Ethernet](#)
- [Serial HTTP Get Request](#)
- [Serial Receive Callback](#)
- [Serial to Serial](#)
- [Serial Application Update](#)
- [TCP to Serial](#)

12.37.1 Dual TCP To Serial

12.37.1.1 DualTCP2Serial Example

A NetBurner embedded application that bridges TCP network connections to serial ports, enabling remote access to serial devices over Ethernet.

12.37.1.1.1 Overview

This application creates TCP-to-serial bridges on two serial ports simultaneously, allowing network clients to communicate with serial devices as if they were directly connected. Each serial port listens on a different TCP port and handles one client connection at a time.

12.37.1.1.2 Features

- **Dual Serial Port Support:** Bridges both serial port 0 and serial port 1
- **Bidirectional Data Transfer:** Data flows seamlessly between TCP clients and serial devices
- **Connection Override:** New clients can override existing connections after a timeout period
- **Configurable Parameters:** Easily adjust baud rates, TCP ports, and timeout values
- **Error Handling:** Robust handling of network and serial port errors

12.37.1.1.3 Configuration

12.37.1.1.3.1 Default Settings

Parameter	Port 0	Port 1
TCP Port	2000	2001
Baud Rate	115200	115200
Data Bits	8	8
Stop Bits	1	1
Parity	None	None
Override Timeout	10 seconds	10 seconds

12.37.1.1.3.2 Customization

Modify these constants in `main.cpp` to change the configuration:

```
#define BAUDRATE_TO_USE (115200) // Baud rate for both serial ports
#define STOP_BITS (1) // Number of stop bits
#define DATA_BITS (8) // Number of data bits
#define TCP_PORT0_TO_USE (2000) // TCP port for serial port 0
#define TCP_PORT1_TO_USE (2001) // TCP port for serial port 1
#define OVERRIDE_TIMEOUT (TICKS_PER_SECOND * 10) // Override timeout
```

12.37.1.1.4 How It Works

12.37.1.1.4.1 Connection Process

1. **Startup:** Application initializes both serial ports and begins listening on configured TCP ports
2. **Client Connection:** When a TCP client connects, a dedicated bridge is established
3. **Data Transfer:** All data received from the network is sent to the serial port, and vice versa
4. **Connection Management:** Only one client per serial port at a time

12.37.1.1.4.2 Override Feature

The override timeout prevents stale connections from blocking new clients:

- When a client connects, the listen socket is closed to prevent additional connections
- After the timeout period expires, a new listen socket opens
- If a new client attempts to connect, the old connection is automatically closed
- This handles cases where clients crash or disconnect improperly

12.37.1.1.5 Usage

12.37.1.1.5.1 Network Client Connection

Connect to the NetBurner device using any TCP client:

```
# Connect to serial port 0
telnet <netburner_ip> 2000

# Connect to serial port 1
telnet <netburner_ip> 2001
```

12.37.1.1.5.2 Example Use Cases

- **Remote Serial Console:** Access device debug output over network
- **Serial Device Control:** Control industrial equipment remotely
- **Data Logging:** Collect serial data from remote sensors
- **Protocol Bridging:** Convert between network and serial protocols

12.37.1.1.6 Architecture

12.37.1.1.6.1 Task Structure

- **UserMain Task:** Handles serial port 0 and TCP port 2000
- **SerialTask2:** Handles serial port 1 and TCP port 2001 (lower priority)

12.37.1.1.6.2 Data Flow

TCP Client <-> Network Stack <-> SerialToEthernetFunction <-> Serial Port <-> Connected Device

12.37.1.1.7 Technical Details

12.37.1.1.7.1 Buffer Management

- Uses 80-byte buffers for data transfer
- Non-blocking I/O with `select()` for efficient multiplexing
- Immediate data forwarding (no buffering delays)

12.37.1.1.7.2 Error Handling

- Automatic socket cleanup on network errors
- Graceful handling of serial port errors
- Connection state monitoring and recovery

12.37.1.1.7.3 Performance Considerations

- SerialTask2 runs at lower priority than UserMain
- 2-second select timeout for responsive operation
- Efficient file descriptor monitoring

12.37.1.1.8 Building and Deployment

1. **Requirements:** NetBurner development environment and hardware
2. **Compilation:** Use standard NetBurner build tools
3. **Deployment:** Flash to NetBurner device
4. **Network Setup:** Ensure device has network connectivity

12.37.1.1.9 Troubleshooting

12.37.1.1.9.1 Common Issues

No Connection**: Verify network connectivity and TCP port accessibility
 Data Loss**: Check baud rate and serial settings match connected device
 Stale Connections**: Override timeout will eventually clear blocked connections
 Performance Issues**: Consider adjusting buffer sizes for high-throughput applications

12.37.1.1.9.2 Debug Output

The application provides console output showing:

- Listen socket creation
- Client connections and disconnections
- Override timeout events
- Socket file descriptor information

12.37.2 Serial To Ethernet

12.37.2.1 Serial to Ethernet Bridge Application

12.37.2.1.1 Overview

This NetBurner NNDK application creates a bidirectional bridge between an RS-232 serial device and an Ethernet network. The program enables real-time data transmission between serial and network clients, effectively allowing serial devices to communicate over TCP/IP networks.

Note

Excellent example of creating a user web page configuration, using the Configuration System (`config_object`), Configuration Tags, and configuration objects in an application.

12.37.2.1.2 Features

- **Bidirectional Data Flow:** Forwards data seamlessly between serial port and TCP connections
- **Web-based Configuration:** HTML interface for configuring settings without recompilation
- **Connection Management:** Handles multiple connection attempts with configurable timeout and override policies
- **Real-time Data Pumping:** Efficient `select()` based I/O multiplexing for simultaneous data transfer
- **Debug Support:** Configurable debug output to separate or shared serial ports
- **Persistent Settings:** Configuration stored in flash memory

12.37.2.1.3 Architecture

12.37.2.1.3.1 Core Components

- **main.cpp:** Application entry point, network setup, and connection handling
- **datapump.cpp:** Core data transfer engine using `select()` for I/O multiplexing
- **nvsettings.h:** Configuration class definitions and default values
- **datapump.h:** Data pump interface and message definitions
- **index.html:** Web-based configuration interface

12.37.2.1.3.2 Data Flow

```
[Serial Device] <----> [Serial Port] <----> [DataPump] <----> [TCP Socket] <----> [Network Client]
```

12.37.2.1.4 Configuration Options

12.37.2.1.4.1 Network Settings

- **Listen Port:** TCP port for incoming connections (default: 23 - Telnet)
- **Client Timeout:** Inactivity timeout in seconds (default: 60)
- **Client Override Timeout:** Time before allowing new connections to override existing ones (default: 20)

12.37.2.1.4.2 Serial Settings

- **Baud Rate:** Configurable via web interface (9600, 19200, 38400, 57600, 115200, 230400)
- **Data Format:** 8 data bits, 1 stop bit, no parity (fixed)
- **Flow Control:** None (configurable in code)

12.37.2.1.4.3 Connection Override Policies

- **Ignore New Connections:** Set override timeout to 0xFFFFFFFF
- **Replace After Timeout:** Set override timeout to desired seconds
- **Always Replace:** Set override timeout to 0

12.37.2.1.5 Build Configuration

12.37.2.1.5.1 Preprocessor Definitions

- `SETTINGS_KEY`: Flash memory configuration key (0x48666050)
- `DATA_SERIAL_PORT`: Serial port number for data (1)
- `DEBUG_SERIAL_PORT`: Serial port for debug output (0)
- `DEBUG`: Enable/disable debug output (1)

12.37.2.1.5.2 Buffer Sizes

- `BUFFER_SIZE`: Data transfer buffer size (1500 bytes)
- `CLIENT_WRITE_BUF_SIZE`: Client write buffer (256 bytes)

12.37.2.1.6 Usage

12.37.2.1.6.1 Initial Setup

1. Connect serial device to the configured data serial port
2. Connect NetBurner device to Ethernet network
3. Power on and wait for network initialization

12.37.2.1.6.2 Web Configuration

1. Navigate to the device's IP address in a web browser
2. Configure TCP and serial port settings as needed
3. Save settings (optionally reboot on save)

12.37.2.1.6.3 Client Connection

1. Connect TCP client to device IP on configured port
2. Data will flow bidirectionally between serial device and TCP client
3. Connection status messages are sent to both serial and network endpoints

12.37.2.1.7 Connection Management

12.37.2.1.7.1 Message Types

- **MTS (Message To Serial):** Status messages sent to serial port
- **MTN (Message To Network):** Status messages sent to network client

12.37.2.1.7.2 Status Messages

- Connection opened/closed notifications
- Timeout warnings
- Connection override notifications

12.37.2.1.8 Data Pump Algorithm

The DataPump function implements efficient I/O multiplexing:

1. **Setup:** Initialize file descriptor sets for read, write, and error monitoring
2. **Select:** Wait for I/O activity with configurable timeout
3. **Process:** Handle data transfer in both directions simultaneously
4. **Buffer Management:** Manage separate buffers for each direction
5. **Error Handling:** Detect and handle connection errors gracefully

12.37.2.1.9 Error Handling

- **Connection Errors:** Automatic cleanup and restart
- **Timeout Management:** Configurable inactivity timeouts
- **Buffer Overflow:** Fixed-size buffers with proper bounds checking
- **Network Errors:** Graceful socket closure and restart

12.37.2.1.10 Performance Characteristics

- **Throughput:** Limited by slowest link (typically serial port)
- **Latency:** Low latency due to `select()` based I/O
- **Memory Usage:** Fixed buffer allocation for predictable memory footprint
- **CPU Usage:** Event-driven architecture minimizes CPU overhead

12.37.2.1.11 Development Notes

12.37.2.1.11.1 Adding Features

- Modify `classSerialSettings` in `nvsettings.h` for new configuration options
- Update `index.html` for web interface changes
- Extend `DataPump` function for additional protocols

12.37.2.1.11.2 Debug Configuration

- Set `DEBUG_SERIAL_PORT` to -1 to share debug and data ports
- Set `DEBUG` to 0 to disable debug output entirely
- Use separate debug port for isolation during development

12.37.2.1.12 Hardware Requirements

- NetBurner embedded module with NNDK support
- RS-232 serial interface
- Ethernet connection

12.37.2.1.13 Software Dependencies

- NetBurner NNDK (NetBurner Network Development Kit)
- Config server system for web-based configuration
- Standard POSIX socket and file descriptor APIs

12.37.3 Serial HTTP Get Request

Example of sending a HTTP GET request through serial port when running a serial to Ethernet application.

Hardware Configuration:

Serial Device <--serial--> NetBurner Serial to Ethernet Device <--ethernet--> Internet

In this example we will be using a SB800EX as the "Serial Device", but this would typically be a microprocessor or FPGA with a UART that needs to communicate over a network. The source code in this file is an example of what you would need to implement in your own microprocessor to send a GET request through a NetBurner device to some other device on the network/Internet running a web server.

The code in the main.cpp source file was tested with the SB800EX, but should work with any of the NetBurner standard devices. A serial cable was connected from port 1 of the SB800EX to port 1 of the SBL2e development board. Since the SBL2e development board DB9 connector is cross-wired for RX and TX, all you need is a straight through serial cable.

SB800EX <--serial--> SBL2e <--ethernet--> Internet

The web page contacted is myip.dnssdynamic.com, which return the IP address of the HTTP GET request.

Software Configuration for SBL2e, serial port 1:

Running the SBL2e factory serial to Ethernet application. This was done through the web page, but you can also do it through serial AT commands.

1. Incoming TCP Settings: Uncheck Listen for Incoming Network Connections
2. Outgoing TCP Settings: Make outgoing connections: If serial data received
3. Outgoing TCP Settings: Connect on network port: 80
4. Outgoing TCP Settings: Connect to this address: myip.dnssdynamic.com

12.37.4 Serial Receive Callback

12.37.4.1 Serial Receive Callback Example

12.37.4.1.1 Overview

This NetBurner embedded application demonstrates how to register a custom callback function to intercept and handle serial port receive processing. The example shows how to bypass the default system serial receive handling and implement custom processing using a circular buffer.

12.37.4.1.2 Application Description

The application creates a serial receive callback system that:

- Opens serial port 1 at 115200 baud rate
- Registers a custom callback function to handle incoming serial data
- Uses a circular buffer to store received data
- Continuously processes and displays received characters

12.37.4.1.3 Key Features

12.37.4.1.3.1 Serial Receive Callback

- **Function:** `SerialReceiveCallback(int uartNum, unsigned char dataByte)`
- **Purpose:** Intercepts serial data at the interrupt level
- **Restrictions:** Called from interrupt context - no I/O functions allowed, only RTOS post functions

12.37.4.1.3.2 Circular Buffer Implementation

- **Size:** 256 bytes (RX_BUF_SIZE)
- **Variables:**
 - `indexGet`: Read pointer for the circular buffer
 - `indexPut`: Write pointer for the circular buffer
 - `CircBufferArray`: The actual buffer storage
- **Buffer Management:** Automatically wraps around when reaching buffer limits

12.37.4.1.3.3 Main Processing Loop

- Opens serial port 1 at 115200 baud
- Assigns the custom callback to UART1 receive processing
- Continuously reads from the circular buffer and displays characters
- Uses `OSTimeDly(1)` for task scheduling

12.37.4.1.4 Hardware Requirements

- NetBurner embedded device with UART1 capability
- Serial connection to UART1 at 115200 baud rate

12.37.4.1.5 Code Structure

```
main.cpp
  Headers and includes
  Global variables (circular buffer)
  SerialReceiveCallback() - Interrupt-level callback
  UserMain() - Main application loop
```

12.37.4.1.6 Important Notes

12.37.4.1.6.1 Interrupt Context Limitations

The `SerialReceiveCallback` function operates in interrupt context, which means:

- No standard I/O functions (`printf`, `iprintf`, etc.) can be called
- Only RTOS post functions are safe to use
- Keep processing minimal and fast

12.37.4.1.6.2 Buffer Overflow Handling

The circular buffer implements a simple overflow strategy:

- When the buffer is full, the oldest data is overwritten
- Both read and write pointers automatically wrap around

12.37.4.1.6.3 System Diagnostics

The application enables system diagnostics with `EnableSystemDiagnostics()`. This should be removed for production code.

12.37.4.1.7 Usage

1. Compile and flash the application to a NetBurner device
2. Connect a serial terminal to UART1 at 115200 baud
3. Send data to the serial port
4. Observe the echoed characters in the application output

12.37.4.1.8 Build Information

The application displays build timestamp information on startup, showing when the code was compiled.

12.37.5 Serial to Serial

12.37.5.1 Serial to Serial Example

Note

Refer to the OpenAllUARTS example for your particular platform to see all possible serial configurations and pin locations

12.37.5.1.1 Overview

This application demonstrates a simple serial port bridge that forwards data bidirectionally between two serial ports on a NetBurner embedded system. The program uses the `select()` function to efficiently monitor both serial ports simultaneously and forward data from one port to the other in real-time.

12.37.5.1.2 Description

The Serial to Serial example opens two serial ports and creates a bridge between them, allowing data sent to one port to be automatically forwarded to the other port. This is useful for applications such as:

- Serial port debugging and monitoring
- Creating a serial bridge between different devices
- Testing serial communication systems
- Bridging different serial interfaces

12.37.5.1.3 Key Features

- **Bidirectional Communication:** Data flows in both directions between the two serial ports
- **Interrupt-Driven Mode:** Uses buffered interrupt-driven serial communication for efficient operation
- **Non-blocking I/O:** Utilizes the `select()` function to monitor multiple file descriptors simultaneously
- **Configurable Timeout:** Uses a 5-second timeout for the select operation
- **LED Indicators:** On MOD5441X platforms, LEDs indicate when data is being transferred

12.37.5.1.4 Technical Implementation

12.37.5.1.4.1 Serial Port Configuration

Both serial ports are configured with identical settings:

- **Baud Rate:** 115,200 bps
- **Stop Bits:** 1
- **Data Bits:** 8
- **Parity:** None

12.37.5.1.4.2 Operation Flow

1. **Initialization:**

- System initialization and network startup
- Serial ports are closed (they start in polled mode from monitor)
- Serial ports are reopened in interrupt-driven mode

2. **Initial Test:**

- Sends "Test1" to serial port 1
- Sends "Test0" to serial port 0

3. **Main Loop:**

- Sets up file descriptor set for both serial ports
- Uses `select ()` to wait for data on either port (5-second timeout)
- When data arrives on port 1, forwards it to port 0
- When data arrives on port 0, forwards it to port 1
- On MOD5441X platforms, toggles LEDs to indicate activity

12.37.5.1.4.3 Buffer Management

- Uses 40-byte buffers for data transfer
- Reads available data and immediately forwards it to the opposite port
- No data modification or processing - pure pass-through operation

12.37.5.1.5 Hardware Requirements

- NetBurner embedded system with at least two serial ports
- Compatible with MOD5441X platforms (includes LED indicators)
- Serial devices or cables connected to both serial ports for testing

12.37.5.1.6 Usage

1. Connect serial devices or use serial cables to connect to both serial ports
2. Compile and deploy the application to your NetBurner device
3. Power on the device - it will automatically start bridging the serial ports
4. Send data to either serial port and observe it being forwarded to the other port
5. On MOD5441X platforms, watch for LED activity indicating data transfer

12.37.5.1.7 Code Structure

- **Initialization:** Sets up the system and network
- **Serial Port Setup:** Configures both serial ports for interrupt-driven operation
- **Main Loop:** Implements the select-based data forwarding logic
- **Platform-Specific Features:** Conditional LED control for supported platforms

12.37.5.1.8 Notes

- The system diagnostics are enabled in this example but should be removed for production code
- The application waits up to 5 seconds for network activation at startup
- The select timeout of 5 seconds means the loop will cycle even if no data is received
- This is a blocking application that runs indefinitely

12.37.6 Serial Application Update

12.37.6.1 Overview

Updating a device application can be done many ways. The most common is over a network connection, but there are times when it is preferable or necessary to update an applicatoin over a serial connection.

The Serial Update Example demonstrates two approaches: #- Serial config server. This can be though of as being the same as manually entering the serial config server with an A to abort command and using the fla command to flash the application. #- Direct. This method assumed 100% control over the update and does not use the serial configuration server.

12.37.6.2 Methods

12.37.6.2.1 Method 1:

The `void ResumeSerialConfig(int fd_cfg, bool persist)` system function is used to trigger the serial configuraiton server to use the specified file descriptor to process the serial stream. Nothing more is required. This is the most common method.

12.37.6.2.2 Method 2:

The direct method puts the update responsibility on the application. The example demonstrates two scenarios: The serial port is being used for both applications data as well as a serial application update. In this case a mechanism is required to identify an update vs serial data. To accomodate this situation, the example provides an approach to using a configurable preamble and escape mechanisms. It is up to the application to decide what the best mechanisam is to identify an update vs data; the example provides one such method. A preamble and/or escape mechanism may or may not be necessary in your specific use case.

12.37.7 TCP to Serial

12.37.7.1 TCP to Serial Bridge

A NetBurner embedded application that creates a bidirectional bridge between TCP network connections and serial communication ports.

12.37.7.1.1 Overview

This application enables remote access to serial devices over a network by creating a TCP server that forwards data between network clients and a serial port. It's commonly used for remote device management, debugging, and data acquisition from serial-based equipment.

Note

You can test with on a single PC by using a telnet application and serial terminal like MTTY

12.37.7.1.2 Features

- **Bidirectional Communication:** Data flows seamlessly between TCP clients and serial devices
- **Telnet Compatible:** Listens on port 23 (standard Telnet port) for easy connection
- **Connection Management:** Handles multiple connection attempts with configurable override behavior
- **Timeout Protection:** Automatically closes idle connections after 60 seconds

- **Multi-Platform Support:** Supports various NetBurner platforms (SOMRT1061, MODRT1171, SB800EX)
- **Status Monitoring:** Provides connection status messages to both serial and network interfaces

12.37.7.1.3 Configuration

12.37.7.1.3.1 Serial Port Settings

- **Baud Rate:** 115,200 bps
- **Data Bits:** 8
- **Stop Bits:** 1
- **Parity:** None

12.37.7.1.3.2 Network Settings

- **TCP Listen Port:** 23 (Telnet)
- **Connection Timeout:** 60 seconds of inactivity
- **Override Timeout:** 20 seconds (configurable)

12.37.7.1.3.3 Connection Override Behavior

The application supports three modes for handling new connections when one is already active:

1. **Ignore New Connections** (`OVERIDE_TIMEOUT = 0xFFFFFFFF`)
 - Maintains current connection, rejects new attempts
2. **Timed Override** (`OVERIDE_TIMEOUT = 20 seconds`)
 - Allows new connection to replace existing one after 20 seconds of current connection activity
3. **Always Override** (`OVERIDE_TIMEOUT = 0`)
 - Immediately replaces existing connection with new one

12.37.7.1.4 Platform Support

The application automatically configures pins for different NetBurner platforms where necessary:

- **SOMRT1061:** Uses LPUART4 on pins 87 (RX), 88 (TX), with flow control on pins 2 (RTS), 3 (CTS)
- **MODRT1171:** Uses LPUART2 on pins 21 (RX), 22 (TX)
- **SB800EX:** Uses UART2

Notes for SOMRT1061

- The console port for status messages is J13 on the development board, which is routed to LPUART3 on the processor.
- The data port is J14 on the development board, which is routed to LPUART4 on the processor.
- RX, TX, RTS, CTS pin selection is always required before opening the serial port.

Note

Refer to the OpenAllUARTS example for your particular platform to see all possible pin configurations.

12.37.7.1.5 Usage

1. **Compile and Deploy:** Build the application for your NetBurner platform and deploy to the device
2. **Connect Serial Device:** Attach your serial device to the configured UART pins
3. **Network Connection:** Connect via Telnet client to the device's IP address on port 23
`telnet <device-ip-address> 23`
4. **Data Exchange:** Data typed in the Telnet session is sent to the serial device, and serial responses appear in the Telnet session

12.37.7.1.6 Status Messages

The application provides informative status messages:

To Serial Port:**

- "Waiting for connection"
- "New Connection Opened"
- "Connection Closed by Network"
- "Connection Timed out and Closed"
- "This Connection is being Overridden"
To Network Client:**
- "Connection Opened"
- "Your Connection was just Overridden"
- "Your Connection Timed out and will be Closed"

12.37.7.1.7 Technical Details

- Uses NetBurner's RTOS with `select()` for efficient I/O multiplexing
- Implements proper socket management with error handling
- Supports hardware flow control (RTS/CTS) where available
- Buffer size: 40 bytes for data transfers
- Non-blocking I/O operations for responsive performance

12.37.7.1.8 Use Cases

- Remote serial device configuration and monitoring
- Data logging from serial sensors over network
- Remote debugging of embedded systems
- Industrial automation equipment access
- Legacy serial device integration into modern networks

12.37.7.1.9 Requirements

- NetBurner development kit
- NetBurner development environment
- Network connectivity (Ethernet)
- Serial device or equipment to bridge

12.37.7.1.10 Notes

- Ensure proper pin configuration for your specific NetBurner platform
- Test connection override behavior matches your application requirements

12.37.8 Serial Webserver

12.37.8.1 Serial Webserver

A NetBurner RTOS application that bridges serial communication with HTTP web services, allowing HTTP requests to be received and processed over a serial port connection.

12.37.8.1.1 Overview

The Serial Webserver demonstrates how to create a bidirectional communication bridge between a serial port and TCP/HTTP connections. This application enables HTTP requests to be sent over a serial connection and receive corresponding web responses back through the same serial interface.

It will receive and reply to HTTP requests over a serial port, using the NetBurner web server implementation. The example will display a Hello World message on the device's index page `index.html`.

12.37.8.1.2 Key Features

- **Serial-to-HTTP Bridge:** Receives HTTP requests via serial port and forwards them to the built-in web server
- **Bidirectional Communication:** Splices data between serial and TCP connections in both directions
- **Automatic Connection Management:** Handles TCP connection creation and cleanup automatically
- **Error Recovery:** Automatically reopens serial connections on errors
- **Built-in Web Server:** Serves static content including HTML, CSS, and images

12.37.8.1.3 Technical Specifications

- **Serial Port:** Port 1 at 115200 baud
- **HTTP Port:** Standard port 80
- **Buffer Size:** Uses Ethernet buffer size for data transfer
- **Network Stack:** NetBurner RTOS with TCP/IP support

12.37.8.1.4 Application Architecture

The application follows a simple event-driven architecture:

1. **Initialization:** Sets up network stack, enables diagnostics, and starts HTTP server
2. **Serial Monitoring:** Waits for incoming serial data
3. **Connection Creation:** Establishes TCP connection to local web server when data arrives
4. **Data Splicing:** Uses `select()` to monitor both serial and TCP file descriptors
5. **Bidirectional Transfer:** Forwards data between serial and TCP connections
6. **Error Handling:** Closes and reopens connections on errors

12.37.8.1.5 HTTP Request Format

The application expects standard HTTP requests over the serial connection. A typical request format:

```
GET /INDEX.HTML HTTP/1.1\r\n\r\n
```

Important**: The web server requires a double carriage return line feed (`\r\n\r\n`) to properly parse HTTP requests.

12.37.8.1.6 Expected Response

A successful request to the index page returns:

```
HTTP/1.0 200 OK
Pragma: no-cache
MIME-version: 1.0
Content-Type: text/html
Content-length: 231
```

```
<html>
<head><link rel="stylesheet" type="text/css" href="style.css"></head>
<body>
<a href="http://www.netburner.com"></a>
<h1>Thank you for NetBurning!</h1>
</body>
</html>
```

12.37.8.1.7 Web Content

The application serves the following static files:

- **index.html**: Main page with NetBurner branding and welcome message
- **style.css**: Stylesheet defining Arial font family for the page
- **logo.jpg**: NetBurner logo image (referenced but not included in source)

12.37.8.1.8 Usage

1. Flash the application to your NetBurner device
2. Connect to the device's serial port (Port 1, 115200 baud)
3. Send HTTP requests through the serial connection
4. Receive HTTP responses back through the same serial connection

12.37.8.1.9 Development Notes

- System diagnostics are enabled for development (consider removing for production)
- The application uses blocking I/O operations
- Memory allocation uses `FAST_USER_VAR` for the splice buffer

12.37.8.1.10 Use Cases

This application is ideal for:

- Testing HTTP communication through serial interfaces
- Bridging legacy serial devices to modern web services
- Remote web server access through serial connections

12.37.8.1.11 Build Requirements

- NetBurner NBRTOS development environment
- Standard NetBurner libraries (init, system, iosys, serial, tcp, netinterface)
- Compatible NetBurner hardware platform

12.38 SHA1 Digest

Calculate the SHA1 128-bit digest on an application. To display the digest when building the application in NBEclipse, go to the project properties and add `-D` to the compcode flags.

- **Formatted display** - Clean HTML tables with organized information
- **Multiple protocol links** - Both IPv4 and IPv6 connectivity testing

12.39.1.3.3 Development and Debugging

- **Serial console output** - Detailed information for development
- **DHCP lease tracking** - Timing information for address renewals
- **Link status reporting** - Physical connection monitoring
- **Optional features** - WiFi and static IPv6 configuration support

12.39.1.4 Implementation Details

12.39.1.4.1 Main Application (main.cpp)

12.39.1.4.1.1 System Initialization and Main Loop

```
void UserMain(void *pd) {
    init(); // Initialize network stack
    EnableSystemDiagnostics(); // Enable debug output
    StartHttp(); // Start HTTP server on port 80
    WaitForActiveNetwork(TICKS_PER_SECOND * 5); // Wait for network connectivity

    printf("Application: %s\nNNDK Revision: %s\n", AppName, GetReleaseTag());

#ifdef USE_WIFI
    InitWifi_SPI(); // Initialize WiFi if enabled
#endif

#ifdef STATIC_IP6_TEST
    // Add static IPv6 address for testing
    IPv6Interface *pIPv6If = IPv6Interface::GetFirst_IP6_Interface();
    IPADDR i6 = IPADDR6::AsciiToIp6("1234:5678:abcd::1234");
    pIPv6If->AddStaticAddress(i6, 64);
#endif

    // Interactive main loop
    while (1) {
        printf("\nType any key to display address information\n");
        printf("Note that IPv6 routable addresses may take a few seconds to be received\n");
        getchar();
        showIpAddressesSerial();
        showLinkStatus();
        printf("\n\n");
    }
}
```

12.39.1.4.1.2 Configuration Options

```
// Optional WiFi support
#define USE_WIFI (1)

// Optional static IPv6 testing
#define STATIC_IP6_TEST (1)

// IPv6 support (typically defined globally)
#ifdef IPV6
```

12.39.1.4.2 Network Information Utilities (ip_util.cpp)

12.39.1.4.2.1 Serial Console Display Function

```
void showIpAddressesSerial() {
    int ifNumber = GetFirstInterface();

    while (ifNumber) {
        InterfaceBlock *ifBlock = GetInterfaceBlock(ifNumber);

        printf("\nInterface %d, %s, MAC:", ifNumber, ifBlock->GetInterfaceName());
        InterfaceMAC(ifNumber).print();
        printf("\n\n");

        // Display IPv4 information
        printf("IPv4 Addresses:\n");
        printf("IP: %hI\n", InterfaceIP(ifNumber));
        printf("Mask: %hI\n", InterfaceMASK(ifNumber));
    }
}
```

```

printf("DNS:      %hI\n", InterfaceDNS(ifNumber));
printf("DNS2:     %hI\n", InterfaceDNS2(ifNumber));
printf("Gateway:  %hI\n", InterfaceGate(ifNumber));
printf("Auto IP:   %hI\n", InterfaceAutoIP(ifNumber));

#ifdef IPV6
// Display IPv6 information
printf("IPv6 Addresses:\n");
IPv6Interface *pIPv6If = IPv6Interface::GetInterfaceN(ifNumber);
if (pIPv6If) {
    IPV6_PREFIX *pPrefix = pIPv6If->FirstPrefix();
    while (pPrefix) {
        if (pPrefix->bValidForInterface && pPrefix->AgeStillValidTest()) {
            ePrefixSource pSrc = pPrefix->Source();
            printf("%-10s: ", SourceName(pSrc));
            pPrefix->m_IPAddress.print();
            printf("/%d\n", pPrefix->PrefixLen);

            // Display DHCP lease information if applicable
            if (pPrefix->pDHCPD) {
                char buf[120];
                getLeaseTimeInfo(pPrefix, buf, 120);
                printf("      %s\n", buf);
            }
        }
        pPrefix = pPrefix->GetNext();
    }
}
#endif
ifNumber = GetNextInterface(ifNumber);
}
}

```

12.39.1.4.2.2 Web Interface Display Function

```

void showIpAddressesWeb(int socket, const char *url) {
    IPADDR localIP = GetSocketLocalAddr(socket);
    uint32_t remotePort = GetSocketRemotePort(socket);

    fdprintf(socket, "<br>Web browser request came from:");
    localIP.fprintf(socket);
    fdprintf(socket, ": %d<br>\n", remotePort);

    int ifNumber = GetFirstInterface();
    while (ifNumber) {
        InterfaceBlock *ifBlock = GetInterfaceBlock(ifNumber);

        fdprintf(socket, "<hr>\n");
        fdprintf(socket, "<strong>Interface # %d, %s, MAC: ", ifNumber, ifBlock->GetInterfaceName());
        MACADDR MacAddr = InterfaceMAC(ifNumber);
        fdShowMac(socket, &MacAddr);
        fdprintf(socket, "</strong><br>");

        // Create IPv4 information table
        fdprintf(socket, "<br><strong>IPv4 Addresses: </strong><br>");
        fdprintf(socket, "<table border=0>\n");
        fdprintf(socket, "<tr><td>IP:      </td><td>%hI</td></tr>\n", InterfaceIP(ifNumber));
        fdprintf(socket, "<tr><td>Mask:    </td><td>%hI</td></tr>\n", InterfaceMASK(ifNumber));
        fdprintf(socket, "<tr><td>DNS1:   </td><td>%hI</td></tr>\n", InterfaceDNS(ifNumber));
        fdprintf(socket, "<tr><td>DNS2:   </td><td>%hI</td></tr>\n", InterfaceDNS2(ifNumber));
        fdprintf(socket, "<tr><td>Gateway: </td><td>%hI</td></tr>\n", InterfaceGate(ifNumber));
        fdprintf(socket, "<tr><td>AutoIP: </td><td>%hI</td></tr>\n", InterfaceAutoIP(ifNumber));
        fdprintf(socket, "</table>\n");

        // Create clickable IPv4 link
        if (GetInterfaceLink(ifNumber)) {
            fdprintf(socket, "Make an IPv4 request: <a href=\"http://");
            InterfaceIP(ifNumber).fprintf(socket);
            fdprintf(socket, "\">");
            InterfaceIP(ifNumber).fprintf(socket);
            fdprintf(socket, "</a><br>\n");
        }
    }

#ifdef IPV6
// Create IPv6 information table with clickable links
IPv6Interface *pIPv6If = IPv6Interface::GetInterfaceN(ifNumber);
if (pIPv6If) {
    fdprintf(socket, "<br><strong>IPv6 Addresses:</strong><br>\n");
    fdprintf(socket, "<table border=0 cellpadding=5>\n");

    IPV6_PREFIX *pPrefix = pIPv6If->FirstPrefix();
    while (pPrefix) {
        if (pPrefix->bValidForInterface) {
            ePrefixSource pSrc = pPrefix->Source();
            fdprintf(socket, "<tr> <td><a href=\"http://[%I]\">%I</a></td> <td>Assigned by %s",

```

```

        pPrefix->m_IPAddress, pPrefix->m_IPAddress, SourceName(pSrc));

        if (pPrefix->pDHCPCD) {
            char buf[120];
            getLeaseTimeInfo(pPrefix, buf, 120);
            fdprintf(socket, ": %s", buf);
        }
        fdprintf(socket, "</td></tr>\n");
    }
    pPrefix = pPrefix->GetNext();
}
fdprintf(socket, "</table>\n");
}
#endif
    ifNumber = GetNextInterface(ifNumber);
}
}

```

12.39.1.4.2.3 Link Status Monitoring

```

void showLinkStatus() {
    int ifNumber = GetFirstInterface();

    while (ifNumber) {
        InterfaceBlock *ifBlock = GetInterfaceBlock(ifNumber);

        if (ifBlock) {
            printf("Interface %d, %s:\n", ifNumber, ifBlock->GetInterfaceName());
            if (ifBlock->LinkActive()) {
                printf("Link Status: UP, %dMB, ", ifBlock->LinkSpeed());
                if (ifBlock->LinkDuplex()) {
                    printf("Full Duplex\n");
                } else {
                    printf("Half Duplex\n");
                }
            } else {
                printf("Link Status: DOWN\n");
            }
        }
        ifNumber = GetNextInterface(ifNumber);
    }
}

```

12.39.1.4.3 IPv6 Address Source Management

12.39.1.4.3.1 Address Source Identification

```

const char *SourceName(ePrefixSource e) {
    switch (e) {
        case eLinkLocal: return "Link Local";
        case eRouter: return "Router";
        case eDHCP: return "DHCP";
        case eStatic: return "Static";
        case eUnknown:
        default: return "Unknown";
    }
}

```

12.39.1.4.3.2 DHCP Lease Time Tracking

```

void getLeaseTimeInfo(IPV6_PREFIX *pPrefix, char *timeStr, uint32_t maxTimeStrLen) {
    const uint32_t maxLen = 80;
    char strCurrentTime[maxLen];
    char strRenewTime[maxLen];
    char strRebindTime[maxLen];

    uint32_t seconds = TimeTick / TICKS_PER_SECOND;
    getTimeStringFromSeconds(seconds, strCurrentTime, maxLen);

    seconds = (pPrefix->pDHCPCD->m_renewTick) / TICKS_PER_SECOND;
    getTimeStringFromSeconds(seconds, strRenewTime, maxLen);

    seconds = (pPrefix->pDHCPCD->m_rebindTick) / TICKS_PER_SECOND;
    getTimeStringFromSeconds(seconds, strRebindTime, maxLen);

    snprintf(timeStr, maxTimeStrLen,
        "Time Since Boot: %s, Renew: %s, Rebind: %s",
        strCurrentTime, strRenewTime, strRebindTime);
}

```

12.39.1.4.3.3 Time Formatting Utility

```
void getTimeStringFromSeconds(uint32_t seconds, char *strTime, uint32_t maxLen) {
    uint32_t hour = seconds / 3600;
    uint32_t min = (seconds % 3600) / 60;
    uint32_t sec = seconds % 60;

    snprintf(strTime, maxLen, "%02u:%02u:%02u", hour, min, sec);
}
```

12.39.1.5 Web Interface Structure

12.39.1.5.1 Main Page Layout (index.html)

```
<html>
<head>
<title>NetBurner IPv4/IPv6 Show Addresses Example</title>
<meta http-equiv="Content-Type" content="text/html; charset=iso-8859-1">
</head>

<body bgcolor="#FFFFFF" text="#000000">
<table width="850" border="0" cellpadding="0" cellspacing="0" height="121">
  <tr>
    <td width="200"><a href="http://www.netburner.com"></a></td>
    <td width="50"></td>
    <td width="600" align="right">
      <b><font face="Arial, Helvetica, sans-serif" size="5" color="#0000FF">
        NetBurner IPv4/IPv6 Show Addresses Example</font></b>
    </td>
  </tr>
</table>

<font face="Arial, Helvetica, sans-serif" size="3">
<table width="850" border="0" cellpadding="0" cellspacing="0">
  <tr>
    <td>This example program demonstrates how to access the NetBurner web server
      using either an IPv4 or IPv6 IP address.</td>
  </tr>
</table>

<!--CPPCALL showIpAddressesWeb -->
</font>
</body>
</html>
```

12.39.1.5.2 Dynamic Content Integration

- **CPPCALL tag** - `<!--CPPCALL showIpAddressesWeb -->` dynamically generates network information
- **Interactive links** - IP addresses become clickable links for connectivity testing
- **Real-time data** - Information reflects current network state when page loads

12.39.1.6 Network Information Display

12.39.1.6.1 IPv4 Address Information

- **IP Address** - Current assigned IPv4 address
- **Subnet Mask** - Network mask for local subnet
- **DNS Servers** - Primary and secondary DNS server addresses
- **Default Gateway** - Router address for external connectivity
- **AutoIP Address** - Link-local address (169.254.x.x) if **DHCP** unavailable

12.39.1.6.2 IPv6 Address Information

- **Link Local** - Automatically generated local addresses (fe80::/64)
- **Router Assigned** - Addresses from Router Advertisement messages
- **DHCP Assigned** - Addresses from DHCPv6 server

- **Static Assigned** - Manually configured addresses
- **DNS Servers** - IPv6 DNS server information with source attribution

12.39.1.6.3 Physical Interface Details

- **Interface Number** - System interface identifier
- **Interface Name** - Human-readable interface name (e.g., "Ethernet 0")
- **MAC Address** - Hardware address in standard format
- **Link Status** - UP/DOWN physical connection state
- **Connection Speed** - 10/100/1000 Mbps negotiated speed
- **Duplex Mode** - Half/Full duplex communication mode

12.39.1.6.4 DHCP Lease Management

- **Current Time** - System uptime in HH:MM:SS format
- **Renew Time** - When **DHCP** lease renewal will occur
- **Rebind Time** - When **DHCP** lease rebinding will occur
- **Lease Source** - Whether address came from **DHCP** or Router Advertisement

12.39.1.7 Usage Instructions

12.39.1.7.1 Build and Deployment

1. **Build application:**
2. **Deploy to device:**
3. **Monitor startup:**
 - Connect serial terminal (115200 baud, 8-N-1)
 - Observe network initialization and IP address assignment

12.39.1.7.2 Serial Console Interface

12.39.1.7.2.1 Interactive Operation

1. **Wait for prompt:** "Type any key to display address information"
2. **Press any key** to trigger information display
3. **View output:** Complete network interface information
4. **Repeat as needed** to monitor network changes

12.39.1.7.2.2 Expected Console Output

Application: Show Interfaces
NNDK Revision: 3.x.x Build xxxx

Type any key to display address information
Note that IPv6 routable addresses may take a few seconds to be received

Interface 1, Ethernet 0, MAC: 00:03:F4:XX:XX:XX

IPv4 Addresses:
IP: 192.168.1.100
Mask: 255.255.255.0
DNS: 192.168.1.1
DNS2: 0.0.0.0
Gateway: 192.168.1.1

```

Auto IP: 0.0.0.0

IPv6 Addresses:
Link Local: fe80::203:f4ff:fexx:xxxx/64
Router      : 2001:db8::203:f4ff:fexx:xxxx/64
              Time Since Boot: 00:05:23, Renew: 01:00:00, Rebind: 01:45:00

DNS:
  2001:db8::1 - Source: Router

Interface 1, Ethernet 0:
Link Status: UP, 100MB, Full Duplex

```

12.39.1.7.3 Web Interface Operation

12.39.1.7.3.1 Access and Navigation

1. **Open browser** to device IP address (e.g., <http://192.168.1.100>)
2. **View network information** in formatted HTML tables
3. **Test connectivity** by clicking any displayed IP address
4. **IPv6 testing** - Click IPv6 addresses to test IPv6 connectivity

12.39.1.7.3.2 Interactive Features

- **IPv4 Links** - Format: <http://192.168.1.100>
- **IPv6 Links** - Format: [http://\[2001:db8::203:f4ff:fexx:xxxx\]](http://[2001:db8::203:f4ff:fexx:xxxx])
- **Connectivity Testing** - Each link opens new page to test reachability
- **Real-time Information** - Refresh page to see current network status

12.39.1.7.3.3 Expected Web Display

Web browser request came from: 192.168.1.50: 54321

Device Interfaces:

Interface # 1, Ethernet 0, MAC: 00:03:F4:XX:XX:XX

```

IPv4 Addresses:
IP:      192.168.1.100
Mask:    255.255.255.0
DNS1:    192.168.1.1
DNS2:    0.0.0.0
Gateway: 192.168.1.1
AutoIP:  0.0.0.0

```

Make an IPv4 request: [192.168.1.100] (clickable link)

```

IPv6 Addresses:
[fe80::203:f4ff:fexx:xxxx] (clickable)   Assigned by Link Local
[2001:db8::203:f4ff:fexx:xxxx] (clickable) Assigned by Router: Time Since Boot: 00:05:23, Renew: 01:00:00,
Rebind: 01:45:00

```

12.39.1.8 Advanced Features

12.39.1.8.1 Multiple Interface Support

The application automatically detects and displays all available network interfaces:

```

int ifNumber = GetFirstInterface();
while (ifNumber) {
    // Process each interface
    InterfaceBlock *ifBlock = GetInterfaceBlock(ifNumber);
    // ... display interface information
    ifNumber = GetNextInterface(ifNumber);
}

```

12.39.1.8.2 WiFi Integration

Optional WiFi support can be enabled:

```

#ifdef USE_WIFI
    InitWifi_SPI(); // Initialize WiFi interface
#endif

```

12.39.1.8.3 IPv6 Address Assignment Monitoring

The application tracks IPv6 addresses from multiple sources:

- **Link Local** - Automatic based on MAC address
- **Router Advertisement** - Assigned by network router
- **DHCPv6** - Assigned by [DHCP](#) server
- **Static Configuration** - Manually configured addresses

12.39.1.8.4 DHCP Lease Tracking

For DHCP-assigned addresses, the system tracks:

- **Current system uptime** - Time since device boot
- **Lease renewal time** - When address renewal will occur
- **Lease rebind time** - When address rebinding will happen

12.39.1.8.5 Development and Testing Features

12.39.1.8.5.1 Static IPv6 Testing

```
#ifdef STATIC_IP6_TEST
    IPv6Interface *pIPv6If = IPv6Interface::GetFirst_IP6_Interface();
    IPADDR i6 = IPADDR6::AsciiToIp6("1234:5678:abcd::1234");
    pIPv6If->AddStaticAddress(i6, 64);
#endif
```

12.39.1.8.5.2 Network Timing Considerations

- **IPv6 Address Assignment** - May take 5-30 seconds depending on router
- **DHCP Lease Updates** - Renewals happen automatically in background
- **Link Status Changes** - Detected immediately on physical connection changes

12.39.1.9 Troubleshooting

12.39.1.9.1 Common Issues

12.39.1.9.1.1 No IPv6 Addresses Displayed

Symptoms**: Only IPv4 information shown Solutions**:

- Wait 30 seconds for router advertisement
- Check router IPv6 configuration
- Verify IPv6 enabled in build configuration
- Test with known IPv6-enabled network

12.39.1.9.1.2 Link Status Shows DOWN

Symptoms**: "Link Status: DOWN" in output Solutions**:

- Check Ethernet cable connection
- Verify cable is good (test with PC)
- Check switch/router port status
- Test with different network port

12.39.1.9.1.3 DHCP Address Not Assigned

Symptoms*: IP shows 0.0.0.0 or AutoIP address Solutions*:

- Verify [DHCP](#) server is running on network
- Check [DHCP](#) server has available addresses
- Test with static IP configuration
- Monitor [DHCP](#) server logs for requests

12.39.1.9.1.4 Web Interface Not Accessible

Symptoms*: Browser cannot connect to device Solutions*:

- Verify IP address from serial console
- Check network connectivity with ping
- Confirm HTTP server started successfully
- Test with different browser or incognito mode

12.39.1.9.2 Debug Procedures

12.39.1.9.2.1 Network Connectivity Testing

```
# Test IPv4 connectivity
ping 192.168.1.100

# Test IPv6 connectivity (if supported)
ping6 2001:db8::203:f4ff:fexx:xxxx

# Test HTTP connectivity
curl -v http://192.168.1.100/
curl -v http://[2001:db8::203:f4ff:fexx:xxxx]/
```

12.39.1.9.2.2 Serial Console Monitoring

```
// Add debug output to track network changes
printf("Debug: Interface %d status changed\n", ifNumber);
printf("Debug: Link speed: %d, Duplex: %s\n",
    ifBlock->LinkSpeed(),
    ifBlock->LinkDuplex() ? "Full" : "Half");
```

12.39.1.9.2.3 Address Assignment Verification

```
// Check specific address types
if (InterfaceIP(ifNumber) == IPADDR::NullIP()) {
    printf("Warning: No IPv4 address assigned\n");
}

#ifdef IPV6
if (!pIPv6If || !pIPv6If->FirstPrefix()) {
    printf("Warning: No IPv6 addresses assigned\n");
}
#endif
```

12.39.1.10 Performance Considerations

12.39.1.10.1 Memory Usage

- **Static allocation** - Fixed memory for interface tracking
- **Dynamic enumeration** - Scales with number of interfaces
- **String formatting** - Temporary buffers for display functions
- **Web output** - Streaming output to minimize memory usage

12.39.1.10.2 Network Efficiency

- **On-demand display** - Information gathered only when requested
- **Minimal network overhead** - No background polling or monitoring
- **Efficient iteration** - Single pass through interface list
- **Cached interface data** - Uses system-maintained interface information

12.39.1.10.3 Real-time Considerations

- **Non-blocking display** - Information gathering doesn't block network stack
- **Quick response** - Fast enumeration of current network state
- **Background updates** - Network stack handles address changes automatically
- **Event-driven** - User-initiated display prevents unnecessary processing

12.39.1.11 Build Configuration

12.39.1.11.1 Makefile Components

```
NAME = ShowInterfaces

# Source files
CPP_SRC += src/main.cpp src/ip_util.cpp

# HTML compilation
CREATEDTARGS += src/htmldata.cpp
CPP_SRC += src/htmldata.cpp
src/htmldata.cpp : $(wildcard html/*.*)
    comphtml html -osrc/htmldata.cpp

include $(NNDK_ROOT)/make/boilerplate.mk
```

12.39.1.11.2 Compile-Time Options

- **IPv6 Support** - Enabled via global IPv6 preprocessor definition
- **WiFi Support** - Optional, enabled via `USE_WIFI` definition
- **Static IPv6 Testing** - Optional, enabled via `STATIC_IP6_TEST` definition

12.39.1.11.3 Dependencies

- **NetBurner NNDK** - Network Development Kit with IPv4/IPv6 support
- **Network Interface Libraries** - Built-in interface management
- **IPv6 Libraries** - For IPv6 address and prefix management (optional)
- **WiFi Libraries** - For wireless interface support (optional)

12.39.1.12 Learning Objectives

This example teaches:

- **Network interface enumeration** - How to discover and iterate through interfaces
- **IPv4/IPv6 address management** - Understanding dual-stack networking
- **DHCP lease management** - Tracking address assignment and renewal
- **Link status monitoring** - Physical layer connection management
- **Web-based network tools** - Creating interactive network diagnostic interfaces
- **Cross-platform networking** - Handling multiple interface types and protocols

12.39.1.13 Related Examples

For additional network programming learning, see:

- Basic networking examples for fundamental TCP/IP concepts
- [DHCP](#) client examples for dynamic address configuration
- IPv6 examples for advanced IPv6 features and protocols
- Web server examples for HTTP interface development
- WiFi examples for wireless network integration

12.40 SOCKS5 Client

This program demonstrates how to create a client connection using the SOCKS5 protocol. This protocol is detailed in RFC 1928. The NetBurner libraries support no authorization and plain text username/password options, and provide a callback for the user to implement their own version of GSSAPI, [AuthWithGssApi\(\)](#). This function can be overridden to implement GSSAPI according to specific requirements.

To test this, you can use a Docker image that will run a SOCK5 server, found here: <https://hub.docker.com/r/serjs/go-socks5-proxy/>

12.41 SPI

These SPI examples are common to all 3.x platforms.

Note

These SPI examples work on multiple processor/product architectures. There are additional SPI examples in the processor/product specific folders that may be of interest. For example, the MODM7AE70 has a quad SPI peripheral, but the MOD5441x does not.

- [DSPI Multiplex](#)
- [Serial to SPI](#)
- [SPI PicKit Demo Board](#)

12.41.1 DSPI Multiplex

Supported Platforms: MOD5441X NANO54415 MODM7AE70 SBE70LC SB800EX

This example demonstrates how to use the [DSPIModule](#), object based DSPI driver, to use multiple bus configurations on the same DSPI hardware module without having to re-initialize the driver every time when switching configurations.

12.41.2 Serial to SPI

Supported Platforms: MOD5441X NANO54415 MODM7AE70 SBE70LC

The Serial to SPI example demonstrates the basic configuration of the SPI driver and sending and receiving data over an SPI interface.

12.41.3 SPI PicKit Demo Board

Microchip PicKit Serial SPI Demo Board Driver

Supported Platforms: MODM7AE70, SBE70LC, SOMRT1061

Demonstrates the use of 7 Microchip SPI Peripherals:

- 25LC020A 2K SPI Bus Serial EEPROM
- TC77-5.0 Thermal Sensor with SPI Interface

- MCP3201 2.7V 12-Bit A/D Converter with SPI Serial Interface
- MCP4822 12-Bit DAC with Internal VREF and SPI Interface
- MCP41010 Single/Dual Digital Potentiometer with SPI Interface
- MCP6S92 Single-Ended, Rail-to-Rail I/O, Low-Gain PGA
- MCP23S08 8-Bit I/O Expander with Serial Interface

12.42 SSH

Secure Shell (SSH) Examples:

- [SSH Server](#)
- [SSH Server with User Key](#)
- [SSH Client](#)
- [SSH Server with User Authorization](#)
- [SecureSerToEthFactoryApp](#)

12.42.1 SSH Server

12.42.1.1 SSH Minimal Server Example

12.42.1.1.1 Overview

This NetBurner application implements a minimal SSH server that listens for incoming SSH client connections on TCP port 22. The server demonstrates basic SSH functionality using the NetBurner's built-in SSH library and certificate management system.

12.42.1.1.2 Features

- SSH server listening on port 22
- Automatic certificate and key generation
- Bidirectional communication between SSH client and server
- Serial console integration for monitoring and sending data
- Connection timeout handling (120 seconds)
- TCP error state reporting
- Multi-client support with connection queuing

12.42.1.1.3 Architecture

The application consists of two main components:

12.42.1.1.3.1 SSH Server Task

- Runs as a separate high-priority task
- Listens for incoming SSH connections
- Handles client authentication and session management
- Processes incoming data from SSH clients
- Manages connection lifecycle and cleanup

12.42.1.1.3.2 Main User Interface

- Provides serial console interface for monitoring
- Allows sending data to connected SSH clients via keyboard input
- Displays connection status and diagnostic information

12.42.1.1.4 Usage Instructions

12.42.1.1.4.1 Setup

1. Compile and load the application into your NetBurner device
2. Ensure the device is connected to your network
3. Run MTTTY or similar terminal emulator to connect to the device's USB/Serial port

12.42.1.1.4.2 Connecting SSH Clients

1. Use any SSH client (PuTTY, OpenSSH, etc.)
2. Connect to the NetBurner device's IP address on port 22
3. The server will display a welcome message: "Welcome to the NetBurner SSH Server"
4. Connection details will be shown on both the SSH client and serial console

12.42.1.1.4.3 Sending Data

- **From Serial Console:** Type ASCII strings followed by Enter to send data to connected SSH clients
- **From SSH Client:** Any data sent from the SSH client will be displayed on the serial console

12.42.1.1.5 Configuration

12.42.1.1.5.1 Key Parameters

- `SSH_LISTEN_PORT`: Server listening port (default: 22)
- `CONNECTION_TIMEOUT`: Inactivity timeout in seconds (default: 120)
- `BUFSIZE`: Buffer size for data transmission (default: 4096 bytes)

12.42.1.1.5.2 Security

- Uses NetBurner's built-in SSH key management
- Automatic certificate creation is enabled via `EnableOnboardCertificateCreation()`
- Standard SSH encryption and authentication protocols

12.42.1.1.6 Error Handling

The application includes comprehensive error handling for various TCP and SSH conditions:

- TCP connection errors (timeout, reset, abort)
- SSH negotiation failures
- Session establishment failures
- Socket availability issues
- Connection timeouts

Error states are reported through the serial console with descriptive messages.

12.42.1.1.7 Technical Details

12.42.1.1.7.1 Memory Usage

- SSH Server task stack: 4x standard user task stack size
- Separate receive and transmit buffers (4KB each)
- Efficient memory management with proper cleanup

12.42.1.1.7.2 Network Interface

- Automatically detects and uses the first available network interface
- Displays IP address and interface information on startup
- Supports standard Ethernet connections

12.42.1.1.7.3 Task Management

- SSH server runs at higher priority than UserMain
- Proper task synchronization and resource management
- Clean connection handling and resource cleanup

12.42.1.1.8 Dependencies

- NetBurner RTOS
- NetBurner SSH library ([ssh/NetBurner/NbWolfSsh.h](#))
- Certificate generation library ([crypto/certgen.h](#))
- Standard NetBurner networking and system libraries

12.42.1.1.9 Build Requirements

- NetBurner development environment
- SSH library support enabled in NetBurner configuration
- Certificate generation support

12.42.1.1.10 Troubleshooting

12.42.1.1.10.1 Common Issues

1. **Connection refused:** Verify network connectivity and firewall settings
2. **Authentication failures:** Check SSH key configuration
3. **Timeouts:** Adjust `CONNECTION_TIMEOUT` value if needed
4. **Memory issues:** Monitor task stack usage and buffer sizes

12.42.1.1.10.2 Diagnostic Features

- System diagnostics are enabled for development (consider disabling for production)
- Detailed error reporting through serial console
- Connection state monitoring and logging

12.42.2 SSH Server with User Key

12.42.2.1 SSH Server with User Key Example

12.42.2.1.1 Overview

This NetBurner application demonstrates how to create an SSH server that supports multiple key sources and provides a web-based interface for key management. The application showcases secure SSH connections with user-uploadable keys while maintaining fallback security through default keys.

Additional pdf documentation is located in the example directory

12.42.2.1.2 Features

- **SSH Server:** Accepts secure SSH connections on port 22
- **Multiple Key Sources:**
 - NetBurner SSH library default keys
 - Application compiled-in keys
 - User-uploaded keys via web interface
- **Web Interface:** Upload and manage SSH keys through a browser
- **Key Types Supported:** RSA and ECC (Elliptic Curve Cryptography)
- **File System:** EFFS-STD on-chip flash storage for persistent key storage
- **NTP Time Sync:** Automatic time synchronization for accurate timestamps
- **Serial Debug Interface:** Command-line interface for system diagnostics

12.42.2.1.3 Key Management Hierarchy

The application uses a three-tier key priority system:

1. **User-Uploaded Keys** (Highest Priority): Keys uploaded via web interface
2. **Application Default Keys** (Medium Priority): Keys compiled into the application
3. **Library Default Keys** (Lowest Priority): NetBurner SSH library fallback keys

This ensures the device always has a valid key for SSH connections.

12.42.2.1.4 Hardware Requirements

- NetBurner module with supported flash memory:
 - Spansion AM29LV160B, S29AL016D
 - Atmel AT49BV163D
 - SST39VF040
- Network connection
- Optional: Serial connection for debug interface

12.42.2.1.5 Software Requirements

- NetBurner Development Kit
- NetBurner SSH/SSL Encryption software (optional add-on)
- Compatible platforms: MOD5441X, NANO54415, SB800EX, MODM7AE70, SBE70LC, SOMRT1061, MODRT1171

12.42.2.1.6 Important Configuration Notes

12.42.2.1.6.1 Memory Configuration

CRITICAL**: Before building, you must configure the linker memory range to match your flash chip. Incorrect settings can corrupt the flash memory.

For Spansion AM29LV160B, S29AL016D, or Atmel AT49BV163D:

```
COMPCODEFLAGS = 0xFFC08000 0xFFD80000
```

For SST39VF040:

```
COMPCODEFLAGS = 0xFFC08000 0xFFC70000
```

12.42.2.1.6.2 Library Configuration

Replace `FatFile.a` with `StdFFile.a` in your linker settings to use the on-chip flash file system.

12.42.2.1.7 Usage Instructions

12.42.2.1.7.1 Initial Setup

1. Configure memory settings for your specific flash chip
2. Build and deploy the application to your NetBurner device
3. Use IPSetup to determine the device's IP address
4. Connect to the serial port (115200 baud) for debug output

12.42.2.1.7.2 Web Interface

1. Open a web browser and navigate to the device's IP address
2. View current key status and sources
3. Upload new RSA or ECC keys using the file upload form
4. Reset keys to factory defaults if needed
5. Display public keys for SSH client configuration

12.42.2.1.7.3 SSH Connection

1. Use an SSH client (such as PuTTY) to connect to the device
2. Connect to the device's IP address on port 22
3. Any username/password combination is accepted (for demonstration purposes)
4. The connection timeout is set to 120 seconds

12.42.2.1.7.4 Serial Commands

Access the debug menu via serial connection:

- [1] - EDFS Read/Write Test
- [2] - Display Directory
- [3] - Display TestFile.txt
- [4] - Format Flash (WARNING: Data loss)
- [5] - Display EDFS Space Usage
- [6] - Display System Time
- [7] - Reset to Factory Defaults

12.42.2.1.8 Key Requirements

12.42.2.1.8.1 RSA Keys

- Minimum size: 512 bits
- Maximum size: 4096 bits
- Format: OpenSSH/OpenSSL PEM format
- Must be unencrypted (no passphrase)

12.42.2.1.8.2 ECC Keys

- Minimum size: 192 bits
- Maximum size: 256 bits (384, 521, and ED25519 available with additional defines)
- Format: OpenSSH/OpenSSL PEM format
- Must be unencrypted (no passphrase)

12.42.2.1.9 File Structure

12.42.2.1.9.1 Core Application Files

- `main.cpp` - Main application thread and system initialization
- `sshuser.cpp/h` - SSH authentication and key management functions
- `web.cpp` - Web server interface for key upload and display
- `nvsettings.cpp/h` - Non-volatile settings management

12.42.2.1.9.2 Key Files

- `permanentkeyrsa.h` - Default RSA key compiled into application
- `permanentkeyecc.h` - Default ECC key compiled into application
- `openSsh*.key` - Example key files for testing

12.42.2.1.9.3 Web Interface

- `index.html` - Main web page for key management

12.42.2.1.9.4 File System Support

- `FileSystemUtils.cpp/h` - EDFS-STD file system utilities
- `fs_main.cpp/h` - File system initialization
- `edfs_time.cpp/h` - File timestamps and NTP support

12.42.2.1.10 Security Considerations

- The example uses simple authentication (any username/password where they don't match)
- In production, implement proper user authentication
- The web interface is unencrypted HTTP - consider HTTPS for production use
- Private keys are stored in flash memory - ensure physical security of devices
- Default keys are compiled into the application - replace with your own keys for production

12.42.2.1.11 Troubleshooting

12.42.2.1.11.1 Common Issues

1. **Flash Corruption:** Usually caused by incorrect COMPCODEFLAGS settings
2. **Key Upload Failures:** Verify key format and encryption status
3. **Connection Timeouts:** Check network configuration and firewall settings
4. **File System Errors:** May require formatting the EDFS partition

12.42.2.1.11.2 Debug Output

The serial interface provides detailed debug information including:

- SSH connection status
- Key validation results
- File system operations
- Network configuration
- System diagnostics

12.42.2.1.12 Development Notes

This example demonstrates several NetBurner development concepts:

- EDFS-STD flash file system usage
- Multi-part form handling in web applications
- SSH server implementation
- Non-volatile parameter storage
- Task creation and management
- Network service integration

12.42.3 SSH Client

12.42.3.1 SSH Minimal Client Example

12.42.3.1.1 Overview

This NetBurner application demonstrates a minimal SSH client implementation that connects to an SSH server and reads data continuously until the connection is closed. The client establishes an encrypted SSH connection and can be used as a foundation for building more complex SSH-based applications.

12.42.3.1.2 Features

- Establishes SSH connection to a remote server
- User authentication with password
- Continuous data reading from SSH server
- Automatic reconnection on connection failure
- Built-in diagnostics and logging
- Certificate and key generation support

12.42.3.1.3 Configuration

12.42.3.1.3.1 Server Settings

The application is configured to connect to an SSH server using the following constants in `main.cpp`:

```
#define SSH_SERVER_NAME "10.1.1.131"    // Target SSH server IP address
#define SSH_REMOTE_PORT 22             // SSH server port (standard port 22)
#define CONNECTION_TIMEOUT 120         // Connection timeout in seconds
```

12.42.3.1.3.2 Authentication

The application uses password-based authentication with these default credentials:

- Username: "guest" (specified in `SshConnect` call)
- Password: "TestPassword" (set in `ClientUserAuth` function)

12.42.3.1.4 Hardware Requirements

- NetBurner device with network connectivity
- Active network connection ([DHCP](#) or static IP)
- USB or Serial connection for monitoring

12.42.3.1.5 Setup Instructions

1. Configure Target Server

- Update `SSH_SERVER_NAME` with your SSH server's IP address
- Ensure the SSH server is running and accessible on port 22
- Verify firewall settings allow SSH connections

2. Compile and Deploy

- Compile the application using NetBurner development tools
- Load the compiled firmware onto your NetBurner device

3. Monitor Operation

- Connect to the device using MTTTY via USB or Serial port
- View connection status and received data in the terminal

12.42.3.1.6 Code Structure

12.42.3.1.6.1 Main Components

- **UserMain():** Primary application entry point
 - Initializes system components
 - Configures SSH client settings
 - Manages connection loop
- **ClientUserAuth():** Authentication callback
 - Called when server requests user credentials
 - Returns username and password for authentication

12.42.3.1.6.2 Key Functions

- [NbSshInit\(\)](#): Initializes SSH subsystem
- [SshConnect\(\)](#): Establishes SSH connection to server
- [ReadWithTimeout\(\)](#): Reads data from SSH connection with timeout
- [EnableOnboardCertificateCreation\(\)](#): Enables automatic certificate generation

12.42.3.1.7 Operation Flow

1. System initialization and network setup
2. SSH subsystem initialization
3. Connection attempt to configured server
4. User authentication when prompted
5. Continuous data reading loop
6. Connection monitoring and automatic reconnection

12.42.3.1.8 Buffer Configuration

The application uses a 4KB receive buffer:

```
#define RX_BUF_SIZE (4096)
char RXBuffer[RX_BUF_SIZE];
```

12.42.3.1.9 Task Stack

SSH operations use an extended stack size:

```
#define SSHSERVER_TASK_STACK_SIZE (USER_TASK_STK_SIZE * 4)
```

12.42.3.1.10 Troubleshooting

12.42.3.1.10.1 Common Issues

- **Connection Failed:** Verify server IP address and network connectivity
- **Authentication Failed:** Check username/password credentials
- **Network Timeout:** Ensure [DHCP](#) is working or configure static IP
- **Certificate Errors:** Verify certificate generation is enabled

12.42.3.1.10.2 Debug Output

The application provides detailed logging including:

- SSH initialization status
- Connection attempts and results
- Data received from server
- Connection closure notifications

12.42.3.1.11 Customization

12.42.3.1.11.1 Modifying Authentication

Update the `ClientUserAuth()` function to implement different authentication methods:

```
int ClientUserAuth(const NBString &usernamePtr, NBString &passwordPtr)
{
    // Custom authentication logic here
    passwordPtr = "YourPassword";
    return 1; // Return 1 for success, 0 for failure
}
```

12.42.3.1.11.2 Adding Data Processing

Extend the data reading loop in `UserMain()` to process received data:

```
if (n != 0)
{
    printf("Read %d bytes: %s\n", n, RXBuffer);
    // Add custom data processing here
}
```

12.42.3.1.12 Dependencies

- NetBurner SSH library ([ssh/NetBurner/NbWolfSsh.h](#))
- Certificate generation support ([crypto/certgen.h](#))
- Standard NetBurner system libraries

12.42.3.1.13 Notes

- The application includes system diagnostics which should be disabled for production use
- Automatic certificate creation is enabled for SSL/TLS support
- The client will continuously attempt to reconnect if the connection is lost
- All received data is null-terminated and printed to the console

12.42.4 SSH Server with User Authorization

12.42.4.1 SSH Server with User Authorization

A NetBurner embedded application that implements a secure SSH server with customizable user authentication management.

12.42.4.1.1 Overview

This application creates an SSH server that listens on TCP port 22 for incoming SSH client connections. The server uses an automatically generated onboard key for encryption and implements a flexible user authentication system that supports both password and key-based authentication.

12.42.4.1.2 Key Features

- **SSH Server:** Full SSH server implementation listening on port 22
- **User Authentication Management:** Custom user authentication system with support for:
 - Password-based authentication
 - Key-based authentication
 - User authorization levels
- **Automatic Certificate Generation:** Self-signed certificates generated on first boot
- **Persistent User Storage:** User credentials stored in device UserParam space
- **Interactive Management:** Serial console interface for user management
- **Connection Timeout:** Configurable connection timeout (default: 120 seconds)

12.42.4.1.3 Architecture

12.42.4.1.3.1 Core Components

1. **main.cpp:** Main application with SSH server task and user interface
2. **UserAuth.cpp:** User authentication manager implementation
3. [UserAuth.h](#): Authentication interface definitions

12.42.4.1.3.2 Key Classes and Functions

- `UserAuthManager`: Manages user authentication records and validation
- `SshServerTask()`: Main SSH server listening and connection handling
- `AuthenticateUser()`: SSH authentication callback function
- `SaveAuthRecordsUserParam()` / `LoadAuthRecordsUserParam()`: Persistent storage functions

12.42.4.1.4 Configuration

12.42.4.1.4.1 Default Settings

```
#define SSH_LISTEN_PORT 22      // SSH server port
#define CONNECTION_TIMEOUT 120 // Connection timeout in seconds
#define BUFSIZE (4096)        // Buffer size for data transfer
```

12.42.4.1.4.2 Authentication Types

- `eAuthTypePassword (1)`: Password-based authentication
- `eAuthTypeKey (2)`: SSH key-based authentication

12.42.4.1.5 Usage

12.42.4.1.5.1 Building and Deployment

1. Compile the application using NetBurner development tools
2. Load the firmware onto your NetBurner device
3. Connect via MTTTY to the USB/Serial port for configuration

12.42.4.1.5.2 Initial Setup

1. **Certificate Generation**: On first boot, the device automatically generates SSL certificates
2. **Network Connection**: Wait for active network connection
3. **SSH Server Start**: Server begins listening on port 22

12.42.4.1.5.3 User Management Commands

Access these commands via the serial console when no SSH client is connected:

- **A**: Add new user (prompts for username, auth value, and auth type)
- **D**: Delete existing user (prompts for username)
- **L**: List all configured users
- **?**: Show command list

12.42.4.1.5.4 SSH Client Connection

1. Use any SSH client (PuTTY, OpenSSH, etc.)
2. Connect to the NetBurner device's IP address on port 22
3. Authenticate using configured username and password/key
4. Interactive session allows bidirectional communication

12.42.4.1.6 Security Features

12.42.4.1.6.1 Certificate Management

- Automatic onboard certificate and key generation
- One-year certificate validity period
- Optional automatic certificate regeneration (enable `ENABLE_AUTOCERT_REGEN`)

12.42.4.1.6.2 User Authentication

- Secure password hashing using SHA-256
- Support for SSH public key authentication
- Configurable user authorization levels
- Persistent storage of authentication records

12.42.4.1.6.3 Connection Security

- Full SSH protocol implementation
- Encrypted communication channels
- Connection timeout protection
- Proper session management

12.42.4.1.7 Data Storage

User authentication records are stored in JSON format in the device's UserParam space:

```
{
  "0": {
    "un": "username",
    "at": 1,
    "al": 0,
    "ah": [hash_array]
  }
}
```

Where:

- `un`: Username
- `at`: Authentication type (1=password, 2=key)
- `al`: Authorization level
- `ah`: SHA-256 hash array

12.42.4.1.8 Error Handling

The application includes comprehensive error handling for:

- TCP connection errors (timeout, reset, abort)
- SSH negotiation failures
- Authentication failures
- Certificate generation errors
- User management errors

12.42.4.1.8.1 Common Error Codes

- `TCP_ERR_TIMEOUT`: Connection timeout
- `TCP_ERR_CON_RESET`: Connection reset by peer
- `SSH_ERROR_FAILED_NEGOTIATION`: SSH handshake failure
- `SSH_ERROR_FAILED_SESSION_FAILED`: SSH session establishment failure

12.42.4.1.9 Development Notes

12.42.4.1.9.1 Memory Usage

- SSH Server task stack: `USER_TASK_STK_SIZE * 4`
- Buffer allocation: 4KB for both TX and RX
- JSON buffer: 1.5KB for user record storage

12.42.4.1.9.2 Task Priority

SSH Server task runs at `MAIN_PRIO - 1` (higher priority than UserMain) to ensure responsive connection handling.

12.42.4.1.9.3 Dependencies

- NetBurner SSH library ([ssh/NetBurner/NbWolfSsh.h](#))
- Certificate generation ([crypto/certgen.h](#))
- JSON parsing ([json_lexer.h](#))
- Standard NetBurner networking and serial libraries

12.42.4.1.10 Troubleshooting

12.42.4.1.10.1 Connection Issues

1. Verify network connectivity
2. Check if SSH server task started successfully
3. Confirm firewall settings allow port 22
4. Validate certificate generation completed

12.42.4.1.10.2 Authentication Problems

1. List users to verify account exists
2. Check authentication type matches client configuration
3. Verify user authorization level
4. Review SSH client logs for specific errors

12.42.4.1.10.3 Performance Considerations

- Maximum 5 concurrent connection queue
- 120-second connection timeout
- 4KB buffer size may limit large data transfers
- JSON parsing occurs on user record changes

12.42.4.1.11 Example Session

Starting SSH Server Task, Listening for SSH connection on port 22

```
Waiting for connection on port 22...
Connected to: 192.168.1.100:54321
Welcome to the NetBurner SSH Server
You are connected to IP Address 192.168.1.50, port 22
```

[Interactive SSH session follows...]

12.42.5 SecureSerToEthFactoryApp

12.42.5.1 NetBurner Secure Serial-to-Ethernet Factory Application

12.42.5.1.1 Overview

The NetBurner Secure Serial-to-Ethernet Factory Application is a comprehensive embedded application that provides secure bi-directional communication between serial interfaces and Ethernet networks. This application is pre-programmed into NetBurner Serial-to-Ethernet devices and serves as a bridge between various serial protocols and network connectivity. The application pre-programmed into NetBurner Serial to Ethernet devices. This application source code is provided for customers that wish to customize the application.

Interfaces:

- RS-232
- RS-422
- RS-485
- CAN Bus
- I2C
- Ethernet
- Wifi

Note

Please refer to the Secure Serial Factory App Users Manual for a detailed description of this application at www.netburner.com.

12.42.5.1.2 Application Architecture

12.42.5.1.2.1 Entry Point

The application starts in `UserMain()` (located in `src/main.cpp`), which is the standard entry point for all NetBurner applications, rather than the typical C/C++ `main()` function.

12.42.5.1.2.2 Core Features

Multi-Protocol Support:**

- TCP/IP communication
- UDP communication
- SSH (Secure Shell) connections
- TLS/SSL encrypted connections
- Multiple serial interface protocols (RS-232, RS-485, CAN Bus, I2C)

Network Capabilities:**

- DHCP and static IP addressing

- WiFi connectivity support
- Network Time Protocol (NTP) synchronization
- DNS resolution
- HTTPS web server interface
- Security Features:**
- SSL/TLS encryption for secure data transfer
- SSH authentication and key management
- Certificate and key management system
- Configurable user authentication

12.42.5.1.3 Supported Hardware Platforms

- **SBE70LC** - NetBurner SBE70LC modules
- **SB800EX** - NetBurner SB800EX modules
- **NANO54415** - NetBurner NANO54415 modules
- **MODM7AE70** - NetBurner MODM7AE70 modules
- **SOMRT1061** - NetBurner SOMRT1061 modules
- **MOD5441X** - NetBurner MOD5441X modules

12.42.5.1.4 Key Source Files

12.42.5.1.4.1 Main Application

- `**src/main.cpp**` - Main application entry point and core logic
- `**src/nbfactory.h**` - Factory configuration definitions and platform-specific settings

12.42.5.1.4.2 Serial Communication

- `**src/serialrecord.cpp/h**` - Core serial port management and data handling
- `**src/serialburnerdata.h**` - Serial port configuration structures
- `**src/atparserforssh.cpp**` - AT command parser for SSH configuration

12.42.5.1.4.3 Network & Security

- `**src/sshuser.cpp/h**` - SSH user authentication and key management
- `**src/ssluser.cpp/h**` - SSL/TLS user authentication
- `**src/certificatekey.cpp**` - Certificate and key management
- `**src/ServerKey.cpp**` - Server key handling
- `**src/ServerCert.cpp**` - Server certificate handling

12.42.5.1.4.4 Hardware Interface

- `**src/gpioserver.cpp/h**` - GPIO server for pin control
- `**src/i2cserver.cpp/h**` - [I2C](#) server implementation
- `**src/i2cfuns.cpp/h**` - [I2C](#) utility functions
- `**src/analog.cpp/h**` - Analog input handling

12.42.5.1.4.5 Web Interface

- `**src/configweb.cpp**` - Web-based configuration interface
- `**src/configweb_wifi.cpp**` - WiFi-specific web configuration
- `**src/formtools.cpp/h**` - HTML form processing utilities
- `**src/post.cpp**` - HTTP POST request handling

12.42.5.1.4.6 File System & Storage

- `**src/effs_std.cpp/h**` - EFFS (Embedded Flash File System) STD implementation
- `**src/effsStdPartition.cpp**` - Flash partition management
- `**src/FileSystemUtils.cpp/h**` - File system utility functions
- `**src/ftp_fs.cpp/h**` - FTP file system interface

12.42.5.1.4.7 System Utilities

- `**src/fdtimer.cpp/h**` - File descriptor timer management
- `**src/fnbrtosdump.cpp**` - RTOS debugging and diagnostics
- `**src/autoupdate.cpp**` - Remote firmware update functionality

12.42.5.1.5 Configuration and Web Interface

The application includes a comprehensive web-based configuration interface with the following pages:

12.42.5.1.5.1 Network Configuration

- `**html/network.html**` - Main network settings
- `**html/tcp.html**` - TCP protocol configuration
- `**html/udp.html**` - UDP protocol configuration
- `**html/wifi.html**` - WiFi connectivity settings

12.42.5.1.5.2 Security Configuration

- `**html/ssh.html**` - SSH server configuration
- `**html/ssl.html**` - SSL/TLS settings
- `**html/certificate.html**` - Certificate management
- `**html/keys.html**` - Cryptographic key management

12.42.5.1.5.3 Serial Port Configuration

- `**html/serial.html**` - Serial port settings
- `**html/advancedserial.html**` - Advanced serial configuration
- `**html/i2c.html**` - [I2C](#) interface settings

12.42.5.1.5.4 System Management

- `**html/advanced.html**` - Advanced system settings
- `**html/gpio.html**` - GPIO pin configuration
- `**html/password.html**` - User authentication settings

12.42.5.1.6 Build Configuration

12.42.5.1.6.1 Makefile Structure

The project uses a standardized NetBurner makefile with the following key components:

- **Target Name:** `SecureSerToEthFactoryApp`
- **Supported Platforms:** All major NetBurner platforms
- **Dependencies:** EDFS STD file system library
- **Generated Files:** HTML content is compiled into `src/htmldata.cpp`

12.42.5.1.6.2 Memory Configuration

Platform-specific memory settings:

- **MOD5441X/NANO54415/SB800EX:** 1MB reserved for EDFS STD file system
- **MODM7AE70/SBE70LC:** Application memory relocation disabled

12.42.5.1.7 Key Features Implementation

12.42.5.1.7.1 Data Flow Management

The `SerialRecord` class manages bidirectional data flow between serial ports and network connections, implementing:

- Circular buffering for serial-to-network and network-to-serial data
- Connection state management
- Timeout handling
- Keep-alive functionality

12.42.5.1.7.2 Protocol Handling

The application supports multiple connection modes:

- **Server Mode:** Listens for incoming connections
- **Client Mode:** Initiates outbound connections
- **UDP Mode:** Connectionless datagram communication
- **SSH Mode:** Secure shell connections with authentication

12.42.5.1.7.3 Security Implementation

- Certificate and key management with support for RSA and ECDSA
- SSL/TLS encryption for web interface and data connections
- SSH authentication with public key support
- Configurable user credentials and access control

12.42.5.1.8 Configuration Methods

The device can be configured through multiple interfaces:

1. **Web Interface (HTTP/HTTPS)** - Full-featured browser-based configuration
2. **Configuration Interface** - NetBurner's standard configuration protocol
3. **AT Commands** - Serial port based command interface
4. **Remote Updates** - Over-the-air firmware updates

12.42.5.1.9 Development and Customization

This source code is provided to enable customers to customize the factory application for specific requirements. Key customization points include:

- **Protocol Extensions:** Add support for custom protocols
- **Hardware Integration:** Interface with specific sensors or actuators
- **Security Policies:** Implement custom authentication mechanisms
- **Data Processing:** Add filtering, transformation, or logging capabilities

12.42.5.1.10 System Requirements

- NetBurner development environment with SDK
- Compatible NetBurner hardware platform
- Network connectivity for web-based configuration
- Optional: WiFi module for wireless connectivity

12.42.5.1.11 Additional Resources

For detailed documentation and user manuals, visit www.netburner.com and refer to the Secure Serial Factory App Users Manual.

12.43 SSL/TLS

Obtaining certificates:

- [Easy SSL/TLS Onboard Certificates](#)
- [ACME Certificate Generation \(Easy Servlet\)](#)

SSL/TLS examples. Note that all references to SSL represent TLS.

12.43.1 Easy SSL/TLS Onboard Certificates

For ACME (Public Certificate Authority) Certificate Generation:

- [ACME Certificate Generation \(Easy Servlet\)](#)

For Self-Signed Certificate Generation:

- [On-board Cert Generation - Simple](#)
- [On-board Cert Generation - Advanced](#)
- [On-board Cert Generation - Compiled Certificate Authority](#)

12.43.1.1 ACME Certificate Generation (Easy Servlet)

```
<NNDK install>\examples\SSL\acmeservlet
```

12.43.1.1.1 ACME Certificate Generation (Easy Servlet)

A NetBurner NNDK SSL/TLS example application that demonstrates automatic ACME certificate generation using Let's Encrypt or other ACME-compliant certificate authorities.

12.43.1.1.1.1 Overview

This application provides a web-based demonstration of automatic SSL/TLS certificate generation using the ACME (Automatic Certificate Management Environment) protocol as defined in RFC 8555. The application includes a built-in web server that serves both HTTP and HTTPS content, with automatic certificate provisioning through ACME providers.

SSL/TLS example program that demonstrates getting an ACME cert automatically. It will only work for a device with Internet access with a public IP address and DNS entry. Make sure to change the `DEFAULT_CERT_COM_NAME` constant in `main.cpp` to match.

This example makes use of the [acmeRFC8555Servlet.h](#) builtin to the NNDK which reduces how much code is required to add the functionality to your project and will more easily take advantage of future NNDK updates.

12.43.1.1.1.2 Requirements

- NetBurner device with public IP address
- Public DNS entry pointing to the device
- NNDK (NetBurner Network Development Kit)
- Device must be accessible from the internet for ACME validation

12.43.1.1.1.3 Features

- Automatic SSL/TLS certificate generation via ACME protocol
- Support for multiple ACME providers (Let's Encrypt, BuyPass, custom)
- Web server with both HTTP (port 80) and HTTPS (port 443) support
- Access control based on SSL/TLS connection status
- Certificate reissue functionality
- NTP client integration for accurate time synchronization
- Web-based status and control interface

12.43.1.1.1.4 Configuration

Certificate Information

Before running the application, update the following constants in `main.cpp` to match your environment:

```
const char * DEFAULT_CERT_COUNTRY= "US";
const char * DEFAULT_CERT_STATE= "CA";
const char * DEFAULT_CERT_LOCALITY= "San Diego";
const char * DEFAULT_CERT_ORG= "Netburner";
const char * DEFAULT_CERT_UNIT= "Demo";
const char * DEFAULT_CERT_EMAIL= "changeme@example.com";
const char * DEFAULT_CERT_ALT_NAMES= "test.example.com,example.com";
const char * DEFAULT_CERT_COM_NAME= "test.example.com";
```

Important*: The `DEFAULT_CERT_COM_NAME` must match your device's public DNS name.

ACME Provider Selection

The application supports multiple ACME providers. Choose one by uncommenting the appropriate line:

```
/* Production Let's Encrypt (default): */
LetsEncryptAcmeServletObject AcmeClient;

/* Let's Encrypt Staging (for testing): */
// LetsEncryptAcmeServletObject AcmeClient(true);

/* BuyPass ACME: */
// BuyPassAcmeServletObject AcmeClient;

/* Custom ACME server: */
// AcmeServletObject AcmeClient("https://your-acme-server.com/dir");
```

12.43.1.1.1.5 Building and Running

1. Ensure your NetBurner device has a public IP and DNS entry
2. Update the certificate configuration constants
3. Build the application using the NNDK toolchain
4. Deploy to your NetBurner device
5. Access the web interface via HTTP or HTTPS

12.43.1.1.1.6 Web Interface

The application provides several web endpoints:

- `/index.html` - Main interface page
- Counter functionality - Displays page reload count
- SSL status indicators - Shows connection security status
- Certificate management controls

Access Control

The application implements access control based on connection type:

- Access level 0: Available to all connections
- Access level 1: Requires SSL/TLS connection
- Other levels: Default allow access

12.43.1.1.1.7 Runtime Options

When the application starts, you can:

- Press 'R', 'r', 'Y', or 'y' to reissue certificates
- Monitor certificate status through diagnostic output
- View ACME client state information

12.43.1.1.1.8 ACME Certificate Process

1. Application generates a Certificate Signing Request (CSR)
2. Contacts the ACME server to request a certificate
3. Completes domain validation challenges
4. Receives and installs the signed certificate
5. Automatically renews certificates before expiration

12.43.1.1.1.9 Key Components

- **ACME Client:** Handles certificate requests and renewals
- **Web Server:** Serves HTTP/HTTPS content
- **NTP Client:** Maintains accurate time for certificate validation
- **SSL Context:** Manages SSL/TLS connections and certificates
- **Access Control:** Enforces connection security requirements

12.43.1.1.1.10 Troubleshooting

Common Issues

1. **Certificate generation fails:** Verify public DNS and IP accessibility
2. **ACME validation fails:** Check firewall settings and port accessibility
3. **Time sync issues:** Ensure NTP client can reach time servers
4. **Domain mismatch:** Verify `DEFAULT_CERT_COM_NAME` matches DNS

Debug Options

Enable diagnostic output:

```
AcmeClient.SetDiag(true);
```

Force certificate reissue:

```
AcmeClient.Delete_Everything_Restart();
```

12.43.1.1.1.11 Security Notes

- Certificates are automatically managed by the ACME client
- Production deployment should disable system diagnostics
- Consider implementing additional access controls for production use
- Monitor certificate expiration and renewal processes

12.43.1.1.1.12 License

This example code is provided as part of the NetBurner NNDK and follows the NetBurner licensing terms.

12.43.1.1.1.13 Support

For technical support and documentation:

- NetBurner NNDK Documentation
- NetBurner Support Portal
- ACME RFC 8555 specification

12.43.1.2 On-board Cert Generation - Simple

12.43.1.2.1 On-board Certificate Generation - Simple

A NetBurner embedded application that demonstrates automatic SSL/TLS certificate generation and secure web server functionality.

12.43.1.2.1.1 Overview

This application showcases NetBurner's capability to automatically generate SSL certificates on embedded devices, enabling both HTTP and HTTPS web interfaces. The application sets up a secure web server with automatic certificate creation, time synchronization, and provides multiple access methods for device configuration.

This example shows how to enable auto-generation of self-signed certificates. The certificate will enable secure communication to the system configuration web server and the HTTPS web server of the application. On-board generation of certificates are an alternative to creating your own self-signed certificates and uploading them to your NetBurner device. This simple example should cover most use cases. Please refer to the other examples for additional functionality.

Auto-generated certificates will operate as follows:

- If enabled and no certificate exists, a certificate will be created on first call to `SSL_accept()` or `SslInitServer()`.
- The Common Name (CN) will be the IP address of the device. Alternate names are also supported.
- The application must ensure it has the correct system time, otherwise the certificate dates will be invalid.
- Calling the function `EnableOnboardCertificateCreation()` enables certificate generation.
- If `ENABLE_AUTOCERT_REGEN` is defined in `predef.h`, the certificate will update when it expires, creating a new 1 year certificate. Generation will occur on next SSL/TLS access.
- If `ENABLE_AUTO_CERT_REGEN` is defined in `predef.h`, `AUTO_CERT_GEN_CHECK` will dictate how frequently a certificate is checked for expiration. The default value is one minute.
- The certificate will update if the IP address changes to handle environments such as `DHCP` address assignments.

If the system time is incorrect, the certificate will be invalid.

Additional Examples:

Examples of a HTTPS server with a compiled-in certificate:

- `<NNDK install>\examples\ssl\sslserver`
- `<NNDK install>\examples\ssl\SslWebDemo`

Examples of uploading a certificate/key pair manually:

- `<NNDK install>\examples\ssl\HttpsDualCert`
- `<NNDK install>\examples\ssl\HttpsUploadCert`

Example of handling additional timezones

- `<NNDK install>\examples\TimeFunctions`

12.43.1.2.1.2 Features

- **Automatic Certificate Generation:** Creates SSL certificates on-board without manual intervention
- **Dual Protocol Support:** Serves both HTTP (port 80) and HTTPS (port 443) simultaneously
- **Time Synchronization:** Uses NTP for accurate time setting (required for certificate validity)
- **Timezone Support:** Configurable timezone with automatic daylight savings calculation
- **System Diagnostics:** Built-in diagnostic capabilities for development and troubleshooting
- **Multiple Access Methods:** Provides various ways to access the device via web interfaces

12.43.1.2.1.3 Hardware Requirements

- NetBurner embedded device with network connectivity
- Active network connection for NTP time synchronization
- Internet access (optional, for discover.netburner.com service)

12.43.1.2.1.4 Software Dependencies

This application uses the NetBurner NNDK (NetBurner Network Development Kit) and requires the following libraries:

- [nbrtos.h](#) - NetBurner Real-Time Operating System
- [crypto/certgen.h](#) - Certificate generation functionality
- [netinterface.h](#) - Network interface management
- [nbtime.h](#) - Time management utilities
- [timezones.h](#) - Timezone support

12.43.1.2.1.5 Configuration

Time Zone Setup

The application defaults to Pacific Standard Time (PST). To change the timezone, modify the parameter in `main.c`:

```
cpp:
setSystemTime("PST"); // Change "PST" to your desired timezone
```

Note

Refer to TimeFunctions example for timezone handling

Supported timezone abbreviations include: PST, MST, CST, EST, and others defined in the NetBurner timezone database.

Certificate Configuration

Certificate generation is automatically enabled via:

```
EnableOnboardCertificateCreation();
```

Server Configuration

The secure configuration server is enabled without forcing TLS mode:

```
EnableSecureConfigServer(false);
```

12.43.1.2.1.6 Access Methods

Once running, the device provides several access points:

Web Interfaces

- **HTTP Application:** [http://\[device-ip\]](http://[device-ip])
- **HTTPS Application:** [https://\[device-ip\]](https://[device-ip])
- **HTTP System Config:** [http://\[device-ip\]:20034](http://[device-ip]:20034)
- **HTTPS System Config:** [https://\[device-ip\]:20034](https://[device-ip]:20034)

Discovery Service

- **NetBurner Discovery:** <http://discover.netburner.com> (requires internet access)

12.43.1.2.1.7 Time Synchronization

The application requires accurate time for certificate generation and validation:

1. **NTP Synchronization** (Primary): Automatically attempts to sync with NTP pool servers
2. **Manual Entry** (Fallback): If NTP fails, prompts for manual time entry via serial console

Manual Time Entry

If NTP synchronization fails, the application will prompt for manual time entry through the serial debug port. You'll be asked to provide:

- Year (YYYY format)
- Month (1-12)
- Day of month (1-31)
- Hour (0-23)
- Minute (0-59)
- Seconds (0-59)
- GMT or Local time preference

12.43.1.2.1.8 Usage

1. **Build and Deploy**: Compile using NetBurner development tools and deploy to target hardware
2. **Network Connection**: Ensure device has active network connectivity
3. **Monitor Serial Output**: Connect to serial debug port to monitor startup and get IP address
4. **Access Web Interface**: Use any of the provided URLs to access the device
5. **Certificate Verification**: HTTPS connections will use the automatically generated certificate

12.43.1.2.1.9 Serial Interface

The application provides an interactive serial interface:

- Displays IP address and access links on startup
- Shows time synchronization status
- Press any key to redisplay connection information
- Provides manual time entry interface if needed

12.43.1.2.1.10 Development Notes

- System diagnostics are enabled by default (`EnableSystemDiagnostics()`) - consider removing for production builds
- The application waits up to 5 seconds for network connectivity before proceeding
- Certificate generation happens automatically during startup
- Time synchronization is critical for SSL certificate validity

12.43.1.2.1.11 Troubleshooting

Common Issues

1. **Certificate Warnings:** Browsers may show security warnings for self-signed certificates - this is normal behavior
2. **NTP Sync Failure:** Check network connectivity and firewall settings if NTP synchronization fails
3. **Time Zone Issues:** Verify timezone abbreviation is supported in NetBurner's timezone database
4. **Network Access:** Ensure device IP is accessible from client machines

Debug Information

Monitor the serial debug output for:

- Network connectivity status
- NTP synchronization results
- Certificate generation status
- IP address assignments
- Error messages and diagnostics

12.43.1.3 On-board Cert Generation - Advanced

12.43.1.3.1 NetBurner On-board Certificate Generation - Advanced

12.43.1.3.1.1 Overview

This application demonstrates advanced on-board SSL certificate generation capabilities for NetBurner embedded devices. It provides interactive control over certificate lifecycle management, including creation, validation, expiration checking, and deletion of self-signed certificates.

The simple auto-generate self-signed certificate example is what is normally used in applications. This example provide advanced options, such as interactive control to:

- Generate the certificate
- Delete the certificate
- View certificate expiration date
- Check for a valid certificate
- Manually enter the system time

12.43.1.3.1.2 Features

Certificate Management

- **Automatic Certificate Generation:** Creates self-signed certificates with configurable parameters
- **Certificate Validation:** Verifies certificate and key pair validity
- **Expiration Monitoring:** Checks certificate expiration status and displays expiration dates
- **Certificate Deletion:** Removes existing certificates (requires reboot to take effect)

Time Management

- **NTP Time Synchronization:** Automatically syncs system time with NTP servers
- **Manual Time Entry:** Fallback option for manual time configuration
- **Timezone Support:** Configurable timezone settings with automatic daylight savings

Network Connectivity

- **Dual Protocol Support:** Serves both HTTP (port 80) and HTTPS (port 443)
- **Web Interface:** Provides web-based access to the application
- **System Configuration:** Access to NetBurner system configuration pages
- **Network Discovery:** Integration with NetBurner discovery service

12.43.1.3.1.3 Application Structure

Main Components

`main.cpp`

The primary application file containing:

- **Certificate Generation Logic:** `createCertAndKey()` function
- **Certificate Validation:** `certExpired()` and `printCertExpiration()` functions
- **Interactive Menu System:** Serial console interface for user interaction
- **Web Server Integration:** HTTP/HTTPS server startup and link display
- **Network Configuration:** IP address detection and interface management

`TimeUtil.cpp / TimeUtil.h`

Time management utilities including:

- **NTP Synchronization:** Automatic time setting from network time servers
- **Manual Time Entry:** Interactive time configuration via serial console
- **Timezone Management:** Support for various timezones with DST calculation
- **Time Display Functions:** Formatted time output utilities

`CaCrt.cpp`

Auto-generated certificate data file containing:

- **Certificate Array:** Binary certificate data (501 bytes)
- **Certificate Length:** Size definition for the embedded certificate

12.43.1.3.1.4 Certificate Configuration

The application generates certificates with the following default parameters:

```
Country: US
State: California
Locality: San Diego
Organization: NetBurner
Unit: CodeDemo
Email: Sales@NetBurner.com
Common Name: MyNetburner
Validity Period: 1 year
```

Subject Alternative Names (SAN)

The certificate includes both IP address and DNS entries based on the device's network configuration.

12.43.1.3.1.5 Interactive Menu Options

The application provides a serial console menu with the following options:

1. **Check Certificate Expiration:** Determines if the current certificate is expired
2. **Show Certificate Expiration Date:** Displays the exact expiration timestamp
3. **Generate New Certificate:** Creates a fresh certificate/key pair
4. **Erase Certificate:** Removes the current certificate (requires reboot)
5. **Display System Time:** Shows current system time and timezone
6. **Reboot:** Restarts the device
7. **? - Display Menu:** Shows the menu options

12.43.1.3.1.6 Network Access Points

Once running, the device can be accessed through multiple endpoints:

Discovery Service

- **URL:** <http://discover.netburner.com>
- **Description:** NetBurner's network discovery service

Application Pages

- **HTTP:** [http://\[device-ip\]](http://[device-ip])
- **HTTPS:** [https://\[device-ip\]](https://[device-ip])

System Configuration

- **HTTP:** [http://\[device-ip\]:20034](http://[device-ip]:20034)
- **HTTPS:** [https://\[device-ip\]:20034](https://[device-ip]:20034)

12.43.1.3.1.7 Security Features

Certificate Generation

- **ECC Key Generation:** Uses Elliptic Curve Cryptography for key pairs
- **Self-Signed Certificates:** Generates certificates signed by the device itself
- **Secure Storage:** Certificates and keys are stored in device flash memory
- **Random Number Generation:** Utilizes hardware random number generation

SSL/TLS Support

- **Dual Protocol:** Supports both HTTP and HTTPS simultaneously
- **Certificate Validation:** Built-in certificate and key validation
- **Secure Configuration:** HTTPS access to system configuration pages

12.43.1.3.1.8 Prerequisites

Hardware Requirements

- NetBurner embedded device with SSL/TLS capability
- Network connectivity (Ethernet)
- Sufficient flash memory for certificate storage

Software Requirements

- NetBurner NNDK (NetBurner Network Development Kit)
- Compatible compiler toolchain
- Serial console access for interactive features

Network Requirements

- Active network connection for NTP synchronization
- Internet access (optional, for NTP and discovery service)

12.43.1.3.1.9 Build and Deployment

1. **Compile:** Build the application using the NetBurner development environment
2. **Deploy:** Upload the compiled application to the target device
3. **Network Setup:** Ensure the device has network connectivity
4. **Time Synchronization:** The application will attempt NTP sync on startup
5. **Certificate Generation:** Certificates can be generated via the interactive menu

12.43.1.3.1.10 Usage Instructions

Initial Setup

1. Connect to the device via serial console
2. Wait for network initialization
3. The application will attempt automatic time synchronization
4. Use the interactive menu to manage certificates

Certificate Lifecycle

1. **Generate:** Use menu option 3 to create a new certificate
2. **Validate:** Use menu option 1 to check expiration status
3. **Monitor:** Use menu option 2 to view expiration dates
4. **Refresh:** Generate new certificates before expiration
5. **Clean:** Use menu option 4 to remove certificates when needed

Web Access

- Navigate to the device's IP address using HTTP or HTTPS
- Use the secure configuration pages for advanced device management
- The discovery service can help locate devices on the network

12.43.1.3.1.11 Troubleshooting

Common Issues

- **Time Synchronization Failures:** Check network connectivity and DNS resolution
- **Certificate Generation Errors:** Ensure sufficient entropy for random number generation
- **HTTPS Access Problems:** Verify certificate validity and browser security settings
- **Menu Unresponsive:** Check serial console connection and baud rate settings

Error Codes

The application provides specific error codes for certificate generation failures:

- **CERT_GEN_RETURN_INVALID_RANDOM:** Insufficient random number generation

12.43.1.3.1.12 Advanced Features

Custom Certificate Parameters

The certificate generation structure can be modified to customize:

- Subject distinguished name fields
- Validity periods
- Subject alternative names
- Key algorithms and parameters

Integration Options

- **Web Server Customization:** Modify HTTP/HTTPS server behavior
- **Certificate Storage:** Custom certificate and key storage implementations
- **Time Sources:** Alternative time synchronization methods
- **Network Interfaces:** Multi-interface support and configuration

12.43.1.4 On-board Cert Generation - Compiled Certificate Authority

12.43.1.4.1 SSL Certificate Generation Application using a Self-Signed Certificate Authority Certificate

12.43.1.4.1.1 Overview

The simple auto-generate self-signed certificate example is the most common method used for most applications. This example provides advanced users with a demonstration of how to write their own onboard certificate generation function, including signing the generated certificate with a compiled in Certificate Authority certificate. To understand how to generate Certificate Authority certificate as well as how to compile it into your program, please see our documentation on creating self-signed certificates, found in the Programmers Guide and other SSL examples.

If you generate your own Certificate Authority (CA) for any network device you must accept responsibility for the security of the CA certificate. If a malicious party obtains your CA from the device or any other means, they will be able to use it to create their own "trusted" certificate and access your devices. This may be less of an issue if you are operating on a closed/private network, rather than devices on the Internet.

Note

This example demonstrates advanced certificate generation techniques beyond the simple self-signed approach. It requires familiarity with the wolfSSL API for full customization. Refer to the NetBurner Programmer's Guide for additional details on Certificate Authority creation and compilation.

12.43.1.4.1.2 Features

- **Automatic Certificate Generation:** Creates self-signed SSL certificates with ECC keys
- **Certificate Authority Support:** Signs certificates with a compiled-in Certificate Authority
- **Interactive Menu System:** Command-line interface for certificate management
- **Time Synchronization:** NTP-based time setting with manual fallback
- **Certificate Validation:** Checks certificate validity and expiration status
- **Web Server Integration:** Supports both HTTP and HTTPS connections
- **Configurable Parameters:** Customizable certificate attributes (country, state, organization, etc.)

12.43.1.4.1.3 Application Components

Main Application (main.cpp)

The core application provides:

- Interactive menu for certificate operations
- System time configuration
- HTTP/HTTPS web server startup
- Certificate creation and validation workflows

Certificate Generation (CertGen.cpp)

Custom certificate generation implementation that:

- Creates ECC private keys with configurable key sizes
- Generates certificates signed by a compiled Certificate Authority
- Supports various ECC curves (secp256r1, secp384r1, secp521r1, etc.)
- Implements proper error handling and cleanup
- Stores certificates and keys in device flash memory

Certificate Authority (CaCrt.cpp)

Contains a compiled-in Certificate Authority certificate for signing generated certificates. This CA is embedded as a byte array in the application.

Time Utilities (TimeUtil.cpp/TimeUtil.h)

Provides comprehensive time management:

- NTP synchronization with fallback to manual entry
- Time zone configuration with automatic daylight savings
- System time display and formatting functions

12.43.1.4.1.4 Security Considerations

Important**: When using a custom Certificate Authority, you must secure the CA certificate. If compromised, an attacker could create trusted certificates to access your devices. This risk is reduced in closed/private networks compared to Internet-facing deployments.

12.43.1.4.1.5 Interactive Menu Options

1. **Check Certificate Expiration** - Verify if the current certificate is expired
2. **Show Certificate Expiration** - Display the certificate expiration date
3. **Generate New Certificate** - Create a new certificate/key pair
4. **Erase Certificate** - Remove existing certificates (requires reboot)
5. **Display System Time** - Show current system time and date
6. **Reboot** - Restart the device

12.43.1.4.1.6 Certificate Configuration

Default certificate attributes can be customized in the `GetDataForCertGen()` function:

- **Country:** US
- **State:** CA (California)
- **Locality:** San Diego
- **Organization:** NetBurner
- **Unit:** CodeDemo
- **Email:** `Sales@NetBurner.com`
- **Common Name:** MyNetburner
- **Validity Period:** 1 year
- **Alternative Names:** Device IP address (both as IP and DNS entry)

12.43.1.4.1.7 Key Features

ECC Key Generation

- Supports multiple ECC curves based on `DEFAULT_KEY_TYPE`
- Key sizes: 24-66 bytes depending on curve selection
- Hardware random number generation on supported platforms
- Secure key storage in device flash memory

Certificate Signing

- Uses compiled Certificate Authority for signing
- SHA256 with RSA signature algorithm
- Proper ASN.1 DER encoding
- Alternative names support for IP and DNS entries

Time Management

- Automatic NTP synchronization from pool.ntp.org
- Manual time entry fallback if NTP fails
- Time zone support with daylight savings calculation
- Minimum time validation for certificate generation

12.43.1.4.1.8 Web Server Access

Once running, the device can be accessed via:

- HTTP: `http://[device-ip]`
- HTTPS: `https://[device-ip]`
- Configuration: `http://[device-ip]:20034` or `https://[device-ip]:20034`
- Discovery service: discover.netburner.com (if Internet access available)

12.43.1.4.1.9 Build Requirements

- NetBurner NNDK (NetBurner Network Development Kit)
- wolfSSL cryptographic library
- Compatible NetBurner hardware platform (MODM7AE70 recommended for hardware RNG)

12.43.1.4.1.10 Usage Notes

1. **Random Number Generation:** The application waits for valid entropy before generating keys. Network traffic helps build entropy on Coldfire platforms.
2. **System Time:** Accurate time is required for certificate generation and validation. The application attempts NTP synchronization first, then falls back to manual entry.
3. **Memory Management:** The application uses dynamic memory allocation for cryptographic operations and implements proper cleanup on errors.
4. **Certificate Storage:** Generated certificates and keys are stored in device flash memory and persist across reboots.

12.43.1.4.1.11 Error Handling

The application includes comprehensive error handling for:

- Memory allocation failures
- Cryptographic operation errors
- Certificate generation and signing failures
- File system operations
- Network connectivity issues

12.43.1.5 ACME Certificate Generation (Easy Servlet)

```
<NNDK install>\examples\SSL\acmeservlet
```

12.43.1.5.1 ACME Certificate Generation (Easy Servlet)

A NetBurner NNDK SSL/TLS example application that demonstrates automatic ACME certificate generation using Let's Encrypt or other ACME-compliant certificate authorities.

12.43.1.5.1.1 Overview

This application provides a web-based demonstration of automatic SSL/TLS certificate generation using the ACME (Automatic Certificate Management Environment) protocol as defined in RFC 8555. The application includes a built-in web server that serves both HTTP and HTTPS content, with automatic certificate provisioning through ACME providers.

SSL/TLS example program that demonstrates getting an ACME cert automatically. It will only work for a device with Internet access with a public IP address and DNS entry. Make sure to change the `DEFAULT_CERT_COM_NAME` constant in `main.cpp` to match.

This example makes use of the [acmeRFC8555Servlet.h](#) builtin to the NNDK which reduces how much code is required to add the functionality to your project and will more easily take advantage of future NNDK updates.

12.43.1.5.1.2 Requirements

- NetBurner device with public IP address
- Public DNS entry pointing to the device
- NNDK (NetBurner Network Development Kit)
- Device must be accessible from the internet for ACME validation

12.43.1.5.1.3 Features

- Automatic SSL/TLS certificate generation via ACME protocol
- Support for multiple ACME providers (Let's Encrypt, BuyPass, custom)
- Web server with both HTTP (port 80) and HTTPS (port 443) support
- Access control based on SSL/TLS connection status
- Certificate reissue functionality
- NTP client integration for accurate time synchronization
- Web-based status and control interface

12.43.1.5.1.4 Configuration

Certificate Information

Before running the application, update the following constants in `main.cpp` to match your environment:

```
const char * DEFAULT_CERT_COUNTRY= "US";
const char * DEFAULT_CERT_STATE= "CA";
const char * DEFAULT_CERT_LOCALITY= "San Diego";
const char * DEFAULT_CERT_ORG= "Netburner";
const char * DEFAULT_CERT_UNIT= "Demo";
const char * DEFAULT_CERT_EMAIL= "changeme@example.com";
const char * DEFAULT_CERT_ALT_NAMES= "test.example.com,example.com";
const char * DEFAULT_CERT_COM_NAME= "test.example.com";
```

Important*: The `DEFAULT_CERT_COM_NAME` must match your device's public DNS name.

ACME Provider Selection

The application supports multiple ACME providers. Choose one by uncommenting the appropriate line:

```
/* Production Let's Encrypt (default): */
LetsEncryptAcmeServletObject AcmeClient;

/* Let's Encrypt Staging (for testing): */
// LetsEncryptAcmeServletObject AcmeClient(true);

/* BuyPass ACME: */
// BuyPassAcmeServletObject AcmeClient;

/* Custom ACME server: */
// AcmeServletObject AcmeClient("https://your-acme-server.com/dir");
```

12.43.1.5.1.5 Building and Running

1. Ensure your NetBurner device has a public IP and DNS entry
2. Update the certificate configuration constants
3. Build the application using the NNDK toolchain
4. Deploy to your NetBurner device
5. Access the web interface via HTTP or HTTPS

12.43.1.5.1.6 Web Interface

The application provides several web endpoints:

- `/index.html` - Main interface page
- Counter functionality - Displays page reload count
- SSL status indicators - Shows connection security status
- Certificate management controls

Access Control

The application implements access control based on connection type:

- Access level 0: Available to all connections
- Access level 1: Requires SSL/TLS connection
- Other levels: Default allow access

12.43.1.5.1.7 Runtime Options

When the application starts, you can:

- Press 'R', 'r', 'Y', or 'y' to reissue certificates
- Monitor certificate status through diagnostic output
- View ACME client state information

12.43.1.5.1.8 ACME Certificate Process

1. Application generates a Certificate Signing Request (CSR)
2. Contacts the ACME server to request a certificate
3. Completes domain validation challenges
4. Receives and installs the signed certificate
5. Automatically renews certificates before expiration

12.43.1.5.1.9 Key Components

- **ACME Client:** Handles certificate requests and renewals
- **Web Server:** Serves HTTP/HTTPS content
- **NTP Client:** Maintains accurate time for certificate validation
- **SSL Context:** Manages SSL/TLS connections and certificates
- **Access Control:** Enforces connection security requirements

12.43.1.5.1.10 Troubleshooting

Common Issues

1. **Certificate generation fails:** Verify public DNS and IP accessibility
2. **ACME validation fails:** Check firewall settings and port accessibility
3. **Time sync issues:** Ensure NTP client can reach time servers
4. **Domain mismatch:** Verify `DEFAULT_CERT_COM_NAME` matches DNS

Debug Options

Enable diagnostic output:

```
AcmeClient.SetDiag(true);
```

Force certificate reissue:

```
AcmeClient.Delete_Everything_Restart();
```

12.43.1.5.1.11 Security Notes

- Certificates are automatically managed by the ACME client
- Production deployment should disable system diagnostics
- Consider implementing additional access controls for production use
- Monitor certificate expiration and renewal processes

12.43.1.5.1.12 License

This example code is provided as part of the NetBurner NNDK and follows the NetBurner licensing terms.

12.43.1.5.1.13 Support

For technical support and documentation:

- NetBurner NNDK Documentation
- NetBurner Support Portal
- ACME RFC 8555 specification

12.43.2 FTPS Server

12.43.2.1 FTPS Server Example

A simple FTPS (FTP over SSL/TLS) server implementation for NetBurner embedded devices that demonstrates secure file transfer capabilities with SSL encryption.

12.43.2.1.1 Overview

This example creates a basic FTPS server that runs on a NetBurner device and listens for secure client connections on port 990. The server implements the core functionality needed for encrypted file transfers while maintaining simplicity for educational and development purposes.

Key Features:**

- SSL/TLS encrypted FTP server (FTPS)
- Self-signed certificate authentication
- File download capability
- File upload with content display
- Real-time connection monitoring
- Configurable data channel encryption

12.43.2.1.2 Architecture

The application consists of several key components:

12.43.2.1.2.1 Core Files

- `main.cpp` - Main server implementation and callback functions
- `ServerCert.cpp` - Embedded self-signed SSL certificate
- `ServerKey.cpp` - Embedded SSL private key

12.43.2.1.2.2 SSL Configuration

- **Command Channel:** Always encrypted when FTPS is enabled
- **Data Channel:** Optionally encrypted (configurable)
- **Certificate:** Built-in self-signed certificate for testing
- **Port:** 990 (standard FTPS implicit SSL port)

12.43.2.1.3 Functionality

12.43.2.1.3.1 File Operations

Download (Client -> Server)

- **Available File:** `ReadFile.txt`
- **Content:** Hardcoded text string demonstrating file serving
- **Purpose:** Shows how to serve files to FTPS clients

Upload (Server -> Client)

- **Accepted File:** `WriteFile.txt` only
- **Processing:** Content is displayed on the serial debug port
- **Storage:** Files are not permanently stored (memory only)
- **Purpose:** Demonstrates file reception and processing

12.43.2.1.3.2 Authentication

- Simple authentication mechanism (currently accepts any credentials)
- Extensible design for custom authentication logic
- Session management with start/end callbacks

12.43.2.1.3.3 Directory Operations

- Basic file listing support
- Single-level directory structure
- No subdirectory creation/deletion (returns `FTPD_FAIL`)
- No file deletion or renaming capabilities

12.43.2.1.4 Configuration Options

12.43.2.1.4.1 Network Settings

```
const int listenPort = 990;           // FTPS port (21 for plain FTP)
const bool enableFTPS = true;        // Enable SSL encryption
const bool enableEncryptedDataChannel = false; // Data channel encryption
```

12.43.2.1.4.2 Security Notes

- Uses implicit SSL (connection encrypted from start)
- Self-signed certificate included for testing
- Data channel encryption disabled by default for compatibility
- Authentication currently accepts any credentials

12.43.2.1.5 Usage Instructions

12.43.2.1.5.1 Setup Requirements

1. NetBurner device with network connectivity
2. FTPS client software (WinSCP, FileZilla with FTPS support)
3. Serial terminal software (MTTTY) for monitoring

12.43.2.1.5.2 Running the Server

1. Flash the application to your NetBurner device
2. Connect serial terminal to debug port
3. Wait for network initialization (5 seconds timeout)
4. Server will start and display status messages

12.43.2.1.5.3 Connecting with FTPS Client

1. Configure client for FTPS (not SFTP)
2. Connect to NetBurner device IP on port 990
3. Use any username/password (authentication currently accepts all)
4. Accept the self-signed certificate when prompted

12.43.2.1.5.4 File Operations

- **Download:** Select `ReadFile.txt` to download sample content
- **Upload:** Send a text file named `WriteFile.txt` to see content on serial port

12.43.2.1.6 Development Notes

12.43.2.1.6.1 Extending the Example

This basic implementation can be enhanced by:

- Adding proper file system support (EFFS-FAT or EFFS-STD)
- Implementing robust authentication
- Adding directory navigation
- Supporting file deletion and renaming
- Using production certificates

12.43.2.1.6.2 Callback Functions

The server implements these FTPD callback functions:

- `FTPD_ListFile()` - File listing
- `FTPD_SendFileToClient()` - File downloads
- `FTPD_GetFileFromClient()` - File uploads
- `FTPD_FileExists()` - File existence checks
- `FTPD_AbleToCreateFile()` - Upload permissions
- `FTPDSessionStart()` / `FTPDSessionEnd()` - Session management

12.43.2.1.6.3 Monitoring and Debugging

- Serial port displays server status and connection information
- SSL socket status updated every 5 seconds
- File upload content shown in real-time
- Error messages and diagnostic information available

12.43.2.1.7 Security Considerations

12.43.2.1.7.1 Production Deployment

For production use, consider:

- Replace self-signed certificate with CA-signed certificate
- Implement proper user authentication
- Enable data channel encryption if required
- Add input validation and error handling
- Implement proper file system permissions

12.43.2.1.7.2 Current Limitations

- Self-signed certificate (browser warnings)
- Basic authentication (accepts any credentials)
- No persistent file storage
- Limited file operations
- Single file download/upload support

12.43.2.1.8 Compatibility

12.43.2.1.8.1 FTPS Clients

Tested with:

- WinSCP (recommended)
- FileZilla (FTPS mode)
- Other RFC 4217 compliant FTPS clients

12.43.2.1.8.2 NetBurner Platform

- Requires NNDK (NetBurner Network Development Kit)
- SSL/TLS library support
- Network stack initialization
- Serial debugging capabilities

12.43.2.1.9 Troubleshooting

12.43.2.1.9.1 Common Issues

- **Connection refused:** Check network connectivity and port configuration
- **Certificate errors:** Accept self-signed certificate in client
- **Authentication failed:** Verify FTPS (not SFTP) mode in client
- **File not found:** Ensure exact filename match (`ReadFile.txt`)
- **Upload rejected:** Use exact filename `WriteFile.txt`

12.43.2.1.9.2 Debug Information

Monitor serial output for:

- Server startup status
- SSL socket connections
- File transfer progress
- Error messages and diagnostics

12.43.3 HTML File Post

12.43.3.1 SSL/TLS File Post with Multipart Form

12.43.3.1.1 Overview

This NetBurner application demonstrates secure file uploading capabilities using SSL/TLS encryption. It provides a web interface that allows users to select and upload files to the NetBurner device through an HTTPS connection. The uploaded files are then processed and displayed back to the user on a web page.

Note

Browsers require a valid device certificate signed by a Certificate Authority known to the browser. Unless you install your self-signed Certificate Authority certificate in the web browser, you will see a warning message in the browser and should select the option to "continue anyway".

12.43.3.1.2 Features

- **SSL/TLS Security:** Secure file transfers using HTTPS protocol
- **Multipart Form Support:** Handles file uploads through HTML multipart forms
- **File Display:** Shows uploaded file content in both text and binary formats
- **Web Interface:** Simple HTML form for file selection and upload
- **Real-time Processing:** Immediate processing and display of uploaded files

12.43.3.1.3 Application Components

12.43.3.1.3.1 Core Files

- **main.cpp:** Main application entry point that initializes the network stack, enables HTTPS server, and manages the main application loop
- **formcode.cpp:** Contains the file processing logic and HTTP POST callback handlers
- **index.html:** Web interface with file upload form
- **ServerCert.cpp:** SSL certificate data for HTTPS connections
- **ServerKey.cpp:** SSL private key data for HTTPS connections

12.43.3.1.3.2 Key Functions

File Processing (`formcode.cpp`)

- `ProcessPostFile()`: Reads uploaded file data into a buffer
- `ShowFileData()`: Displays file content with optional binary format
- `PostCallBack()`: Handles HTTP POST events during file upload process

Main Application (`main.cpp`)

- `UserMain()`: Initializes network, starts HTTPS server, and waits for network connectivity

12.43.3.1.4 How It Works

1. **Initialization:** The application starts by initializing the network stack and enabling system diagnostics
2. **HTTPS Server:** Starts the HTTPS web server with SSL/TLS encryption
3. **Network Wait:** Waits up to 5 seconds for an active network connection ([DHCP](#))
4. **File Upload Process:**
 - User accesses the web interface through HTTPS
 - Selects a file using the HTML form
 - Clicks "Send File" to initiate upload
 - Server processes the multipart form data
 - File content is read and stored in a buffer
 - Processed file is displayed back to the user

12.43.3.1.5 Security Features

12.43.3.1.5.1 SSL/TLS Implementation

- Uses embedded SSL certificate and private key
- Provides encrypted communication between browser and device
- Protects file uploads from interception

12.43.3.1.5.2 Browser Requirements

Modern browsers require valid certificates for file uploads. This application includes:

- Self-signed certificate embedded in the firmware
- Certificate Authority (CA) certificate may need installation in browser
- Warning messages in browsers must be handled properly for file uploads to work

12.43.3.1.6 Technical Specifications

12.43.3.1.6.1 Buffer Management

- **File Buffer Size:** 10,000 bytes maximum
- **Read Buffer:** 16-byte chunks for binary display
- **Memory Safety:** Prevents buffer overflows during file processing

12.43.3.1.6.2 File Display Formats

- **Text Mode:** Shows readable characters with HTML entity encoding
- **Binary Mode:** Displays hexadecimal values alongside ASCII representation
- **HTML Safe:** Converts special characters (&, <, >, ") to HTML entities

12.43.3.1.7 Usage Instructions

1. **Deploy the Application:** Flash the firmware to your NetBurner device
2. **Network Connection:** Ensure the device has network connectivity
3. **Access Web Interface:** Navigate to the device's IP address using HTTPS
4. **Upload Files:** Use the file selection form to choose and upload files
5. **View Results:** The uploaded file content will be displayed on the result page

12.43.3.1.8 Testing

A quick test can be performed by uploading the included `ReadMe.txt` file to verify the application is working correctly.

12.43.3.1.9 Important Notes

12.43.3.1.9.1 Certificate Warnings

- Browsers may display security warnings for self-signed certificates
- For form variables, users can typically choose to continue despite warnings
- For file uploads, proper certificate handling is more critical
- Consider installing a valid CA certificate in browsers for production use

12.43.3.1.9.2 File Size Limitations

- Maximum file size is limited to 10,000 bytes
- Larger files will be truncated to fit within the buffer
- Consider increasing `FILE_BUFFER_SIZE` for larger file support

12.43.3.1.9.3 Production Considerations

- Remove `EnableSystemDiagnostics()` for production deployments
- Consider implementing additional file type validation
- Add error handling for network connectivity issues
- Implement proper certificate management for production environments

12.43.3.1.10 Development Environment

This application is built for the NetBurner platform using the NetBurner Network Development Kit (NNDK). The code utilizes NetBurner-specific libraries for HTTP handling, SSL/TLS support, and network operations.

12.43.3.1.11 Related Examples

This example builds upon the standard `examples\web\HtmlFilePost` example by adding SSL/TLS encryption capabilities for secure file transfers.

12.43.4 HTML Form Post

12.43.4.1 NetBurner SSL HTML Form Post Example

12.43.4.1.1 Overview

This application demonstrates how to implement secure HTML form processing using SSL/TLS on NetBurner embedded devices. It extends the basic HTML form post functionality by adding SSL encryption for secure web communication.

12.43.4.1.2 Application Description

The **HTML Form Post Example** is a web-based application that runs on NetBurner devices and provides:

- SSL/TLS encrypted web server functionality
- Multiple HTML forms with POST data processing
- Server-side form validation and data handling
- Page redirection after form submission
- Embedded SSL certificate and private key management

12.43.4.1.3 Key Features

12.43.4.1.3.1 Security

- **SSL/TLS Support:** Uses HTTPS for encrypted communication
- **Embedded Certificates:** Self-contained SSL certificate and private key
- **Secure Form Processing:** All form data transmitted over encrypted connections

12.43.4.1.3.2 Web Interface

- **Multi-page Workflow:** Three-page form processing sequence
- **Two Form Types:** Different forms demonstrating various input handling
- **Dynamic Content:** Server-side variable substitution in HTML pages
- **Error Handling:** Form validation with error reporting

12.43.4.1.3.3 Form Processing

- **Form 1:** Single text input field with simple processing
- **Form 2:** Multiple variable input fields (Var0-Var3)
- **Callback System:** Event-driven form processing with multiple callback points
- **Data Persistence:** Form data maintained between page transitions

12.43.4.1.4 File Structure

```
\src
  main.cpp           # Main application entry point
  web.cpp            # Web server and form processing logic
  ServerCert.cpp     # Embedded SSL certificate data
  ServerKey.cpp      # Embedded SSL private key data

\html
  index.html         # First form page
  page2.html         # Second form page
  complete.html      # Completion/results page
```

12.43.4.1.5 Application Flow

1. Initialization

- Network stack initialization
- HTTPS server startup (SSL-enabled)
- **DHCP** network configuration
- System diagnostics enablement

2. Form Processing Workflow

`index.html > form1 POST > page2.html > form2 POST > complete.html`

3. Form Callbacks

- `eStartingPost`: Initialize form processing
- `eVariable`: Process each form variable
- `eFile`: Handle file uploads (if present)
- `eEndOfPost`: Complete processing and redirect

12.43.4.1.6 Technical Implementation

12.43.4.1.6.1 SSL Configuration

- Uses embedded certificate and private key data
- Certificate validity: 2019-2029
- Elliptic Curve (EC) cryptography
- Self-signed certificate for development/testing

12.43.4.1.6.2 Form Handlers

- **postForm1**: Handles single text input from `index.html`
- **postForm2**: Processes multiple variables from `page2.html`
- **URL Patterns**: "form1*" and "form2*" for flexible routing

12.43.4.1.6.3 Data Storage

- **Form 1**: Single 80-character text buffer
- **Form 2**: Array of 4 variables, 80 characters each
- **Error Tracking**: Boolean flags for form validation

12.43.4.1.6.4 HTML Integration

- **Dynamic Content**: `<!--CPPCALL FunctionName -->` for server-side includes
- **WebTextForm1()**: Displays Form 1 data
- **WebTextForm2()**: Displays Form 2 data with formatting

12.43.4.1.7 Network Configuration

- **Protocol**: HTTPS (SSL/TLS encrypted HTTP)
- **Port**: Default HTTPS port (443)
- **Network**: **DHCP** client configuration
- **Timeout**: 5-second network initialization wait

12.43.4.1.8 Development Notes

12.43.4.1.8.1 Security Considerations

- Uses development/test SSL certificate
- Replace embedded certificate for production use
- Certificate includes localhost and IP address subjects
- Self-signed certificate will trigger browser warnings

12.43.4.1.8.2 Memory Usage

- Fixed-size buffers for form data
- Embedded certificate data: 672 bytes
- Embedded private key data: 310 bytes
- Form variables: configurable buffer sizes

12.43.4.1.8.3 Customization Points

- Form variable names and counts
- Buffer sizes for form data
- SSL certificate replacement
- HTML page content and styling

12.43.4.1.9 Building and Deployment

1. Compile with NetBurner NNDK (NetBurner Network Development Kit)
2. Flash to NetBurner device
3. Configure network settings ([DHCP](#) or static IP)
4. Access via HTTPS in web browser
5. Accept security warning for self-signed certificate

12.43.4.1.10 Browser Compatibility

- Supports all modern web browsers
- Requires JavaScript disabled for basic functionality
- HTML form POST method compatibility
- SSL/TLS certificate acceptance required

12.43.4.1.11 Troubleshooting

12.43.4.1.11.1 Common Issues

- **Certificate Warnings:** Expected with self-signed certificates
- **Network Connectivity:** Verify [DHCP](#) configuration
- **Form Submission:** Check POST URL patterns and handlers
- **SSL Handshake:** Ensure certificate validity and browser compatibility

12.43.4.1.11.2 Debug Output

- Console logging for all form processing events
- Variable value tracking
- Error condition reporting
- Network initialization status

12.43.4.1.12 API Reference

12.43.4.1.12.1 Key Functions

- `init()`: Initialize network stack
- `StartHttps()`: Start SSL-enabled web server
- `WaitForActiveNetwork()`: Wait for network connectivity
- `RedirectResponse()`: Send HTTP redirect response
- `fdprintf()`: Formatted output to socket

12.43.4.1.12.2 Callback Events

- `eStartingPost`: Form processing initialization
- `eVariable`: Individual variable processing
- `eFile`: File upload handling
- `eEndOfPost`: Form completion processing

12.43.5 HTTPS Dual Cert

12.43.5.1 NetBurner HTTPS Dual Certificate Server

12.43.5.1.1 Overview

This NetBurner application demonstrates a dual-certificate HTTPS/HTTP server implementation that supports both compiled-in certificates and dynamically loaded certificates from external storage. The application provides a web interface accessible via both secure (HTTPS) and non-secure (HTTP) connections, along with FTP server functionality for remote file management.

12.43.5.1.2 Supported Platforms

- MODM7AE70
- SBE70LC
- MOD5441X
- NANO54415
- SOMRT1061
- MODRT1171

12.43.5.1.3 Key Features

12.43.5.1.3.1 Dual Certificate Support

- **Compiled-in Certificate:** Server includes a built-in certificate and private key for immediate SSL/TLS functionality
- **External Certificate Loading:** Automatically detects and uses certificate files (`DEVICE.CRT`) and private key files (`DEVICE.KEY`) from external flash storage when available
- **Fallback Mechanism:** Gracefully falls back to compiled-in certificates if external files are not found or invalid

12.43.5.1.3.2 Network Services

- **HTTPS Server:** Secure web server running on port 443
- **HTTP Server:** Non-secure web server running on port 80
- **FTP Server:** File transfer protocol server on port 21 for remote file management

12.43.5.1.3.3 External Storage Support

- **Multiple Flash Card Types:** Supports SD/SDHC, MMC, and Compact Flash cards
- **FAT32 File System:** Full read/write access to external storage using EFFS FAT library
- **Hot-swappable Storage:** Runtime detection of card insertion/removal with write protection checks

12.43.5.1.3.4 Time Management

- **NTP Client:** Automatic time synchronization from network time servers
- **Manual Time Setting:** Fallback manual time configuration
- **Timezone Support:** Configurable timezone settings (defaults to PST/PDT)
- **RTC Integration:** Support for hardware real-time clock when available

12.43.5.1.3.5 Web Interface Features

- **Dynamic Content:** Web pages with embedded function calls for dynamic content generation
- **SSL/HTTP Switching:** Links to switch between secure and non-secure versions of pages
- **Auto-refresh Pages:** Demonstration pages with automatic reload functionality
- **Flash Card Formatting:** Web-based flash card formatting utility

12.43.5.1.4 File Structure

12.43.5.1.4.1 Core Application Files

- `main.cpp` - Main application entry point and initialization
- `cardtype.h` - Flash card type configuration and selection
- `dual_mode_file_key.cpp` - Dual certificate management implementation

12.43.5.1.4.2 File System Utilities

- `FileSystemUtils.cpp/.h` - EFFS FAT file system wrapper functions
- `effs_time.cpp/.h` - Time management and NTP client implementation

12.43.5.1.4.3 Network Services

- `ftp_f.cpp/.h` - FTP server implementation for EDFS file systems
- `http_f.h` - HTTP server function registration

12.43.5.1.4.4 Certificate Management

- `ServerCert.cpp` - Compiled-in server certificate (PEM format)
- `ServerKey.cpp` - Compiled-in private key (PEM format)

12.43.5.1.4.5 Web Content

- `index.html` - Main web page with SSL/HTTP switching links
- `format.html` - Flash card formatting utility page
- `repeat.html` - Auto-refreshing demonstration page
- `robots.txt` - Web crawler control file

12.43.5.1.4.6 Platform-Specific Files

- `ramdrv_mcf.cpp` - RAM drive configuration for testing

12.43.5.1.5 Configuration Options

12.43.5.1.5.1 Flash Card Types

The application supports multiple flash card types configured in `cardtype.h`:

- **USE_SDHC**: SD/SDHC cards (default for SB800EX and SOMRT1061)
- **USE_MMC**: SD/MMC cards
- **USE_CFC**: Compact Flash cards
- **USE_RAM**: RAM-based file system for testing

12.43.5.1.5.2 Certificate Loading Priority

1. External certificates from flash card (`DEVICE.CRT` and `DEVICE.KEY`)
2. Compiled-in certificates (if external files not found or invalid)

12.43.5.1.5.3 Network Configuration

- HTTPS Port: 443
- HTTP Port: 80
- FTP Port: 21

12.43.5.1.6 Usage Instructions

12.43.5.1.6.1 Initial Setup

1. Configure flash card type in `cardtype.h` based on your hardware
2. Insert properly formatted flash card (FAT32 recommended)
3. Optionally copy certificate files (`DEVICE.CRT`, `DEVICE.KEY`) to flash card root directory
4. Compile and deploy application to NetBurner device

12.43.5.1.6.2 Web Interface Access

- **HTTP:** `http://[device-ip]/index.html`
- **HTTPS:** `https://[device-ip]/index.html`
- **Format Flash:** `http://[device-ip]/format.html`

12.43.5.1.6.3 FTP Access

- Connect to `ftp://[device-ip]` for file management
- Upload/download certificate files
- Manage web content and application files

12.43.5.1.6.4 Serial Console Commands

- Press 'F' to format the flash card
- Monitor application status and debug information

12.43.5.1.7 Technical Implementation Details

12.43.5.1.7.1 Certificate Validation

The application validates external certificates using the NetBurner SSL library function `IsSSL_CertNKeyValid()` to ensure compatibility before use.

12.43.5.1.7.2 Memory Management

- External certificate files are loaded into dynamically allocated memory
- Automatic cleanup of memory buffers after certificate processing
- Graceful handling of memory allocation failures

12.43.5.1.7.3 Error Handling

- Comprehensive EDFS error code reporting with descriptive messages
- Network retry mechanisms for robust file transfers
- Graceful fallback to compiled-in certificates on external certificate failure

12.43.5.1.7.4 Security Considerations

- Example certificates included are for demonstration only
- Production deployments should use properly signed certificates
- Web browsers will display warnings for self-signed certificates

12.43.5.1.8 Build Requirements

12.43.5.1.8.1 Required Libraries

- **FatFile.a:** EDFS FAT file system library
- **SSL/TLS Libraries:** NetBurner cryptographic libraries
- **Network Libraries:** HTTP/HTTPS and FTP server libraries

12.43.5.1.8.2 NBEclipse Configuration

To include the FatFile library in NBEclipse:

1. Right-click project and select "Properties"
2. Navigate to "C/C++ Build -> Settings"
3. Select "GNU C/C++ Linker -> Libraries"
4. Add "FatFile" to the libraries list

12.43.5.1.9 Development Notes

This application serves as a comprehensive example of:

- SSL/TLS certificate management in embedded systems
- External storage integration with embedded web servers
- Network service coordination (HTTP/HTTPS/FTP)
- Time synchronization in embedded applications
- Robust error handling and fallback mechanisms

12.43.6 HTTPS Upload Cert

12.43.6.1 NetBurner SSL Certificate Upload Application

12.43.6.1.1 Overview

This NetBurner embedded application provides a comprehensive SSL/TLS certificate management system with web-based certificate upload functionality. The application enables users to replace default compiled-in certificates with their own SSL/TLS certificates and private keys through a secure web interface, supporting modern HTTPS connectivity for embedded devices.

12.43.6.1.2 Key Features

12.43.6.1.2.1 Certificate Management

- **Web-based Upload Interface:** User-friendly web forms for uploading SSL/TLS certificates and private keys
- **Multiple Certificate Sources:** Support for library default, compiled-in default, and user-installed certificates
- **Certificate Validation:** Automatic validation of certificate and private key pairs before installation
- **PEM Format Support:** Handles Privacy-Enhanced Mail (PEM) encoded certificates and keys
- **Certificate Authority Management:** Support for multiple CA certificates for client verification

12.43.6.1.2.2 File System Integration

- **EFFS-STD File System:** Uses NetBurner's Enhanced Flash File System Standard for persistent storage
- **On-chip Flash Storage:** Certificates stored in protected flash memory
- **Atomic Updates:** Safe certificate installation with automatic rollback on failure
- **File Size Limits:** 3KB maximum for certificates, 4KB maximum for private keys

12.43.6.1.2.3 Network and Security

- **Dual Stack Support:** Full IPv4 and IPv6 HTTPS connectivity
- **NetBIOS Integration:** Automatic device name publishing
- **NTP Time Synchronization:** Required for proper certificate validation
- **Debug Console:** Serial interface for system monitoring and configuration

12.43.6.1.3 Supported Platforms

- **MOD5441X**: 32MB parallel flash with 128KB sectors
- **NANO54415**: 8MB SPI flash with 4KB sectors
- **SB800EX**: 8MB SPI flash with 4KB sectors
- **MODM7AE70**: 2MB parallel flash with 8KB sectors
- **SBE70LC**: 2MB parallel flash with 8KB sectors

12.43.6.1.4 Application Architecture

12.43.6.1.4.1 Core Components

Main Application (`main.cpp`)

The main application handles system initialization and provides the primary user interface:

- **System Initialization**: Network configuration, SSL service startup, and file system mounting
- **NTP Time Sync**: Automatic time synchronization using configurable timezone (default PST/PDT)
- **Debug Interface**: Serial console with commands for system management
- **NetBIOS Configuration**: Automatic device name publishing based on MAC address
- **Certificate Scanning**: Automatic CA certificate discovery and validation

Certificate Management (`certificatekey.cpp`)

Handles all certificate-related operations:

- Certificate and key file upload processing
- Validation of certificate/key pairs
- CA certificate management (up to 20 certificates)
- Web interface functions for certificate display and status

SSL User Interface (`ssluser.cpp`)

Provides certificate retrieval and management functions:

- Default certificate management
- PEM format handling and conversion
- Certificate source switching between library default, compiled default, and user-installed

File System (`effsStdFlashDrv.cpp`, `FileSystemUtils.cpp`)

Platform-specific flash drivers and utilities:

- Hardware abstraction for different flash types (parallel vs SPI)
- File system operations (read, write, delete, format)
- Error handling and reporting

12.43.6.1.5 File System Structure

```
/
cert.crt           # Active SSL certificate (max 3KB)
cert.key           # Corresponding private key (max 4KB)
CACert0.crt        # Certificate Authority cert #0
CACert1.crt        # Certificate Authority cert #1
...                # Additional CA certs (up to CACert19.crt)
```

12.43.6.1.6 Web Interface

The main configuration page ([https://...html](https://...)) provides:

- **Certificate Status Display:** Shows current certificate source (Default vs User Installed)
- **Upload Forms:** Separate forms for certificate and key file uploads
- **Certificate Information:** View current certificate details and validity
- **Factory Reset:** Option to restore default certificates
- **Network Information:** Display of HTTP and HTTPS access addresses

12.43.6.1.7 Debug Console Commands

Available via serial interface:

- 0 - Turn off debug messages
- 1 - Turn on debug messages
- D - Reset to factory default parameters
- F - Show file system information and statistics
- G - Format file system (WARNING: Erases all data)
- N - Display current NV settings
- T - Display current system time
- B - Force system reboot

12.43.6.1.8 Certificate Requirements

12.43.6.1.8.1 Supported Formats

- **Encoding:** PEM (Privacy-Enhanced Mail) format only
- **Key Types:** RSA, DSA, and ECDSA keys supported
- **Certificate Chain:** Multiple CA certificates supported for client verification

12.43.6.1.8.2 Size Limitations

- **Certificate Files:** Maximum 3KB in PEM format
- **Private Key Files:** Maximum 4KB in PEM format
- **CA Certificates:** Maximum 3KB each, up to 20 total

12.43.6.1.9 Configuration

12.43.6.1.9.1 Network Settings

- **Device Naming:** Automatic device name based on MAC address
- **DHCP Support:** Automatic IP address assignment
- **Dual Stack:** IPv4/IPv6 support for maximum compatibility

12.43.6.1.9.2 SSL/TLS Settings

- **Certificate Sources:** Configurable between library default, compiled default, and user-installed
- **Client Verification:** Optional client certificate verification using CA certificates
- **Peer Verification:** Configurable peer certificate validation

12.43.6.1.10 Security Features

12.43.6.1.10.1 Certificate Validation

- Automatic verification of certificate and private key pairs
- Certificate format and structure validation
- Certificate chain verification for CA certificates
- Expiration date checking (requires accurate system time)

12.43.6.1.10.2 Secure Storage

- Protected flash memory storage for certificates and keys
- Atomic update operations prevent corruption during uploads
- Automatic rollback to default certificates on validation failure
- Memory protection and cleanup for sensitive data

12.43.6.1.11 Getting Started

12.43.6.1.11.1 Initial Setup

1. **Build and Deploy:** Compile for your target NetBurner platform
2. **Network Connection:** Connect device to network ([DHCP](#) recommended)
3. **Initial Access:** Browse to device IP address via HTTP
4. **Time Synchronization:** Verify NTP time sync (required for certificate validation)

12.43.6.1.11.2 Certificate Installation

1. **Access Web Interface:** Navigate to `https.html` page
2. **Upload Certificate:** Use the certificate upload form (PEM format, max 3KB)
3. **Upload Private Key:** Use the key upload form (PEM format, max 4KB)
4. **Verification:** System automatically validates certificate/key pair
5. **HTTPS Access:** Test secure connectivity using HTTPS

12.43.6.1.11.3 CA Certificate Management

1. **Upload CA Certificates:** Use CA certificate upload form
2. **Client Verification:** Enable client certificate verification if needed
3. **Multiple CAs:** Upload additional CA certificates as required (max 20)

12.43.6.1.12 Troubleshooting

12.43.6.1.12.1 Common Issues

Certificate Upload Problems

- **File Size Errors:** Verify certificate < 3KB and key < 4KB in PEM format
- **Certificate Validation Failures:** Ensure certificate and key are properly paired and in valid PEM format
- **Upload Timeouts:** Large files may timeout; check network connectivity and file size limits
- **Invalid File Format:** Only PEM-encoded certificates and keys are supported

Time Synchronization Issues

- **NTP Failures:** Check network connectivity, DNS resolution, and firewall settings
- **Certificate Validation Errors:** Accurate system time required for certificate expiry checking
- **Timezone Problems:** Use `tzsetchar()` for proper timezone configuration

Browser Connection Issues

- **Self-Signed Certificate Warnings:** Install CA certificate in browser or use proper CA-signed certificates
- **HTTPS Connection Failures:** Verify certificate installation and SSL service startup
- **IPv6 Connectivity:** Ensure proper IPv6 configuration if using IPv6 addresses

File System Problems

- **Flash Corruption:** May require file system format and factory reset
- **Insufficient Space:** Check available flash memory before certificate upload
- **Mount Failures:** Verify flash hardware and driver configuration

12.43.6.1.12.2 Recovery Options

Factory Reset Procedures

- **Debug Command:** Use serial command 'D' to reset to factory defaults
- **Web Interface:** Use factory reset option on configuration page
- **NV Settings Reset:** Clears user certificates and restores default configuration
- **File System Impact:** May require file system format depending on corruption level

File System Recovery

- **Format Command:** Use debug command 'G' to format file system (WARNING: Erases all data)
- **Automatic Recovery:** System detects corruption and attempts automatic recovery
- **Manual Recovery:** Delete specific certificate files via FTP or debug interface

Certificate Recovery

- **Default Fallback:** System automatically uses compiled-in certificates on errors
- **Library Defaults:** Use `SslUserSetDefault()` to restore NetBurner default certificates
- **Backup Restoration:** Restore certificates from backup files if available

12.43.6.1.12.3 Debug and Monitoring

Serial Console Diagnostics

- **Debug Level Control:** Commands '0' and '1' to control debug message verbosity
- **File System Status:** Command 'F' shows detailed file system information
- **Network Status:** Command 'N' displays current NV settings
- **Time Verification:** Command 'T' shows current system time

Log Analysis

- **SSL Errors:** Look for certificate validation failures in debug output
- **File System Errors:** Check for flash read/write/erase failures
- **Network Issues:** Monitor for [DHCP](#), DNS, or NTP synchronization problems
- **Memory Issues:** Watch for allocation failures during file uploads

Performance Monitoring

- **Flash Wear:** Monitor bad block count and wear leveling statistics
- **Memory Usage:** Check heap usage during certificate operations
- **Network Performance:** Monitor connection establishment times for HTTPS
- **Certificate Chain Length:** Verify CA certificate chain length for client verification

12.43.6.1.12.4 Platform-Specific Issues

MOD5441X Parallel Flash

- **Address Conflicts:** Verify COMPCODEFLAGS settings in makefile
- **Flash Programming:** Check parallel flash programming voltage levels
- **Sector Alignment:** Ensure proper 128KB sector boundary alignment

NANO54415/SB800EX SPI Flash

- **SPI Interface:** Verify SPI clock frequency and signal integrity
- **RAM Mirror:** Monitor RAM usage for file system mirror
- **Write Performance:** SPI flash writes slower than parallel flash

MODM7AE70/SBE70LC On-Chip Flash

- **Background Erase:** Disable background erase feature in NBEclipse
- **Fixed Address:** Enable "Locate Application at Fixed Address in Flash"
- **Library Linking:** Ensure StdFFile.a library is properly linked

12.43.6.1.13 Development Notes

12.43.6.1.13.1 Memory Management

- Dynamic memory allocation for file uploads with automatic cleanup
- Buffer size limits prevent memory exhaustion
- Careful handling of certificate data to prevent memory leaks

12.43.6.1.13.2 Error Handling

- Comprehensive error checking for all file operations
- Graceful degradation on certificate validation failures
- User feedback through both web interface and debug console
- Automatic recovery mechanisms for corrupted installations

12.43.6.1.13.3 Browser Compatibility

Modern browsers require valid certificates and may reject self-signed certificates. For development:

- Install the Certificate Authority certificate in the browser
- Use NetBurner SDK certificate generation scripts (`makeca`, `makeserver`)
- Consider using proper CA-signed certificates for production deployment

12.43.6.1.14 Version Information

- **Application Version:** 01.00.0000
- **Supported OS:** NetBurner RTOS 3.x
- **File System:** EFFS-STD (Enhanced Flash File System Standard)
- **SSL/TLS:** NetBurner SSL library with OpenSSL compatibility

12.43.7 HTTPS Web Server Demo

The `HTTP_ACCESS CheckHttpAccess(int sock, int access_level, HTTP_Request &Req)` function is used to authenticate the web page access. It will allow access or redirect depending on the file and access rights.

12.43.7.1 SSL/TLS Web Server Demo

A NetBurner embedded web server application demonstrating secure HTTPS and non-secure HTTP access controls with SSL/TLS certificate authentication.

12.43.7.1.1 Overview

This application creates a dual-protocol web server that serves content over both HTTP (port 80) and HTTPS (port 443). It implements access control mechanisms to restrict certain content to secure connections only, demonstrating how to build embedded web applications with security-conscious file serving.

12.43.7.1.2 Features

- **Dual Protocol Support:** Serves content over both HTTP and HTTPS
- **Access Control:** Implements file-level security restrictions
- **SSL/TLS Authentication:** Uses embedded certificates for secure connections
- **Dynamic Content:** Provides callback functions for server-side processing
- **Automatic Redirection:** Handles unauthorized access attempts gracefully

12.43.7.1.3 Directory Structure

```
html
|-- index.html           # Public page (HTTP/HTTPS accessible)
|-- images               # Image directory (HTTP/HTTPS accessible)
    |-- SSL-Good.gif      # Displayed for HTTPS connections
    |-- SSL-Bad.gif       # Displayed for HTTP connections
    |-- Other misc images
|-- httpsdir             # Secure directory (HTTPS only)
    |-- repeat.html       # Secure page requiring SSL/TLS
```

12.43.7.1.4 Access Control System

The application implements a two-tier access control system:

12.43.7.1.4.1 Access Level 0 (Public)

- **Files:** `index.html`, content in `images/` directory
- **Access:** Available via both HTTP and HTTPS
- **Authentication:** None required

12.43.7.1.4.2 Access Level 1 (Secure)

- **Files:** Content in `httpsdir/` directory (e.g., `repeat.html`)
- **Access:** HTTPS connections only
- **Authentication:** Valid SSL/TLS connection required
- **Behavior:** HTTP requests return `HTTP_FORBIDDEN` status

12.43.7.1.5 Core Components

12.43.7.1.5.1 Main Application (`main.cpp`)

Key Functions:**

- `UserMain()`: Application entry point, initializes network stack and starts web server
- `CheckHttpAccess()`: Custom access control function that overrides system defaults
- `DoCounter()`: Demonstrates server-side content generation for SSL connections
- `SSL_Image()`: Returns different images based on connection security
- `GetHost()` / `ShowHost()`: Host header parsing utilities
- `HTTPS_Ref()` / `HTTP_Ref()`: Generate protocol-specific URL references

Network Initialization:**

- Waits for `DHCP` address assignment (5-second timeout)
- Starts web server on default ports (80 for HTTP, 443 for HTTPS)
- Enables system diagnostics for debugging

12.43.7.1.5.2 Security Certificates

Server Certificate (`ServerCert.cpp`)**

- Contains embedded SSL/TLS certificate data
- 672-byte PEM-encoded certificate
- Used for HTTPS connection authentication

Private Key (`ServerKey.cpp`)**

- Contains embedded private key data
- 310-byte PEM-encoded EC private key
- Used for SSL/TLS handshake and encryption

12.43.7.1.6 How It Works

1. **Server Startup:** Application initializes network stack and starts dual-protocol web server
2. **Connection Handling:** Server accepts both HTTP and HTTPS connections
3. **Access Control:** `CheckHttpAccess()` function evaluates each request:
 - Level 0: Grants access regardless of protocol
 - Level 1: Requires SSL/TLS connection (`IsSSLfd()` check)
4. **Content Serving:**
 - Public content served over any protocol
 - Secure content only served over HTTPS
 - Dynamic content generated via callback functions

12.43.7.1.7 Security Features

- **Protocol Enforcement:** Secure directories reject non-SSL connections
- **Certificate-Based Authentication:** Uses embedded certificates for identity verification
- **Graceful Degradation:** Non-secure requests to secure content return proper HTTP error codes
- **Dynamic Security Indicators:** Different visual feedback based on connection security

12.43.7.1.8 Network Configuration

- **DHCP:** Automatically obtains IP address via DHCP
- **Ports:**
 - HTTP: 80 (configurable)
 - HTTPS: 443 (configurable)
- **Protocols:** HTTP/1.1, HTTPS with SSL/TLS

12.43.7.1.9 Usage Example

1. Deploy application to NetBurner device
2. Connect device to network (DHCP-enabled)
3. Access public content:
 - `http://device-ip/index.html` (works)
 - `https://device-ip/index.html` (works)
4. Access secure content:
 - `http://device-ip/httpsdir/repeat.html` (forbidden)
 - `https://device-ip/httpsdir/repeat.html` (works)

12.43.7.1.10 Customization

To modify access control:

1. Edit `CheckHttpAccess()` function logic
2. Adjust access levels in HTML files or `.nbaccess` files
3. Modify directory structure as needed
4. Update certificate/key files for production deployment

12.43.7.1.11 Dependencies

- NetBurner RTOS
- NetBurner HTTP/HTTPS libraries
- SSL/TLS crypto libraries
- Network interface libraries

12.43.8 HTTPS GET Request

12.43.8.1 SSL HTTPS GET Example

12.43.8.1.1 Overview

This application demonstrates how to create an SSL/TLS client that can retrieve web pages from HTTPS servers using the NetBurner RTOS platform. The example shows basic secure HTTP communication over SSL/TLS connections.

12.43.8.1.2 Description

The SSL HTTPS GET Example is a command-line application that allows users to:

- Connect to HTTPS servers by hostname
- Establish secure SSL/TLS connections on port 443
- Send HTTP GET requests to retrieve web page content
- Display the response data in a terminal interface

12.43.8.1.3 Key Features

- **DNS Resolution:** Resolves hostnames to IP addresses using the built-in DNS client
- **SSL/TLS Support:** Establishes secure connections with certificate verification
- **Interactive Interface:** Command-line prompt for entering server hostnames
- **Error Handling:** Comprehensive error reporting for SSL connection failures
- **Network Diagnostics:** Optional system diagnostics for debugging

12.43.8.1.4 Prerequisites

Important Certificate Requirements:**

You must either:

1. Include a CA (Certificate Authority) certificate list in your project, OR
2. Recompile the cryptolib with `NB_SSL_CLIENT_CERTIFICATE_CHECKING_ENABLED` defined in `sslclient.cpp`

Without proper certificate configuration, SSL connections may fail with certificate verification errors.

12.43.8.1.5 Usage

1. **Build and Deploy:** Compile and deploy the application to your NetBurner device
2. **Run Terminal:** Start the MTTY serial terminal application
3. **Network Setup:** Ensure the device has obtained a [DHCP](#) address (5-second timeout)
4. **Enter Hostname:** When prompted, enter an HTTPS server name (e.g., `www.google.com`)
5. **View Results:** The application will display the retrieved web page content

12.43.8.1.5.1 Example Session

```
Enter the destination HTTPS server name: www.google.com

Getting [www.google.com]

www.google.com = 172.217.164.100

We connected
Read 1024 bytes
[HTTP/1.1 200 OK
Content-Type: text/html
...]
```

12.43.8.1.6 Application Flow

1. **Initialization:** Network stack initialization and [DHCP](#) address acquisition
2. **User Input:** Prompts for HTTPS server hostname
3. **DNS Lookup:** Resolves hostname to IP address
4. **SSL Connection:** Establishes secure connection on port 443
5. **HTTP Request:** Sends GET / request to the server
6. **Response Handling:** Reads and displays up to 20KB of response data
7. **Cleanup:** Closes connection and repeats for next request

12.43.8.1.7 Error Handling

The application provides detailed error messages for common SSL connection failures:

- `SSL_ERROR_FAILED_NEGOTIATION`: SSL handshake failed
- `SSL_ERROR_CERTIFICATE_UNKNOWN`: Server certificate not recognized
- `SSL_ERROR_CERTIFICATE_NAME_FAILED`: Certificate hostname mismatch
- `SSL_ERROR_CERTIFICATE_VERIFY_FAILED`: Certificate verification failed
- DNS resolution failures

12.43.8.1.8 Technical Details

12.43.8.1.8.1 Buffer Specifications

- **Receive Buffer:** 20KB capacity for response data
- **Display Limit:** First 512 bytes shown in terminal output
- **Hostname Buffer:** 255 character maximum length

12.43.8.1.8.2 Network Configuration

- **Protocol:** HTTPS over SSL/TLS
- **Port:** 443 (standard HTTPS port)
- **Timeout:** 400 ticks for SSL connection attempts
- **Retry Logic:** Automatic retry on initial connection failure

12.43.8.1.8.3 Dependencies

- NetBurner RTOS
- SSL/TLS crypto library
- DNS resolution system
- Network I/O subsystem

12.43.8.1.9 Debugging

The application includes optional network debugging capabilities when compiled with the `_DEBUG` flag. System diagnostics are enabled by default but should be removed for production deployments.

12.43.8.1.10 Limitations

- Maximum response size: 20KB
- Single-threaded operation
- Basic HTTP GET requests only
- No support for HTTP authentication
- Limited certificate validation options

12.43.9 SSL/TLS Client

12.43.9.1 SSL/TLS Client Example

A NetBurner embedded device application that demonstrates SSL/TLS client connections with automated testing and connection monitoring.

12.43.9.1.1 Overview

This application performs automated SSL/TLS client connections to a specified server, tracking both successful and failed connection attempts. It provides real-time status updates through both network messages and serial debug output, making it useful for testing SSL/TLS connectivity and performance analysis.

12.43.9.1.2 Features

- Automated SSL/TLS client connections with configurable target server
- Connection attempt tracking (successes and failures)
- Performance timing measurements
- Dual output channels: network messages to server and serial debug
- Comprehensive error reporting with specific SSL error codes
- Built-in retry mechanism with configurable delays
- DNS hostname resolution support

12.43.9.1.3 Configuration

12.43.9.1.3.1 Server Settings

Modify the following definitions in `main.cpp` to configure your target SSL server:

```
#define SSL_SERVER_NAME "192.168.0.53" // Server IP address or hostname
#define SSL_SERVER_PORT 4433          // Server port number
```

12.43.9.1.3.2 Certificate Checking (Optional)

Certificate checking is disabled by default. To enable certificate verification:

1. Include a CA certificate list in your project
2. Uncomment `#define NB_SSL_CLIENT_CERTIFICATE_CHECKING_ENABLED` in `sslclient.cpp`
3. Rebuild the system libraries

12.43.9.1.4 Application Behavior

12.43.9.1.4.1 Connection Process

1. **Initialization:** Waits for active network ([DHCP](#)) for up to 5 seconds
2. **DNS Resolution:** Resolves the server hostname to IP address (15-second timeout)
3. **SSL Connection:** Attempts SSL/TLS connection (20-second timeout)
4. **Message Exchange:** Sends connection statistics to the server
5. **Cleanup:** Closes connection and waits before next attempt

12.43.9.1.4.2 Test Parameters

- **Maximum Attempts:** 50 connections
- **Connection Timeout:** 20 seconds
- **DNS Timeout:** 15 seconds
- **Retry Delay:** 0.5 seconds between attempts
- **Network Wait:** 5 seconds for [DHCP](#)

12.43.9.1.4.3 Output Information

For each connection attempt, the application reports:

- Target server and port
- Connection start timestamp
- Success/failure status with error details
- Total connection time in system ticks and seconds
- Running totals of successful and failed attempts

12.43.9.1.5 Testing with OpenSSL

You can test the client using OpenSSL's server functionality:

```
openssl s_server -accept 4433 -cert Server.crt -key Server.key
```

Replace `Server.crt` and `Server.key` with your certificate files. These can be created using:

- NetBurner development tools
- OpenSSL certificate generation commands
- Certificate Authority (CA) issued certificates

Refer to the OpenSSL `s_server` documentation for additional configuration options.

12.43.9.1.6 Error Handling

The application provides detailed error reporting for SSL connection failures:

- **SSL_ERROR_FAILED_NEGOTIATION:** SSL handshake negotiation failed
- **SSL_ERROR_CERTIFICATE_UNKNOWN:** Unknown certificate error
- **SSL_ERROR_CERTIFICATE_NAME_FAILED:** Certificate name verification failed
- **SSL_ERROR_CERTIFICATE_VERIFY_FAILED:** Certificate verification failed
- **Other errors:** Generic SSL connection errors

12.43.9.1.7 Performance Monitoring

Connection timing is measured and reported for each attempt:

- System tick timestamps for precise timing
- Approximate duration in seconds
- Running statistics for performance analysis

12.43.9.1.8 Build Requirements

- NetBurner development environment
- SSL/TLS libraries enabled
- Network stack with DNS resolution support
- Serial debug output capability

12.43.9.1.9 Usage Notes

- The application runs continuously until 50 connections are completed
- After completion, the device must be reset to repeat the test
- Enable system diagnostics for development (remove for production)
- Ensure target server is accessible and properly configured
- Monitor both serial output and network messages for complete status

12.43.9.1.10 Development Considerations

- Remove `EnableSystemDiagnostics()` call for production builds
- Adjust timeout values based on network conditions
- Consider certificate validation requirements for production use
- Monitor memory usage during extended connection testing

12.43.10 SSL/TLS Client Certificate

12.43.10.1 SSL Client Certificate Example

12.43.10.1.1 Overview

This application demonstrates how to implement an SSL/TLS client with client certificate authentication using the NetBurner platform. The example shows how to establish secure connections to an SSL server that requires client certificates for authentication.

12.43.10.1.2 Program Description

The SSL Client Certificate Example demonstrates three key concepts:

1. **SSL Client Connections** - How to establish SSL/TLS connections from a NetBurner device
2. **Client Certificate Loading** - How to load and use client certificates compiled into the application
3. **Certificate-Based Authentication** - How to authenticate with servers that require client certificates

12.43.10.1.3 How It Works

The application performs the following operations:

1. **Network Initialization** - Initializes the network stack and waits for [DHCP](#) configuration
2. **SSL Setup** - Initializes SSL and configures client certificate credentials
3. **Connection Loop** - Repeatedly attempts to connect to the specified SSL server
4. **Status Reporting** - Tracks and reports successful and failed connection attempts

12.43.10.1.4 Key Features

12.43.10.1.4.1 Connection Process

- Connects to SSL server on port 4433
- Uses embedded client certificate and private key for authentication
- Sends connection statistics to both the server and debug console
- Handles various SSL error conditions with detailed error reporting

12.43.10.1.4.2 Error Handling

The application provides detailed error reporting for common SSL failures:

- `SSL_ERROR_FAILED_NEGOTIATION` - SSL handshake negotiation failed
- `SSL_ERROR_CERTIFICATE_UNKNOWN` - Certificate not recognized
- `SSL_ERROR_CERTIFICATE_NAME_FAILED` - Certificate name validation failed
- `SSL_ERROR_CERTIFICATE_VERIFY_FAILED` - Certificate verification failed

12.43.10.1.5 File Structure

```
main.cpp           # Main application logic
clientcert.cpp     # Embedded client certificate data
clientkey.cpp      # Embedded private key data
```

12.43.10.1.6 Configuration

12.43.10.1.6.1 Target Server

Modify the `SSL_SERVER_IP` definition in `main.cpp` to specify your target SSL server:

```
#define SSL_SERVER_IP "192.168.1.100" // Replace with your server IP
```

12.43.10.1.6.2 Certificates

The client certificate and private key are embedded as C arrays in the application:

- Certificate: 672 bytes in PEM format
- Private key: 310 bytes in PEM format (EC parameters and private key)

12.43.10.1.7 Important Distinctions

This example demonstrates **client certificate authentication**, which is different from standard certificate authority (CA) validation:

12.43.10.1.7.1 CA Certificate Checking

- Client validates server certificate against known Certificate Authorities
- Requires modification to `predef.h` to enable
- Standard SSL/TLS client behavior

12.43.10.1.7.2 Client Certificate Authentication

- Client sends its own certificate to the server for authentication
- Server validates the client certificate
- Provides mutual authentication (both parties verify each other)
- **This is what this example demonstrates**

12.43.10.1.8 Usage

1. **Setup:** Configure the target server IP address
2. **Compile:** Build the application with the embedded certificates
3. **Deploy:** Flash to NetBurner device
4. **Run:** The application will wait for network initialization, then prompt for connection attempts
5. **Interact:** Press any key to initiate connection attempts, press 'C' to retry after failures

12.43.10.1.9 Requirements

- NetBurner development platform with SSL/TLS support
- SSL server configured to request and validate client certificates
- Network connectivity ([DHCP](#) recommended)

12.43.10.1.10 Output

The application provides real-time feedback including:

- Connection attempt notifications
- Success/failure statistics
- Detailed error codes for troubleshooting
- Performance timing information

12.43.10.1.11 Security Notes

- Client certificates provide strong authentication but must be properly managed
- Private keys should be protected and not exposed in production environments
- Consider using secure storage mechanisms for production deployments
- Ensure proper certificate lifecycle management (expiration, revocation, etc.)

12.43.10.1.12 Troubleshooting

Common issues and solutions:

- **Connection timeouts:** Verify server IP and network connectivity
- **Certificate errors:** Ensure server is configured to accept the client certificate
- **SSL negotiation failures:** Check SSL/TLS version compatibility
- **Network issues:** Verify [DHCP](#) configuration and routing

12.43.11 SSL/TLS Client Verify Peer - Basic

12.43.11.1 SSL/TLS Client Verify Peer - Basic

12.43.11.1.1 Overview

This application demonstrates how to implement SSL/TLS client connections with peer certificate verification using embedded CA (Certificate Authority) lists. The program establishes secure connections to HTTPS servers and validates their certificates against a trusted root certificate.

12.43.11.1.2 Features

- **SSL/TLS Client Connection:** Establishes secure connections to HTTPS servers on port 443
- **Certificate Verification:** Validates server certificates using embedded CA certificates
- **Interactive Domain Testing:** Allows users to test connections to any domain
- **NTP Time Synchronization:** Automatically synchronizes system time for accurate certificate validation
- **Comprehensive Error Handling:** Provides detailed SSL error reporting

12.43.11.1.3 Application Components

12.43.11.1.3.1 Core Files

- **main.cpp:** Main application logic with SSL connection handling
- **caList.h:** Contains embedded DigiCert High Assurance EV Root CA certificate for GitHub
- **ServerCert.cpp:** Auto-generated server certificate data (binary format)
- **ServerKey.cpp:** Auto-generated EC private key data (binary format)

12.43.11.1.3.2 Key Functionality

SSL Connection Process

1. Prompts user for domain name input
2. Resolves domain to IP address using DNS
3. Establishes SSL connection with certificate verification enabled
4. Sends basic HTTP GET request
5. Reads and displays server response
6. Provides detailed error information on connection failures

Time Synchronization

- Uses NTP (Network Time Protocol) to set system time
- Connects to `pool.ntp.org` for time synchronization
- Ensures accurate certificate validity period checking

12.43.11.1.4 Usage Instructions

12.43.11.1.4.1 Running the Application

1. **Start the Application:** The program initializes network connections and synchronizes time
2. **Access Debug Menu:** Press any key to display available commands
3. **Test SSL Connection:** Press 'C' to initiate an SSL connection test
4. **Enter Domain:** Type the domain name you want to test (e.g., `github.com`, `google.com`)
5. **View Results:** The application will display connection status and any errors

12.43.11.1.4.2 Sample Session

```
Commands :  
C: Attempt SSL Connection  
  
[Press 'C']  
  
Enter the domain you would like to connect to: github.com  
  
Attempting to connect to: github.com:443 (140.82.114.4)  
Good SSL connection  
Read 1024 bytes  
Read 512 bytes  
Connection closed with response: 0  
Read 1536 total bytes
```

12.43.11.1.5 Certificate Verification

The application uses a hardcoded DigiCert High Assurance EV Root CA certificate to verify connections. This certificate is specifically configured for GitHub connections but can validate any server using certificates signed by this CA.

12.43.11.1.5.1 Supported Error Types

- **SSL_ERROR_FAILED_NEGOTIATION:** SSL handshake failed
- **SSL_ERROR_CERTIFICATE_UNKNOWN:** Certificate not recognized
- **SSL_ERROR_CERTIFICATE_NAME_FAILED:** Certificate name mismatch
- **SSL_ERROR_CERTIFICATE_VERIFY_FAILED:** Certificate validation failed

12.43.11.1.6 Technical Details

12.43.11.1.6.1 Dependencies

- **NBRTOS:** Real-time operating system
- **DNS:** Domain name resolution
- **TCP:** Network communication
- **SSL/TLS:** Secure socket layer implementation
- **NTP:** Network time protocol

12.43.11.1.6.2 Memory Usage

- **RX Buffer:** 20KB buffer for reading server responses
- **Certificate Storage:** Embedded certificates stored in program memory
- **Domain Buffer:** 255 character buffer for domain name input

12.43.11.1.6.3 Network Configuration

- **SSL Port:** 443 (HTTPS)
- **Connection Timeout:** 60 seconds
- **Read Timeout:** 5 seconds per operation
- **NTP Timeout:** 10 seconds for time synchronization

12.43.11.1.7 Security Considerations

12.43.11.1.7.1 Certificate Validation

- Peer verification is enabled for all connections
- Uses embedded root CA certificates for trust chain validation
- Validates certificate names against requested domains
- Checks certificate validity periods (requires accurate system time)

12.43.11.1.7.2 Limitations

- Only includes DigiCert root CA certificate
- Cannot verify certificates from other CAs without modification
- No certificate revocation checking (CRL/OCSP)

12.43.11.1.8 Development Notes

12.43.11.1.8.1 Customization

To add support for additional CAs:

1. Obtain the root CA certificate in PEM format
2. Add certificate data to `caList.h`
3. Update certificate length and data arrays
4. Recompile the application

12.43.11.1.8.2 Error Handling

The application provides comprehensive error reporting for:

- DNS resolution failures
- Network connection issues
- SSL handshake problems
- Certificate validation errors

12.43.11.1.9 Example Use Cases

- **Security Testing:** Verify SSL configuration of web servers
- **Certificate Validation:** Test certificate chain validity
- **Network Diagnostics:** Debug SSL connection issues
- **Educational Purposes:** Learn SSL/TLS implementation details

12.43.11.1.10 Build Requirements

- NBR-TOS development environment
- Network-enabled target hardware
- Internet connectivity for DNS and NTP
- Sufficient memory for SSL operations and certificate storage

12.43.12 SSL/TLS Client Verify Peer - EFFS-STD

12.43.12.1 SSL/TLS Client Verify Peer - EFFS-STD

12.43.12.1.1 Overview

This application demonstrates how to implement SSL/TLS client-side certificate verification using Certificate Authority (CA) lists stored in the EFFS Standard on-chip embedded flash file system (EFFS-STD). The application provides both a web interface and serial debug menu for managing CA certificates and testing SSL connections.

12.43.12.1.2 Features

12.43.12.1.2.1 SSL/TLS Certificate Verification

- Client-side verification of server certificates using uploaded CA certificates
- Support for PEM-format certificate files
- Dynamic loading and management of CA certificate lists
- Secure storage of certificates in on-chip flash memory using EFFS-STD

12.43.12.1.2.2 Web Interface

- Upload CA certificates through a web interface
- View and manage stored certificates
- Delete certificates with confirmation dialogs
- Display certificate details and public keys
- Automatic certificate scanning and loading

12.43.12.1.2.3 File System Management

- Embedded Flash File System (EFFS-STD) for persistent storage
- Automatic formatting and initialization
- File system statistics and directory listing
- Support for multiple platforms (MOD5441X, NANO54415, MODM7AE70, SB800EX, SBE70LC)

12.43.12.1.2.4 Debug and Testing

- Serial console interface for debugging
- Interactive SSL connection testing
- System time synchronization via NTP
- Comprehensive logging and error reporting

12.43.12.1.3 Hardware Support

The application supports multiple NetBurner platforms:

- MOD5441X (32MB flash with 128KB sectors)
- NANO54415 (8MB SPI flash with 4KB sectors)
- MODM7AE70 (2MB flash with 8KB sectors)
- SB800EX (8MB SPI flash with 4KB sectors)
- SBE70LC (2MB flash with 8KB sectors)

12.43.12.1.4 File Structure

12.43.12.1.4.1 Core Application Files

- `main.cpp` - Main application entry point and user interface
- `certificatekey.cpp` - CA certificate management and SSL operations
- `configweb.cpp` - Web interface configuration and NV settings
- `post.cpp` - HTTP POST handlers for web interface

12.43.12.1.4.2 File System Components

- `effs_std.cpp` - EFFS-STD initialization and operations
- `effsStdFlashDrv.cpp` - Platform-specific flash drivers
- `FileSystemUtils.cpp` - File system utility functions
- `fs_main.cpp` - File system initialization

12.43.12.1.4.3 Supporting Modules

- `effs_time.cpp` - Time management and NTP synchronization
- `ftp_fs.cpp` - FTP server integration with file system
- `ramdrv_mcf.cpp` - RAM drive configuration

12.43.12.1.4.4 Configuration Headers

- `nbfactory.h` - Platform-specific factory settings
- `serialburnerdata.h` - Configuration structures and constants
- `effs_std.h` - EFFS-STD definitions and prototypes

12.43.12.1.5 Quick Start

12.43.12.1.5.1 Initial Setup

1. Flash the application to your NetBurner device
2. Connect to the device's network interface
3. Access the web interface at the device's IP address
4. The default page will be `CaCert.html` for certificate management

12.43.12.1.5.2 Adding CA Certificates

1. Navigate to the certificate management page via web interface
2. Upload PEM-format CA certificate files
3. Certificates are automatically scanned and loaded into the SSL engine
4. Certificate files are stored as `CACertN.crt` where N is an incremental number

12.43.12.1.5.3 Testing SSL Connections

1. Access the serial debug interface
2. Press 'C' to attempt an SSL connection
3. Enter the domain name when prompted
4. The application will verify the server certificate against loaded CA certificates

12.43.12.1.6 Debug Commands

Access the debug menu through the serial interface:

- 0 - Turn debug messages off
- 1 - Turn debug messages on
- C - Attempt SSL connection test
- D - Reset to factory default parameters
- F - Show file system information
- G - Format file system (caution: erases all data)
- N - Display NV settings
- T - Display system time

12.43.12.1.7 Certificate Management

12.43.12.1.7.1 Supported Formats

- PEM-encoded X.509 certificates
- Maximum certificate size: 5KB
- Automatic parsing of certificate common names

12.43.12.1.7.2 Storage Details

- Certificates stored in on-chip flash memory
- Maximum 20 CA certificates supported
- Automatic verification of certificate validity
- Certificates persist across power cycles

12.43.12.1.7.3 Web Interface Operations

- Upload new certificates
- View certificate details and public keys
- Delete certificates with confirmation
- Automatic rescanning after modifications

12.43.12.1.8 Network Configuration

12.43.12.1.8.1 Default Settings

- [DHCP](#) client enabled by default
- NetBIOS name publishing
- HTTPS server on port 443
- NTP time synchronization

12.43.12.1.8.2 Time Management

- Automatic NTP synchronization on startup
- Configurable timezone support (defaults to PST8PDT)
- Manual time setting capability
- RTC support on compatible platforms

12.43.12.1.9 Error Handling

The application includes comprehensive error handling for:

- File system operations
- SSL/TLS connection failures
- Certificate validation errors
- Network connectivity issues
- Memory allocation failures

Common SSL error codes:

- `SSL_ERROR_FAILED_NEGOTIATION` - SSL handshake failed
- `SSL_ERROR_CERTIFICATE_UNKNOWN` - Unknown certificate error
- `SSL_ERROR_CERTIFICATE_NAME_FAILED` - Certificate name verification failed
- `SSL_ERROR_CERTIFICATE_VERIFY_FAILED` - Certificate verification failed

12.43.12.1.10 Security Considerations

- Certificates are validated before storage
- SSL connections require valid certificate chains
- Peer verification is enabled by default when CA certificates are loaded
- Factory reset capability to clear all certificates
- Secure storage in flash memory with verification keys

12.43.12.1.11 Troubleshooting

12.43.12.1.11.1 Common Issues

1. **SSL Connection Failures:** Ensure CA certificates are properly loaded and system time is correct
2. **File System Errors:** Use format command ('G') to reinitialize file system
3. **Certificate Upload Failures:** Verify certificate is in PEM format and under 5KB
4. **Time Synchronization:** Check network connectivity and DNS settings for NTP

12.43.12.1.11.2 Factory Reset

Use debug command 'D' to reset to factory defaults, which will:

- Clear all user configuration
- Format the file system
- Remove all uploaded certificates
- Reset network settings

12.43.12.1.12 Example Usage

The application includes `github.pem` as a test certificate. To test:

1. Upload the `github.pem` file through the web interface
2. Use the serial debug menu (command 'C')
3. Enter "github.com" as the test domain
4. Verify successful SSL connection with certificate validation

12.43.13 SSL/TLS Receive Mail (POP3)

12.43.13.1 SSL POP3 Mail Example

12.43.13.1.1 Overview

This NetBurner embedded application demonstrates how to retrieve email from a server that requires SSL/TLS using the POP3 protocol. The application provides a web interface for configuring mail server settings and retrieving messages, which are then saved to external flash storage.

Note

When connecting to a Google Account, you will likely need to enable less secure application access. If you use two-factor authentication with your account, you will need to setup an application password for the account being connected to. This can be done at the following URL: <https://myaccount.google.com/apppasswords>. The application password is not saved and will need to be reentered for every request.

12.43.13.1.2 Key Features

- **SSL/TLS POP3 Email Retrieval:** Secure connection to POP3 mail servers
- **Web-based Configuration Interface:** HTML forms for setting up mail server credentials
- **File System Integration:** Saves retrieved emails to SD/MMC/SDHC cards or Compact Flash
- **FTP Server:** Built-in FTP server for file management
- **HTTPS Web Server:** Secure web interface on port 443
- **Multiple Storage Support:** Compatible with various flash storage types

12.43.13.1.3 Application Components

12.43.13.1.3.1 Main Application (main.cpp)

The main application initializes:

- Network stack with [DHCP](#) support
- File system for multiple task priorities
- External flash storage (SD/MMC/SDHC/CFC)
- HTTPS web server on port 443
- FTP server on port 21

12.43.13.1.3.2 File System Utilities

- **FileSystemUtils.cpp/h:** Comprehensive file system operations including mount/unmount, format, read/write operations, and directory management
- **cardtype.h:** Hardware abstraction for different storage types (SD/MMC, SDHC, CFC, RAM)

12.43.13.1.3.3 Network Services

- **FTP Server (ftp_f.cpp/h):** Full FTP implementation with file transfer, directory operations, and multi-drive support
- **Web Interface (webfuncs.cpp):** HTTP POST/GET handlers for email configuration and retrieval

12.43.13.1.3.4 Time Management

- **effs_time.cpp/h:** Time synchronization using NTP servers, manual time setting, and RTC integration for file timestamps

12.43.13.1.4 Web Interface

The application provides an HTML-based interface accessible via HTTPS:

12.43.13.1.4.1 Main Page (index.html)

- Network configuration display (IP, gateway, DNS)
- POP3 server settings form:
 - Mail username and password
 - POP3 server hostname/IP
 - Port number (default 995 for SSL)
 - Number of messages to retrieve

12.43.13.1.4.2 Results Page (sent.html)

- Displays retrieval status
- Provides links to downloaded email files
- Shows error details if retrieval fails

12.43.13.1.5 Storage Configuration

The application supports multiple storage types configured in `cardtype.h`:

- **SDHC:** SD/SDHC cards (default for SB800EX and SOMRT1061 platforms)
- **MMC:** SD/MMC cards
- **CFC:** Compact Flash cards
- **RAM:** RAM-based file system for testing

12.43.13.1.6 Gmail Integration Notes

When connecting to Gmail accounts:

1. Enable "Less secure app access" or use App Passwords for 2FA accounts
2. Configure App Password at: <https://myaccount.google.com/apppasswords>
3. Use server: pop.gmail.com, port: 995
4. The App Password must be re-entered for each session (not stored)

12.43.13.1.7 File Operations

Retrieved emails are automatically:

- Converted to HTML format for web viewing
- Saved with sequential filenames (email1.html, email2.html, etc.)
- Accessible via web browser or FTP client
- Timestamped using system time

12.43.13.1.8 Error Handling

The application includes comprehensive error handling for:

- Network connectivity issues
- DNS resolution failures
- SSL/TLS connection problems
- File system errors
- Storage device detection and write protection

12.43.13.1.9 Build Requirements

- NetBurner development environment
- SSL/TLS library support
- EDFS (Embedded Flash File System) libraries
- Network stack with [DHCP](#) and DNS support

12.43.13.1.10 Usage Instructions

1. Connect and power the NetBurner device
2. Ensure SD card or other storage is inserted
3. Access the web interface via HTTPS
4. Configure network settings if using static IP
5. Enter POP3 server credentials
6. Click "Get Mail" to retrieve messages
7. Access downloaded emails via provided links or FTP

12.43.14 SSL/TLS Send Mail

12.43.14.1 SSL/TLS Send Mail Example

A NetBurner embedded application that demonstrates secure email transmission using SSL/TLS protocols.

12.43.14.1.1 Overview

This application illustrates how to send email messages from a NetBurner device to mail servers that require SSL/TLS encryption. The implementation provides a web-based interface for configuring email settings and sending messages securely over HTTPS connections.

12.43.14.1.2 Key Features

- SSL/TLS encrypted email transmission
- Web-based configuration interface
- Support for both direct SSL and STARTTLS negotiation methods
- SMTP authentication support
- Network time synchronization via NTP
- File system utilities for external storage devices

12.43.14.1.3 SSL/TLS Connection Methods

The application supports two SSL/TLS handshake methods:

12.43.14.1.3.1 Direct SSL Connection

- Connects directly to SSL/TLS ports (465 or 587)
- Uses `SSL_connect` for immediate secure connection
- Recommended for servers known to support SSL/TLS
- Suitable for services like Yahoo that expect SSL connections on specific ports

12.43.14.1.3.2 STARTTLS Method

- Initially connects to standard SMTP port 25
- Performs `EHLO` command to check server capabilities
- If server responds with "STARTTLS", initiates SSL negotiation
- Required for Gmail and servers that mandate TLS encryption

12.43.14.1.4 Configuration Requirements

12.43.14.1.4.1 Network Setup

- Valid IP address, network mask, gateway, and DNS configuration
- Internet connectivity for NTP time synchronization and mail transmission
- [DHCP](#) support available (set IP address to 0.0.0.0 to enable)

12.43.14.1.4.2 Gmail Configuration

When connecting to Gmail accounts:

1. Enable "less secure application access" in account settings
2. For two-factor authentication accounts, create an application-specific password
3. Use server: `smtp.gmail.com`
4. Use port: 465 or 587
5. Leave STARTTLS unchecked
6. Generate app passwords at: <https://myaccount.google.com/apppasswords>

12.43.14.1.4.3 Yahoo Configuration

- Requires premium services (mailplus or bizmail) - free accounts not supported
- Does not support STARTTLS detection
- Connect to port 465/587 for SSL or port 25 for non-SSL

12.43.14.1.5 Application Structure

12.43.14.1.5.1 Core Components

main.cpp**

- Application entry point and initialization
- Network stack setup and HTTPS server startup
- NTP time synchronization
- System diagnostics enablement

webfuncs.cpp**

- Web interface implementation
- Form handling for email configuration
- SSL email transmission logic
- Network and DNS management

index.html**

- Web-based user interface
- Dynamic port selection based on STARTTLS setting
- Network configuration display
- Email form with validation

12.43.14.1.5.2 File System Support

The application includes comprehensive file system utilities supporting:

- SD/MMC cards
 - SDHC cards
 - Compact Flash (CFC)
 - RAM drives
- Supported Operations:**
- File creation, reading, writing, and deletion
 - Directory management
 - FTP server functionality
 - Multiple storage device types

12.43.14.1.6 Usage Instructions

1. Network Configuration

- Verify IP gateway and DNS settings
- Enable [DHCP](#) by setting IP to 0.0.0.0 (optional)

2. Email Configuration

- Enter mail username and password
- Specify SMTP server hostname
- Set appropriate port (25, 465, or 587)
- Configure STARTTLS if required by server

3. Send Email

- Fill in sender and recipient addresses
- Enter subject and message body
- Click "Send Mail" to transmit

12.43.14.1.7 Technical Implementation

12.43.14.1.7.1 Security Features

- SSL/TLS encryption for all mail transmission
- HTTPS web interface
- Secure credential handling
- DNS lookup validation

12.43.14.1.7.2 Error Handling

- Comprehensive DNS failure detection
- SSL connection error reporting
- File system error codes with descriptions
- Network timeout management

12.43.14.1.7.3 Development Requirements

NBEclipse Linker Configuration:** Add `libStdFFile.a` library:

1. Right-click project, select "Properties"
2. Navigate to "C/C++ Builds -> Settings"
3. Select "GNU C/C++ Linker -> Libraries"
4. Add "StdFFile" to Libraries list

12.43.14.1.8 Platform Support

- NetBurner embedded platforms
- Multiple storage device interfaces
- Real-time clock integration
- Timezone management with DST support

12.43.14.1.9 Error Codes and Troubleshooting

The application provides detailed error reporting for:

- File system operations (38 defined error codes)
- Network connectivity issues
- SSL/TLS handshake failures
- SMTP authentication problems
- DNS resolution failures

12.43.15 SSL/TLS Send Mail w/ Attachment

12.43.15.1 SSL/TLS SendMail with Attachment

12.43.15.1.1 Overview

This application demonstrates how to send emails with plain text attachments using a secure SSL/TLS connection. The application provides a web-based interface for composing and sending emails through an SMTP server with authentication.

12.43.15.1.2 Features

- Secure SSL/TLS email transmission
- Web-based user interface
- SMTP authentication support
- Plain text email attachments
- Real-time feedback and error reporting
- DNS resolution for SMTP servers

12.43.15.1.3 Requirements

- Network connection with [DHCP](#) support
- SSL/TLS capable SMTP server
- Compatible web browser for interface access

12.43.15.1.4 Application Components

12.43.15.1.4.1 main.cpp

The main application entry point that:

- Initializes the network stack
- Enables system diagnostics
- Starts the HTTPS web server on default port 443
- Waits for network connectivity via [DHCP](#)
- Runs the main application loop

12.43.15.1.4.2 webfuncs.cpp

Contains the web interface functionality including:

- Form data handling for email parameters
- POST request processing
- Email composition and transmission
- Error handling and status reporting
- MIME attachment support

12.43.15.1.4.3 Web Interface

The application provides form fields for:

- **Username:** SMTP authentication username
- **Password:** SMTP authentication password
- **Server:** SMTP server hostname or IP address
- **Port:** SMTP server port (default: 465 for SSL/TLS)
- **From:** Sender email address
- **To:** Recipient email address
- **Subject:** Email subject line
- **Body:** Email message content
- **Attachment:** Plain text attachment content

12.43.15.1.5 Configuration

12.43.15.1.5.1 SMTP Server Settings

- Default port: 465 (SSL/TLS)
- Authentication: Required
- Connection type: SSL/TLS (not STARTTLS)

12.43.15.1.5.2 Google Account Setup

When using Gmail or Google Workspace accounts:

1. Enable "Less secure app access" in account settings
2. For 2FA-enabled accounts, create an application password at: <https://myaccount.google.com/apppasswords>

12.43.15.1.6 Usage

1. **Network Setup:** Ensure the device has network connectivity and can obtain a [DHCP](#) address
2. **Access Interface:** Navigate to the device's HTTPS web interface
3. **Configure Email:** Fill in all required form fields
4. **Send Email:** Submit the form to transmit the email
5. **View Results:** Check the results page for success/failure status

12.43.15.1.7 Technical Details

12.43.15.1.7.1 Memory Allocation

- Username: 80 characters
- Password: 80 characters
- Server: 80 characters
- Server Port: 6 characters
- From/To addresses: 80 characters each
- Subject: 256 characters
- Body: 16,000 characters
- Attachment: 16,000 characters

12.43.15.1.7.2 Error Handling

The application provides detailed error reporting including:

- DNS resolution status
- SMTP server connection results
- Authentication success/failure
- Detailed server response logs

12.43.15.1.7.3 Security Considerations

- Uses SSL/TLS encryption for all SMTP communications
- Passwords are handled securely in memory
- Web interface operates over HTTPS

12.43.15.1.8 Limitations

- Supports plain text attachments only
- Single attachment per email
- Does not support STARTTLS (use dedicated SSL/TLS connection)
- No file system integration (attachment content entered via web form)

12.43.15.1.9 Troubleshooting

12.43.15.1.9.1 Common Issues

1. **DNS Resolution Failed:** Verify SMTP server hostname is correct
2. **Authentication Failed:** Check username/password and account settings
3. **Connection Timeout:** Verify server address and port number
4. **SSL/TLS Errors:** Ensure server supports SSL/TLS on specified port

12.43.15.1.9.2 Debug Information

Enable system diagnostics in the code to view detailed connection and transmission logs through the serial console.

12.43.15.1.10 Related Examples

For applications requiring file system integration, refer to the EDFS (Embedded Flash File System) SendMail examples that support file-based attachments.

12.43.16 SSL/TLS Send Mail w/ EDFS Attachment

12.43.16.1 SSL Send Mail with EDFS Attachment

12.43.16.1.1 Overview

This NetBurner application demonstrates how to send email messages with file attachments using SSL/TLS encryption and the EDFS (Embedded Flash File System) FAT32 file system. The application provides a web-based interface for configuring email settings and sending messages with attachments from SD/MMC cards or other supported storage devices.

12.43.16.1.2 Features

- **Secure Email Transmission:** Uses SSL/TLS encryption for secure SMTP connections
 - **Web-Based Interface:** Complete email configuration and sending through a web page
 - **File Attachments:** Attach files from the EDFS FAT32 file system
 - **Text Attachments:** Create text file attachments directly from web form input
 - **SMTP Authentication:** Supports authenticated SMTP connections
 - **FTP Server:** Built-in FTP server for file management on the storage device
 - **Multiple Storage Types:** Supports SD/MMC, SDHC, Compact Flash, and RAM drives
 - **Time Synchronization:** NTP time synchronization with manual fallback
- NBEclipse Linker Configuration:** Add `LibStdFFile`, a library:

1. Right-click project, select "Properties"
2. Navigate to "C/C++ Builds -> Settings"
3. Select "GNU C/C++ Linker -> Libraries"
4. Add "StdFFile" to Libraries list

12.43.16.1.3 Application Components

12.43.16.1.3.1 Core Modules

- **main.cpp:** Main application entry point and initialization
- **webfuncs.cpp:** Web interface functions for email configuration and sending
- **FileSystemUtils.cpp/h:** File system utilities for EDFS operations
- **effs_time.cpp/h:** Time management functions (NTP, manual, RTC)
- **ftp_f.cpp/h:** FTP server implementation for file system access
- **cardtype.h:** Storage device type configuration

12.43.16.1.3.2 Web Interface

- **index.html:** Main configuration page for email settings
- Web form includes fields for:
 - SMTP server settings (server, port, username, password)
 - Email details (from, to, subject, message body)
 - Attachment options (text creation, SD card file selection)

12.43.16.1.4 Getting Started

12.43.16.1.4.1 Hardware Requirements

1. NetBurner development board from supported platforms
2. SD/MMC card, SDHC card, or Compact Flash card (depending on configuration)
3. Network connection (Ethernet)
4. Storage device properly inserted and formatted as FAT32

12.43.16.1.4.2 Network Configuration

1. Configure IP address, gateway, and DNS settings
2. For [DHCP](#), set IP address to 0.0.0.0 using IPSetup
3. Ensure internet connectivity for NTP time synchronization

12.43.16.1.4.3 Email Server Configuration

The application uses SSL/TLS on port 465 by default. For Gmail:

1. Server: `smtp.gmail.com`
2. Port: 465
3. Enable "Less secure app access" or use an application-specific password
4. For two-factor authentication, generate an app password at: <https://myaccount.google.com/apppasswords>

12.43.16.1.4.4 Usage

1. **Power on and Initialize:** The device will automatically:
 - Initialize the network stack
 - Mount the storage device
 - Synchronize time via NTP
 - Start the web and FTP servers
2. **Access Web Interface:** Connect to the device's IP address via HTTPS
 - All connections must use HTTPS due to SSL configuration
3. **Configure Email Settings:** Fill out the web form with:
 - SMTP server credentials
 - Email addresses and content
 - Attachment options
4. **Send Email:** Click "Send Mail" to transmit the email with attachments

12.43.16.1.4.5 File Management

The application includes an FTP server for convenient file management:

- Upload files to the storage device via FTP
- View and organize files on the SD card
- Prepare files for email attachment

12.43.16.1.5 Storage Device Support

The application supports multiple storage types through compile-time configuration:

- **SD/MMC Cards:** Standard SD and MultiMedia cards
- **SDHC Cards:** High-capacity SD cards
- **Compact Flash:** CF cards with appropriate hardware interface
- **RAM Drive:** In-memory file system for testing

Storage type is configured in `cardtype.h` - only one type can be used at a time.

12.43.16.1.6 Security Features

- **SSL/TLS Encryption:** All SMTP communications are encrypted
- **HTTPS Web Interface:** Secure web-based configuration
- **Authentication Support:** SMTP username/password authentication
- **Application Passwords:** Support for modern email provider security

12.43.16.1.7 Error Handling

The application includes comprehensive error handling:

- EDFS file system error codes and descriptions
- Network timeout and retry mechanisms
- DNS resolution error reporting
- Detailed error logging for troubleshooting

12.43.16.1.8 Time Management

Accurate timestamps are maintained through:

1. **NTP Synchronization:** Primary time source from internet time servers
2. **Manual Time Setting:** Fallback when NTP is unavailable
3. **RTC Support:** Real-time clock integration where available
4. **Timezone Configuration:** Proper timezone handling for file timestamps

12.43.16.1.9 File System Operations

The EDFS utilities provide:

- File reading/writing operations
- Directory listing and navigation
- Space usage statistics
- File deletion and management
- Support for long filenames (platform dependent)

12.43.16.1.10 Development Notes

- The application uses the HCC Embedded EDFS FAT32 file system
- File system access requires proper task initialization with `f_enterFS()`
- Multiple tasks can access the file system simultaneously (up to 10)
- Storage devices must be properly formatted as FAT32
- Write protection detection and handling included

12.43.16.1.11 Troubleshooting

12.43.16.1.11.1 Common Issues

1. **Storage Device Not Detected:** Ensure card is properly inserted and supported
2. **Write Protection:** Remove write protection from SD card
3. **Email Send Failures:** Verify SMTP settings and network connectivity
4. **Time Sync Issues:** Check internet connectivity for NTP
5. **File Access Errors:** Ensure proper FAT32 formatting

12.43.16.1.11.2 Error Codes

The application provides detailed EDFS error codes for file system operations. Common errors include:

- `F_ERR_CARDREMOVED`: Storage device was removed
- `F_ERR_WRITEPROTECT`: Device is write-protected
- `F_ERR_NOTFORMATTED`: Device needs formatting
- `F_ERR_NOMOREENTRY`: Directory full

12.43.17 SSL/TLS Server

12.43.17.1 NetBurner SSL/TLS Server Example

12.43.17.1.1 Overview

This application demonstrates a simple SSL/TLS server implementation using the NetBurner RTOS platform. The server uses Elliptic Curve Cryptographic (ECC) keys to establish secure connections and serves as an example of how to implement SSL/TLS communication in embedded systems.

12.43.17.1.2 Features

- SSL/TLS server listening on port 8883 ([MQTT](#) secure port)
- Elliptic Curve Cryptography (ECC) support
- Client connection handling with secure data transmission
- Large data buffer transmission demonstration
- Real-time connection status reporting

12.43.17.1.3 Application Architecture

12.43.17.1.3.1 Main Components

1. **TcpServerTask:** The main server task that handles incoming SSL/TLS connections
2. **Certificate and Key Files:** Pre-generated ECC certificate and private key
3. **Network Interface Management:** Automatic network configuration and IP address handling

12.43.17.1.3.2 Key Files

- `main.cpp` - Main application logic and server implementation
- `ServerCert.cpp` - Auto-generated SSL certificate data (672 bytes)
- `ServerKey.cpp` - Auto-generated ECC private key data (310 bytes)

12.43.17.1.4 How It Works

1. **Initialization:** The application initializes the NetBurner system and waits for network connectivity
2. **Server Setup:** Creates a listening socket on port 8883 using SSL/TLS
3. **Client Handling:** Accepts incoming connections and establishes secure sessions
4. **Data Exchange:**
 - Sends a welcome message to connected clients
 - Transmits a large buffer containing pi digits (demonstration data)
 - Displays client IP address and port information
 - Echoes back any data received from clients
5. **Connection Management:** Properly closes connections and cleans up resources

12.43.17.1.5 Testing the Application

12.43.17.1.5.1 Using OpenSSL Command Line

You can test the SSL/TLS server using OpenSSL from a command line:

For ECC Cipher Suite

```
openssl s_client -cipher ECDHE-ECDSA-AES256-GCM-SHA384 -connect <ip_address>:8883
```

Example:

```
openssl s_client -cipher ECDHE-ECDSA-AES256-GCM-SHA384 -connect 10.1.1.191:8883
```

For RSA (if using RSA keys)

```
openssl s_client -connect <ip_address>:8883
```

Example:

```
openssl s_client -connect 10.1.1.191:8883
```

12.43.17.1.5.2 Expected Behavior

When a client connects successfully, you should see:

1. Welcome message: "Welcome to the NetBurner SSL/TLS Server Example"
2. A large buffer of pi digits (demonstration data)
3. Server IP address and port information
4. Echo of any data you send to the server

12.43.17.1.6 Configuration

12.43.17.1.6.1 Network Settings

- **Listen Port:** 8883 ([MQTT](#) secure port)
- **Buffer Size:** 4096 bytes for receiving data
- **Network Wait:** 5 seconds timeout for [DHCP](#) address acquisition

12.43.17.1.6.2 Task Configuration

- **Stack Size:** USER_TASK_STK_SIZE
- **Priority:** MAIN_PRIO - 1 (higher priority than main task)
- **Task Name:** "TcpServerTask"

12.43.17.1.7 Customization Options

12.43.17.1.7.1 Using RSA Keys Instead of ECC

If your application requires RSA keys instead of ECC:

1. Navigate to `\nburn\CreateCerts\RSA` directory
2. Run the key generation scripts
3. Replace `ServerKey.cpp` and `ServerCert.cpp` with the newly generated files
4. Rebuild the application

The RSA version can be tested with the standard OpenSSL command without specifying cipher suites.

12.43.17.1.8 Technical Details

12.43.17.1.8.1 SSL/TLS Implementation

- Uses NetBurner's built-in SSL/TLS stack
- Supports modern cipher suites including ECDHE-ECDSA-AES256-GCM-SHA384
- Automatic certificate and key loading from embedded data

12.43.17.1.8.2 Memory Usage

- RX Buffer: 4KB for incoming data
- Task Stack: Configurable via USER_TASK_STK_SIZE
- Certificate: 672 bytes
- Private Key: 310 bytes

12.43.17.1.8.3 Error Handling

- Connection timeout handling
- Graceful client disconnection
- Resource cleanup on connection termination

12.43.17.1.9 Security Considerations

- Uses strong ECC encryption by default
- Certificates are embedded in the application binary
- For production use, consider:
 - Using production certificates from a trusted CA
 - Implementing certificate validation
 - Adding additional security measures as required

12.43.17.1.10 Dependencies

- NetBurner RTOS
- NetBurner SSL/TLS library
- Standard NetBurner networking stack

12.43.17.1.11 Troubleshooting

12.43.17.1.11.1 Common Issues

1. **Connection Refused:** Ensure the device has a valid IP address and port 8883 is not blocked
2. **SSL Handshake Failure:** Verify that the client supports the cipher suites used by the server
3. **Network Issues:** Check [DHCP](#) configuration and network connectivity

12.43.18 HTTPS Configuration Mirror

12.43.18.1 SSL Configuration Mirror

12.43.18.1.1 Overview

This NetBurner embedded web server application demonstrates SSL/TLS security implementation with mixed HTTP/HTTPS access control. The application showcases how to create a web server that serves both secure and non-secure content while enforcing SSL requirements for protected resources.

SSL/TLS Server example program with web page redirection for unauthorized access. The example demonstrates how you can have both secure and non-secure access to files and directories.

The application starts the web server with SSL/TLS capability. The directory structure is such that index.html and the files in the images subdirectory can be viewed with a http or https connection. However, files in the httpsdir directory (ie repeat.html) can only be viewed with a secure https connection.

```
html
|-- index.html
|-- images
|   |-- (various image files)
|-- httpsdir
|   |-- repeat.html
```

The `HTTP_ACCESS CheckHttpAccess(int sock, int access_level, HTTP\_Request &Req)` function is used to authenticate the web page access. It will allow access or redirect depending on the file and access rights.

12.43.18.1.2 Application Features

12.43.18.1.2.1 Core Functionality

- **Dual Protocol Support:** Operates on both HTTP (port 80) and HTTPS (port 443)
- **Access Control:** Implements granular security policies for different content areas
- **SSL Redirection:** Automatically redirects HTTP requests to HTTPS for protected content
- **Configuration Management:** Provides secure configuration interface with JSON API endpoints
- **Post Data Logging:** Captures and stores HTTP POST requests with timestamps and payloads

12.43.18.1.2.2 Security Implementation

- **Certificate-based SSL/TLS:** Uses embedded server certificate and private key
- **Access Groups:** Three-tier authentication system (0=public, 1=SSL required, 2=password protected)
- **Automatic Redirection:** Non-secure requests to protected content trigger HTTPS redirects
- **Authentication:** HTTP Basic Auth for password-protected areas

12.43.18.1.3 Directory Structure

```
html/
|-- index.html           # Main page (accessible via HTTP/HTTPS)
|-- images/             # Public image assets
|   |-- NetBurnerSSLDemo.gif
|   |-- SSL-Good.gif     # Shown for HTTPS connections
|   |-- SSL-Bad.gif      # Shown for HTTP connections
|-- httpsdir/           # SSL-only protected directory
|   |-- repeat.html      # Requires HTTPS access
|-- Put.json            # Protected JSON endpoint (password required)
|-- robots.txt          # Search engine directives
```

12.43.18.1.4 Access Control Levels

12.43.18.1.4.1 Level 0 (Public Access)

- No authentication required
- Accessible via HTTP or HTTPS
- Examples: `index.html`, `images/` directory

12.43.18.1.4.2 Level 1 (SSL Required)

- Requires HTTPS connection
- HTTP requests receive 302 redirect to HTTPS
- Examples: `httpsdir/` content, configuration endpoints

12.43.18.1.4.3 Level 2 (Password Protected)

- Requires HTTPS + HTTP Basic Authentication
- Default credentials: `username="user"`, `password="password"`
- Examples: `Put.json`, administrative functions

12.43.18.1.5 Key Components

12.43.18.1.5.1 Main Application (`main.cpp`)

- **UserMain()**: Entry point that initializes network stack, SSL, and web server
- **CheckHttpAccess()**: Central access control function implementing security policies
- **SSL Helper Functions**: Utilities for SSL connection detection and certificate management
- **Post Handlers**: JSON POST request processing with data storage and retrieval

12.43.18.1.5.2 SSL Configuration (`HTTPSSConfigMirror.cpp`)

- **CheckSSL()**: Validates SSL connections and handles redirections
- **Configuration Handlers**: Secure endpoints for system configuration management
- **Schema Support**: JSON schema generation for configuration validation

12.43.18.1.5.3 Certificate Management

- **ServerCert.cpp**: Embedded SSL certificate data
- **ServerKey.cpp**: Embedded private key data
- Self-signed certificate valid for IP address access

12.43.18.1.6 API Endpoints

12.43.18.1.6.1 Configuration APIs (SSL Required)

- GET /Config/* - Retrieve configuration data as JSON
- POST /Config/* - Update configuration settings
- GET /Schema/* - Get JSON schema for configuration validation

12.43.18.1.6.2 Data APIs

- GET /GetJson* - Public JSON endpoint
- GET /PGetJson* - Password-protected JSON endpoint
- POST /Post* - Accept and log POST data
- GET /Show* - Display logged POST data as HTML table
- GET /JShow* - Display logged POST data as JSON

12.43.18.1.7 Build and Deployment

12.43.18.1.7.1 Prerequisites

- NetBurner development environment
- NNDK (NetBurner Network Development Kit)
- Target NetBurner device with network capability

12.43.18.1.7.2 Compilation

The application uses standard NetBurner build tools. Key dependencies:

- [nbrtos.h](#) - Real-time operating system
- [crypto/ssl.h](#) - SSL/TLS implementation
- [config_server.h](#) - Configuration management
- [httppost.h](#) - HTTP POST handling

12.43.18.1.7.3 Network Configuration

- [DHCP](#) client automatically obtains IP address
- NTP time synchronization from pool servers
- Pacific Time Zone configuration (PST8PDT)

12.43.18.1.8 Usage Examples

12.43.18.1.8.1 Basic Access

1. Connect to device IP via HTTP - shows "NOT secure" indicator
2. Access `httpsdir/repeat.html` via HTTP - receives FORBIDDEN response
3. Click "View index.html with HTTPS" - establishes secure connection
4. Access protected content successfully via HTTPS

12.43.18.1.8.2 Configuration Management

1. Navigate to <https://device-ip/Config/AppData> (requires SSL)
2. Authenticate with system credentials if configured
3. View/modify JSON configuration data
4. Changes automatically saved to persistent storage

12.43.18.1.8.3 POST Data Testing

1. Send JSON POST to `/Post*` endpoints
2. View logged data at `/Show*` for HTML table format
3. View logged data at `/JShow*` for JSON format
4. Access individual payloads via `/PlShow*` endpoints

12.43.18.1.9 Security Considerations

- Self-signed certificate generates browser warnings in production
- Default passwords should be changed for production deployment
- SSL implementation uses industry-standard encryption
- All configuration changes require secure HTTPS connection
- Automatic certificate validation for embedded applications

12.43.18.1.10 Technical Notes

- Uses NetBurner RTOS with cooperative multitasking
- Memory-efficient design suitable for embedded systems
- Real-time timestamp logging with timezone support
- Graceful handling of SSL handshake failures
- Configurable reboot capability after configuration changes

12.43.18.1.11 Development Features

- Diagnostic monitoring integration
- Build timestamp tracking
- Runtime statistics collection
- Comprehensive error handling and logging
- Extensible callback architecture for custom handlers

12.44 Stack Protection

12.44.1 Stack Protection Example

This application demonstrates various stack overflow and underflow protection methods for embedded systems using the NBRTOS real-time operating system.

12.44.1.1 Overview

The Stack Protection Example is designed to showcase how stack protection mechanisms work by intentionally triggering stack overflow conditions in a controlled manner. This educational tool helps developers understand stack protection features and their importance in embedded system development.

12.44.1.2 Features

- **Buffer Overflow Detection:** Demonstrates overflow caused by writing past buffer boundaries
- **Call Stack Overflow Detection:** Shows overflow through infinite recursion
- **Cross-Platform Support:** Works on both ARM Cortex-M7 and Coldfire processors
- **Real-time Stack Monitoring:** Provides live stack usage information
- **Interactive Menu System:** User-selectable overflow scenarios

12.44.1.3 Architecture Support

12.44.1.3.1 ARM Cortex-M7

- Supports monitoring of **both** stack overflow AND underflow simultaneously
- Can monitor 2 memory ranges concurrently
- Full stack protection capabilities enabled

12.44.1.3.2 Coldfire

- Limited to monitoring a **single** memory range
- Must choose between overflow OR underflow protection (not both)
- Typically configured for overflow protection

12.44.1.4 Prerequisites

12.44.1.4.1 Required Configuration

To enable full functionality, the following preprocessor definitions must be set:

```
#define NBRTOS_STACKCHECK (1)
#define NBRTOS_STACKOVERFLOW (1)
#define NBRTOS_STACKUNDERFLOW (1)
```

Note**: For Coldfire processors, only enable either NBRTOS_STACKOVERFLOW or NBRTOS_STACKUNDERFLOW, not both.

12.44.1.4.2 Compiler Settings

The application requires the `-fstack-check` compiler flag to be enabled:

- **NBEclipse IDE:** Right-click project > Properties > C/C++ Build > Settings > GNU C++ Compiler > Debugging > Enable "Enable stack checking (-fstack-check)"
- **Command Line:** The flag is automatically included in the provided makefile

12.44.1.4.3 File Configuration

The configuration is handled through the `predef-overload.h` file, which automatically sets appropriate definitions based on the target processor:

- **Coldfire:** Enables only stack overflow protection
- **Cortex-M7:** Enables both overflow and underflow protection

12.44.1.5 Application Structure

12.44.1.5.1 Main Components

1. **bufferOverflow()**: Creates a buffer overflow by writing beyond array boundaries
2. **callStackOverflow()**: Triggers overflow through recursive function calls with multiple parameters
3. **UserMain()**: Main application loop with interactive menu system

12.44.1.5.2 Menu Options

The application presents an interactive menu with the following options:

1. **Buffer Underflow** - Demonstrates buffer boundary violations
2. **Call Stack Overflow** - Shows recursive call stack exhaustion

12.44.1.6 Usage

1. **Build and Deploy**: Compile the application with the provided makefile or IDE project
2. **Run Application**: Execute on target hardware
3. **Monitor Output**: Observe stack range information displayed at startup
4. **Select Test**: Choose overflow scenario from the interactive menu
5. **Trigger Event**: Press any key when prompted to initiate the overflow condition
6. **Observe Results**: Watch as the stack protection mechanisms detect and respond to violations

12.44.1.7 Expected Output

Upon startup, the application displays:

- Current stack space range (top and bottom addresses)
- Available protection features status
- Interactive menu for selecting overflow scenarios
- Real-time feedback during overflow events

12.44.1.8 Safety Features

- **Stack Range Monitoring**: Displays current stack boundaries
- **Controlled Overflow**: Intentional violations for educational purposes
- **System Diagnostics**: Built-in diagnostic capabilities
- **Protection Mechanisms**: Hardware-assisted stack monitoring

12.44.1.9 Development Notes

12.44.1.9.1 Stack Monitoring

The application uses `OSDumpTCBStacks()` to display current stack information and `EnableOSStack↵ Protector()` to activate protection mechanisms.

12.44.1.9.2 Memory Layout

Stack boundaries are defined by:

- `OSTCBStkTop`: Top of stack address
- `OSTCBStkBot`: Bottom of stack address

12.44.1.9.3 Time Delays

Strategic delays (`OSTimeDly(1)`) are inserted to allow observation of the overflow progression.

12.44.1.10 Important Warnings

This application is designed for **educational and testing purposes only**. It intentionally creates stack overflow conditions that would be catastrophic in production code. Do not use these techniques in production systems.

12.44.1.11 Build Instructions

12.44.1.11.1 Command Line

```
make clean
make all
```

12.44.1.11.2 IDE

Import the project into NBEclipse and build using the standard build process to rebuild libraries.

12.44.1.12 Troubleshooting

If stack protection features don't work as expected:

1. Verify preprocessor definitions are correctly set
2. Ensure `-fstack-check` compiler flag is enabled
3. Confirm target processor type matches configuration
4. Check that NBRTOS stack protection is supported on your platform

12.45 Syslog

12.45.1 NetBurner Syslog Demo

12.45.1.1 Overview

This application demonstrates how to use the NetBurner Syslog utility to send logging information to a destination host computer via UDP on port 514. The demo sends a simple counting variable that increments every second to show elapsed time.

12.45.1.2 Features

- Network stack initialization with [DHCP](#) support
- Built-in web server on port 80
- Syslog messaging via UDP
- Support for both broadcast and targeted syslog transmission
- Real-time counting demonstration

12.45.1.3 How It Works

The application initializes the NetBurner network stack, waits for [DHCP](#) configuration to complete, and then begins sending syslog messages every second. Each message contains an incrementing counter showing elapsed seconds since startup.

12.45.1.3.1 Syslog Modes

The application supports two syslog transmission modes:

1. **Broadcast Mode:** When `SysLogAddress` is not set, syslog data is sent as UDP broadcast to 255.255.255.255:514
2. **Targeted Mode:** When `SysLogAddress` is configured, syslog data is sent to the specified IP address on port 514

12.45.1.4 Setup Instructions

12.45.1.4.1 Prerequisites

- NetBurner device with network connectivity
- Properly configured IP address and subnet mask
- NetBurner "UDP Terminal Tool" application (for receiving syslog messages)

12.45.1.4.2 Configuration Steps

1. Verify Network Connection

- Ensure your NetBurner device has proper network communication
- Verify the device has obtained an IP address and subnet mask

2. Configure Target Address (Optional)

- In `main.cpp`, locate the line: `SysLogAddress =AsciiToIp ("10.1.1.193") ;`
- Replace "10.1.1.193" with your computer's IP address
- Comment out this line to use broadcast mode instead

3. Setup Syslog Receiver

- Run the NetBurner "UDP Terminal Tool" application
- Set the local listening port to 514 (default syslog port)

4. Deploy Application

- Download and run the application on your NetBurner device

12.45.1.5 Code Structure

12.45.1.5.1 Main Components

- **Network Initialization:** Sets up network stack and waits for [DHCP](#) completion
- **System Diagnostics:** Enables diagnostic features (should be removed for production)
- **Web Server:** Starts HTTP server on default port 80
- **Syslog Loop:** Continuously sends elapsed time messages every second

12.45.1.5.2 Key Functions

- `init ()` : Initializes the network stack
- `StartHttp ()` : Starts the web server
- `WaitForActiveNetwork ()` : Waits for network connectivity
- `showIpAddresses ()` : Displays current IP configuration
- `SysLog ()` : Sends formatted syslog messages

12.45.1.6 Expected Output

Once running, the application will:

1. Display startup messages on the console
2. Show IP address information
3. Indicate whether syslog is running in broadcast or targeted mode
4. Begin sending messages like: "Seconds elapsed: 0", "Seconds elapsed: 1", etc.

12.45.1.7 Network Requirements

- **Protocol:** UDP
- **Port:** 514 (standard syslog port)
- **Default Target:** 255.255.255.255 (broadcast) or configured IP address

12.45.1.8 Production Considerations

- Remove `EnableSystemDiagnostics()` call for production deployments
- Consider implementing proper error handling for network failures
- Adjust timing intervals based on logging requirements
- Implement log rotation or filtering for long-running applications

12.45.1.9 Troubleshooting

- **No syslog messages received:** Verify firewall settings and UDP port 514 access
- **DHCP issues:** Check network configuration and DHCP server availability
- **Wrong target address:** Verify the configured IP address in `SysLogAddress`
- **Network connectivity:** Ensure proper physical network connection and IP configuration

12.46 System Diagnostics

12.46.1 System Diagnostics Example

12.46.1.1 Overview

This application demonstrates how to integrate system diagnostics into a NetBurner device application. The program enables a web-based diagnostic interface that displays both system information and custom application variables through the device's Configuration Server web page.

12.46.1.2 Features

- **System Diagnostics:** Enables built-in system diagnostic information display
- **Custom Variable Monitoring:** Demonstrates how to add application-specific variables to the diagnostic web page
- **Web Interface:** Provides access to diagnostics through HTTP server on port 80
- **Real-time Updates:** Variables are updated in real-time and can be monitored through the web interface

12.46.1.3 Application Components

12.46.1.3.1 Main Functionality

The application performs the following operations:

1. Initializes the network stack
2. Enables system diagnostics functionality
3. Starts the HTTP web server on default port 80
4. Waits for network connectivity
5. Continuously increments a counter variable every second

12.46.1.3.2 Monitored Variables

The application includes two example variables that are displayed on the diagnostic web page:

- **myInt**: An integer counter that increments every second
- **myString**: A string variable initialized with "My String Variable"

12.46.1.4 Code Structure

12.46.1.4.1 Key Components

- **Network Initialization**: Standard NetBurner network stack setup
- **Diagnostic Integration**: Uses `EnableSystemDiagnostics()` to activate the diagnostic interface
- **Variable Monitoring**: Implements `DiagVarMon` and `DiagStrMon` for custom variable display
- **Web Server**: HTTP server provides access to the diagnostic interface

12.46.1.4.2 Header Dependencies

```
#include <init.h>
#include <nbrtos.h>
#include <system.h>
#include <string.h>
#include <diagnostics.h>
```

12.46.1.5 Usage Instructions

12.46.1.5.1 Building and Running

1. Compile the application using the NetBurner development tools
2. Deploy to your NetBurner device
3. Ensure the device is connected to your network
4. The application will display network information on the console

12.46.1.5.2 Accessing Diagnostics

1. Open a web browser
2. Navigate to your device's IP address (port 80)
3. Access the Configuration Server web page
4. Click the "Diagnostics" button to view system and application variables

12.46.1.6 Adding Custom Variables

To add your own variables to the diagnostic display:

12.46.1.6.1 For Integer Variables

```
int yourVariable;  
static DiagVarMon YourVarMon("Variable Description", yourVariable);
```

12.46.1.6.2 For String Variables

```
char yourString[SIZE];  
static DiagStrMon YourStrMon("String Description", yourString);
```

12.46.1.6.3 Supported Variable Types

- Integers ([DiagVarMon](#))
- Strings ([DiagStrMon](#))
- Floats (using appropriate diagnostic monitor classes)
- Other data types as supported by the diagnostics library

12.46.1.7 Important Notes

12.46.1.7.1 Production Considerations

- The `EnableSystemDiagnostics()` function should likely be removed or conditionally compiled for production code
- Consider security implications of exposing diagnostic information in production environments
- The web server runs on port 80 by default and may conflict with other web services

12.46.1.7.2 Network Requirements

- Device must be connected to an active network
- The application waits up to 5 seconds for network connectivity before proceeding
- HTTP server accessibility depends on network configuration and firewall settings

12.46.1.8 Output Example

When running, the application displays:

```
Web Application: System Diagnostics Example  
NNDK Revision: [Current NetBurner SDK Version]
```

The web diagnostic interface will show:

- Standard system diagnostic information
- "My Int": Incrementing counter value
- "My String": "My String Variable"

12.47 TCP

TCP Examples:

- [TCP Client](#)
- [TCP No Block Connect Test](#)
- [TCP Keepalive Simple](#)
- [TCP Keepalive Multiple](#)
- [Multiple TCP Interface Test](#)
- [TCP Multi-Socket Server](#)

- [TCP Resource Information](#)
- [TCP Server](#)
- [TCP Server Using Via](#)
- [TCP Speed Test](#)
- [TCP Stress Test](#)

12.47.1 TCP Client

12.47.1.1 TCP Client Example Application

12.47.1.1.1 Overview

This is a simple TCP client application built for NetBurner hardware that demonstrates how to create and use a TCP client connection. The application provides a web-based interface that allows users to send messages to any TCP server by specifying the destination IP address, port number, and message content.

12.47.1.1.2 Features

- **Web-based Interface:** Complete interaction through a web page interface
- **Configurable Connection:** Set destination IP address and port number
- **Message Transmission:** Send custom messages to TCP servers
- **Auto-fill Functionality:** Automatically fills in the requesting client's IP address as default destination
- **Error Handling:** Comprehensive error reporting and logging
- **Real-time Feedback:** Connection status and transmission results displayed

12.47.1.1.3 Application Structure

12.47.1.1.3.1 Core Files

- **main.cpp:** Main application entry point and initialization
- **clientweb.cpp:** Web interface implementation and TCP client functionality
- **clientweb.h:** Header file for web interface functions

12.47.1.1.3.2 Key Components

Main Application (main.cpp)

- Initializes the NetBurner system
- Enables system diagnostics
- Starts HTTP server for web interface
- Waits for active network connection
- Displays IP addresses
- Runs main application loop

Web Interface (clientweb.cpp)

- Implements web page form handling
- Processes POST variables from web form
- Manages TCP client connections
- Handles message transmission
- Provides real-time status feedback

12.47.1.1.4 How It Works

1. **Initialization:** The application starts up, initializes the network, and launches the HTTP server
2. **Web Interface:** Users access the web page which displays form fields for:
 - Destination IP address (auto-filled with requesting client's IP)
 - Destination port number (defaults to 2000)
 - Message content
3. **Message Transmission:** When the form is submitted:
 - A TCP connection is established to the specified server
 - The message is transmitted
 - Connection status and results are logged
 - The connection is closed
4. **Response:** The web page redirects back to the main interface

12.47.1.1.5 Configuration

12.47.1.1.5.1 Default Settings

- **Default Port:** 2000
- **Connection Timeout:** 5 seconds
- **Maximum Message Size:** 1024 characters

12.47.1.1.5.2 Web Form Fields

- `tfDestIpAddr`: Destination IP address field
- `tfDestPortNum`: Destination port number field
- `tfMessage`: Message content field
- `SendMessage`: Submit button trigger

12.47.1.1.6 Usage Instructions

1. **Setup:** Deploy the application to NetBurner hardware
2. **Network:** Ensure the device is connected to your network
3. **Access:** Open a web browser and navigate to the device's IP address
4. **Configure:**
 - Enter the destination TCP server IP address
 - Set the destination port number
 - Type your message
5. **Send:** Click the submit button to transmit the message
6. **Monitor:** Check the console output (MTTTY) for connection status and errors

12.47.1.1.7 Testing

12.47.1.1.7.1 TCP Server Requirement

A TCP server must be running and listening on the specified IP address and port before sending messages.

12.47.1.1.7.2 Included Test Server

NetBurner provides a Windows-based TCP server for testing:

- **Location:** \nburn\pctools\TCP\TcpServerWin
- **Includes:** Executable and source code
- **Purpose:** Simple TCP server for testing client connections

12.47.1.1.8 Technical Details

12.47.1.1.8.1 Network Functions Used

- `connect()` : Establishes TCP connection with timeout
- `write()` : Sends data over TCP connection
- `close()` : Closes TCP connection
- `GetSocketRemoteAddr()` : Gets client IP address

12.47.1.1.8.2 Error Handling

- Connection failure detection and reporting
- Invalid parameter validation
- Timeout handling
- Detailed error logging to console

12.47.1.1.8.3 Memory Management

- Static buffers for message storage
- Automatic cleanup on connection close
- Bounds checking for message size

12.47.1.1.9 Troubleshooting

12.47.1.1.9.1 Common Issues

1. **Connection Failed:** Ensure TCP server is running and accessible
2. **Network Not Ready:** Wait for network initialization to complete
3. **Invalid IP Address:** Verify IP address format and reachability
4. **Port Conflicts:** Ensure destination port is not blocked or in use

12.47.1.1.9.2 Debug Output

All debug information is sent to stdout and can be viewed using MTTY terminal application.

12.47.2 TCP No Block Connect Test

12.47.2.1 TCP No Block Connect Test

12.47.2.1.1 Overview

This application demonstrates the difference between blocking and non-blocking TCP connections using NetBurner embedded networking hardware. The program provides an interactive menu system that allows users to test both standard blocking `connect()` calls and non-blocking `NoBlockConnect()` calls.

12.47.2.1.2 Purpose

The standard TCP connect call will block until the connection is either made or fails. The non-blocking connect call will initiate a TCP connection and return immediately, allowing the application to continue processing while the connection is established in the background.

12.47.2.1.3 Features

- Interactive menu-driven interface
- Support for both blocking and non-blocking TCP connections
- Real-time connection state monitoring
- Automatic periodic data transmission (every 5 seconds)
- User input forwarding over established connections
- Configurable destination IP address and port

12.47.2.1.4 Menu Options

The application provides the following commands:

- **C** - Make a connection using standard blocking `connect()`
- **N** - Make a connection using non-blocking `NoBlockConnect()`
- **X** - Close the current connection
- **I** - Specify the destination IP address and port number
- **Any other character** - Send the character over the TCP connection (if established)

12.47.2.1.5 How It Works

12.47.2.1.5.1 Blocking Connection (C command)

1. Prompts for destination IP and port if not already set
2. Calls `connect()` which blocks until connection succeeds or fails
3. Immediately reports success or failure
4. Connection is ready for data transmission upon success

12.47.2.1.5.2 Non-Blocking Connection (N command)

1. Prompts for destination IP and port if not already set
2. Calls `NoBlockConnect()` which returns immediately
3. Reports "Connect started" if the call succeeds
4. Continuously monitors connection state using `TcpGetSocketState()`
5. Reports "NoBlock connection is done" when `TCP_STATE_ESTABLISHED` is reached

12.47.2.1.5.3 Automatic Features

- Sends a timestamp message every 5 seconds over established connections
- Displays current TCP state during non-blocking connection attempts
- Forwards any typed characters to the remote host when connected

12.47.2.1.6 Technical Details

- **Key APIs Used:**
 - `connect()` - Standard blocking TCP connection
 - `NoBlockConnect()` - Non-blocking TCP connection initiation
 - `TcpGetSocketState()` - Connection state monitoring
 - Standard socket operations (`write()`, `close()`)

12.47.2.1.7 Build Requirements

- NetBurner development environment
- NetBurner hardware platform
- Standard NetBurner libraries (`tcp.h`, `utils.h`, `iosys.h`, etc.)

12.47.2.1.8 Usage Example

1. Run the application on NetBurner hardware
2. When prompted, enter the destination IP address
3. Enter the destination port number
4. Use menu commands to test different connection methods:
 - Try 'C' for blocking connection
 - Try 'N' for non-blocking connection
 - Use 'X' to close connections
 - Use 'I' to change destination settings
5. Type any characters to send data over established connections

12.47.2.1.9 Connection State Monitoring

For non-blocking connections, the application continuously displays the TCP state:

- State values correspond to standard TCP states
- Connection is ready when `TCP_STATE_ESTABLISHED` is reached
- Failed connections will show appropriate error states

12.47.2.1.10 Notes

- Only one connection can be active at a time
- IP address and port cannot be changed while connected
- System diagnostics are enabled for debugging (should be disabled in production)
- The application runs in an infinite loop until manually terminated

12.47.3 TCP Keepalive Simple

12.47.3.1 TCP Keep-Alive Server

12.47.3.1.1 Overview

This NetBurner application demonstrates a TCP server implementation with keep-alive functionality. The server listens for incoming TCP connections and uses keep-alive packets to detect when clients become unresponsive or disconnect unexpectedly.

Keep-alive is implemented with the `TcpGetLastRxTime()` and `TcpSendKeepAlive()` functions. `TcpGetLastRxTime()` returns the number of time ticks since the last time a packet was received. `TcpSendKeepAlive()` sends a keep-alive packet to the client, which is used when no data has been transmitted within the timeout period.

The general concept is to call `TcpGetLastRxTime()`, call `TcpSendKeepAlive()`, wait a bit, then call `TcpSendKeepAlive()` a second time and verify the number of time ticks is different. If not, no packets were received and the client is not responding. Make sure to allow time for the client to respond to the keep alive packet. Do not call `TcpGetLastRxTime` more often than once every second to avoid performance issues.

12.47.3.1.2 Features

- TCP server listening on port 23 (Telnet)
- Automatic keep-alive packet transmission
- Client connection monitoring and detection of unresponsive clients
- Connection cleanup for dead connections
- Debug output to console/serial port

12.47.3.1.3 How It Works

12.47.3.1.3.1 Keep-Alive Implementation

The keep-alive functionality is implemented using two key NetBurner functions:

- `TcpGetLastRxTime()` - Returns the number of time ticks since the last received packet
- `TcpSendKeepAlive()` - Sends a keep-alive packet to the client

12.47.3.1.3.2 Keep-Alive Process

The example creates a TCP server task that listens on port 23 by default. The server blocks with "ReadWithTimeOut" until data is received or the timer times out. If a timeout occurs the time of the last received packet is recorded and a keep-alive packet is sent. Then, the server goes back to waiting for a read again. If ReadWithTimeOut times out a second time, the value of the last received TCP packet is checked again. If the client is still active the value of lastRxTime will be different than the previous value (due to the keep-alive packet that was sent). If the client did not respond to the keep-alive packet the number will remain the same and the client is assumed to be non-responsive, and the connection is closed.

1. **Initial Read:** Server waits for incoming data using `ReadWithTimeout()` with a 1-second timeout
2. **First Timeout:** If no data is received within the timeout period:
 - Record the timestamp of the last received packet
 - Send a keep-alive packet to the client
 - Continue waiting for data
3. **Second Timeout:** If timeout occurs again:
 - Check if the last received packet timestamp has changed
 - If timestamp is different: Client responded to keep-alive (connection is alive)
 - If timestamp is unchanged: Client is unresponsive, close the connection

12.47.3.1.3.3 Connection Flow

Client Connects -> Welcome Message -> Data Loop -> Keep-Alive Check -> Connection Management

12.47.3.1.4 Configuration

12.47.3.1.4.1 Default Settings

- **Listen Port:** 23 (Telnet)
- **Read Timeout:** 1 second
- **Buffer Size:** 4096 bytes
- **Maximum Pending Connections:** 5

12.47.3.1.4.2 Customization

To modify the listening port, change the `TCP_LISTEN_PORT` constant:

```
#define TCP_LISTEN_PORT 23 // Change to desired port number
```

12.47.3.1.5 Testing the Application

12.47.3.1.5.1 Using Telnet

From a Windows command prompt:

```
telnet <NetBurner_IP_Address>
```

From Linux/Mac terminal:

```
telnet <NetBurner_IP_Address> 23
```

12.47.3.1.5.2 Using PuTTY

1. Open PuTTY
2. Select "Raw" or "Telnet" connection type
3. Enter the NetBurner device IP address
4. Set port to 23
5. Click "Open"

12.47.3.1.5.3 Expected Behavior

1. Upon connection, you'll see: "Welcome to the NetBurner TCP Server"
2. The server will display your connection information
3. Any data you type will be echoed back with byte count information
4. If you stop sending data, keep-alive packets will be sent automatically
5. Status messages appear on the NetBurner's debug/console serial port

12.47.3.1.6 Code Structure

12.47.3.1.6.1 Main Components

- **UserMain():** Initializes the system and creates the TCP server task
- **TcpServerTask():** Main server loop that handles client connections
- **Keep-Alive Logic:** Integrated within the data reading loop

12.47.3.1.6.2 Key Variables

- `fdListen`: Listening socket file descriptor
- `fdNet`: Client connection file descriptor
- `LastRxTime`: Timestamp of last received packet
- `keepAliveSent`: Flag to track keep-alive state
- `RXBuffer`: Buffer for incoming data

12.47.3.1.7 Performance Considerations

- Do not call `TcpGetLastRxTime()` more frequently than once per second to avoid performance issues
- Allow sufficient time for clients to respond to keep-alive packets before determining they are unresponsive
- The server can handle multiple sequential connections but processes them one at a time

12.47.3.1.8 Debug Output

The application provides detailed debug information including:

- Connection establishment notifications
- Data reception logs with byte counts
- Keep-alive packet transmission notifications
- Client response status
- Connection closure notifications

All debug output is sent to the NetBurner's debug/console serial port.

12.47.4 TCP Keepalive Multiple

12.47.4.1 TCP Multi-Socket Server with Keep-Alive

A robust TCP server implementation that handles multiple concurrent connections with automatic dead connection detection using TCP keep-alive mechanisms.

12.47.4.1.1 Overview

This application demonstrates a production-ready TCP server that can:

- Handle up to 10 simultaneous TCP connections
- Automatically detect and close dead/disconnected clients
- Implement TCP keep-alive to prevent resource waste from zombie connections
- Use efficient I/O multiplexing with `select()` for scalable connection management

12.47.4.1.2 Features

12.47.4.1.2.1 Multi-Socket Connection Handling

- **Concurrent Connections:** Supports up to 10 simultaneous TCP connections
- **Non-blocking I/O:** Uses `select()` for efficient multiplexing of multiple sockets
- **Dynamic Connection Management:** Automatically accepts new connections and manages connection slots

12.47.4.1.2.2 Keep-Alive Mechanism

- **Idle Detection:** Monitors connections for inactivity (default: 5 seconds)
- **Automatic Probing:** Sends keep-alive packets to idle connections
- **Dead Connection Cleanup:** Closes connections that don't respond to keep-alive probes (timeout: 3 seconds)
- **Resource Protection:** Prevents server resource exhaustion from zombie connections

12.47.4.1.2.3 Connection Monitoring

- **Real-time Status:** Displays connection events, data transfers, and keep-alive activities
- **Client Information:** Shows client IP addresses and port numbers
- **Debug Output:** Comprehensive logging of connection lifecycle events

12.47.4.1.3 Configuration

12.47.4.1.3.1 Server Settings

```
#define listenPort (23)           // TCP port (Telnet)
#define maxConnections (10)      // Max simultaneous connections
#define readBufferSize (1024)   // Read buffer size per connection
```

12.47.4.1.3.2 Keep-Alive Timers

```
#define keepAliveTimeout (5 * TICKS_PER_SECOND) // 5 seconds idle timeout
#define keepAliveResponseTimeout (3 * TICKS_PER_SECOND) // 3 seconds response timeout
```

12.47.4.1.4 Usage

12.47.4.1.4.1 Starting the Server

1. Compile and deploy the application to your NetBurner device
2. The server automatically starts listening on port 23 (Telnet)
3. Monitor the console for connection status and debug information

12.47.4.1.4.2 Connecting Clients

```
# Connect using telnet
telnet <device_ip> 23

# Or using netcat
nc <device_ip> 23
```

12.47.4.1.4.3 Client Commands

- **Send any data:** Resets the keep-alive timer and echoes confirmation
- **Send 'Q' or 'q':** Gracefully disconnects from the server
- **Stay idle:** Triggers keep-alive mechanism after 5 seconds

12.47.4.1.5 How It Works

12.47.4.1.5.1 Connection Lifecycle

1. **Accept:** New connections are accepted and assigned to available slots
2. **Monitor:** Each connection is monitored for data activity using `select()`
3. **Keep-Alive:** Idle connections receive keep-alive probes
4. **Cleanup:** Dead or disconnected clients are automatically removed

12.47.4.1.5.2 Keep-Alive Process

1. **Idle Detection:** Server tracks last received data timestamp for each connection
2. **Probe Transmission:** After 5 seconds of inactivity, a TCP keep-alive packet is sent
3. **Response Monitoring:** Server waits up to 3 seconds for any TCP-level response
4. **Connection Termination:** Connections that don't respond are closed and removed

12.47.4.1.5.3 TCP Stack Integration

- Uses `TcpGetLastRxTime()` to track TCP-level packet reception
- Calls `TcpSendKeepAlive()` to send keep-alive probes
- Monitors both application data and TCP acknowledgments

12.47.4.1.6 Testing Scenarios

12.47.4.1.6.1 Normal Operation

```
# Connect and send data
telnet <device_ip> 23
> hello
Data received
> Q
Goodbye!
```

12.47.4.1.6.2 Keep-Alive Testing

1. Connect to the server but don't send any data
2. After 5 seconds, observe keep-alive probe message in server console
3. Continue to stay idle for 3+ more seconds
4. Connection will be automatically closed

12.47.4.1.6.3 Dead Connection Testing

1. Connect to the server
2. Physically disconnect the network cable or crash the client
3. After 8 seconds total (5 + 3), the server will detect and close the dead connection

12.47.4.1.7 Error Handling

- **Socket Errors:** Automatically detected and connections are closed
- **Accept Failures:** Gracefully handled with appropriate error messages
- **Buffer Overflows:** Protected by fixed buffer sizes
- **Resource Limits:** New connections rejected when server is full

12.47.4.1.8 Use Cases

12.47.4.1.8.1 Production Applications

- **Long-lived Connections:** Services that maintain persistent client connections
- **Resource Management:** Systems with limited connection resources
- **Network Monitoring:** Applications requiring dead connection detection
- **Embedded Systems:** Resource-constrained environments needing efficient connection handling

12.47.4.1.8.2 Network Scenarios

- **Unreliable Networks:** Environments with frequent network interruptions
- **Mobile Clients:** Connections that may drop without proper closure
- **Firewall Traversal:** Maintaining connections through NAT/firewall devices
- **Load Balancing:** Backend services requiring connection health monitoring

12.47.4.1.9 Performance Considerations

- **Memory Usage:** Each connection uses approximately 1KB for read buffers plus keep-alive tracking
- **CPU Overhead:** Minimal - keep-alive checks only run once per second
- **Network Traffic:** Keep-alive probes are small TCP packets sent only when needed
- **Scalability:** Can be extended to support more connections by increasing `maxConnections`

12.47.4.1.10 Dependencies

- NetBurner RTOS and TCP/IP stack
- Standard NetBurner includes: `init.h`, `iosys.h`, `tcp.h`, `ipshow.h`, `nbrtos.h`
- TCP keep-alive functions: `TcpGetLastRxTime()`, `TcpSendKeepAlive()`

12.47.4.1.11 Customization

12.47.4.1.11.1 Timeout Values

Adjust the keep-alive timing constants for your specific application requirements:

- Shorter timeouts for faster dead connection detection
- Longer timeouts for reduced network overhead

12.47.4.1.11.2 Connection Limits

Modify `maxConnections` based on available system resources and application needs.

12.47.4.1.12 Troubleshooting

12.47.4.1.12.1 Common Issues

- ****"Server Full" message**:** All connection slots are occupied
- **Immediate disconnections:** Check network connectivity and firewall settings
- **Keep-alive not working:** Verify TCP stack support and timing configuration

12.47.4.1.12.2 Debug Output

The application provides detailed console output for monitoring:

- Connection establishment and termination
- Keep-alive probe transmission and responses
- Error conditions and socket states

12.47.5 Multiple TCP Interface Test

12.47.5.1 TCP Multiple Interface Test

12.47.5.1.1 Overview

This NetBurner application demonstrates TCP client functionality with support for multiple network interfaces. The application provides a web-based interface for testing TCP connections to remote servers using various connection methods and network interfaces.

12.47.5.1.2 Application Description

The TCP Multiple Interface Test is a comprehensive example that showcases different ways to establish TCP connections from a NetBurner device. It consists of two main components:

1. **Web Interface** (`clientweb.cpp`)** - Provides an HTML form for configuring and initiating TCP connections
2. **Main Application** (`main.cpp`)** - Initializes the system and starts the HTTP server

12.47.5.1.3 Features

12.47.5.1.3.1 Connection Testing Methods

The application tests multiple TCP connection approaches:

- **Standard Connection** - Basic TCP connection using `connect ()`
- **Non-blocking Connection** - Asynchronous connection using `NoBlockConnect ()`
- **Interface-specific Connections** - Connections via specific network interfaces
- **IPv4 and IPv6 Support** - Dual-stack networking capabilities

12.47.5.1.3.2 Web Interface

The web interface allows users to:

- Specify destination IP address (auto-populated with client's IP)
- Set destination port number (defaults to 2000)
- Initiate connection tests through a web form
- View connection results in the console output

12.47.5.1.3.3 Key Functions

SendMsg(IPADDR destIp, int destPort)

Main function that performs comprehensive connection testing by:

- Testing standard and non-blocking connections
- Iterating through all available network interfaces
- Testing both IPv4 and IPv6 connections (when available)
- Attempting connections via interface number and interface IP

TestConnect(int fd, const char *msg)

Helper function that:

- Validates connection file descriptors
- Waits for connection establishment (2-second timeout)
- Reports connection status and local interface information
- Properly closes connections after testing

Web Callback Functions

- `WebDestPort()` - Displays current destination port in web form
- `WebDestIp()` - Displays current destination IP in web form
- `WebShowClientIp()` - Shows the client's IP address
- `PostCallBack()` - Processes form submissions and initiates connections

12.47.5.1.4 Usage

12.47.5.1.4.1 Setup

1. Compile and deploy the application to NetBurner hardware
2. Connect the device to your network
3. Note the device's IP address from the console output

12.47.5.1.4.2 Testing Connections

1. Open a web browser and navigate to the device's IP address
2. The form will auto-populate with your client IP as the destination
3. Modify the destination IP and port as needed
4. Click submit to initiate connection tests
5. Monitor console output (via MTTTY) for detailed connection results

12.47.5.1.4.3 Prerequisites

- A TCP server must be running at the specified destination IP and port
- NetBurner provides `TcpServerWin.exe` in the `\nburn\pctools` directory for testing

12.47.5.1.5 Network Interface Testing

The application systematically tests connections through:

12.47.5.1.5.1 IPv4 Interfaces

- Direct interface number specification
- Interface IP address specification
- Both standard and non-blocking variants

12.47.5.1.5.2 IPv6 Interfaces (when enabled)

- Interface number specification
- All valid IPv6 prefixes on each interface
- Standard and non-blocking connection methods

12.47.5.1.6 Console Output

Connection attempts generate detailed logging including:

- Connection method being tested
- Source IP address and interface number
- Success/failure status with error codes
- Timeout notifications for failed connections

12.47.5.1.7 Error Handling

The application includes error handling for:

- Invalid connection parameters
- Connection timeouts (2-second limit)
- Network interface enumeration failures
- Form processing errors

12.47.5.1.8 Configuration

12.47.5.1.8.1 Default Values

- Default destination port: 2000
- Connection timeout: 5 seconds
- Status check timeout: 2 seconds

12.47.5.1.8.2 Compilation Options

- IPv6 support can be enabled/disabled via `#ifdef IPV6`
- System diagnostics are enabled by default (consider disabling for production)

12.47.5.1.9 Development Notes

This example serves as a comprehensive reference for:

- NetBurner TCP client implementation
- Multi-interface network programming
- Web-based device configuration
- IPv4/IPv6 dual-stack networking
- Non-blocking socket operations

12.47.6 TCP Multi-Socket Server

12.47.6.1 TCP Multi-Socket Server

12.47.6.1.1 Overview

This application demonstrates a TCP server implementation that can handle multiple simultaneous client connections using the NetBurner embedded platform. The server uses the `select()` function to efficiently manage multiple TCP connections concurrently without blocking.

12.47.6.1.2 Features

- **Multi-client support:** Handles up to 10 simultaneous TCP connections
- **Non-blocking I/O:** Uses `select ()` to efficiently manage multiple file descriptors
- **Connection management:** Automatically accepts new connections and manages client disconnections
- **Simple protocol:** Clients can send 'Q' to quit their connection
- **Debug output:** Status messages displayed on debug serial port

12.47.6.1.3 Configuration

The application uses the following configurable parameters:

- **Listen Port:** 23 (Telnet port)
- **Maximum Connections:** 10 simultaneous clients
- **Read Buffer Size:** 1024 bytes per connection

These values can be modified by changing the corresponding `#define` statements in `main.cpp`.

12.47.6.1.4 How It Works

12.47.6.1.4.1 Server Initialization

1. Initializes the NetBurner system and waits for network connectivity
2. Creates a listening socket on port 23
3. Displays the device's IP addresses for client connection reference

12.47.6.1.4.2 Connection Management

The server uses a file descriptor array (`fdArray`) to track active client connections. The main loop:

1. **Sets up file descriptor sets** for `select ()` monitoring
2. **Calls `select()`** to block until activity occurs on any socket
3. **Processes new connections** when clients connect to the listening port
4. **Handles client data** when existing connections have data to read
5. **Manages errors** by closing problematic connections

12.47.6.1.4.3 Client Interaction

- **Welcome message:** New clients receive a greeting upon connection
- **Quit command:** Clients can send 'Q' to cleanly disconnect
- **Echo behavior:** The server reads client data and logs it to the debug port
- **Connection limits:** If the server is full (10 connections), new clients are rejected with an error message

12.47.6.1.5 Testing the Application

12.47.6.1.5.1 Using Telnet

The easiest way to test this application is using multiple Telnet sessions:

```
telnet <netburner_ip_address> 23
```

You can open up to 10 simultaneous Telnet connections to test the multi-client functionality.

12.47.6.1.5.2 Expected Behavior

1. **Successful connection:** You'll see "Welcome to the NetBurner Multi-Socket TCP Server! 'Q' to quit."
2. **Server full:** If you try to connect when 10 clients are already connected, you'll see "I am sorry, but the server is full"
3. **Quit command:** Type 'Q' to cleanly disconnect
4. **Debug output:** Connection status, received data, and errors are logged to the serial debug port

12.47.6.1.6 Code Structure

12.47.6.1.6.1 Key Functions

- `**UserMain()` **: Main application entry point and event loop
- `**select()` **: Monitors multiple file descriptors for activity
- `**accept()` **: Accepts new client connections
- `**read()` **: Reads data from client connections
- `**close()` **: Closes file descriptors and cleans up connections

12.47.6.1.6.2 File Descriptor Management

The application maintains an array of file descriptors (`fdArray`) where:

- Index 0-9: Active client connections (0 = unused slot)
- Separate `fdListen`: The listening socket for new connections

12.47.6.1.6.3 Error Handling

- **Connection errors:** Automatically detected and connections are closed
- **Read errors:** Treated as connection problems and handled gracefully
- **Listen socket errors:** The listening socket is closed and reopened

12.47.6.1.7 Troubleshooting

- **Cannot connect:** Verify the NetBurner device has network connectivity and check IP address
- **Connection refused:** Ensure no other service is using port 23
- **Unexpected disconnections:** Check debug serial output for error messages
- **Server appears full:** Existing connections may not have closed properly; restart the application

12.47.7 TCP Resource Information

12.47.7.1 TCP Resource Information

12.47.7.1.1 Overview

This NetBurner embedded application demonstrates system resource monitoring capabilities by providing real-time information about TCP buffers, network sockets, and file descriptors. The application is designed to help developers understand and monitor network resource usage in embedded systems.

12.47.7.1.2 Features

The application provides three main monitoring functions:

- **System Buffer Monitoring:** Display the number of free system buffers
- **Socket Resource Tracking:** Show available network sockets and file descriptors
- **Dynamic Resource Testing:** Create and close listening sockets to demonstrate resource consumption

12.47.7.1.3 System Requirements

- NetBurner Hardware
- NetBurner SDK (tested with revision 3.5.4)
- Active network connection

12.47.7.1.4 Application Structure

12.47.7.1.4.1 Core Functions

The application utilizes three key system functions for resource monitoring:

- `GetFreeCount ()` - Returns the number of free system buffers
- `GetFreeSocketCount ()` - Returns the number of free sockets/file descriptors (excluding extra FDs)
- `GetFreeExtraFDCount ()` - Returns the number of extra file descriptors

12.47.7.1.4.2 Menu System

The application provides an interactive serial menu with the following options:

1. **Show free buffers and sockets** - Displays current resource availability
2. **Add a listen socket, display info, and close the socket** - Demonstrates resource consumption by creating a temporary listening socket on port 10000
3. **Get extra fd count** - Shows the count of extra file descriptors

12.47.7.1.5 Usage

1. Compile and deploy the application to your NetBurner device
2. Connect to the device via serial terminal
3. The application will automatically initialize the network and display the menu
4. Enter the number corresponding to your desired action:
 - Press '1' to view current resource status
 - Press '2' to test socket creation and see resource impact
 - Press '3' to check extra file descriptor count

12.47.7.1.6 Important Notes

12.47.7.1.6.1 Resource Management

- Each active socket (listening or connected) consumes system resources
- When the system runs out of buffers or sockets, it cannot accept incoming connections or make outgoing connections
- The listening socket test (option 2) temporarily uses port 10000 with a backlog of 5 connections

12.47.7.1.6.2 Network Initialization

- The application waits up to 10 seconds for an active network connection during startup
- System diagnostics are enabled by default (consider disabling for production builds)

12.47.7.1.7 Code Structure

```
main.cpp
  UserMain()           - Main application entry point
  showMenu()           - Display menu options
  processCommand()     - Handle user input
  System Functions     - Network resource monitoring
```

12.47.7.1.8 Development Notes

- System diagnostics are enabled for development purposes
- The code is designed for continuous operation with a command loop
- Error handling is implemented for socket operations

12.47.8 TCP Server

12.47.8.1 Simple TCP Server Example

A NetBurner embedded TCP server application that creates a listening socket on port 23 (Telnet) and accepts client connections for communication.

12.47.8.1.1 Overview

This application demonstrates how to implement a basic TCP server on NetBurner hardware. The server listens for incoming connections and provides a simple echo-style communication interface where it receives data from clients and displays it locally.

12.47.8.1.2 Features

- **TCP Server:** Creates a listening socket on port 23 (standard Telnet port)
- **Client Connection Handling:** Accepts incoming TCP connections from clients
- **Data Reception:** Reads data from connected clients using a simple `read()` function
- **Connection Management:** Handles client disconnections gracefully
- **Multi-tasking:** Uses RTOS tasks for concurrent operation

12.47.8.1.3 Technical Details

12.47.8.1.3.1 Configuration

- **Listen Port:** 23 (Telnet)
- **Receive Buffer Size:** 4096 bytes
- **Maximum Pending Connections:** 5
- **Task Priority:** MAIN_PRIO - 1 (higher than UserMain)

12.47.8.1.3.2 Key Components

TcpServerTask

The main server task that:

1. Creates a listening socket bound to INADDR_ANY on the specified port
2. Waits for client connections using `accept()`
3. Sends welcome messages to connected clients
4. Continuously reads data from clients until disconnection
5. Closes connections and waits for new ones

Buffer Management

- Uses a global receive buffer (`RXBuffer`) of 4096 bytes
- Null-terminates received data for string processing
- Displays received data length and content via `iprintf()`

12.47.8.1.4 Usage

12.47.8.1.4.1 Testing with Telnet

To test the TCP server, use a Telnet client from any system on the same network:

```
telnet <netburner_ip_address>
```

Where `<netburner_ip_address>` is the IP address of your NetBurner device.

12.47.8.1.4.2 Expected Behavior

1. The server displays "Waiting for connection on port 23..."
2. When a client connects, it shows the client's IP address
3. The client receives welcome messages:
 - "Welcome to the NetBurner TCP Server"
 - Connection details with server IP and port
4. Any data sent by the client is echoed to the server console
5. When the client disconnects, the server closes the connection and waits for new ones

12.47.8.1.5 Implementation Notes

12.47.8.1.5.1 Connection Lifecycle

- The server uses a blocking `accept()` call to wait for connections
- Each client connection is handled sequentially (single client at a time)
- The `read()` function blocks until data is received or connection closes
- Connection closure is detected when `read()` returns 0 or negative value

12.47.8.1.5.2 Limitations

- **Single Client:** This example handles one client connection at a time
- **Sequential Processing:** New connections must wait until the current client disconnects
- **No Timeout:** Connections remain open indefinitely until client closes

12.47.8.1.5.3 For Multiple Clients

This example uses a simple `read()` approach for single client connections. For handling multiple simultaneous client connections, refer to the "TCP Multi Socket Server" example.

12.47.8.1.6 System Requirements

- NetBurner hardware platform
- NetBurner RTOS (NBRRTOS)
- Network connectivity (Ethernet)
- Telnet client for testing

12.47.8.1.7 Troubleshooting

12.47.8.1.7.1 Common Issues

1. **Connection Refused:** Verify the NetBurner device IP address and network connectivity
2. **Port Already in Use:** Ensure no other service is using port 23
3. **No Response:** Check if the TCP server task started successfully

12.47.8.1.7.2 Debug Output

The application provides console output for:

- Server startup and port binding
- Client connection events with IP addresses
- Received data content and byte counts
- Connection closure events

12.47.8.1.8 Code Structure

```
main.cpp
TcpServerTask()    - Main TCP server loop
  listen()         - Create listening socket
  accept()         - Accept client connections
  read()           - Receive client data
  close()          - Close connections
UserMain()         - Application initialization
  init()           - System initialization
  OSTaskCreate()   - Create server task
```

12.47.8.1.9 Related Examples

For more advanced TCP server implementations, see:

- TCP Multi Socket Server - Handles multiple simultaneous client connections

12.47.9 TCP Server Using Via

12.47.9.1 TCP Server Via Example

12.47.9.1.1 Overview

This application demonstrates a TCP server implementation for multi-interface NetBurner devices using the `listenvia()` function. The server creates multiple listening sockets - one that listens on all network interfaces and additional sockets that listen on specific network interfaces.

12.47.9.1.2 Features

- **Multi-Interface Support:** Creates listening sockets for each available network interface
- **Multiple Concurrent Connections:** Supports up to 10 simultaneous TCP connections
- **Port Management:** Uses incrementing port numbers starting from port 23
- **Single-Task Architecture:** Uses `select()` to handle multiple sockets within one task
- **Connection Monitoring:** Provides detailed logging of connections and interface information

12.47.9.1.3 Technical Details

12.47.9.1.3.1 Configuration

- **Base Port:** 23 (Telnet)
- **Maximum Connections:** 10 concurrent connections
- **Read Buffer Size:** 1,024 bytes
- **Connection Queue:** Up to 5 pending connection requests per listening socket

12.47.9.1.3.2 Socket Architecture

The application creates the following listening sockets:

1. One socket listening on all interfaces (port 23)
2. For each available network interface:
 - One socket on port 24 (`listenPort + 1`)
 - One socket on port 24 + `interface_number`

12.47.9.1.3.3 Network Interface Handling

- Automatically detects available network interfaces using `GetInterfaceBlock()`
- Creates dedicated listening sockets for each interface using `listenvia()`
- Provides interface-specific connection information to clients

12.47.9.1.4 Usage

12.47.9.1.4.1 Building and Running

1. Compile the application for your NetBurner device
2. Deploy to the target hardware
3. The application will automatically start listening on configured ports

12.47.9.1.4.2 Testing Connections

Use Telnet to test connections from the command line:

```
telnet <ip_address> <port>
```

Examples:

- `telnet 192.168.1.100 23` - Connect to the all-interfaces socket
- `telnet 192.168.1.100 24` - Connect to interface 1, port 24
- `telnet 192.168.1.100 25` - Connect to interface 1, port 25

12.47.9.1.4.3 Client Interaction

- Upon connection, clients receive a welcome message
- Interface information is displayed showing which interface accepted the connection
- Type 'Q' to quit and close the connection
- Server echoes received data and provides connection status

12.47.9.1.5 Code Structure

12.47.9.1.5.1 Main Components

Initialization**

- System diagnostics enabled
- Waits for active network (10-second timeout)

- Displays IP addresses for all interfaces

Socket Management**

- `listeners[]` array stores all listening socket file descriptors
- `fdArray[]` manages active client connections
- Automatic socket recovery on errors

Event Loop**

- Uses `select()` for efficient I/O multiplexing
- Processes new connections, data reception, and errors
- Automatic cleanup of closed connections

12.47.9.1.5.2 Key Functions Used

- `listen()` - Creates socket listening on all interfaces
- `listenvia()` - Creates socket listening on specific interface
- `accept()` - Accepts incoming connections
- `select()` - Monitors multiple sockets for I/O events
- `TcpGetSocketInterface()` - Retrieves interface information

12.47.9.1.6 Error Handling

- **Connection Limit:** When server is full, new connections are rejected with a message
- **Socket Errors:** Automatic detection and recovery of failed listening sockets
- **Read Errors:** Proper cleanup of corrupted client connections
- **Interface Failures:** Continues operation even if some interfaces fail

12.47.9.1.7 Application Output

The application provides detailed console output including:

- Network interface discovery and socket creation status
- Connection acceptance with client IP and port information
- Interface identification for each connection
- Data reception logging
- Connection closure notifications
- Error condition reporting

12.47.9.1.8 Requirements

- NetBurner hardware platform
- NetBurner SDK with TCP networking support
- Multi-interface network configuration (optional for full functionality)

12.47.9.1.9 Notes

- System diagnostics are enabled by default (should be disabled for production)
- Socket file descriptors are automatically managed and cleaned up
- The server continues running indefinitely until manually stopped

12.47.10 TCP Speed Test

12.47.10.1 TCP Speed Test Application

12.47.10.1.1 Overview

This is a TCP speed test application designed for NetBurner embedded devices. The application creates a TCP server that measures network transmission performance by sending data to connected clients. It's designed to test the send speed capabilities of NetBurner hardware.

12.47.10.1.2 Features

- TCP server listening on configurable port (default: 1234)
- Automatic data buffer initialization with test patterns
- Network interface detection and IP address display
- Optional WiFi interface support
- Socket optimization for performance testing
- Real-time throughput measurement and reporting
- Client connection management with timeout handling

12.47.10.1.3 Hardware Requirements

- NetBurner embedded device
- Ethernet or WiFi network connectivity
- Debug serial port for monitoring

12.47.10.1.4 Software Components

12.47.10.1.4.1 Key Functions

Network Initialization

- Waits for active network connection
- Displays IP addresses of available interfaces
- Optional WiFi interface initialization (when ADD_WIFITEST is defined)

TCP Server Operation

- Creates listening socket on specified port
- Accepts incoming client connections
- Configures socket options for optimal performance:
 - Enables SO_NOPUSH option
 - Sets ACK buffers to 20
 - Sets TX buffers to 20

Speed Test Protocol

1. Server waits for client start signal (single byte)
2. Continuously sends 1460-byte data packets
3. Measures transmission time and byte count
4. Reports results when client disconnects

Data Pattern

- Test data consists of repeating ASCII characters ('A' + (index % 64))
- Creates predictable pattern for data integrity verification

12.47.10.1.5 Usage Instructions

12.47.10.1.5.1 Device Setup

1. Connect NetBurner device to network
2. Connect to debug serial port using terminal (MTTTY recommended)
3. Build and download the application to the device
4. Device will display its IP address and listening status

12.47.10.1.5.2 Running Speed Test

1. Note the IP address displayed by the device
2. Use the provided TcpSpeedTest.exe PC application:
`./TcpSpeedTest <ip_address>`
3. Add `-r` flag for continuous testing:
`./TcpSpeedTest <ip_address> -r`

12.47.10.1.5.3 Test Results

- Results displayed on both device serial output and PC command prompt
- Metrics include:
 - Total bytes sent
 - Time duration (in system ticks and seconds)
 - Calculated throughput

12.47.10.1.6 Configuration Options

12.47.10.1.6.1 WiFi Support

Uncomment `#define ADD_WIFITEST` to enable WiFi interface:

- Scans and displays available networks
- Attempts connection to configured network
- Note: Enable `FAST_WIFI_STACK` in [constants.h](#) for improved performance

12.47.10.1.6.2 Performance Optimization

- FlexSPI overclock option available (commented by default)
- Socket buffer optimization enabled
- System diagnostics available for debugging

12.47.10.1.7 Error Handling

- Connection timeout handling (10-second timeout for start signal)
- Socket operation error detection
- Graceful connection termination
- Automatic server restart after client disconnect

12.47.10.1.8 Performance Notes

- Uses aligned memory buffers for optimal performance
- Implements socket options for reduced latency
- Sends data in optimal 1460-byte chunks (standard Ethernet MTU)
- Continuous operation until manual reset

12.47.10.1.9 Troubleshooting

12.47.10.1.9.1 Common Issues

- **No network connection:** Check cable/WiFi configuration
- **Port binding failure:** Verify port 1234 is available
- **Client connection timeout:** Ensure PC application can reach device IP
- **Performance issues:** Consider enabling `FAST_WIFI_STACK` for WiFi

12.47.10.1.9.2 Debug Information

- Verbose mode available (set bVerbose = TRUE)
- System diagnostics enabled by default
- Serial output provides detailed connection status

12.47.11 TCP Stress Test

12.47.11.1 TCP Stress Test Application

12.47.11.1.1 Overview

This is a NetBurner embedded TCP stress testing application designed to measure various network performance metrics and response times. The application runs a series of sequential tests to evaluate TCP connection handling, data transfer speeds, and `select()` function performance.

12.47.11.1.2 Description

The TCP Stress Test application is designed to work in conjunction with a Windows program to exercise various test cases and measure network performance. It provides comprehensive testing of TCP socket operations including connection establishment, data exchange, and bulk data transfer capabilities.

12.47.11.1.3 Features

The application performs five sequential stress tests:

12.47.11.1.3.1 1. Listening Test

- Listens for incoming TCP connections on port 10000
- Exchanges single characters with connecting clients
- Measures the time and number of connections processed
- Terminates when it receives an 'X' character from a client

12.47.11.1.3.2 2. Connecting Test

- First accepts one incoming connection to determine the client's IP address
- Then repeatedly makes outgoing connections back to that client
- Exchanges single characters with each connection
- Measures connection establishment performance
- Terminates when it receives an 'X' character

12.47.11.1.3.3 3. Response Test

- Tests worst-case TCP performance by sending one byte at a time
- Listens for incoming bytes and echoes them back immediately
- Measures response time for single-byte exchanges
- Demonstrates TCP overhead for minimal data transfers

12.47.11.1.3.4 4. Select Response Test

- Tests the `select()` function performance for monitoring multiple file descriptors
- Uses `select()` to wait for data availability before reading
- Measures the response time of the `select()` system call
- Includes error handling for `select()` failures

12.47.11.1.3.5 5. Bulk Speed Test

- Tests maximum data transfer throughput
- Sends large buffers (`TCP_BUFFER_SEGMENTS * 1460` bytes per write)
- Uses socket options for optimized bulk transfer (`SO_NOPUSH`)
- Measures total bytes transferred until connection closes

12.47.11.1.4 Configuration

- **Listen Port:** 10000 (default)
- **Buffer Size:** 20,000 bytes for bulk data test
- **Time Resolution:** 20 ticks per second (`TICKS_PER_SECOND`)
- **Stack Size:** `USER_TASK_STK_SIZE` for the test task
- **Priority:** `MAIN_PRIO - 1` for the test task

12.47.11.1.5 Technical Details

12.47.11.1.5.1 Key Components

- **TestTask:** Main task that runs all five tests sequentially in a loop
- **UserMain:** Initialization function that sets up networking and creates the test task
- **DataBuffer:** 20KB aligned buffer used for bulk data transfers
- **Socket Options:** Uses `SO_NOPUSH` and custom ACK buffer settings for optimization

12.47.11.1.5.2 Network Requirements

- Active network connection required
- Compatible with NetBurner hardware platforms
- Requires a Windows client program (not included in NetBurner project)
- Uses standard TCP/IP sockets

12.47.11.1.5.3 Timing and Measurements

All timing measurements are reported in "ticks" where the default resolution is 20 ticks per second. The application measures:

- Connection establishment time
- Single-byte response time
- `Select()` function response time
- Bulk data transfer rates
- Total connections processed

12.47.11.1.6 Usage

1. Compile and deploy to NetBurner hardware
2. Ensure network connectivity is established
3. Run the corresponding Windows client program
4. The application will automatically cycle through all five tests
5. Press any key during execution to display network counters
6. Monitor serial output for test results and timing information

12.47.11.1.7 Project Structure

```
tcp-stress-test/
  main.cpp      # Main application source code
  ReadMe.txt    # Original documentation
  pc/           # Windows client program (exclude from NetBurner build)
```

Warning

Do not include the `pc` folder in your NetBurner project build as it contains Windows-specific client code.

12.47.11.1.8 Output Format

Each test provides timing results in the following format: Output Format Each test provides timing results in the following format:

"Accepted X times in Y ticks" (Listening Test) "Connected X times in Y ticks" (Connecting Test) "Responded X times in Y ticks" (Response Test) "Select Responded X times in Y ticks" (Select Response Test) "Nsent = X" (Bulk Speed Test)

12.48 Telnet Command**12.48.1 NetBurner Telnet Command Example**

A demonstration application that implements a multi-interface command processor using the NetBurner Command Processor Library. This application provides remote command access through serial port, TCP/Telnet, and optionally SSH connections.

12.48.1.1 Overview

The TelnetCmd example showcases how to create a command-line interface that can accept connections and process user commands from multiple sources simultaneously:

- Serial port (UART) connection
- TCP/Telnet connection on port 23
- SSH connection on port 22 (if SSH support is enabled)

12.48.1.2 Features**12.48.1.2.1 Multi-Interface Support**

- **Serial Port:** Direct UART connection at 115,200 baud, 8 data bits, 1 stop bit, no parity
- **Telnet:** Standard TCP connection on port 23 with up to 5 concurrent connections
- **SSH:** Encrypted connection on port 22 with up to 5 concurrent connections (optional)

12.48.1.2.2 Authentication System

- Simple username/password authentication
- Rejects credentials where username matches password (for testing)
- Separate SSH authentication handler with support for key-based authentication
- Configurable login prompts and timeouts

12.48.1.2.3 Session Management

- Session tracking with unique identifiers
- Connection counters and session state management
- Customizable prompts showing connection type (Serial0, Serial1, or Remote)
- Automatic timeout handling (60-second idle timeout)

12.48.1.2.4 Command Processing

- Extensible command framework
- Built-in "logout" command to close connections
- Command echo and response system
- Graceful connection handling and cleanup

12.48.1.3 Configuration

12.48.1.3.1 Serial Port Settings

```
#define SERIALPORT_TO_USE (0)      // Serial port 0
#define BAUDRATE_TO_USE (115200)  // 115.2k baud
#define STOP_BITS (1)             // 1 stop bit
#define DATA_BITS (8)            // 8 data bits
```

12.48.1.3.2 Network Settings

```
#define TCP_PORT_TO_USE (23)       // Standard Telnet port
```

12.48.1.4 Callback Functions

The application implements five main callback functions:

12.48.1.4.1 Authentication Callbacks

- `ProcessTcpAndSerialAuth()`: Handles TCP and serial authentication
- `ProcessSshAuth()`: Handles SSH authentication with key/password support

12.48.1.4.2 Connection Management

- `ProcessConnect()`: Called when new connections are established
- `ProcessDisconnect()`: Handles connection cleanup and goodbye messages
- `ProcessPrompt()`: Generates custom prompts for each session

12.48.1.4.3 Command Processing

- `ProcessCommand()`: Processes all user commands and responses

12.48.1.5 Connection Types and Prompts

The application identifies different connection types and provides appropriate prompts:

- **Serial0:** Direct serial connection on UART 0
- **Serial1:** Direct serial connection on UART 1
- **Remote:** TCP/Telnet or SSH network connections

Example session prompt: `NB:Remote>`

12.48.1.6 Disconnect Handling

The application handles various disconnect scenarios:

- **Timeout:** 60-second idle timeout
- **Socket Closed:** Network connection terminated
- **Authentication Failed:** Invalid credentials provided
- **Manual Logout:** User-initiated logout command
- **System Closed:** Application-initiated disconnect

12.48.1.7 SSH Support (Optional)

When SSH support is enabled (`NB_SSH_SUPPORTED`):

- Automatic certificate and key generation
- Secure encrypted connections
- Key-based authentication support
- Automatic retry logic for SSH listener startup

12.48.1.8 Usage

1. **Serial Connection:** Connect to the configured serial port at 115,200 baud
2. **Telnet Connection:** `telnet <device_ip> 23`
3. **SSH Connection:** `ssh <username>@<device_ip>` (if SSH enabled)

12.48.1.8.1 Authentication

- Enter any username and password combination
- Username and password must be different (test restriction)
- Type "logout" to disconnect

12.48.1.8.2 Sample Session

```
Hello!
Welcome to the NetBurner Test Command Program
Number of connections since boot since boot: 1
Please Log in
Username: admin
Password: password123

NB:Remote>help
# Remote Sent Cmd[help]

NB:Remote>logout
GoodBye
```

12.48.1.9 Build Requirements

- NetBurner development environment
- Command Processor Library
- Optional: SSH support libraries (NB_SSH_SUPPORTED)

12.48.1.10 System Integration

The application integrates with NetBurner's RTOS:

- Runs command processor at `MAIN_PRIO + 1` priority
- Uses system diagnostics (should be disabled for production)
- Waits for active network before starting SSH services
- Replaces standard I/O streams with serial port

12.48.1.11 Customization

To extend this application:

1. **Add Commands:** Modify `ProcessCommand()` to handle new command strings
2. **Change Authentication:** Update authentication callbacks for different credential checking
3. **Modify Prompts:** Customize `ProcessPrompt()` for different prompt formats
4. **Add Connection Types:** Extend connection handling for additional interfaces
5. **Configure Timeouts:** Adjust `CmdIdleTimeout` for different session timeouts

12.48.1.12 Security Notes

- This is a demonstration application with simplified authentication
- Production deployments should implement secure credential storage
- Consider disabling system diagnostics for production use
- SSH provides encrypted communication when available

12.48.1.13 Related Documentation

See NetBurner Command Processor Library documentation for additional API details and advanced configuration options.

12.49 TFTP Client

12.49.1 TFTP Client Application

12.49.1.1 Overview

This NetBurner TFTP Client example demonstrates how to use a NetBurner device to communicate with a TFTP (Trivial File Transfer Protocol) server for both file upload and download operations.

12.49.1.2 Features

- **File Download:** Retrieve files from a TFTP server using the `GetTFTP ()` function
- **File Upload:** Send files to a TFTP server using the `SendTFTP ()` function
- **Configurable Server:** Support for specifying TFTP server IP address
- **Error Handling:** Comprehensive error checking and timeout management
- **Binary and Text Modes:** Support for both binary ("b") and text ("t") transfer modes

12.49.1.3 Requirements

12.49.1.3.1 TFTP Server Configuration

1. The TFTP server must be configured to handle both read and write operations
2. Ensure the server allows file transfers in the directory where test files will be stored

12.49.1.3.2 NetBurner Device Configuration

The TFTP server address can be configured through multiple methods:

- NetBurner device's Configuration Server web interface
- Direct modification in the application code (currently set to 10.1.1.100)
- Serial Configuration Server of the device
- Application data flash memory using configuration parameters

12.49.1.4 Application Flow

12.49.1.4.1 Initialization

1. Initialize the network stack
2. Enable system diagnostics
3. Start HTTP web server on default port 80
4. Wait for DHCP address assignment (5-second timeout)

12.49.1.4.2 TFTP Operations

1. **File Upload Test:** Creates a sample text file with 10 lines and uploads it as "tftp.txt"
2. **File Download Test:** Downloads "tftp.txt" from the TFTP server
3. **Results Display:** Shows operation results and data content

12.49.1.5 Code Structure

12.49.1.5.1 Key Functions

12.49.1.5.1.1 SendTFTP_Test ()

- Creates sample data (10 lines of text)
- Uploads data to TFTP server as "tftp.txt"
- Handles upload results and error conditions

12.49.1.5.1.2 ReadTFTP_Test ()

- Downloads "tftp.txt" from TFTP server
- Displays received data and byte count
- Handles download results and error conditions

12.49.1.5.1.3 UserMain ()

- Main application entry point
- Performs initialization sequence
- Executes both send and receive tests
- Enters infinite loop after completion

12.49.1.5.2 Configuration Parameters

```
#define TFTP_SERVER_IP "10.1.1.100" // Default TFTP server IP address
const int bufferSize = 1024;      // Transfer buffer size
```

12.49.1.5.3 TFTP Function Parameters

Both `GetTFTP ()` and `SendTFTP ()` functions use similar parameter structures:

- **Filename:** Name of file to transfer ("tftp.txt")
- **Mode:** Transfer mode - "b" for binary, "t" for text
- **Buffer:** Data buffer for transfer operations
- **Length:** Data length for transfers
- **Timeouts:** Operation and packet-level timeout values
- **Server IP:** TFTP server IP address

12.49.1.6 Return Codes

The application handles three main TFTP return codes:

- **TFTP_OK:** Operation completed successfully
- **TFTP_TIMEOUT:** Operation timed out
- **TFTP_ERROR:** Error occurred during operation

12.49.1.7 Usage Instructions

1. **Setup TFTP Server:** Configure a TFTP server on your network with read/write permissions
2. **Configure IP Address:** Update `TFTP_SERVER_IP` to match your TFTP server's IP address
3. **Build and Deploy:** Compile and deploy the application to your NetBurner device
4. **Network Connection:** Ensure the NetBurner device is connected to the same network as the TFTP server
5. **Monitor Output:** Use a serial terminal to view application output and results
6. **Reset to Repeat:** Reset the device to run the test sequence again

12.49.1.8 Test Files

The application works with a test file named "tftp.txt":

- **Upload Test:** Creates and sends a file with 10 numbered lines
- **Download Test:** Retrieves the same file from the server
- **Content Verification:** Displays received data for verification

12.49.1.9 Network Requirements

- DHCP-enabled network for automatic IP assignment
- Network connectivity between NetBurner device and TFTP server
- TFTP server listening on standard port 69
- Firewall permissions for TFTP traffic

12.49.1.10 Troubleshooting

12.49.1.10.1 Common Issues

- **Timeout Errors:** Check network connectivity and TFTP server status
- **Permission Errors:** Verify TFTP server write permissions
- **File Not Found:** Ensure test file exists on server for download operations
- **Network Issues:** Confirm [DHCP](#) assignment and IP connectivity

12.49.1.10.2 Debug Information

- System diagnostics are enabled by default
- Serial output provides detailed operation status
- HTTP server runs on port 80 for additional configuration options

12.49.1.11 Customization Options

12.49.1.11.1 Server Configuration

Replace hardcoded IP with configurable parameters:

```
static config_string gTftpServerName(appdata, "DNS_or_IPAddress", "TFTP_SERVER");  
// or  
static config_IPADDR4 gTftpServerAddress(appdata, "10.1.1.123", "TFTP_SERVER");
```

12.49.1.11.2 Buffer Size

Adjust `bufferSize` constant to handle larger file transfers as needed.

12.49.1.11.3 Timeout Values

Modify timeout parameters in function calls:

- `TICKS_PER_SECOND * 10`: Overall operation timeout
- `TICKS_PER_SECOND * 5`: Individual packet timeout

12.49.1.12 Development Notes

- Remove `EnableSystemDiagnostics()` for production deployments
- Consider implementing error recovery mechanisms for production use
- The application demonstrates basic TFTP functionality suitable for embedded systems
- HTTP server provides additional configuration capabilities through web interface

12.50 TFTP Server

12.50.1 TFTP Server Application

12.50.1.1 Overview

This application implements a TFTP (Trivial File Transfer Protocol) Server as a servlet on an embedded device. The server allows clients to transfer files using the TFTP protocol, which is a simplified version of FTP designed for minimal overhead and ease of implementation.

12.50.1.2 Application Description

The TFTP Server application is built on the NetBurner NNDK (NetBurner Network Development Kit) platform and provides the following functionality:

- **TFTP Server Implementation:** Runs as a servlet on the device
- **File Serving:** Makes specific files available for TFTP transfer
- **Web Interface:** Includes an HTTP web server for device management
- **Network Integration:** Full network stack initialization and management

12.50.1.3 Key Components

12.50.1.3.1 Main Application (`main.cpp`)

The main application file contains:

- **Application Name:** "TFTP_Server"
- **TFTP Server Object:** `MyServer` - the main TFTP server instance
- **File Source:** `file1` - makes test data available as "test.dat"
- **Test Data:** References embedded test data array (5500 bytes)

12.50.1.3.2 Test Data (`data.cpp`)

Contains auto-generated test data:

- **Array Name:** `testdata_array`
- **Size:** 5500 bytes
- **Content:** Formatted hexadecimal test data representing numbered lines
- **Format:** Each line contains line numbers and repeating digit patterns

12.50.1.3.3 Sample File (`filetosend.txt`)

Provides a human-readable version of the test data:

- 50 lines of formatted text
- Each line prefixed with a 4-digit line number (0000-0059)
- Contains repeating digit patterns for testing transfer integrity

12.50.1.4 Functionality

12.50.1.4.1 Network Services

1. **TFTP Server:**

- Serves files via TFTP protocol
- Makes "test.dat" available for download
- Uses embedded test data array

2. **HTTP Web Server:**

- Starts on default port 80
- Provides web-based interface
- Enables system diagnostics

3. **Network Stack:**

- Full network initialization
- Active network detection with 5-second timeout
- Continuous operation loop

12.50.1.4.2 File Serving

The application demonstrates TFTP file serving by:

- Creating a TFTP server instance
- Registering a file source named "test.dat"
- Mapping the file to the embedded test data array
- Making the file available for TFTP client downloads

12.50.1.5 System Requirements

- NetBurner NNDK platform
- Network connectivity
- Sufficient memory for test data (5500+ bytes)

12.50.1.6 Usage

1. **Startup Sequence:**

- Network stack initialization
- System diagnostics enablement
- HTTP server startup
- Network connection wait (up to 5 seconds)
- Status reporting

2. **Operation:**

- Continuous operation with 1-second intervals
- TFTP server runs in background
- Web server provides management interface

3. **File Access:**

- TFTP clients can connect to the device
- Request file "test.dat" for download
- Receive the 5500-byte test data array

12.50.1.7 Development Notes

- Built using NetBurner NNDK framework
- Includes system diagnostics (recommended for development only)
- Uses standard TFTP protocol implementation
- Embedded test data for demonstration purposes

12.50.1.8 File Structure

```
main.cpp          # Main application entry point
data.cpp          # Auto-generated test data array
filetosend.txt    # Human-readable test data sample
ReadMe.txt        # Basic application description
```

12.50.1.9 Output Information

Upon startup, the application displays:

- Application name and version
- NNDK revision information
- Network status updates

12.50.1.10 Protocol Support

- **TFTP**: File transfer protocol implementation
- **HTTP**: Web server for device management
- **TCP/IP**: Full network stack support

12.51 Time Functions

12.51.1 Time Functions Application

A comprehensive embedded C++ application demonstrating system time management, time zone handling, and various time-related operations on NetBurner embedded systems.

12.51.1.1 Overview

This application provides a complete example of how to work with system time functions in an embedded environment. It includes capabilities for setting system time via NTP or manual entry, managing time zones, and displaying time information in various formats.

12.51.1.2 Features

12.51.1.2.1 Core Time Operations

- **System Time Display**: Shows current time in multiple formats (GMT, UTC, Local)
- **NTP Time Synchronization**: Automatically sets system time using Network Time Protocol
- **Manual Time Setting**: Interactive prompts for setting system time manually
- **Time Zone Management**: Comprehensive time zone selection for US and international locations
- **Boot Time Tracking**: Displays elapsed time since system boot with millisecond precision

12.51.1.2.2 Time Formats Supported

- **time_t**: Calendar time since epoch
- **struct tm**: Calendar time structure with individual components
- **GMT/UTC**: Greenwich Mean Time and Coordinated Universal Time
- **Local Time**: Time adjusted for current time zone and daylight savings

12.51.1.2.3 Interactive Menu System

The application provides a user-friendly serial interface with the following options:

1. Display system time information
2. Set system time using NTP
3. Set local time zone
4. Set system time manually
5. Test time zone functionality
6. Display time since boot with millisecond precision 0. Reboot system

12.51.1.3 File Structure

12.51.1.3.1 main.cpp

The primary application file containing:

- **displaySystemTime()**: Comprehensive time display function showing various time formats
- **setSystemTimeNTP()**: NTP-based time synchronization
- **setSystemTimeManual()**: Manual time setting with parameter input
- **setSystemTimeManualPrompt()**: Interactive time setting via user prompts
- **setSystemTimeZone()**: Time zone selection interface
- **displayTimeSinceBootInMsec()**: Boot time calculation and display
- **UserMain()**: Main application loop with menu-driven interface

12.51.1.3.2 TimezoneTest.cpp

Specialized testing module for time zone functionality:

- **testTimeZone()**: Validates time zone settings and displays daylight savings transitions
- **showHumanTimeGMT()**: GMT time formatting and display
- **showHumanTimeLocal()**: Local time formatting with timezone offset
- **getOffsetAt()**: Calculates timezone offset for specific timestamps

12.51.1.4 Key Time Functions Demonstrated

12.51.1.4.1 Standard C Time Functions

- `time()`: Current calendar time retrieval
- `gmtime_r()`: Convert `time_t` to UTC struct `tm` (thread-safe)
- `localtime_r()`: Convert `time_t` to local struct `tm` (thread-safe)
- `mktime()`: Convert struct `tm` to `time_t`
- `timegm()`: Convert GMT struct `tm` to `time_t`
- `strftime()`: Format time strings for display
- `difftime()`: Calculate time differences

12.51.1.4.2 NetBurner-Specific Functions

- `SetTimeNTPFromPool()`: NTP synchronization
- `set_time()`: System time setting
- `tzsetchar()`: Time zone configuration
- `Get_msec()`: Millisecond-precision system uptime

12.51.1.5 Time Zone Support

The application includes comprehensive time zone support:

- **US/Canada Time Zones**: Major North American time zones
- **International Time Zones**: Global time zone coverage
- **Daylight Savings Time**: Automatic DST transitions
- **POSIX Time Zone Strings**: Standard timezone specification format

12.51.1.5.1 Time Zone Testing

The timezone test functionality provides:

- Current timezone display with offset
- Start and end of year boundary analysis
- Automatic daylight savings time transition detection
- Precise timing of DST changes

12.51.1.6 Usage Requirements

12.51.1.6.1 Prerequisites

Before using the time functions:

1. **Network Connectivity**: Required for NTP synchronization
2. **System Initialization**: Proper embedded system startup
3. **Time Zone Configuration**: Must be set for accurate local time display

12.51.1.6.2 Compilation Dependencies

- NetBurner SDK headers: `init.h`, `hal.h`, `nbttime.h`, `iosys.h`, `timezones.h`
- Standard C library time functions
- Network stack for NTP functionality

12.51.1.7 Time Precision and Accuracy

12.51.1.7.1 Precision Levels

- **Second Precision:** Standard `time_t` and struct tm operations
- **Millisecond Precision:** Boot time tracking via `Get_msec()`
- **NTP Accuracy:** Network-synchronized time with sub-second accuracy

12.51.1.7.2 Boot Time Calculations

The application calculates and displays:

- Days, hours, minutes, seconds since boot
- Remaining milliseconds for complete precision
- Multiple format options for different use cases

12.51.1.8 Error Handling

The application includes robust error handling for:

- **NTP Failures:** Graceful fallback when network time is unavailable
- **Invalid Input:** Input validation for manual time entry
- **Time Zone Errors:** Validation of timezone selection
- **System Time Issues:** Error reporting for time setting operations

12.51.1.9 Example Output

```
System Time Information ***
Seconds obtained from time(): time_t = 1609459200
Seconds since program start = 1234

Time obtained from gmtime_r():
UTC Time   = Fri, 01 Jan 2021 00:00:00

Time obtained from localtime_r():
Local Time = Thu, 31 Dec 2020 16:00:00 PST [-0800 offset UTC]

Current Time Zone: PST (-0800)
Daylight Savings Time Changes:
At Time: Sun, 08 Mar 2020 01:59:59 (-0800)
Offset change is: -28800 to -25200
```

12.51.1.10 Development Notes

12.51.1.10.1 Thread Safety

- Uses thread-safe time functions (`gmtime_r`, `localtime_r`)
- Suitable for multi-threaded embedded environments
- Proper buffer management for string operations

12.51.1.10.2 Memory Management

- Static buffer allocation for time string formatting
- Minimal dynamic memory usage
- Embedded-friendly memory patterns

12.51.1.10.3 Performance Considerations

- Efficient boot time calculations using integer arithmetic
- Minimal system calls for time operations
- Optimized timezone transition detection algorithms

12.51.1.11 Integration

This application serves as a reference implementation for:

- Real-time clock (RTC) integration
- Network time synchronization systems
- Time-aware embedded applications
- Logging systems requiring accurate timestamps
- Scheduling and timing-critical applications

The modular design allows individual functions to be extracted and integrated into larger embedded systems requiring time management capabilities.

12.52 Timers

System timer examples:

- [Timer](#)
- [Interval Timer](#)
- [Stopwatch Timer](#)

12.52.1 Timer

12.52.1.1 HiRes Delay Timer Example

12.52.1.1.1 Overview

The HiRes Delay Timer Example is a test application that demonstrates and validates the precision of microsecond-level delays using hardware timers. This application provides benchmarking capabilities for the HiResDelay class, which uses hardware timers to achieve high-precision timing delays.

12.52.1.1.2 Features

- **High-Resolution Timing:** Uses hardware timers for microsecond-precision delays
- **Precision Measurement:** Accurately measures actual delay times vs. requested delays
- **Error Analysis:** Calculates and displays timing errors for performance evaluation
- **Comprehensive Testing:** Tests delays ranging from 1 microsecond to 100+ milliseconds
- **Priority Control:** Runs tests at high priority to minimize interference from other tasks

12.52.1.1.3 How It Works

The application uses the `HiResDelay` class in conjunction with a `StopWatch` to:

1. Request a specific delay duration in microseconds
2. Measure the actual time taken for the delay
3. Calculate the error between requested and actual delay times
4. Display results for analysis

12.52.1.1.3.1 Test Sequence

The application runs a comprehensive test suite with the following delay values (each tested twice):

- Ultra-short delays: 1, 2 microseconds
- Short delays: 5, 10, 15, 20, 21 microseconds
- Medium delays: 50, 100 microseconds
- Long delays: 1ms, 2ms, 10ms, 20ms
- Very long delays: 100ms, 100.001ms

12.52.1.1.4 Usage

1. **Start the Application:** The program initializes and displays "Application Started"
2. **Run Tests:** Press any key when prompted to execute the delay test sequence
3. **View Results:** Each test displays:
 - Requested delay time (microseconds)
 - Actual measured delay time
 - Error between requested and actual time

12.52.1.1.4.1 Sample Output Format

```
1:      1.05  err:   0.05
2:      2.12  err:   0.12
5:      4.98  err:  -0.02
```

12.52.1.1.5 Key Components

12.52.1.1.5.1 DelayObject Class

- Provides the `DelayUsec()` method for microsecond delays
- Utilizes hardware timers for precision timing

12.52.1.1.5.2 StopWatch Class

- High-precision timer for measuring elapsed time
- Converts timer ticks to microseconds for analysis
- **Methods:** `Start()`, `Stop()`, `Clear()`, `Convert()`

12.52.1.1.5.3 DOTest Function

Parameters:

- `DelayObject &dob`: Reference to the delay object
- `int usec`: Requested delay in microseconds

Functionality:

- Starts precision timing measurement
- Executes the requested delay
- Measures actual delay duration
- Calculates and displays timing error

12.52.1.1.6 System Requirements

- Compatible with embedded systems supporting:
 - Hardware timers
 - Real-time operating system with priority control
 - Standard I/O operations (`printf`, `getchar`)

12.52.1.1.7 Technical Notes

- **Priority Handling**: Tests run at priority level 2 to minimize task interference
- **System Diagnostics**: Enabled for development (should be disabled in production)
- **Precision**: Capable of measuring sub-microsecond timing differences
- **Error Reporting**: Displays both positive and negative timing errors

12.52.1.1.8 Build Dependencies

Required header files:

- `init.h` - System initialization
- `iosys.h` - I/O system functions
- `stopwatch.h` - High-precision timing
- `HiResDelay.h` - Hardware timer delay functionality

12.52.1.1.9 Purpose

This application serves as:

- **Validation Tool**: Verifies HiResDelay class accuracy
- **Benchmarking Utility**: Measures system timing performance
- **Development Aid**: Helps optimize timing-critical applications
- **Quality Assurance**: Ensures timing requirements are met in embedded systems

The comprehensive test suite helps developers understand the timing characteristics and limitations of their hardware platform, enabling them to make informed decisions about timing-critical code implementation.

12.52.2 Interval Timer

12.52.2.1 Interval Timer Example Application

12.52.2.1.1 Overview

The Interval Timer Example demonstrates how to use hardware timers on NetBurner platforms to schedule periodic interrupts for time-critical applications. This example showcases three different methods of utilizing interval timers for reliable timing operations.

The default for the timer constructor is to use the next available system timer, but you can also specify a specific timer as an optional parameter. Depending on the application requirements, the system may also use one or more of the available timers.

Warning

Always check the return value when creating a timer object. A value of less than 0 means a timer could not be allocated.

12.52.2.1.2 Features

The application provides three distinct timing mechanisms:

1. **Semaphore Posting** - Posts to an OS semaphore at regular intervals
2. **Flag Posting** - Posts to OS flags at specified frequencies
3. **Interrupt Callback** - Triggers custom interrupt service routines

12.52.2.1.3 Hardware Timer Availability

The number of available timers varies by NetBurner platform:

- **MODM7AE70**: Timers 0-11 (12 timers)
- **MOD54415**, **MOD54417**, **NANO54415**, **SB800EX**: Timers 1-3 (3 timers)
- **MODRT1061**: Timers 0-20 (21 timers)

12.52.2.1.4 Key Components

12.52.2.1.4.1 Timer Management

- Automatic timer allocation using next available system timer
- Manual timer specification supported via optional constructor parameter
- Error handling for timer allocation failures (return value < 0)

12.52.2.1.4.2 Synchronization Objects

- `OS_SEM timerSem` - Semaphore for timer-based synchronization
- `OS_FLAGS timerFlag` - Flag group for event signaling
- Global interrupt counter for callback demonstration

12.52.2.1.5 Application Menu Options

12.52.2.1.5.1 Option 1: Semaphore Timer

- Prompts user for desired frequency (minimum 20 Hz)
- Creates interval timer that posts to semaphore
- Demonstrates semaphore counting mechanism
- Reports total semaphore posts after completion

12.52.2.1.5.2 Option 2: Flag Timer

- User-configurable flag posting frequency (minimum 20 Hz)
- Interactive mode with manual termination
- Shows flag pending and clearing operations
- Counts and reports flag post events

12.52.2.1.5.3 Option 3: Interrupt Callback

- Configurable interrupt frequency (minimum 20 Hz)
- Demonstrates custom ISR callback implementation
- Interactive termination via keypress
- Tracks and reports interrupt occurrences

12.52.2.1.6 Important Implementation Notes

12.52.2.1.6.1 Timer Allocation

Always verify timer allocation success:

```
int timerNumber = IntervalOSSem(&timerSem, freq);
if (timerNumber < 0) {
    printf("Error %d\r\n", timerNumber);
    // Handle allocation failure
}
```

12.52.2.1.6.2 Interrupt Service Routine Guidelines

The timer callback function (`timerInterruptCallbackFunc`) operates in interrupt context:

- Keep execution time minimal
- Avoid blocking operations
- Use interrupt-safe functions only

12.52.2.1.6.3 Frequency Limitations

- Minimum frequency enforced at 20 Hz for all timer modes
- Higher frequencies possible but dependent on system capabilities
- Consider system load when selecting frequencies

12.52.2.1.7 Code Structure

12.52.2.1.7.1 Main Components

- `UserMain()` - Application entry point and main loop
- `displayMenu()` - User interface display
- `processCommand()` - Command processing and timer setup
- `timerInterruptCallbackFunc()` - ISR callback demonstration

12.52.2.1.7.2 Dependencies

- `<IntervalTimer.h>` - Timer functionality
- `<nbstring.h>` - String processing utilities
- `<init.h>` - System initialization

12.52.2.1.8 Usage Instructions

1. Compile and flash the application to your NetBurner device
2. Connect via serial terminal
3. Wait for network initialization to complete
4. Select desired timer mode (1, 2, or 3) from menu
5. Enter frequency when prompted (minimum 20 Hz)
6. Observe timer operation and results
7. For interrupt mode, press any key to stop timing

12.52.2.1.9 System Requirements

- NetBurner development environment
- Compatible NetBurner hardware platform
- Serial terminal for user interaction
- Active network connection (for system diagnostics)

12.52.2.1.10 Error Handling

The application includes comprehensive error checking:

- Timer allocation validation
- Frequency boundary enforcement
- User input validation
- System timer availability verification

12.52.2.1.11 Performance Considerations

- Timer precision depends on system clock accuracy
- High frequencies may impact overall system performance
- Multiple simultaneous timers share system resources
- ISR execution time affects maximum achievable frequencies

12.52.2.1.12 Development Notes

- System diagnostics enabled for development (consider removing for production)
- Application runs in continuous loop for repeated testing
- Memory cleanup handled automatically by RTOS
- Thread-safe operations using NetBurner RTOS primitives

12.52.3 Stopwatch Timer

12.52.3.1 Stopwatch Example Application

12.52.3.1.1 Overview

This application demonstrates the usage of a [StopWatch](#) timer object for measuring execution time of code segments. The [StopWatch](#) class provides precise timing capabilities for performance measurement and profiling.

12.52.3.1.2 Application Description

The Stopwatch Example application is a NetBurner RTOS-based program that showcases how to use the [StopWatch](#) class to measure the execution time of a simple counting loop.

12.52.3.1.2.1 Key Features

- Demonstrates [StopWatch](#) object creation and usage
- Measures execution time of a 10,000 iteration loop
- Displays timing results with high precision
- Shows timer resolution capabilities
- Includes system diagnostics and network initialization

12.52.3.1.3 Code Structure

12.52.3.1.3.1 Main Components

- **StopWatch Object:** Core timing functionality
- **Performance Test:** Simple counting loop for demonstration
- **System Initialization:** Network and diagnostic setup
- **Continuous Operation:** Maintains application state

12.52.3.1.3.2 Execution Flow

1. Initialize system and enable diagnostics
2. Wait for active network connection
3. Create [StopWatch](#) instance
4. Start timing measurement
5. Execute 10,000 iteration counting loop
6. Stop timing measurement
7. Display elapsed time and timer resolution
8. Enter continuous operation mode

12.52.3.1.4 Usage

The application automatically runs the timing demonstration upon startup. The output includes:

- Elapsed time in timer ticks
- Elapsed time converted to seconds (scientific notation)
- Timer resolution in seconds

12.52.3.1.4.1 Sample Output

```
Starting stopwatch on for loop of 10000 counts...complete
Elapsed time: [ticks], [seconds] seconds
Resolution: [resolution] seconds
```

12.52.3.1.5 Stopwatch Class Interface

Based on the documentation, the [StopWatch](#) class provides:

- **Start()**: Begin timing measurement
- **Stop()**: End timing measurement
- **GetTime()**: Retrieve elapsed time in timer ticks
- **Convert()**: Convert timer ticks to seconds
- **CountResolution()**: Get timer resolution

12.52.3.1.6 System Requirements

- NetBurner RTOS environment
- Network connectivity (application waits for active network)
- Compatible NetBurner hardware platform

12.52.3.1.7 Build Dependencies

- [init.h](#) - System initialization
- [nbrtos.h](#) - NetBurner RTOS functions
- [string.h](#) - Standard C string operations
- [stopwatch.h](#) - [StopWatch](#) class definition

12.52.3.1.8 Notes

- System diagnostics are enabled for development/debugging
- Application enters infinite loop after demonstration
- Uses `OSTimeDly(TICKS_PER_SECOND)` for timing delays
- Designed for embedded NetBurner platforms

12.53 UDP

The UDP API includes both socket based and object based (UDP Packet) implementations.
UDP Examples:

- [UDP to Serial](#)
- [UDP Notify Callback Function](#)
- [UDP C++ Packet Class](#)
- [UDP Echo](#)
- [UDP Send/Receive](#)
- [UDP Sockets](#)
- [UDP Sockets Via](#)

12.53.1 UDP to Serial

12.53.1.1 NetBurner UDP to Serial Bridge

A NetBurner embedded application that provides bidirectional communication between UDP network traffic and a serial port interface.

12.53.1.1.1 Overview

This application acts as a bridge between UDP network packets and serial communication, enabling remote devices to communicate with serial-connected equipment over a network. It's particularly useful for:

- Remote monitoring and control of serial devices
- Network-enabling legacy serial equipment
- Creating distributed serial communication systems
- Debugging and testing serial protocols over network

12.53.1.1.2 Features

- **Bidirectional Communication:** Data flows seamlessly between UDP and serial interfaces
- **Web-based Configuration:** Easy setup through browser interface
- **Configurable Parameters:** Customizable baud rates, ports, and IP addresses
- **Real-time Operation:** Low-latency data transfer with `select()` based I/O
- **Remote Console:** Web-based console access for monitoring and debugging
- **Persistent Settings:** Configuration stored in non-volatile memory

12.53.1.1.3 Architecture

The application consists of two main communication paths:

12.53.1.1.3.1 UDP to Serial (UdpReaderMain Task)

- Listens for incoming UDP packets on configured port
- Forwards received data to the serial port
- Displays packet information for debugging

12.53.1.1.3.2 Serial to UDP (UserMain Task)

- Monitors serial port for incoming data using `select()`
- Packages serial data into UDP packets
- Sends packets to configured destination IP and port

12.53.1.1.4 Configuration Parameters

Parameter	Default Value	Description
UDP Listen Port	24	Local port for receiving UDP packets
UDP Destination Port	8888	Remote port for sending serial data
UDP Destination IP	192.168.1.188	Remote IP address for outgoing packets
Serial Baud Rate	115200	Serial communication speed
Serial Port	1	Physical serial port number

12.53.1.1.4.1 Available Baud Rates

- 9600
- 19200
- 38400

- 57600
- 115200
- 234000

12.53.1.1.5 File Structure

```
main.cpp           # Main application logic and UDP/Serial handlers
nvsettings.h       # Configuration class definitions
htmlvars.h         # Web interface variable declarations
index.html         # Web configuration interface
style.css          # Web interface styling
```

12.53.1.1.6 Hardware Configuration

- **Data Serial Port:** Port 1 (configurable baud rate)
- **Debug Serial Port:** Port 0 (115200 baud, fixed).
- **Serial Parameters:** 8 data bits, 1 stop bit, no parity

Note

Debug serial port can be viewed on the console.html web page.

12.53.1.1.7 Network Configuration

The application automatically:

- Waits for [DHCP](#) network configuration
- Starts HTTP server on port 80
- Enables remote console access via web browser

12.53.1.1.8 Web Interface

Access the configuration interface by navigating to [http://\[device-ip\]/](http://[device-ip]/) in a web browser. The interface allows real-time modification of:

- UDP listen port
- Destination IP address and port
- Serial baud rate

Visit [http://\[device-ip\]/console.html](http://[device-ip]/console.html) for real-time console output and debugging information.

12.53.1.1.9 Usage Examples

12.53.1.1.9.1 Example 1: Serial Device Monitoring

Configure the bridge to receive data from a serial sensor and forward it to a network monitoring system:

- Set destination IP to your monitoring server
- Configure appropriate baud rate for your sensor
- Monitor data flow through the web console

12.53.1.1.9.2 Example 2: Remote Serial Control

Send commands to a serial device from a network application:

- Configure UDP listen port (e.g., 24)
- Send UDP packets containing serial commands to the bridge
- Commands are automatically forwarded to the serial device

12.53.1.1.10 Protocol Details

12.53.1.1.10.1 UDP Packet Structure

- **Source Port:** 8889 (fixed for outgoing packets)
- **Destination Port:** Configurable
- **Data:** Serial data plus null terminator and padding bytes
- **Padding:** 4 additional zero bytes added to prevent packet filtering

12.53.1.1.10.2 Serial Configuration

- **Data Bits:** 8
- **Stop Bits:** 1
- **Parity:** None
- **Flow Control:** None

12.53.1.1.11 Debugging and Monitoring

The application provides debugging output:

- UDP packet reception notifications with source information
- Serial data transmission confirmations
- Configuration parameter display on startup
- Real-time data flow visualization

Note

A python program is included for UDP packet receive on a host computer: ReceiveUDP.py.

All debug information is available through:

- Serial console (UART0 at 115200 baud)
- Web console interface ([http://\[device-ip\]/console.html](http://[device-ip]/console.html))

12.53.1.1.12 Building and Deployment

This application is designed for the NetBurner embedded platform and requires:

- NetBurner NNDK (NetBurner Network Development Kit)
- Compatible NetBurner hardware module
- Network connectivity (Ethernet)
- Serial interface hardware

12.53.1.1.13 Technical Notes

- Uses NetBurner RTOS for multitasking
- Implements I/O with `select()` for optimal performance
- Configuration changes require restart
- UDP packets with minimal data include padding to prevent firewall filtering
- Thread-safe operation with separate tasks for each communication direction

12.53.1.1.14 Troubleshooting

12.53.1.1.14.1 Common Issues

1. **No UDP Traffic:** Check firewall settings and network connectivity
2. **Serial Communication Problems:** Verify baud rate and wiring
3. **Configuration Not Saved:** Ensure proper form submission through web interface

12.53.1.1.14.2 Debug Steps

1. Monitor web console for real-time status
2. Verify network configuration ([DHCP](#) assignment)
3. Test serial port with external terminal program
4. Use network packet capture tools to verify UDP traffic

12.53.2 UDP Notify Callback Function

12.53.2.1 UDP Notify Example

12.53.2.1.1 Overview

This application demonstrates how to use callback functions to handle incoming UDP packets in a NetBurner NNDK (NetBurner Network Development Kit) environment. The example implements an asynchronous UDP packet receiver that automatically processes incoming data through a registered callback function.

12.53.2.1.2 Application Details

Application Name:** UDP Notify Example

Listen Port:** 2121

Protocol:** UDP (User Datagram Protocol)

12.53.2.1.3 Key Features

- **Callback-based UDP handling:** Uses a notification callback function instead of polling
- **Automatic packet processing:** Incoming UDP packets trigger the callback function automatically
- **Network stack initialization:** Includes proper [DHCP](#) client setup and network interface management
- **Packet validation:** Validates received packets before processing
- **Diagnostic support:** Includes system diagnostics for debugging

12.53.2.1.4 How It Works

12.53.2.1.4.1 Network Initialization

1. Initializes the network stack
2. Enables system diagnostics
3. Waits for active network connection (5 second timeout)
4. Waits for [DHCP](#) address assignment to complete
5. Displays the listening IP address and port

12.53.2.1.4.2 UDP Packet Handling

1. Creates a FIFO (First-In-First-Out) buffer for incoming packets
2. Registers the UDP port with a callback function using `RegisterUDPFifoWithNotify()`
3. When packets arrive, the callback function `UdpListenCallback()` is automatically invoked
4. The callback processes the packet and displays information about the sender and data

12.53.2.1.4.3 Callback Function Behavior

The `UdpListenCallback()` function:

- Creates a `UDPPacket` object from the FIFO
- Validates the received packet
- Extracts packet size and source IP address
- Displays the packet data using `ShowData()`
- Handles invalid packets gracefully

12.53.2.1.5 Technical Components

12.53.2.1.5.1 Key Functions

- `RegisterUDPFifoWithNotify()`: Registers UDP port with callback notification
- `UDPPacket`: Class for handling UDP packet data
- `OS_FIFO`: Operating system FIFO for packet queuing
- `WaitForActiveNetwork()`: Waits for network connectivity
- `GetInterfaceBlock()`: Retrieves network interface information

12.53.2.1.5.2 Callback Function Signature

```
void UdpListenCallback(OS_FIFO *pfifo, uint16_t port)
```

The callback function must match the typedef:

```
typedef void (udp_data_notify)(OS_FIFO *pfifo, uint16_t port);
```

12.53.2.1.6 Usage

1. **Compile and deploy** the application to a NetBurner device
2. **Connect the device** to your network (`DHCP` will assign an IP address)
3. **Monitor the console** output to see the assigned IP address
4. **Send UDP packets** to the displayed IP address on port 2121
5. **View the output** as the callback function processes and displays received packets

12.53.2.1.7 Example Output

```
Application: UDP Notify Example
```

```
NNDK Revision: [version]
```

```
Listening for UDP packets on 192.168.1.100: 2121
```

```
UdpListenCallback()
```

```
Received a UDP packet with 15 bytes from : 192.168.1.50
```

```
[Packet data display]
```

12.53.2.1.8 Differences from Standard UDP Handling

This example uses **callback-based notification** rather than polling:

- **Standard approach:** Use `RegisterUDPFifo()` and manually check for data
- **Notification approach:** Use `RegisterUDPFifoWithNotify()` with automatic callback execution

12.53.2.1.9 Requirements

- NetBurner NNDK development environment
- NetBurner-compatible hardware device
- Network connection with **DHCP** server
- UDP client application for testing (can send packets to port 2121)

12.53.2.1.10 Notes

- The application runs in an infinite loop, continuously listening for UDP packets
- System diagnostics are enabled for development/debugging purposes
- Remove diagnostic features for production deployment
- The callback function executes in the context of the network stack
- Packet timeout can be configured by replacing the 0 parameter in `UDPPacket` constructor

12.53.3 UDP C++ Packet Class

This application will send/receive UDP packets with another host on a network, such as a PC. Use the MTTTY serial port program to access the menu and prompts to specify the destination IP address and port number. NetBurner supplies an API for handling UDP as a C++ Class using `UDPPacket`, or you can use a UDP sockets API (see UDP socket example).

For an external UDP host you can use the NetBurner Java example, or the NetBurner UDP terminal program.

12.53.4 UDP Echo

12.53.4.1 UDP C++ Packet Class Example

12.53.4.1.1 Overview

This application demonstrates how to send and receive UDP packets using NetBurner's C++ `UDPPacket` class. It provides a simple interactive interface for UDP communication between a NetBurner device and another host on the network.

12.53.4.1.2 Description

This example program will receive a UDP packet from another device or host computer and send a response. To run the example, connect a serial port from your PC to the debug serial port on your NetBurner device and run a terminal program such as MTTTY. On the PC, run the NetBurner UDP Terminal (be sure to set the IP address and port numbers to match). Send data from the NetBurner UDP Terminal, and observe that the packet is received in MTTTY. Then observe the response from the device in the NetBurner UDP Terminal.

The application creates a bidirectional UDP communication system that:

- Accepts user input for destination IP address and port configuration
- Sends UDP packets containing user-entered text data
- Receives and displays incoming UDP packets from remote hosts
- Uses NetBurner's `UDPPacket` C++ class for simplified UDP handling

12.53.4.1.3 Features

- **Interactive Configuration:** Prompts user to specify destination IP address and port number via serial console
- **Dual Operation:** Simultaneously sends and receives UDP packets on the same port
- **Real-time Display:** Shows received packet data with source information
- **Multi-tasking:** Uses separate tasks for sending and receiving operations
- **Network Ready:** Waits for active network connection ([DHCP](#)) before starting

12.53.4.1.4 Architecture

12.53.4.1.4.1 Tasks

1. UserMain Task:

- Initializes network stack
- Handles user input and configuration
- Sends outgoing UDP packets
- Creates the UDP reader task

2. UdpReaderTask:

- Monitors specified port for incoming packets
- Processes and displays received data
- Uses FIFO queue for packet management

12.53.4.1.4.2 Key Components

- **UDPPacket Class:** NetBurner's C++ wrapper for UDP operations
- **OS_FIFO:** Queue system for managing incoming packets
- **RegisterUDPFifo():** Registers port for UDP packet reception
- **Serial Interface:** MTTTY terminal for user interaction

12.53.4.1.5 Usage

1. **Setup:** Connect to the device using MTTTY serial port program
2. **Network:** Ensure device has active network connection ([DHCP](#))
3. **Configuration:**
 - Enter destination IP address when prompted
 - Enter port number for both sending and receiving
4. **Operation:**
 - Type messages and press Enter to send UDP packets
 - Incoming packets are automatically displayed with source information

12.53.4.1.6 Network Requirements

- Active Ethernet connection
- [DHCP](#) server for automatic IP configuration (or manual IP setup)
- Network accessibility to destination host
- Open UDP port for bidirectional communication

12.53.4.1.7 Compatible Hosts

The application can communicate with:

- NetBurner Java UDP examples
- NetBurner UDP terminal program
- Any standard UDP client/server application
- Custom UDP applications on PC or other devices

12.53.4.1.8 Technical Details

- **API:** Uses NetBurner's [UDPPacket](#) C++ class (alternative to UDP sockets API)
- **Port Configuration:** Same port used for both transmission and reception
- **Data Format:** Text-based with null termination
- **Task Priority:** Reader task runs at higher priority than main task
- **Timeout Support:** Configurable timeout for packet reception (currently set to blocking)

12.53.4.1.9 Development Notes

- System diagnostics are enabled (consider removing for production)
- Application waits up to 5 seconds for network activation
- Uses standard NetBurner NNDK (NetBurner Network Development Kit)
- Includes proper error handling and packet validation

12.53.5 UDP Send/Receive

12.53.5.1 UDP Send/Receive Example

A NetBurner embedded application that demonstrates bidirectional UDP communication between a NetBurner device and a host computer or another networked device.

12.53.5.1.1 Overview

This application creates a UDP server that can simultaneously send and receive UDP packets on the same port. It features a multi-threaded design with one thread dedicated to receiving packets and displaying them via the debug serial port, while the main thread handles user input and sends UDP packets to a specified destination.

12.53.5.1.2 Features

- **Bidirectional UDP Communication:** Send and receive UDP packets on the same port
- **Multi-threaded Design:** Separate receive thread for non-blocking packet handling
- **Interactive Configuration:** Runtime configuration of port number and destination IP
- **Debug Output:** Received packets displayed with hex dump formatting
- **DHCP Support:** Automatic network configuration with [DHCP](#)

12.53.5.1.3 Hardware Requirements

- NetBurner embedded device with network capability
- Serial connection to PC for debugging and user interaction
- Network connection (Ethernet)

12.53.5.1.4 Software Requirements

- NetBurner NNDK (NetBurner Network Development Kit)
- Terminal program (such as MTTTY) for serial communication
- UDP client application on PC (such as NetBurner UDP Terminal)

12.53.5.1.5 How It Works

12.53.5.1.5.1 Application Flow

1. **Initialization:** Network stack initializes and waits for **DHCP** address assignment
2. **Configuration:** User prompted to enter:
 - UDP port number (used for both sending and receiving)
 - Destination IP address for outgoing packets
3. **Task Creation:** Separate receive task created with higher priority than main task
4. **Operation:**
 - Main thread waits for user input and sends UDP packets
 - Receive thread continuously monitors for incoming packets

12.53.5.1.5.2 Threading Architecture

- **Main Thread:** Handles user input from serial terminal and sends UDP packets
- **Receive Thread:** Listens for incoming UDP packets using OS_FIFO mechanism
- **Priority:** Receive thread runs at higher priority than main thread

12.53.5.1.6 Usage

12.53.5.1.6.1 Setup

1. Connect NetBurner device to network
2. Connect serial cable between PC and NetBurner debug port
3. Open terminal program (MTTTY) and connect to serial port
4. Compile and flash the application to the NetBurner device

12.53.5.1.6.2 Operation

1. **Start Application:** Reset or power on the NetBurner device
2. **Wait for Network:** Application waits up to 5 seconds for **DHCP** address
3. **Configure Port:** Enter the UDP port number when prompted
4. **Configure Destination:** Enter the destination IP address
5. **Send Data:** Type messages and press Enter to send UDP packets
6. **Receive Data:** Incoming packets automatically displayed with source IP and hex dump

12.53.5.1.6.3 Example Session

```

Application: UDP Send/Receive Example
NNDK Revision: [Version]
Enter the UDP port number (will be used for send & receive): 1234
Enter the destination IP Address: 192.168.1.100
Listening/Sending on UDP Port 1234, Sending to IP address: 192.168.1.100
Enter data and hit return to send.
Hello World
Sent "Hello World" to 192.168.1.100:1234

Received UDP packet with 12 bytes from: 192.168.1.100
48 65 6C 6C 6F 20 57 6F 72 6C 64 00   Hello World.

```

12.53.5.1.7 Key Components

12.53.5.1.7.1 UDP Packet Handling

- Uses NetBurner UDP C++ class for packet management
- OS_FIFO mechanism for packet queuing
- Automatic packet validation and parsing

12.53.5.1.7.2 Network Functions

- `RegisterUDPFifo()`: Associates FIFO with UDP port for packet reception
- `UDPPacket`: Class for constructing and sending UDP packets
- `AsciiToIp()`: Converts string IP address to IPADDR format

12.53.5.1.7.3 System Functions

- `OSTaskCreatewName()`: Creates named threads with specified stack and priority
- `WaitForActiveNetwork()`: Blocks until network interface is ready
- `ShowData()`: Utility function for hex dump display

12.53.5.1.8 Configuration Options

- **Port Number**: Any valid UDP port (1-65535)
- **Destination IP**: Any reachable IP address on the network
- **Timeout**: Receive timeout (currently set to wait forever)
- **Stack Size**: Configurable via USER_TASK_STK_SIZE

12.53.5.1.9 Testing

Use the NetBurner UDP Terminal application on your PC:

1. Set the IP address to match your NetBurner device
2. Set the port number to match your configuration
3. Send messages from both PC and NetBurner device
4. Observe bidirectional communication

12.53.5.1.10 Notes

- Application uses the same port for both sending and receiving
- Received packets include source IP address identification
- System diagnostics are enabled (consider removing for production)
- **DHCP** timeout is set to 5 seconds
- Input buffer limited to 80 characters

12.53.6 UDP Sockets

12.53.6.1 UDP Sockets Example Application

12.53.6.1.1 Overview

This NetBurner application demonstrates bidirectional UDP communication using the UDP Sockets API. The application can send and receive UDP packets with another host on a network, making it useful for network communication testing and development.

12.53.6.1.2 Features

- **Bidirectional Communication:** Send and receive UDP packets simultaneously
- **Interactive Configuration:** Runtime configuration of destination IP and port
- **Multi-threaded:** Separate task for receiving packets to ensure real-time processing
- **Serial Interface:** Uses MTTTY serial port program for user interaction
- **Network Stack Integration:** Built on NetBurner's networking framework

12.53.6.1.3 Architecture

The application consists of two main components:

12.53.6.1.3.1 Main Task (UserMain)

- Initializes the network stack and waits for [DHCP](#)
- Prompts user for destination IP address and port number
- Creates a UDP socket for sending packets
- Handles user input and sends UDP packets
- Runs at standard priority

12.53.6.1.3.2 Receive Task (UdpReceiveTask)

- Monitors specified port for incoming UDP packets
- Creates a separate UDP socket for receiving
- Processes incoming packets and displays their contents
- Runs at higher priority than main task for responsive packet handling

12.53.6.1.4 Usage

12.53.6.1.4.1 Setup

1. Connect to the device using MTTTY serial port program
2. Ensure the device is connected to a network with [DHCP](#)

12.53.6.1.4.2 Runtime Configuration

1. When prompted, enter the destination IP address of the UDP server
2. Enter the port number (used for both sending and receiving)
3. The application will create sockets and start the receive task

12.53.6.1.4.3 Operation

- Type messages and press Enter to send UDP packets
- Incoming packets are automatically displayed with source information
- The application runs continuously until reset

12.53.6.1.4.4 Example Session

Application: UDP Sockets Example
NNDK Revision: [version]

Enter the UDP Server destination IP address: 192.168.1.100
Enter the source/destination port number: 12345

Sending/Receiving with host 192.168.1.100: 12345
UdpReceiveTask monitoring port 12345
Listening for UDP packets on port 12345

Enter data and hit enter to send.
Hello World

Sending "Hello World" using UDP to 192.168.1.100 : 12345

Received a UDP packet with 11 bytes from : 192.168.1.100
Response message

12.53.6.1.5 Technical Details

12.53.6.1.5.1 Dependencies

- NetBurner NNDK (NetBurner Network Development Kit)
- Standard C libraries: `stdlib.h`, `string.h`, `stdio.h`
- NetBurner specific: `init.h`, `system.h`, `udp.h`, `utils.h`

12.53.6.1.5.2 Socket Management

- **Transmit Socket:** Created using `CreateTxUdpSocket()`
- **Receive Socket:** Created using `CreateRxUdpSocket()`
- Uses standard BSD socket functions: `sendto()` and `recvfrom()`

12.53.6.1.5.3 Task Management

- Main task priority: `MAIN_PRIO`
- Receive task priority: `MAIN_PRIO - 1` (higher priority)
- Stack allocation: `USER_TASK_STK_SIZE` for receive task

12.53.6.1.5.4 Buffer Limitations

- Maximum message size: 80 characters
- Input buffer: 80 bytes for user input
- Receive buffer: 80 bytes for incoming packets

12.53.6.1.6 Testing with External Applications

The application can be tested with:

- **NetBurner Java Example:** Companion Java application for UDP testing
- **NetBurner UDP Terminal Program:** Specialized terminal for UDP communication
- **Standard UDP Tools:** Any application capable of sending/receiving UDP packets

12.53.6.1.7 Alternative API

Note: NetBurner also provides a C++ Class-based API using [UDPPacket](#) for object-oriented UDP handling.

12.53.6.1.8 Error Handling

The application includes error checking for:

- UDP socket creation failures
- Network initialization issues
- [DHCP](#) timeout scenarios

Failed socket creation will cause the application to enter an infinite loop, requiring a system reset.

12.53.6.1.9 Development Notes

- System diagnostics are enabled for debugging (should be removed for production)
- 5-second timeout for network initialization
- Null-termination is manually added to received packets
- The application uses NetBurner's proprietary IP address formatting ([I](#))

12.53.7 UDP Sockets Via

12.53.7.1 UDP Sockets Via Example

12.53.7.1.1 Overview

This NetBurner application demonstrates UDP socket communication using the NetBurner Development Kit (NNDK). The application creates multiple UDP sockets across different network interfaces and allows bidirectional communication with other hosts on the network.

12.53.7.1.2 Features

- **Multiple Socket Types:** Creates receive-only (RX), transmit-only (TX), and bidirectional (RX/TX) UDP sockets
- **Multi-Interface Support:** Automatically creates sockets for all available network interfaces
- **Port Management:** Uses sequential port numbering starting from port 5000
- **Select-based Receiving:** Demonstrates non-blocking UDP packet reception using the [select\(\)](#) system call
- **Interactive Menu:** Provides a simple command interface via serial terminal

12.53.7.1.3 Application Functionality

12.53.7.1.3.1 Socket Creation

The application creates three types of UDP sockets for each interface:

1. **RX Socket:** Receive-only socket for incoming UDP packets
2. **RX/TX Socket:** Bidirectional socket for both sending and receiving
3. **TX Socket:** Transmit-only socket for outgoing UDP packets

12.53.7.1.3.2 Interface Detection

The program automatically detects all available network interfaces and creates sockets for:

- All interfaces (general sockets)
- Specific interface numbers
- Specific IP addresses

12.53.7.1.3.3 Port Assignment

Starting from port 5000, the application assigns ports sequentially:

- Port N: RX socket
- Port N+1: RX/TX socket
- Port N+2: TX socket

12.53.7.1.4 Usage

12.53.7.1.4.1 Setup

1. Compile and flash the application to your NetBurner device
2. Connect to the device using MTTTY serial port program
3. Wait for the network to initialize and obtain a [DHCP](#) address

12.53.7.1.4.2 Operation

1. **Enter Destination IP:** When prompted, enter the IP address of the UDP host you want to communicate with
2. **View Socket Information:** The application displays a table showing:

```

RX  | RXTX| TX  | On
5000| 5001| 5002|All
5003| 5004| 5005|ifn1 on 192.168.1.100
5006| 5007| 5008|IP:192.168.1.100
```
3. **Send Test Packets:** Press 'T' or 't' to transmit test messages to all TX-capable sockets
4. **Receive Packets:** The application automatically displays received UDP packets with source information

12.53.7.1.4.3 Commands

- **T or t:** Transmit test packets to all transmit-capable sockets

12.53.7.1.5 Code Structure

12.53.7.1.5.1 Main Components

- `AddSocketsIfn()`: Creates sockets for a specific interface number
- `AddSocketsIP()`: Creates sockets for a specific IP address
- `TransmitAll()`: Sends test messages through all transmit sockets
- `UserMain()`: Main application loop handling initialization and packet processing

12.53.7.1.5.2 Key Variables

- `rx_fd[]`: Array of receive-capable socket file descriptors
- `tx_fd[]`: Array of transmit-capable socket file descriptors
- `using_port`: Current port number for socket creation
- `nrxfd, ntxfd`: Counters for RX and TX socket arrays

12.53.7.1.6 Testing

12.53.7.1.6.1 External UDP Hosts

You can test the application using:

- NetBurner Java UDP example application
- NetBurner UDP terminal program
- Any standard UDP client/server application

12.53.7.1.6.2 Packet Reception

When UDP packets are received, the application displays:

- Number of bytes received
- Source IP address
- Local port number
- Remote port number
- Hexadecimal dump of packet data

12.53.7.1.7 API Information

This example demonstrates the NetBurner UDP Sockets API functions:

- `CreateRxUdpSocket()`
- `CreateTxUdpSocket()`
- `CreateRxTxUdpSocket()`
- `CreateRxUdpSocketVia()`
- `CreateTxUdpSocketVia()`
- `CreateRxTxUdpSocketVia()`

For C++ applications, NetBurner also provides a `UDPPacket` class API for object-oriented UDP handling.

12.53.7.1.8 Notes

- The application enables system diagnostics for debugging (should be disabled in production)
- All sockets use UDP protocol for lightweight, connectionless communication
- The `select()` mechanism allows efficient handling of multiple socket file descriptors
- Socket creation spans all detected network interfaces automatically

12.54 VLAN

12.54.1 VLAN Example Application

12.54.1.1 Overview

This NetBurner application demonstrates the creation and management of multiple VLAN (Virtual Local Area Network) interfaces on a single Ethernet port. The application creates three different VLAN interfaces with different configurations and provides both web-based and serial console interfaces for monitoring network status.

To build this example MULTIHOME must be enabled in `predef.h`. Rather than change the file in `\nburn\nbrtos\include`, use the override feature and add `predef.h` to your project.

- Ethernet 0, [DHCP](#), VLAN ID 1
- Ethernet 0, [DHCP](#), VLAN ID 2
- Ethernet 0, Static IP, VLAN ID 10

The serial port interface provides an interactive menu to display interface and VLAN information, as well as other system parameters.

12.54.1.2 Features

- **Multiple VLAN Interface Creation:** Creates 3 VLAN interfaces on Ethernet 0
- **Mixed Configuration Support:** Supports both [DHCP](#) and static IP configurations
- **Interactive Serial Menu:** Command-line interface for network diagnostics
- **Web Interface:** HTTP server displaying network interface information
- **IPv4 and IPv6 Support:** Comprehensive IP address management and display
- **Real-time Network Monitoring:** Link status, [ARP](#) tables, and interface statistics

12.54.1.3 VLAN Configuration

The application automatically creates the following VLAN interfaces:

1. **VLAN ID 1:** Ethernet 0 with [DHCP](#) configuration
2. **VLAN ID 2:** Ethernet 0 with [DHCP](#) configuration
3. **VLAN ID 10:** Ethernet 0 with static IP (198.18.1.20/16)

12.54.1.4 Prerequisites

- **MULTIHOME Support:** Must be enabled in `predef.h`
- **NetBurner Platform:** Compatible NetBurner hardware platform
- **Network Infrastructure:** VLAN-capable switch or router

12.54.1.4.1 Enabling MULTIHOME

To enable MULTIHOME support:

1. Create a local `predef.h` file in your project directory
2. Add `#define MULTIHOME` to enable multiple interface support
3. Include any other required preprocessor definitions

This approach uses the NetBurner override feature instead of modifying the system files directly.

12.54.1.5 Serial Console Commands

The application provides an interactive serial console with the following commands:

Command	Description
A	Show ARP table
C	Show network counters
E	Dump Ethernet information
I	Show all network interfaces and IP addresses
W	Display system tick count and uptime
?	Show help menu
1-9 <vlan_id>	Set VLAN tag on interface (1-9)

12.54.1.5.1 Example Usage

```

I          # Show all interfaces
A          # Display ARP table
1 100     # Set interface 1 to VLAN 100
W          # Show system uptime

```

12.54.1.6 Network Interface Information

The application displays comprehensive network information including:

12.54.1.6.1 IPv4 Information

- IP Address
- Subnet Mask
- DNS Servers (Primary and Secondary)
- Gateway Address
- Auto-IP Address

12.54.1.6.2 IPv6 Information (if enabled)

- Link-local addresses
- Router-assigned addresses
- DHCP-assigned addresses
- Static addresses
- DNS servers with source information
- [DHCP](#) lease timing information

12.54.1.6.3 Physical Interface Details

- MAC Address
- Link Status (UP/DOWN)
- Link Speed (MB)
- Duplex Mode (Full/Half)

12.54.1.7 Web Interface

The application includes an HTTP server that provides:

- **Network Interface Overview:** All active interfaces and their configurations
- **Clickable IP Links:** Direct links to access the device via different IP addresses
- **Real-time Status:** Current network configuration and lease information
- **IPv6 Support:** Complete IPv6 address information with source tracking

Access the web interface by navigating to any of the device's IP addresses in a web browser.

12.54.1.8 File Structure

```
project/
  main.cpp           # Main application logic and VLAN setup
  ip_util.cpp        # IP address utility functions
  ip_util.h          # Header file for IP utilities
  index.html         # Web interface homepage
  predef.h           # Project-specific preprocessor definitions
```

12.54.1.9 Key Functions

12.54.1.9.1 VLAN Management

- `AddVlanInterface()`: Creates new VLAN interface
- `SetVlan()`: Configures VLAN tag on existing interface

12.54.1.9.2 Network Information Display

- `showIpAddressesSerial()`: Displays interface info on serial console
- `showIpAddressesWeb()`: Generates web page with interface information
- `showLinkStatus()`: Shows physical link status

12.54.1.9.3 Utility Functions

- `getTimeStringFromSeconds()`: Converts seconds to HH:MM:SS format
- `getLeaseTimeInfo()`: Formats DHCP lease timing information
- `SourceName()`: Returns human-readable IPv6 address source names

12.54.1.10 Building and Deployment

1. **Setup Project:** Create new NetBurner project
2. **Enable MULTIHOMES:** Add `predef.h` with `#define MULTIHOMES`
3. **Add Source Files:** Include all `.cpp` and `.h` files
4. **Build:** Compile using NetBurner development tools
5. **Deploy:** Flash to NetBurner hardware

12.54.1.11 Network Setup Requirements

- **VLAN-Capable Switch:** Network infrastructure must support VLAN tagging
- **Proper VLAN Configuration:** Switch ports must be configured for appropriate VLAN IDs
- **IP Address Management:** Ensure IP ranges don't conflict across VLANs

12.54.1.12 Troubleshooting

12.54.1.12.1 Common Issues

1. **MULTIHOME Not Enabled:** Verify `predef.h` contains `#define MULTIHOME`
2. **Link Status Down:** Check physical connections and cable
3. **DHCP Not Working:** Verify **DHCP** server availability on VLANs
4. **Web Interface Inaccessible:** Check IP address configuration and routing

12.54.1.12.2 Debug Commands

Use the serial console commands to diagnose issues:

- `E` - Check Ethernet hardware status
- `I` - Verify interface configuration
- `C` - Review network counters for errors
- `A` - Check **ARP** table for connectivity

12.54.1.13 Platform Compatibility

This application is designed for NetBurner embedded platforms with Ethernet capability. It supports both single and dual Ethernet configurations (commented code shows dual-port setup for platforms like the 54417).

12.54.1.14 IPv6 Support

IPv6 functionality is conditionally compiled based on the `IPV6` preprocessor definition. When enabled, the application provides:

- Multiple IPv6 address assignment methods
- **DHCP** v6 lease management
- Router advertisement processing
- Comprehensive IPv6 status reporting

12.55 Web Server

Web Server Examples:

- [Ajax Graph](#)
- [Bootstrap Hello World](#)
- [HTML File Post](#)
- [HTML File Post Task Handoff](#)
- [Flash Form](#)
- [GIF Canvas](#)
- [HTML Application File Post](#)
- [HTML Cookie](#)
- [HTML File Post Task Handoff](#)
- [HTML Form Post](#)

- [HTML Form Post 2.X Compatible](#)
- [HTML Password](#)
- [HtmlPostDateTime](#)
- [HTML Server GET Request](#)
- [HTMLVariables](#)
- [Ping From Web](#)
- [Raw Form Post 2pX](#)
- [Remote Web Console for Serial/stdout](#)
- [Serial Webserver](#)
- [Simple HTML](#)
- [TicTacToe](#)

12.55.1 Ajax Graph

12.55.1.1 NetBurner AJAX Graph Application

12.55.1.1.1 Overview

This application demonstrates how to create a dynamic web-based graph using a NetBurner embedded device. The system continuously logs sensor data from multiple sources and serves this data to a web interface through AJAX calls, allowing real-time visualization of sensor readings.

12.55.1.1.2 Features

- **Real-time Data Logging:** Continuously logs data from two simulated sensors with different sampling periods
- **Web-based Visualization:** Serves sensor data through HTTP for dynamic graph generation
- **AJAX Integration:** Provides JSON and CSV data formats for web consumption
- **Ring Buffer Implementation:** Efficient circular buffer for data storage with configurable size
- **Multiple Data Export Formats:** Supports both JSON (for AJAX) and CSV (for data export)

12.55.1.1.3 System Architecture

12.55.1.1.3.1 Core Components

1. **Data Generator** (`datagenerator.cpp/h`)
 - Simulates two sensors with different characteristics
 - Sensor 1: Period of 13 ticks, initial value 44.23
 - Sensor 2: Period of 11 ticks, initial value -10.0
 - Generates realistic sensor readings using sine wave variations with random noise
2. **Data Logger** (`datalog.cpp/h`)
 - Implements a thread-safe ring buffer for efficient data storage
 - Supports up to 1000 data points by default
 - Provides serialization methods for different output formats
 - Automatic overwriting of old data when buffer is full
3. **Web Server Interface** (`main.cpp`)
 - HTTP server integration for serving web pages and data
 - AJAX endpoints for real-time data retrieval
 - Support for both JSON and CSV data formats

12.55.1.1.3.2 Data Structure

Each logged data point contains:

- `sensorID`: Identifier for the sensor (1 or 2)
- `timeStamp`: System tick when the reading was taken
- `value`: The actual sensor reading (floating-point)

12.55.1.1.4 Web Interface Integration

The application provides several web endpoints:

12.55.1.1.4.1 AJAX Endpoints

- **Data Retrieval:** `getSensorData()` function serves sensor data in JSON format

```
{
  "entries": [
    {"id": 1, "timeStamp": 12345, "value": 44.2567},
    {"id": 2, "timeStamp": 12346, "value": -9.8734},
    ...
  ]
}
```
- **Time Synchronization:** `getHTMLTicks()` provides current system tick for time alignment

12.55.1.1.4.2 HTML Integration Points

The web interface uses the following integration methods:

- `<!--FUNCTIONCALL getHTMLTicks -->` - Embeds current system time
- `<!--CPPCALL getSensorData() -->` - Retrieves sensor data via AJAX
- JavaScript in `index.html` handles the dynamic graph generation

12.55.1.1.5 Configuration

12.55.1.1.5.1 Sensor Settings

```
#define LOG_SIZE 1000           // Maximum number of data points stored
#define SENSOR_1_PERIOD 13      // Sensor 1 sampling period (ticks)
#define SENSOR_2_PERIOD 11      // Sensor 2 sampling period (ticks)
#define SENSOR_1_INIT 44.23     // Sensor 1 initial value
#define SENSOR_2_INIT -10.0     // Sensor 2 initial value
```

12.55.1.1.5.2 System Requirements

- NetBurner embedded platform with NNDK
- Network connectivity for web server functionality
- Sufficient RAM for data logging buffer (configurable)

12.55.1.1.6 Application Flow

1. Initialization

- Network stack initialization
- HTTP server startup on port 80
- **DHCP** address acquisition
- Data log seeding with initial random data

2. Runtime Operation

- Continuous sensor data generation at different periods

- Real-time logging to ring buffer
- Web server handles AJAX requests for data retrieval
- Optional console output for debugging (press any key)

3. Data Management

- Automatic buffer management with oldest data overwritten
- Efficient serialization for web delivery
- Support for both real-time streaming and historical data export

12.55.1.1.7 Usage

12.55.1.1.7.1 Deployment

1. Compile and flash the application to a NetBurner device
2. Ensure network connectivity ([DHCP](#) or static IP)
3. Access the web interface through the device's IP address
4. The graph will automatically update with real-time sensor data

12.55.1.1.7.2 Development

The modular design allows for easy customization:

- **Adding Sensors:** Modify the data generator to support additional sensors
- **Changing Sampling Rates:** Adjust period constants for different update frequencies
- **Buffer Size:** Modify `LOG_SIZE` for different memory/history requirements
- **Data Formats:** Add new serializer functions for different export formats

12.55.1.1.8 Technical Notes

- The ring buffer implementation ensures $O(1)$ insertion and efficient memory usage
- Sensor data generation uses mathematical functions to create realistic, varying readings
- The web server integration is designed to handle multiple concurrent AJAX requests
- All timing is based on the NetBurner system tick counter for precision

12.55.1.1.9 File Structure

```
main.cpp           # Main application and web server endpoints
datalog.cpp/h      # Ring buffer implementation for data storage
datagenerator.cpp/h # Sensor simulation and data generation
readme.txt         # Original project documentation
```

12.55.2 Bootstrap Hello World

12.55.2.1 NetBurner Bootstrap HelloWorld Example

12.55.2.1.1 Overview

The Bootstrap HelloWorld Example demonstrates how to utilize Twitter Bootstrap (<http://twitter.github.io/bootstrap/>) on a NetBurner device. This example loads a simple "Hello World" web page on to the device, along with the Twitter Bootstrap framework (version 4.0).

12.55.2.1.2 Application Description

The main application (`main.cpp`) creates a minimal web server that:

- Initializes the NetBurner network stack
- Enables system diagnostics for debugging
- Starts an HTTP web server on the default port (80)
- Waits for **DHCP** network configuration
- Displays application information and NNDK revision via serial output
- Runs continuously with a 1-second delay loop

12.55.2.1.3 Key Features

12.55.2.1.3.1 Embedded Application (`main.cpp`)

- **Network Stack Initialization:** Automatically configures network connectivity
- **Web Server:** Built-in HTTP server for serving web content
- **DHCP Support:** Automatic IP address assignment
- **System Diagnostics:** Debug information output
- **Real-time Operation:** Uses NBRTOS for task scheduling

12.55.2.1.3.2 Web Interface (`index.html`)

- **Bootstrap Framework:** Modern, responsive web design
- **Image Carousel:** Interactive slideshow showcasing NetBurner products
- **Responsive Design:** Adapts to different screen sizes
- **Professional Styling:** Clean, marketing-focused layout

12.55.2.1.4 Hardware Compatibility

Based on the web interface images, this application supports NetBurner development boards including:

- NANO54415 series
- Serial2Ethernet modules
- Other NetBurner embedded modules

12.55.2.1.5 Development Environment

- **IDE:** NetBurner's customized Eclipse-based development environment
- **Platform Support:** Both Mac and PC development
- **Build System:** One-click compile, link, and load process
- **Web Assets:** HTML, CSS, and JavaScript files served directly from the embedded device

12.55.2.1.6 File Structure

```
project/
  main.cpp           # Main application source code
  index.html         # Web interface homepage
  assets/            # Web assets (referenced in HTML)
    css/             # Bootstrap CSS files
    js/              # JavaScript libraries
    img/             # Product images and screenshots
```

12.55.2.1.7 Getting Started

1. **Development Setup:** Install NetBurner's Eclipse-based IDE
2. **Hardware Connection:** Connect your NetBurner module to the network
3. **Project Build:** Use the IDE's one-click build process
4. **Deployment:** Load the application onto your NetBurner device
5. **Access:** Navigate to the device's IP address in a web browser

12.55.2.1.8 Application Flow

1. Device boots and initializes the network stack
2. HTTP server starts on port 80
3. Device acquires IP address via [DHCP](#)
4. Application information is displayed via serial output
5. Web interface becomes accessible at the device's IP address
6. Main application loop continues indefinitely

12.55.2.1.9 Web Interface Features

- **Welcome Message:** "Hello World. It's that easy."
- **Product Showcase:** Carousel displaying NetBurner development tools
- **Development Information:** Details about the Eclipse-based IDE
- **Cross-platform Support:** Information about Mac and PC compatibility

12.55.2.1.10 Technical Details

- **Operating System:** NetBurner RTOS (NBRTOS)
- **Network Protocol:** HTTP/TCP
- **Frontend Framework:** Bootstrap 4.x
- **JavaScript Libraries:** jQuery 3.3.1, Bootstrap Bundle
- **Styling:** Bootstrap grid system and components

12.55.2.1.11 Use Cases

This example serves as a foundation for:

- IoT device web interfaces
- Embedded system monitoring dashboards
- Remote device configuration portals

12.55.2.1.12 Next Steps

This basic example can be extended with:

- REST API endpoints
- Real-time data visualization
- Device configuration interfaces
- Sensor data collection and display
- Remote control capabilities

12.55.3 HTML File Post

12.55.3.1 File Post with Multipart Form

12.55.3.1.1 Overview

This NetBurner application provides a web-based file upload interface that allows users to upload files to the NetBurner device via HTTP POST requests. The uploaded files are processed and displayed back to the user in a web browser, with options for both text and binary data visualization.

12.55.3.1.2 Features

- **Web-based file upload:** Simple HTML form interface for selecting and uploading files
- **Multipart form data support:** Handles file uploads using the standard multipart/form-data encoding
- **File processing:** Reads and processes uploaded files up to 10KB in size
- **Dual display modes:**
 - Text mode: Shows readable characters with HTML entity encoding
 - Binary mode: Shows both hexadecimal and ASCII representation of file data
- **Real-time feedback:** Console output showing POST processing events

12.55.3.1.3 Architecture

12.55.3.1.3.1 Core Components

1. **main.cpp:** Application initialization and network setup
2. **formcode.cpp:** HTTP POST processing and file handling logic
3. **index.html:** Main web page with file upload form
4. **filepost.html:** Target page for form submission (handled by callback)

12.55.3.1.3.2 Key Functions

- `ProcessPostFile()`: Reads uploaded file data into memory buffer
- `ShowFileData()`: Displays file contents in web browser with formatting
- `PostCallBack()`: Handles POST events and coordinates file processing
- `UserMain()`: Initializes network stack and web server

12.55.3.1.4 Technical Details

12.55.3.1.4.1 Memory Management

- File buffer size: 10,000 bytes (10KB maximum file size)
- Uses static buffer allocation for file storage
- Automatic cleanup of file descriptors after processing

12.55.3.1.4.2 Security Features

- HTML entity encoding for special characters `<`, `>`, `&`, `"`
- Input validation and size limits
- Controlled file access through NetBurner's HTTP framework

12.55.3.1.4.3 Network Configuration

- Uses [DHCP](#) for automatic IP address assignment
- HTTP server runs on default port 80
- 5-second timeout for network initialization

12.55.3.1.5 Usage

12.55.3.1.5.1 Setup

1. Deploy the application to a NetBurner device
2. Connect the device to your network
3. Wait for [DHCP](#) address assignment
4. Note the device's IP address from console output

12.55.3.1.5.2 File Upload Process

1. Open web browser and navigate to the device's IP address
2. Select a file using the "File to process" field
3. Optionally check the binary display option (if available)
4. Click "Send File" to upload
5. View the processed file content on the results page

12.55.3.1.5.3 Supported File Types

- Text files (.txt, .html, .xml, etc.)
- Binary files (images, executables, etc.)
- Any file type up to 10KB in size

12.55.3.1.6 Display Modes

12.55.3.1.6.1 Text Mode

- Shows printable ASCII characters (0x20-0x80)
- Converts HTML special characters to entities
- Preserves line breaks with `<BR>` tags

12.55.3.1.6.2 Binary Mode

- Hexadecimal dump format (16 bytes per line)
- ASCII representation alongside hex values
- Non-printable characters shown as dots

12.55.3.1.7 Development Notes

12.55.3.1.7.1 Dependencies

- NetBurner NNDK (NetBurner Network Development Kit)
- HTTP server libraries ([http.h](#), [httppost.h](#))
- Standard I/O libraries ([iosys.h](#), [fdprintf.h](#))

12.55.3.1.7.2 Error Handling

- File size limits enforced
- Invalid file descriptors handled gracefully
- Network timeout protection during initialization

12.55.3.1.8 Console Output

The application provides diagnostic output showing:

- Application name and NNDK revision
- POST processing events (start, variable, file, end)
- Network initialization status
- System diagnostics (if enabled)

12.55.3.1.9 Limitations

- Maximum file size: 10KB
- Single file upload per request
- No persistent file storage
- Files are processed in memory only

12.55.3.1.10 Security Considerations

- File size limits prevent memory overflow
- HTML encoding prevents XSS attacks
- No file system access beyond temporary processing
- Network access controls should be implemented at infrastructure level

12.55.3.1.11 Troubleshooting

12.55.3.1.11.1 Common Issues

1. **File not uploading:** Check file size (<10KB) and network connectivity
2. **Display issues:** Verify HTML encoding and browser compatibility
3. **Network problems:** Confirm [DHCP](#) configuration and device connectivity

12.55.3.1.11.2 Debug Features

- Console logging for POST events
- System diagnostics output
- Network initialization feedback

12.55.4 HTML File Post Task Handoff

12.55.4.1 File Post Task Handoff Example

12.55.4.1.1 Overview

This application demonstrates two different methods for handling file uploads in a web server environment without blocking the main HTTP task. The example provides a web interface for file uploads and processes them using task handoff techniques to maintain server responsiveness during potentially time-consuming file operations.

12.55.4.1.2 Application Architecture

The application consists of several key components:

- **Main HTTP Server:** Handles incoming web requests
- **File Upload Handlers:** Two different approaches for processing uploaded files
- **Task Handoff System:** Prevents blocking of the main HTTP thread during file processing

12.55.4.1.3 File Upload Methods

12.55.4.1.3.1 Method 1: Buffered File Descriptor Handoff (`filepost_bufferedFD.cpp`)

This method uses a file descriptor buffer to hand off file processing to a separate task.

Key Features:**

- Uses `FDcBuf` adapter for buffered file descriptor operations
- Implements mailbox communication between HTTP and processing tasks
- Supports both binary and text file display
- Buffer size limited to 10,000 bytes
- Selective handoff based on filename (`userfile1` is processed synchronously)

Flow:**

1. HTTP task receives file upload
2. File data is read into a handoff buffer
3. File descriptor is passed to processing task via mailbox
4. Processing task handles file display and socket closure
5. Semaphore coordinates task availability

12.55.4.1.3.2 Method 2: Buffered Request Handoff (`filepost_bufferedReq.cpp`)

This method hands off the entire HTTP request to a separate processing task.

Key Features:**

- Copies the complete HTTP request structure
- Uses raw post callback handler
- Processes files in dedicated task context
- Direct request forwarding to existing callback system
- Buffer size limited to 10,000 bytes

Flow:**

1. Raw post callback intercepts HTTP request
2. Request structure is copied for handoff
3. Socket is passed to processing task via mailbox
4. Processing task uses existing callback system
5. Semaphore ensures single request processing

12.55.4.1.4 Technical Components

12.55.4.1.4.1 Synchronization Primitives

- **OS_MBOX:** Mailbox for passing socket handles between tasks
- **OS_SEM:** Semaphores for coordinating task availability
- **Timeouts:** HTTP_TIMEOUT used for non-blocking operations

12.55.4.1.4.2 Buffer Management

- **FILE_BUFFER_SIZE:** 10,000 byte limit for file processing
- **FileRxBuffer:** Main buffer for synchronous processing
- **HandoffFileRxBuffer:** Separate buffer for handoff operations

12.55.4.1.4.3 Web Interface

- **HTML Forms:** Two different forms for testing each handoff method
- **File Display:** Support for both text and binary file visualization
- **Checkbox Control:** Option to display binary files

12.55.4.1.5 File Processing Features

12.55.4.1.5.1 File Reading

- Reads uploaded files in chunks up to buffer limit
- Handles both text and binary file types
- Graceful handling of files exceeding buffer size

12.55.4.1.5.2 Display Options

- **Text Mode:** Displays file content as readable text
- **Binary Mode:** Shows binary file content (controlled via checkbox)
- **HTML Formatting:** Uses `<PRE>` tags for proper text formatting

12.55.4.1.5.3 Error Handling

- Timeout protection for task handoffs
- Graceful degradation when handoff is unavailable
- Error messages for failed file extractions

12.55.4.1.6 Usage

1. **Compile and Deploy:** Build the application using the NNDK framework
2. **Network Setup:** Application waits for [DHCP](#) address assignment
3. **Web Access:** Navigate to the device's IP address on port 80
4. **File Upload:** Use either form to upload files:
 - `filepost_bufferedFD.html` - for buffered FD method
 - `filepost_bufferedReq.html` - for buffered request method
5. **Options:** Check binary display option if needed

12.55.4.1.7 Configuration

12.55.4.1.7.1 Task Priorities

- **HttpHandoffTask_BufferedFd:** MAIN_PRIO+1
- **HttpHandoffTask_BufferedReq:** MAIN_PRIO+2

12.55.4.1.7.2 Timeouts

- **Network Wait:** 5 seconds for active network
- **Handoff Timeout:** HTTP_TIMEOUT/4 for task availability

12.55.4.1.7.3 Buffer Limits

- **Maximum File Size:** 10,000 bytes per upload
- **Read Chunk Size:** 80 bytes for display operations

12.55.4.1.8 Benefits

12.55.4.1.8.1 Performance

- Non-blocking HTTP server operation
- Concurrent file processing capability
- Responsive web interface during uploads

12.55.4.1.8.2 Flexibility

- Two different handoff approaches for various use cases
- Configurable binary/text display modes
- Selective processing based on file identification

12.55.4.1.9 File Structure

```
/
main.cpp                # Application entry point
filepost_bufferedFD.cpp  # Buffered FD handoff method
filepost_bufferedReq.cpp # Buffered request handoff method
filepost_bufferedFD.html # Web form for FD method (referenced)
filepost_bufferedReq.html # Web form for request method (referenced)
```

12.55.5 Flash Form

12.55.5.1 FlashForm Example Application

12.55.5.1.1 Overview

The FlashForm example is a NetBurner embedded web application that demonstrates three key capabilities:

1. **Dynamic HTML** - Server-side function calls embedded in HTML
2. **HTML Form Processing** - Handling POST requests from web forms
3. **User Flash Parameter Storage** - Persistent data storage in flash memory

12.55.5.1.2 Application Structure

12.55.5.1.2.1 Core Files

- `main.cpp` - Main application entry point and network initialization
- `formcode.cpp` - Web server functionality and form processing logic
- `index.html` - Web interface with dynamic content and form
- `ReadMe.txt` - Original project documentation

12.55.5.1.2.2 Main Application (`main.cpp`)

The main application initializes the NetBurner network stack and starts the web server:

- Initializes the network stack
- Enables system diagnostics
- Starts HTTP server on default port 80
- Waits for [DHCP](#) network configuration
- Displays application information and NNDK revision
- Enters main loop with 1-second delays

12.55.5.1.3 Features

12.55.5.1.3.1 Dynamic HTML Content

The application uses special HTML comments to embed server-side function calls:

```
<!--FUNCTIONCALL DoMessageName -->
<!--FUNCTIONCALL DoMessageBody -->
```

These tags are replaced with dynamic content when the page is served:

- `DoMessageName()` - Displays the stored user name
- `DoMessageBody()` - Displays the stored message

12.55.5.1.3.2 Form Processing

The web interface includes a form that allows users to:

- Enter their name (up to 40 characters)
- Enter a message (up to 128 characters)
- Submit the form to store the data in flash memory

Form data is processed by the `PostCallBack()` function which handles:

- `eStartingPost` - Initialize temporary storage
- `eVariable` - Process each form field (name and comment)
- `eEndOfPost` - Save data to flash and redirect to index page

12.55.5.1.3.3 Flash Storage

User data is stored persistently in flash memory using a structured approach:

```
struct MyOwnDataStore
{
    uint32_t verify_key;    // Verification key (0x48666050)
    char name[40];          // User name
    char msg[128];          // User message
};
```

The application uses NetBurner's user parameter storage functions:

- [GetUserParameters\(\)](#) - Read stored data (read-only)
- [SaveUserParameters\(\)](#) - Write data to flash memory

12.55.5.1.4 Security Features

- **Data Validation** - Uses a verification key to ensure data integrity
- **HTML Escaping** - Uses `writesafestring()` to prevent HTML injection
- **Buffer Protection** - Uses `strncpy()` with size limits to prevent buffer overflows

12.55.5.1.5 Usage

1. **Setup:** Deploy the application to a NetBurner device
2. **Access:** Open a web browser and navigate to the device's IP address
3. **View:** See any previously stored name and message
4. **Update:** Use the form to enter a new name and message
5. **Save:** Click "Save New Message" to store the data in flash

12.55.5.1.6 Technical Details

12.55.5.1.6.1 Network Configuration

- Uses [DHCP](#) for automatic IP configuration
- HTTP server runs on port 80
- Waits up to 5 seconds for network activation

12.55.5.1.6.2 Memory Management

- Static storage for form processing to maintain state across callbacks
- Flash storage persists data across power cycles
- Verification key ensures data integrity

12.55.5.1.6.3 Error Handling

- Displays "?" for invalid/missing name data
- Displays "No Message Stored" for invalid/missing message data
- Reports success/failure of flash programming operations

12.55.5.1.7 Development Notes

- Functions exposed to HTML must be declared as `extern "C"` to prevent C++ name mangling
- The `PostCallBack` function uses static variables to maintain state across multiple calls
- As of NetBurner 3.x release, the configuration server/storage system is recommended for new applications

12.55.5.1.8 Dependencies

- NetBurner NNDK (NetBurner Network Development Kit)
- Standard NetBurner libraries: [http.h](#), [iosys.h](#), [system.h](#), [httppost.h](#)

12.55.6 GIF Canvas

12.55.6.1 GIF Canvas Example

A web-based application that generates dynamic GIF images through a web interface using embedded HTTP server functionality.

12.55.6.1.1 Overview

This application demonstrates real-time GIF image generation on an embedded system. Users can configure various parameters through a web form to create different types of GIF images including solid boxes, gradients, text overlays, and random patterns.

12.55.6.1.2 Features

- **Web-based Interface:** HTML form for configuring image parameters
- **Dynamic GIF Generation:** Real-time creation of GIF images based on user input
- **Multiple Image Types:**
 - Solid filled boxes with borders
 - Gradient-filled boxes
 - Text overlay on colored backgrounds
 - Random pattern generation with transparency support
- **Customizable Parameters:**
 - Canvas dimensions (width/height)
 - Fill colors (RGB values)
 - Border colors (RGB values)
 - Text colors (RGB values)

12.55.6.1.3 Architecture

12.55.6.1.3.1 Core Components

1. **Web Server:** Built-in HTTP server handling GET/POST requests
2. **Image Generation:** DrawImageObject class for creating pixel-based graphics
3. **GIF Compression:** Custom miGIF run-length encoding compression
4. **Font Rendering:** Multiple font sizes (Tiny, Small, Medium, Large, Giant)
5. **Form Processing:** URL parameter parsing and form data handling

12.55.6.1.3.2 Key Files

- `main.cpp`: Application entry point and network initialization
- `web.cpp`: HTTP request handlers and GIF generation functions
- `drawimage.cpp/h`: Core graphics drawing functionality
- `gifCompress.cpp/h`: GIF compression implementation
- `webFormValues.cpp/h`: Form data parsing and URL encoding
- `fontdata.c`: Bitmap font definitions
- `index.html`: Web interface form

12.55.6.1.4 Technical Details

12.55.6.1.4.1 Image Generation Process

1. User submits form with color and dimension parameters
2. Parameters are encoded in URL query string format
3. Web handlers parse parameters and create DrawImageObject
4. Graphics operations (lines, boxes, text) are performed
5. Image is compressed using run-length encoding
6. GIF data is streamed directly to HTTP response

12.55.6.1.4.2 Color Management

- Supports up to 256 colors per image
- RGB color values (0-255 range)
- Transparency support for overlays
- Dynamic color palette generation for gradients

12.55.6.1.4.3 Font System

- Bitmap-based font rendering
- 5 different font sizes available
- Monospace character layout
- Custom font data format with bit-packed character definitions

12.55.6.1.5 Usage

1. Connect to the device's web server (default port 80)
2. Navigate to the main interface
3. Configure canvas dimensions and colors
4. Click "Update Canvas" to apply changes
5. View generated GIF images in the preview grid

12.55.6.1.6 Network Requirements

- DHCP-enabled network for automatic IP assignment
- Standard HTTP port 80 access
- Web browser with HTML form and image support

12.55.6.1.7 Compression Technology

Uses miGIF compression algorithm:

- Run-length encoding instead of LZW to avoid patent issues
- Optimized for images with solid color regions
- Produces GIF-compatible output streams
- Efficient for line art, text, and geometric shapes

12.55.6.1.8 Memory Management

- Dynamic buffer allocation for image data
- Efficient pixel storage and manipulation
- Streaming output to minimize memory usage
- Automatic cleanup of image resources

12.55.7 HTML Application File Post

12.55.7.1 NetBurner Application Update Server

12.55.7.1.1 Overview

This application provides a web-based interface for updating embedded application code remotely. It creates an HTTP server that accepts file uploads to update the device's application firmware through a web browser.

12.55.7.1.2 Features

- **Web-based Update Interface:** Hosts a web page (`Apppost.html`) that allows users to upload application binary files
- **Real-time Processing:** Handles file uploads and immediately processes them for application updates
- **Authentication Support:** Optional username/password protection for the update process
- **Automatic Reboot:** Automatically reboots the device after successful updates
- **Status Feedback:** Provides immediate feedback on upload success or failure

12.55.7.1.3 Application Flow

1. **Initialization:** The application starts the HTTP server and waits for network connectivity
2. **File Upload:** Users access the web interface to upload application binary files
3. **Processing:** The uploaded file is processed through `ReadBinaryApplicationCodeFromStream()`
4. **Response:** The system provides feedback on the update status
5. **Reboot:** On successful update, the device automatically reboots after a 5-second delay

12.55.7.1.4 Security Options

12.55.7.1.4.1 Basic Mode (Default)

- No authentication required
- Direct access to the update interface

12.55.7.1.4.2 Authentication Mode

To enable authentication, uncomment the following line in the source code:

```
#define I_WANT_TO_AUTHENTICATE_UPDATE
```

When authentication is enabled:

- **Username:** `up`
- **Password:** `date`
- **Realm:** `NetBurner`
- Users must provide credentials before accessing the update interface

12.55.7.1.5 Technical Details

12.55.7.1.5.1 Dependencies

- NetBurner RTOS ([nbrtos.h](#))
- HTTP POST handling ([httppost.h](#))
- Stream update functionality ([StreamUpdate.h](#))
- System initialization and HAL components

12.55.7.1.5.2 Callback Events

The application handles the following POST events:

- `eStartingPost`: Initializes the update process
- `eVariable`: Processes form variables (currently unused)
- `eFile`: Handles the uploaded binary file
- `eEndOfPost`: Completes the update and provides status response

12.55.7.1.5.3 Network Configuration

- Uses [DHCP](#) for network address assignment
- Runs HTTP server on default port 80
- Includes system diagnostics (should be disabled for production)

12.55.7.1.6 Usage

1. Build and deploy the application to your NetBurner device
2. Connect the device to your network
3. Access the device's IP address in a web browser
4. Navigate to the `Appppost.html` page
5. Upload your application binary file
6. Wait for the update confirmation and automatic reboot

12.55.7.1.7 Development Notes

- The application includes system diagnostics that should be removed for production builds
- Authentication credentials are hardcoded and should be changed for production use
- The 5-second delay before reboot allows time for the HTTP response to complete
- All POST data is consumed during authentication to prevent buffer issues

12.55.7.1.8 Error Handling

The application provides basic error handling:

- Failed updates return an error message via the web interface
- Network timeouts are handled during authentication
- Invalid credentials prompt for re-authentication

12.55.8 HTML Cookie

12.55.8.1 NetBurner HTML Cookie Example

12.55.8.1.1 Overview

The NetBurner HTML Cookie Example is an embedded web application that demonstrates HTTP cookie handling capabilities on NetBurner devices. This application showcases how to set, retrieve, and display cookies in a web browser through an embedded web server.

Three web pages are created: an index page, a page to set the cookie value to "MyCookie", and a page to view the cookie value.

- Select the "set cookie" link to set the cookie. Note that if you select "show cookie" before setting the value, no value will be displayed.
- Select the "show cookie" link to view the cookie

A cookie will apply to a "site". In this example a "site" will be the IP address of your NetBurner device. The cookie will be sent as part of the HTML header for any page requested from the "site".

12.55.8.1.2 Application Structure

12.55.8.1.2.1 Core Files

- `main.cpp` - Main application entry point and network initialization
- `webfuncs.cpp` - Web server functionality and cookie handling logic
- `index.html` - Web interface with dynamic content display

12.55.8.1.2.2 Main Application (`main.cpp`)

The main application initializes the NetBurner network stack and starts the web server:

- Initializes the network stack using `init()`
- Enables system diagnostics for debugging
- Starts HTTP server on default port 80
- Waits for **DHCP** network configuration (5 second timeout)
- Displays application information and NNDK revision
- Enters main loop with 1-second delays

```
void UserMain(void *pd)
{
    init(); // Initialize network stack
    EnableSystemDiagnostics();
    StartHttp(); // Start web server, default port 80
    WaitForActiveNetwork(TICKS_PER_SECOND * 5); // Wait for DHCP address

    iprintf("Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());

    while (1)
    {
        OSTimeDly(TICKS_PER_SECOND * 1);
    }
}
```

12.55.8.1.3 Cookie Handling Features

12.55.8.1.3.1 Cookie Display (`ShowCookie`)

The application includes a function that demonstrates how to parse and display cookies from HTTP requests:

- Parses HTTP headers to locate "Cookie:" keyword
- Extracts cookie data from the request
- Displays cookie content to the requesting socket
- Handles cases where no cookie is present

12.55.8.1.3.2 Cookie Setting (setCookieGetReqCallback)

The application includes a callback function that sets cookies:

- Intercepts GET requests to `setcookie.html`
- Sends HTTP headers with cookie data ("MyCookie ")
- Serves the appropriate HTML page
- Takes complete responsibility for the HTTP response

12.55.8.1.4 Technical Implementation

12.55.8.1.4.1 Cookie Parsing Logic

The `ShowCookie` function implements a simple cookie parser:

1. Receives the URL and HTTP header data
2. Searches for the "Cookie:" string in the HTTP headers
3. Extracts the cookie value until a space character is found
4. Writes the cookie data back to the client socket

12.55.8.1.4.2 HTTP GET Handler

The application uses NetBurner's callback system to handle specific web requests:

```
CallBackFunctionPageHandler hIndex("setcookie.html",    // Web page to intercept
                                   setCookieGetReqCallback, // Pointer to callback function
                                   tGet,                // Type of request, GET
                                   0,                    // Password level, none
                                   true);               // Take responsibility for entire response
```

12.55.8.1.5 Network Configuration

12.55.8.1.5.1 DHCP Setup

- Automatically obtains IP address via [DHCP](#)
- Waits up to 5 seconds for network activation
- Reports network status to debug console

12.55.8.1.5.2 Web Server

- HTTP server runs on standard port 80
- Serves static HTML files and dynamic content
- Handles both GET requests and cookie operations

12.55.8.1.6 Usage Instructions

1. **Setup:** Deploy the application to a NetBurner device
2. **Network:** Ensure the device is connected to a network with [DHCP](#)
3. **Access:** Open a web browser and navigate to the device's IP address
4. **Set Cookie:** Navigate to `setcookie.html` to set a cookie
5. **View Cookie:** Navigate to `showcookie.html` to display the cookie value

12.55.8.1.7 Development Notes

12.55.8.1.7.1 Function Declarations

- Cookie handling functions must be declared as `extern "C"` to prevent C++ name mangling
- This ensures proper linkage with the NetBurner web server system

12.55.8.1.7.2 Debug Output

- The application outputs debug information to the console
- URL requests and cookie operations are logged for development purposes

12.55.8.1.7.3 Memory Management

- Uses stack-based string parsing for cookie extraction
- No dynamic memory allocation for cookie handling
- Relies on NetBurner's built-in HTTP handling infrastructure

12.55.8.1.8 Dependencies

- NetBurner NNDK (NetBurner Network Development Kit)
- Standard NetBurner libraries:
 - `init.h` - Network initialization
 - `system.h` - System functions
 - `nbrtos.h` - Real-time operating system
 - `http.h` - HTTP server functionality
 - `iosys.h` - Input/output system
 - `htmlfiles.h` - HTML file handling

12.55.8.1.9 Security Considerations

- Cookie data is transmitted in plain text
- No authentication or authorization mechanisms
- Suitable for development and demonstration purposes
- Production use should implement additional security measures

12.55.8.1.10 Troubleshooting

12.55.8.1.10.1 Common Issues

1. **Network Connection:** Ensure [DHCP](#) is available and device is connected
2. **Browser Cache:** Clear browser cache if cookie behavior seems inconsistent
3. **Debug Output:** Monitor console output for network and cookie operation status

12.55.8.1.10.2 Debug Information

The application provides debug output including:

- Application name and NNDK revision
- Network status and IP address assignment
- HTTP request URLs and cookie operations

12.55.9 HTML Form Post

12.55.9.1 HtmlFormPost Example

12.55.9.1.1 Overview

This NetBurner example demonstrates how to handle HTML form submissions using HTTP POST requests on embedded devices. The application showcases complete form processing workflows including data validation, error handling, and user feedback through a multi-page web interface.

12.55.9.1.2 Features

- Interactive HTML form processing with POST request handling
- Multi-page form workflow with user navigation
- Real-time data validation and error reporting
- Persistent data storage during form processing sessions
- Console logging for debugging and monitoring
- Safe string handling with buffer overflow protection

12.55.9.1.3 Project Structure

```

HtmlFormPost/
├── src/
│   ├── main.cpp          # Main application and HTTP server startup
│   └── web.cpp            # POST request handlers and form processing
├── html/
│   ├── index.html        # Form 1 - Single field input
│   ├── page2.html        # Form 2 - Multi-field input
│   ├── complete.html     # Results page with processed data
│   └── images/
│       └── netburner-logo.gif # NetBurner logo image
└── makefile              # Build configuration
  
```

12.55.9.1.4 Architecture

12.55.9.1.4.1 System Components

12.55.9.1.4.2 POST Request Processing Flow

Form Submission Flow:

12.55.9.1.5 Application Flow

12.55.9.1.5.1 User Interaction Sequence

User Workflow:

12.55.9.1.6 Key Components

12.55.9.1.6.1 Main Application (main.cpp)

The main application handles system initialization and HTTP server setup:

```

void UserMain(void *pd) {
    init(); // Initialize network stack
    EnableSystemDiagnostics(); // Enable debug output
    StartHttp(); // Start HTTP server on port 80
    WaitForActiveNetwork(TICKS_PER_SECOND * 5); // Wait for DHCP connectivity

    iprintf("Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());

    // Main application loop - all form processing handled by callbacks
    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

Key Functions:**

- System and network initialization
- HTTP server startup on port 80
- **DHCP** network configuration with 5-second timeout
- Continuous operation loop

12.55.9.1.6.2 Form Processing System (web.cpp)

Form 1: Single Field Processing

Data Storage:**

```

const int varLenForm1 = 80;
char textForm1[varLenForm1];

```

POST Callback Handler:**

```

int form1PostCallBack(int sock, PostEvents event, const char *pName, const char *pValue) {
    switch (event) {
        case eStartingPost:
            // Initialize processing
            break;

        case eVariable:
            // Process form variable
            if (strcmp("textForm1", pName) == 0) {
                strncpy(textForm1, pValue, varLenForm1 - 1);
                textForm1[varLenForm1 - 1] = '\0';
                iprintf("textForm1 set to: \"%s\"\r\n", pValue);
            }
            break;

        case eFile:
            // Handle file uploads (not used)
            break;

        case eEndOfPost:
            // Send response after processing
            RedirectResponse(sock, "page2.html");
            break;
    }
    return 0;
}

```

Registration:**

```

HtmlPostVariableListCallback postForm1("form1*", form1PostCallBack);

```

Form 2: Multi-Field Processing

Data Storage:**

```
const int numVars = 4;
const int varLen = 80;
char strVar[numVars][varLen];
bool form2ParseError = false;
```

POST Callback Handler:**

```
int form2PostCallBack(int sock, PostEvents event, const char *pName, const char *pValue) {
    switch (event) {
        case eStartingPost:
            // Initialize all variables
            for (int i = 0; i < numVars; i++) {
                strVar[i][0] = '\0';
            }
            form2ParseError = false;
            break;

        case eVariable:
            // Process each variable with validation
            if (strcmp("Var0", pName) == 0) {
                strncpy(strVar[0], pValue, varLen - 1);
                strVar[0][varLen - 1] = '\0';
                iprintf("strVar0 set to: \"%s\"\\r\\n", strVar[0]);
            } else if (strcmp("Var1", pName) == 0) {
                // Similar processing for Var1, Var2, Var3
            } else {
                // Unknown variable detected
                iprintf("*** Error: Form variable name not found\\r\\n");
                form2ParseError = true;
            }
            break;

        case eEndOfPost:
            // Display summary and redirect
            iprintf("Variable Summary:\\r\\n");
            for (int i = 0; i < numVars; i++) {
                iprintf("  Var%d = \"%s\"\\r\\n", i, strVar[i]);
            }
            RedirectResponse(sock, "complete.html");
            break;
    }
    return 0;
}
```

12.55.9.1.6.3 Dynamic Content Functions

Form 1 Data Display

```
void WebTextForm1(int sock, PCSTR url) {
    fdprintf(sock, "\\\"%s\\\"", textForm1);
}
```

Form 2 Data Display with Error Reporting

```
void WebTextForm2(int sock, PCSTR url) {
    fdprintf(sock, "<pre>\\r\\n");
    for (int i = 0; i < numVars; i++)
        fdprintf(sock, "  Var%d = \"%s\"\\r\\n", i, strVar[i]);
    if (form2ParseError)
        fdprintf(sock, "*** Error: Form variable name not found\\r\\n </pre>");
}
```

12.55.9.1.7 HTML Form Structure

12.55.9.1.7.1 Form 1: Single Field Input (index.html)

```
<html>
<title>HTML Post Example</title>
<body>

<h1><font face="arial">HTML Form Post Example, First Form</font></h1>

<form action="form1" method=post>
  <table>
    <tr>
      <td width=40> </td>
      <td>Enter data to post:
        <input type="text" name="textForm1" value="<!--CPPCALL WebTextForm1 -->">
      </td>
      <td><input type="submit" value="Submit"></td>
    </tr>
```

```

</table>
</form>
</body>
</html>

```

Form Elements:**

- **Action:** form1 - Routes to Form 1 POST handler
- **Method:** post - Uses HTTP POST for data transmission
- **Input field:** textForm1 - Single text input with preserved value
- **Dynamic content:** <!--CPPCALL WebTextForm1 --> - Shows current value

12.55.9.1.7.2 Form 2: Multi-Field Input (page2.html)

```

<html>
<title>HTML Post Example</title>
<body>

<h1><font face=arial>HTML Form Post Example, Second Form</font></h1>

<form action="form2" method=post>
  Enter data to post var0: <input type="text" name="Var0" value="Var0"><br><br>
  Enter data to post var1: <input type="text" name="Var1" value="Var1"><br><br>
  Enter data to post var2: <input type="text" name="Var2" value="Var2"><br><br>
  Enter data to post var3: <input type="text" name="Var3" value="Var3"><br><br>

  <input type="submit" value="Submit">
</form>
</body>
</html>

```

Form Elements:**

- **Action:** form2 - Routes to Form 2 POST handler
- **Method:** post - HTTP POST transmission
- **Multiple inputs:** Var0, Var1, Var2, Var3 - Four text fields
- **Default values:** Pre-populated with variable names for testing

12.55.9.1.7.3 Results Page: Data Display (complete.html)

```

<html>
<title>HTML Post Example</title>
<body>

<h1><font face="arial">HTML Form Post Example, Completion Page</font></h1>

<font face="arial" size=5>Congratulations, Form Processing Complete</font>

Form1 Data: <!--CPPCALL WebTextForm1 -->

Form2 Data:
<!--CPPCALL WebTextForm2 -->

<font face=veranda><a href="index.html">Back to Home Page</a></font>
</body>
</html>

```

Dynamic Content:**

- **Form 1 results:** <!--CPPCALL WebTextForm1 --> - Displays processed Form 1 data
- **Form 2 results:** <!--CPPCALL WebTextForm2 --> - Shows all Form 2 variables
- **Navigation:** Link back to start page for repeated testing

12.55.9.1.8 POST Event Processing

12.55.9.1.8.1 Event Types and Sequence

Event Processing Timeline:

eStartingPost

- **When:** Called at the beginning of form processing
- **Purpose:** Initialize variables and reset state
- **Use cases:** Clear previous data, reset error flags, prepare for new submission

eVariable

- **When:** Called once for each form variable
- **Purpose:** Process individual form fields
- **Parameters:** Variable name and value provided
- **Use cases:** Data validation, storage, format conversion

eFile

- **When:** Called for file upload fields
- **Purpose:** Handle uploaded files
- **Note:** Not used in this example but available for file upload forms

eEndOfPost

- **When:** Called after all variables processed
- **Purpose:** Send response to browser
- **Use cases:** Generate response pages, redirect to results, send confirmations

12.55.9.1.9 Data Validation and Error Handling

12.55.9.1.9.1 Buffer Overflow Protection

All string operations use safe copying with size limits:

```
// Safe string copying with explicit size limit
strncpy(textForm1, pValue, varLenForm1 - 1);
textForm1[varLenForm1 - 1] = '\0'; // Ensure null termination
```

12.55.9.1.9.2 Variable Name Validation

Form 2 includes comprehensive variable validation:

```
if (strcmp("Var0", pName) == 0) {
    // Valid variable - process normally
    strncpy(strVar[0], pValue, varLen - 1);
    fprintf("strVar0 set to: \"%s\"\r\n", strVar[0]);
} else {
    // Invalid variable - set error flag
    fprintf("*** Error: Form variable name not found\r\n");
    form2ParseError = true;
}
```

12.55.9.1.9.3 Error Reporting Channels

Error Reporting Flow:

Errors are reported through multiple channels:

- **Console output:** Real-time debugging information
- **Error flags:** Boolean variables track processing status
- **Web display:** Error messages shown on result pages

12.55.9.1.10 Usage Instructions

12.55.9.1.10.1 Build and Deployment

1. **Build the application:**

```
make clean
make
```

2. **Deploy to NetBurner device:**

```
make load DEVIP=<device_ip_address>
```

3. **Monitor console output:**

- Connect serial terminal (115200 baud, 8-N-1)
- Observe startup messages and form processing logs

12.55.9.1.10.2 Web Interface Testing

Complete Form Processing Workflow

Testing Flow:

1. **Access main page:**

- Open browser to http://<device_ip>/
- Verify Form 1 display with NetBurner logo

2. **Test Form 1 submission:**

- Enter text in "Enter data to post" field
- Click "Submit" button
- Observe console output: `textForm1 set to: "<your_text>"`
- Verify redirect to `page2.html`

3. **Test Form 2 submission:**

- Modify default values in Var0, Var1, Var2, Var3 fields
- Click "Submit" button
- Observe console output for each variable
- Verify redirect to `complete.html`

4. View results page:

- Check Form1 Data display
- Verify Form2 Data shows all four variables
- Test "Back to Home Page" navigation

12.55.9.1.10.3 Expected Console Output

Application Startup

Application: HTML Form Post Example
NNDK Revision: 3.x.x Build xxxx

Form 1 Processing

textForm1 set to: "User entered text"

Form 2 Processing

```
strVar0 set to: "Modified Var0"
strVar1 set to: "Modified Var1"
strVar2 set to: "Modified Var2"
strVar3 set to: "Modified Var3"
```

```
Variable Summary:
  Var0 = "Modified Var0"
  Var1 = "Modified Var1"
  Var2 = "Modified Var2"
  Var3 = "Modified Var3"
```

Error Conditions

Error: Form variable name not found

12.55.9.1.11 URL Pattern Matching

The POST handler registration uses wildcard patterns:

```
// Matches any URL starting with "form1"
HttpPostVariableListCallback postForm1("form1*", form1PostCallback);
```

```
// Matches any URL starting with "form2"
HttpPostVariableListCallback postForm2("form2*", form2PostCallback);
```

Pattern Examples:**

- form1 - Exact match
- form1.html - With extension
- form1/submit - With path
- form1?param=value - With query parameters

12.55.9.1.12 Technical Implementation

12.55.9.1.12.1 Memory Management

- **Static allocation:** Fixed-size buffers for predictable memory usage
- **Buffer sizing:** Appropriate sizes based on expected input lengths
- **String safety:** Always ensure null termination and bounds checking

12.55.9.1.12.2 Processing Efficiency

- **Minimal processing:** Fast and efficient callback functions
- **Non-blocking:** Avoid long operations in POST callbacks
- **Resource cleanup:** Release resources promptly after processing

12.55.9.1.12.3 Build Configuration

Build Process:

The makefile handles HTML compilation automatically:

NAME = HtmlFormPost

```
# Source files
CPP_SRC += src/main.cpp src/web.cpp
```

```
# HTML compilation
CPP_SRC += src/htmldata.cpp
CREATEDTARGS += src/htmldata.cpp
src/htmldata.cpp : $(wildcard html/*.*)
    comphtml html -osrc/htmldata.cpp
```

```
include $(NNDK_ROOT)/make/boilerplate.mk
```

12.55.9.1.13 Troubleshooting

12.55.9.1.13.1 Common Issues

Troubleshooting Matrix:

Symptom	Possible Cause	Solution
Form not submitting	Action URL mismatch	Check pattern match
Data not appearing	Variable name error	Verify exact names
Redirect not working	Missing eEndOfPost	Check callback
Console output empty	Diagnostics disabled	Enable diagnostics

Form Not Submitting

Symptoms:** Form submission doesn't trigger callback Solutions:**

- Verify form action URL matches registered pattern
- Check HTTP method is set to "post"
- Confirm POST handler is registered properly
- Monitor console for error messages

Data Not Appearing

Symptoms:** Form data not stored or displayed Solutions:**

- Verify variable names match exactly between HTML and callback
- Check case sensitivity of variable names
- Ensure proper string copying and null termination
- Monitor console output for processing messages

Redirect Not Working

Symptoms:** Browser doesn't redirect after form submission Solutions:**

- Verify target page exists and is accessible
- Check [RedirectResponse\(\)](#) is called in eEndOfPost event
- Ensure callback returns 0 for successful processing
- Test with different browsers

12.55.9.1.14 Dependencies

Required NetBurner system libraries:

- `init.h` - System initialization
- `nbrtos.h` - NetBurner RTOS functions
- `http.h` - HTTP server support
- `httppost.h` - POST request handling
- `fdprintf.h` - File descriptor printf functions
- `iosys.h` - I/O system functions
- `string.h` - String manipulation functions

12.55.9.1.15 Learning Objectives

This example teaches:

- **HTTP POST processing:** Complete form submission handling workflows
- **Event-driven programming:** Using callbacks for asynchronous form processing
- **Data validation patterns:** Input validation and error handling techniques
- **Web application workflows:** Multi-page form processing sequences
- **String handling safety:** Buffer overflow protection and safe string operations
- **User interface design:** Creating intuitive web forms and feedback systems

12.55.9.1.16 Advanced Usage

12.55.9.1.16.1 Custom Validation Logic

Extend form processing with custom validation:

```
case eVariable:
    if (strcmp("email", pName) == 0) {
        if (validateEmail(pValue)) {
            strncpy(emailField, pValue, EMAIL_LEN - 1);
            emailField[EMAIL_LEN - 1] = '\0';
        } else {
            validationError = true;
        }
    }
    break;
```

12.55.9.1.16.2 Multi-Step Form Processing

Multi-Step Workflow:

Implement complex workflows:

```
case eEndOfPost:
    if (currentStep == 1) {
        RedirectResponse(sock, "form_step2.html");
    } else if (currentStep == 2) {
        RedirectResponse(sock, "complete.html");
    }
    break;
```

12.55.10 HTML Form Post 2.X Compatible

12.55.10.1 NetBurner HTML Form POST Example

12.55.10.1.1 Overview

This application demonstrates HTML Form POST handling on NetBurner embedded devices using the NetBurner Development Kit (NNDK). It provides backward compatibility with NNDK 2.x POST handling methodology while running on NNDK 3.x platforms.

The standard HTTP POST methodology in 3.x should be used whenever creating a new project. The 3.X methods enable cleaner code, less URL parsing, and better performance.

For customers migrating large and complex applications from legacy NNDK 2.X tools and platforms to NNDK 3.X, it is possible to create a HTTP POST callback function that in turn calls a `MyDoPost()` style 2.X function. This example assumes familiarity with the NNDK 3.X HTTP POST methods.

- A NNDK 3.X HTTP POST callback function is declared with a wildcard mask ("*") so that it is called for all HTTP POST operations.
- Strings are created for the URL containing the form action name and the posted form data
- The 2.X style `MyDoPost()` function is called with the URL and data strings
- The `ExtractPostData()` function is copied from the 2.X tools and included as a function in the application

Once the example has been loaded, interaction is through the device's web page. There are two web pages with forms for data entry, and a summary page at the end to display the assigned values from the post. Status messages are displayed on the serial port that can be viewed with a serial terminal, such as the MTTY utility.

While every attempt has been made to ensure compatibility, every application must be tested to verify proper operation. Also, this example will not work with multi-part forms.

12.55.10.1.2 Purpose

The application illustrates how to:

- Process HTML POST requests from web browsers
- Handle multiple web forms with different data fields
- Extract and parse form data from HTTP POST requests
- Provide web page responses and redirects
- Maintain compatibility between NNDK 2.x and 3.x POST handling methods

12.55.10.1.3 Key Features

- **Dual POST Handling:** Implements both legacy 2.x style `MyDoPost()` function and modern 3.x callback mechanisms
- **Multiple Form Support:** Handles two separate HTML forms with different data fields
- **Data Extraction:** Includes URL decoding for form data (handles spaces, special characters)
- **Web Page Flow:** Demonstrates proper HTTP response handling with redirects
- **Debug Output:** Provides serial console output for monitoring POST operations

12.55.10.1.4 Application Structure

12.55.10.1.4.1 Main Components

1. **main.cpp:** Application entry point and initialization
2. **web.cpp:** Web server POST handling and form processing logic

12.55.10.1.4.2 Form Processing

The application processes two types of forms:

Form 1 (`/form1`)*:

- `formValue1`: First text input
- `formValue2`: Second text input
- `formValue3`: Third text input
- Redirects to `page2.htm` after processing

Form 2 (`/form2`)*:

- `textForm2`: Single text input
- Redirects to `complete.htm` after processing

12.55.10.1.5 Technical Details

12.55.10.1.5.1 POST Data Processing

The `ExtractPostData()` function handles:

- URL-encoded data parsing
- Special character decoding (XX hex codes)
- Space character handling (+ to space conversion)
- Parameter separation (& delimited)

12.55.10.1.5.2 Compatibility Layer

The application provides a bridge between NNDK versions:

- **3.x Callback:** `form1PostCallBack()` handles modern POST events
- **2.x Function:** `MyDoPost()` maintains legacy function signature
- **Event Processing:** Converts 3.x events to 2.x compatible data structures

12.55.10.1.6 Setup and Configuration

12.55.10.1.6.1 Network Configuration

- Uses [DHCP](#) for automatic IP address assignment
- Waits up to 5 seconds for network connectivity
- Default web page: `index.htm`

12.55.10.1.6.2 Build Requirements

- NetBurner Development Kit (NNDK) 3.x
- Compatible NetBurner hardware platform
- Web server files (HTML forms)

12.55.10.1.7 Usage

1. **Compile and Load:** Build the application and load it onto your NetBurner device
2. **Network Connection:** Ensure the device obtains a network connection via [DHCP](#)
3. **Web Interface:** Access the device's IP address through a web browser
4. **Form Interaction:**
 - Fill out Form 1 on the main page
 - Submit to process and redirect to page 2
 - Fill out Form 2 and submit
 - View results on the completion page

12.55.10.1.8 Serial Console Output

The application provides detailed debugging information via serial console:

```
Application: HTML Form Post Example 2.x Port
NNDK Revision: [version]
----- Processing Post -----
Post URL: /form1
Post Data: formValue1=test&formValue2=data&formValue3=example
```

12.55.10.1.9 Migration Notes

12.55.10.1.9.1 For 2.x to 3.x Migration

This example is specifically designed for customers migrating complex applications from NNDK 2.x to 3.x:

- **Minimal Code Changes:** Existing `MyDoPost()` functions can be reused
- **Gradual Migration:** Allows incremental updates to newer POST handling methods
- **Testing Framework:** Provides compatibility verification for existing applications

12.55.10.1.9.2 Limitations

- **Multi-part Forms:** This compatibility layer does not support multi-part form uploads
- **Performance:** 3.x native methods provide better performance for new applications
- **Maintenance:** New projects should use standard 3.x POST methodology

12.55.10.1.10 Web Page Requirements

The application expects the following web pages:

- `index.htm`: Main page with Form 1
- `page2.htm`: Second page with Form 2
- `complete.htm`: Results/completion page

Each form should use appropriate `action` attributes (`form1`, `form2`) and matching input field names.

12.55.10.1.11 Development Recommendations

12.55.10.1.11.1 For New Projects

Use the standard NNDK 3.x HTTP POST methodology for:

- Cleaner code structure
- Better performance
- Reduced URL parsing overhead
- Enhanced functionality

12.55.10.1.11.2 For Legacy Migration

This example provides a proven path for:

- Large application migrations
- Complex form processing systems
- Gradual modernization of existing codebases

12.55.11 HTML Password

Warning

Web browsers will cache the username and password once entered. To force a password request again you will need to clear the browser cache, restart the browser, or open a new private browsing session.

12.55.11.1 Methods to Set an Access Group

Web page user names and passwords are controlled by "Access Group" levels that can range from 0 to 255, with 0 being no password protection. There are 3 methods to set the Access Group levels as described below. An time Access Groups are used in an application, the `CheckHttpAccess()` function must be created in the application to process the access groups and determine if access should be granted. The function is defined as:

```
HTTP_ACCESS CheckHttpAccess(int sock, int access_level, HTTP_Request &Req)
```

1. In a HTML page using `<!--ACCESSGROUP n -->` HTML tag, where n is a number from 0 to 255, typically 1 for admin and 2 for user, etc.. This provides the finest level of control on a page by page basis by adding the ACCESSGROUP tag as the first line in any web page that needs password protection. The application must create a `CheckHttpAccess()` function, that is automatically be called by the system, to process each request, such as checking a user name and password against stored values.

1. For dynamic web content, create a HTML GET handler callback function. If you do not have a web page compiled into an application in which to put an ACCESSGROUP tag, the access group can be specified in the handler callback function declaration:

```
CallbackFunctionPageHandler(const char *pUrl, http_gethandlerfunc *pFunction,
    HTTP_RequestTypes reqType = tGet, int accessGroup = 0,
    bool beforeFiles = false)
```

For example, if you have a dynamically created page for administration of users and passwords that generates a list of such information the access group could be set to 1 in the callback declaration:

```
CallbackFunctionPageHandler getHandlerAdmin("admin.html*", getAdmin, tGet, 1);
```

For reference, a GET callback declaration with no access group specified defaults to 0 and only needs the first two parameters:

```
CallbackFunctionPageHandler getHandlerDynamicPage("dynamicPage.html", getDynamicPage);
```

1. Create a dynamic HTML POST handler callback function:

```
HtmlPostVariableListCallback(const char *pUrl, postvarhandler *pCallback, int accessGroup = 0)
```

Similar to the GET handler above, creating a callback with no access group relies on ACCESSGROUP tags:

```
HtmlPostVariableListCallback postForm1("form1*", form1PostCallBack);
```

And specifying the access group for a post can also be used:

```
HtmlPostVariableListCallback postForm2("form2*", form2PostCallBack, 2);
```

12.55.11.2 ACCESSGROUP HTML Tags

The application consists of an index page with links to three additional pages with access group numbers: 0, 1 and 2.

- Group 0 = Open access
- Group 1 = Admin access
- Group 2 = User access

The function

```
HTTP_ACCESS CheckHttpAccess(int sock, int access_level, HTTP_Request & Req)
```

is used to authenticate the user names and passwords. If you create a function with this signature, it will be called any time one of the following access group tags are encountered in a web page:

Any web pages without an ACCESSGROUP tag will default to open access.

12.55.12 HtmlPostDateTime

12.55.12.1 HTML Date Time Post Application

12.55.12.1.1 Overview

The HTML Date Time Post Application is a web-based embedded system application that demonstrates how to handle date and time operations through a web interface. Built using the NetBurner NNDK (NetBurner Network Development Kit), this application provides a complete example of:

- Web server functionality with HTTP POST handling
- Date/time configuration management through web forms
- Time synchronization via NTP (Network Time Protocol)
- Time zone handling and display formatting
- Configuration persistence across system restarts

Config System Date and Time variables are used to post and display date and time from the config system to/from an HTML form. This uses the config form post helper functions.

12.55.12.1.2 Features

12.55.12.1.2.1 Core Functionality

- **Web Server:** Built-in HTTP server running on port 80
- **Date/Time Forms:** HTML forms for setting and displaying date/time values
- **NTP Synchronization:** Automatic time synchronization from NTP pool servers
- **Time Zone Support:** Configurable for PST/PDT with daylight saving transitions
- **Configuration Persistence:** Saves time settings to non-volatile storage
- **Time Calculations:** Shows time intervals and differences

12.55.12.1.2.2 Web Interface Components

- **Date Input Form** (`dateform`): Manual date/time entry
- **Auto Date Form** (`autodateform`): Automated configuration handling
- **Time Display**: Shows stored time in both local and UTC formats
- **Time Delta**: Displays time difference from current time

12.55.12.1.3 Technical Architecture

12.55.12.1.3.1 Key Components

1. Configuration Management

- `config_time_t` `StoredTimeObj`: Manages persistent time storage
- Default time: "2022-05-14T17:05:00"
- Automatic saving to configuration storage

2. HTTP POST Handling

- `DateformPostCallBack()`: Processes manual date form submissions
- `HtmlPostVariableListCallback`: Handles form variables
- `HtmlPostConfigVariableHandler`: Manages configuration forms

3. Display Functions

- `FillInDateValue()`: Outputs stored time in local format
- `FillInDateValueUtc()`: Outputs stored time in UTC format
- `ShowDeltaTime()`: Calculates and displays time differences
- `ShowTimeInterval()`: Formats time intervals (days, hours, minutes, seconds)

4. Network & Time Services

- **DHCP** network configuration
- NTP time synchronization with retry logic
- Time zone configuration for PST/PDT

12.55.12.1.3.2 System Requirements

- NetBurner NNDK development environment
- Network connectivity for **DHCP** and NTP
- Web browser for interface access

12.55.12.1.4 Configuration

12.55.12.1.4.1 Time Zone Setting

The application is configured for Pacific Time Zone:

```
tzsetchar("PST8PDT7,M3.2.0/02:00:00,M11.1.0/02:00:00");
```

- PST: Pacific Standard Time (UTC-8)
- PDT: Pacific Daylight Time (UTC-7)
- Automatic DST transitions in March and November

12.55.12.1.4.2 Default Values

- **Application Name:** "HTML Date Time Post Example"
- **Default Time:** 2022-05-14T17:05:00
- **Network Timeout:** 5 seconds for [DHCP](#)
- **NTP Retry Interval:** 5 seconds

12.55.12.1.5 Usage

1. System Startup

- Device initializes network stack
- Attempts [DHCP](#) network configuration
- Starts HTTP server on port 80
- Synchronizes time via NTP

2. Web Access

- Navigate to device IP address in web browser
- Use HTML forms to set date/time values
- View current stored time and time differences

3. Form Submission

- Submit new date/time through `dateform`
- Values are parsed and stored persistently
- Browser redirects to `index.html` after submission

12.55.12.1.6 Development Notes

12.55.12.1.6.1 Key Files Expected

- `index.html`: Main web interface page
- Configuration storage for persistent settings
- Network configuration for DHCP/static IP

12.55.12.1.6.2 Debugging Features

- System diagnostics enabled (should be disabled for production)
- Console output for time synchronization status
- Application and NNDK revision information display

12.55.12.1.6.3 Error Handling

- Graceful handling of NTP synchronization failures
- Retry mechanism for time setting
- Validation of submitted date/time values

12.55.12.1.7 Build Requirements

This application requires the NetBurner NNDK with the following modules:

- Network stack initialization
- HTTP POST processing
- Configuration system
- NTP client functionality
- Time zone management

For production deployment, consider disabling system diagnostics and implementing additional security measures for web access.

12.55.12.1.8 API Reference

12.55.12.1.8.1 Main Functions

- `UserMain()`: Application entry point and main loop
- `DateformPostCallBack()`: Handles POST form submissions
- `ShowTimeInterval()`: Formats time duration display
- `FillInDateValue()` / `FillInDateValueUtc()`: Provide time values for web display

12.55.12.1.8.2 Configuration Objects

- `StoredTimeObj`: Persistent time storage with automatic loading/saving
- Time format: ISO 8601 compatible string parsing and generation

12.55.13 HTML Server GET Request

12.55.13.1 HtmlServerGetRequest Example

12.55.13.1.1 Overview

This NetBurner example demonstrates how to implement and use web server GET request callbacks to intercept browser requests. The application showcases custom processing capabilities and dynamic web content generation when specific web pages or URLs are requested, providing developers with powerful tools for creating interactive embedded web applications.

12.55.13.1.2 Features

- HTTP GET request interception and custom processing
- Dynamic content generation based on system state
- File system integration with fallback mechanisms
- Real-time request logging with client information
- Conditional content routing and time-based page selection
- Seamless integration of static and dynamic content

12.55.13.1.3 Project Structure

```

HtmlServerGetRequest/

12.55.13.1.4 Architecture

12.55.13.1.4.1 System Components

12.55.13.1.4.2 Request Processing Flow

Browser Request Processing Flow:

12.55.13.1.5 Key Components

12.55.13.1.5.1 Main Application (main.cpp)

The main application handles system initialization and HTTP server setup:

```

void UserMain(void *pd) {
    init(); // Initialize network stack
    EnableSystemDiagnostics(); // Enable debug output
    StartHttp(); // Start HTTP server on port 80
    WaitForActiveNetwork(TICKS_PER_SECOND * 5); // Wait for network connectivity

    iprintf("Application: %s\r\nNNDK Revision: %s\r\n", AppName, GetReleaseTag());

    // Main application loop - all web processing handled by callbacks
    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

Key Functions:**

- System and network initialization
- HTTP server startup on port 80
- **DHCP** network configuration with 5-second timeout
- Continuous operation loop

12.55.13.1.5.2 Web Server Callbacks (web.cpp)

Callback 1: page2.html Handler

Purpose:** Demonstrates conditional content generation when files don't exist

```
int callbackGetPage2(int sock, HTTP_Request &pHttpRequest) {
    SendHTMLHeader(sock);

    // Custom processing and logging
    iprintf("Executing GET request callback function: callbackGetPage2\r\n");
    iprintf("Called because page2.html was not found in the file system.\r\n");

    // Generate dynamic HTML content
    fdprintf(sock, "<html><body>\r\n");
    fdprintf(sock, "<h1><font face=\"arial\">");
    fdprintf(sock, "Content when a page2.html file does not exist");
    fdprintf(sock, "</font></h1>\r\n");
    fdprintf(sock, "</body></html>\r\n");

    return 1; // Indicate request was handled
}
```

Registration Parameters:**

```
CallbackFunctionPageHandler getHandlerPage2(
    "page2.html", // URL to intercept
    callbackGetPage2, // Callback function pointer
    tGet, // HTTP GET request type
    0, // No authentication required
    false // beforeFiles: only call if file not found
);
```

Callback 2: OddEven.html Handler

Purpose:** Demonstrates time-based dynamic content selection

```
int callbackGetOddEven(int sock, HTTP_Request &pHttpRequest) {
    SendHTMLHeader(sock);

    // Request logging with client details
    iprintf("Executing GET request callback function: callbackGetOddEven\r\n");
    iprintf("Request URL: %s, from: %I\r\n",
        pHttpRequest.pURL, pHttpRequest.client_IPAddr);

    // Time-based content selection
    if ((Secs % 2) == 0) {
        SendFileFragment("even.html", sock);
    } else {
        SendFileFragment("odd.html", sock);
    }

    return 1; // Indicate request was handled
}
```

Registration Parameters:**

```
CallbackFunctionPageHandler getHandlerOddEven(
    "OddEven.html", // URL to intercept (virtual URL)
    callbackGetOddEven, // Callback function pointer
    tGet, // HTTP GET request type
    0, // No authentication required
    true // beforeFiles: always call callback
);
```

12.55.13.1.6 Callback Control Mechanisms

12.55.13.1.6.1 beforeFiles Parameter Behavior

beforeFiles Parameter Control Flow:

beforeFiles = true		
Request > Execute Callback > Generate Dynamic Content		

beforeFiles = false (File System Priority)

Behavior:**

- File system checked first for requested URL
 - If file exists, static file served directly
 - If file missing, callback executes to generate content
 - Callback only runs as fallback mechanism
- Use Cases:**
- Fallback content when files are missing
 - Development with uploadable content
 - Conditional dynamic generation

beforeFiles = true (Callback Priority)

Behavior:**

- Callback always executes regardless of file existence
 - No file system check performed
 - Complete control over response generation
 - Always dynamic content
- Use Cases:**
- Always dynamic content requirements
 - Real-time data streams
 - Custom processing for every request

12.55.13.1.6.2 HTTP_Request Structure

The callback functions receive detailed request information:

[HTTP_Request](#) Structure:

Field	Type	Description
pURL	char*	Requested URL string
client_IPaddr	IPADDR	Client IP address
Additional fields...	Various	Headers, parameters, etc.

Available Information:**

- **Request URL:** Complete URL path requested
- **Client IP:** Source IP address of requesting client
- **HTTP headers:** Additional request header information
- **Query parameters:** URL parameters and values

12.55.13.1.7 HTML Content Structure

12.55.13.1.7.1 Static Web Pages

Main Navigation Page (index.html)

```
<html>
<title>HTML GET Request Example</title>
<body>

<font face="arial">

<h1>HTML Server GET Request Response Example</h1>

<a href="page2.html">Run GET Request Example for page2.html</a><br><br>
<a href="OddEven.html">Run GET Request Example for OddEven.html</a><br><br>

</font>
</body>
</html>
```

Navigation Elements:**

- NetBurner logo display
- Links to demonstration pages
- Clear page structure and formatting

Time-based Content Pages

odd.html - Content for Odd Seconds:**

```
<html>
<title>HTML GET Request Example</title>
<body>

<font face="arial">

<h1>System seconds timer has an odd value: <!--VARIABLE Secs --></h1>
<a href="index.html"><< Back</a>

</font>
</body>
</html>
```

even.html - Content for Even Seconds:**

```
<html>
<title>HTML GET Request Example</title>
<body>

<font face="arial">

<h1>System seconds timer has an even value: <!--VARIABLE Secs --></h1>
<a href="index.html"><< Back</a>

</font>
</body>
</html>
```

Demo File for Testing (page2-rename.html)

```
<html>
<title>HTML GET Request Example</title>
<body>

<h1><font face="arial">page2.html from file system</font></h1>
</body>
</html>
```

Purpose:**

- Demonstrates file system precedence behavior
- Shows difference between static and dynamic content
- Testing tool for beforeFiles parameter functionality

12.55.13.1.7.2 Dynamic Variable Integration

Variable Substitution Process:

The HTML files use NetBurner's variable substitution system:

- ******** - Displays current system seconds timer
- **Automatic substitution** - Variables replaced with actual values when page served
- **Real-time updates** - Values reflect current system state when page loaded

12.55.13.1.8 File System Integration

12.55.13.1.8.1 HTML Content Compilation Process

Build Process Flow:

12.55.13.1.8.2 File System Precedence Testing

File Precedence Testing Workflow:

The example includes demonstration of file system precedence:

1. **Initially:** No `page2.html` file exists, callback executes
2. **Rename test file:** Change `page2-rename.html` to `page2.html`
3. **Rebuild application:** Static file now embedded in application
4. **Result:** Static file served instead of callback execution

12.55.13.1.9 Usage Instructions

12.55.13.1.9.1 Web Interface Testing

Complete Testing Workflow

Testing Sequence:

Access Main Page

1. **Open browser** to `http://<device_ip>/`
2. **Verify display** of main page with navigation links
3. **Check images** - NetBurner logo should load correctly

Test page2.html Callback

1. **Click link** "Run GET Request Example for page2.html"
2. **Observe result** - Dynamic content from callback function
3. **Check console** - Callback execution messages displayed
4. **Expected content:** "Content when a page2.html file does not exist"

Test OddEven.html Callback

1. **Click link** "Run GET Request Example for OddEven.html"
2. **Observe content** - Either odd.html or even.html content
3. **Note timer value** - System seconds displayed in page
4. **Refresh page** - Content may change based on timer parity
5. **Check console** - Request logging with client IP address

Test File System Precedence

1. **Rename file** - Change page2-rename.html to page2.html
2. **Rebuild application** - Recompile with new file included
3. **Redeploy** to device
4. **Test page2.html** - Now serves static file instead of callback
5. **Expected content:** "page2.html from file system"

12.55.13.1.9.2 Expected Console Output**Application Startup**

Application: HTML Server GET Request
 NNDK Revision: 3.x.x Build xxxx

Callback Execution Logging

Executing GET request callback function: callbackGetPage2
 Called because page2.html was not found in the file system.

Executing GET request callback function: callbackGetOddEven
 Request URL: OddEven.html, from: 192.168.1.50

12.55.13.1.10 Advanced Usage Patterns**12.55.13.1.10.1 Custom Processing Integration**

Custom Processing Flow:

Callbacks can include any custom processing before generating responses:

```

int customCallback(int sock, HTTP_Request &pHttpRequest) {
    SendHTMLHeader(sock);

    // Custom business logic
    readSensorData();
    updateDatabase();
    logUserActivity(pHttpRequest.client_IPAddr);
  }
  
```

```
// Generate response based on processing results
generateDynamicContent(sock);

return 1;
}
```

12.55.13.1.10.2 Error Handling Implementation

Implement robust error handling in callbacks:

```
int errorHandlerCallback(int sock, HTTP_Request &pHttpRequest) {
    try {
        SendHTMLHeader(sock);

        // Potentially failing operations
        if (!performOperation()) {
            fdprintf(sock, "<html><body>");
            fdprintf(sock, "<h1>Operation Failed</h1>");
            fdprintf(sock, "</body></html>");
            return 1;
        }

        // Success path
        generateSuccessContent(sock);
        return 1;
    } catch (...) {
        // Error recovery
        fdprintf(sock, "<html><body><h1>Internal Error</h1></body></html>");
        return 1;
    }
}
```

12.55.13.1.10.3 Multiple Callback Registration

Register multiple callbacks for different URL patterns:

```
// Different callbacks for various URL patterns
CallbackFunctionPageHandler handler1("api/data.json", jsonDataCallback, tGet, 0, true);
CallbackFunctionPageHandler handler2("status/*", statusCallback, tGet, 0, true);
CallbackFunctionPageHandler handler3("config.html", configCallback, tGet, 1, false);
```

12.55.13.1.11 Performance Considerations

12.55.13.1.11.1 Callback Efficiency Guidelines

Performance Optimization:

Callback Performance Best Practices
- Minimize processing time to avoid blocking web server - Avoid long-running operations in callback functions - Use efficient string operations and memory management - Clean up resources properly before returning - Consider caching for frequently requested dynamic content

Efficiency Best Practices

- **Minimize processing time** - Keep callback execution fast
- **Avoid blocking operations** - Don't block web server threads
- **Memory management** - Clean up resources properly
- **Connection handling** - Return promptly to free connections

Caching Strategies

- **Static content** - Use compiled files for frequently accessed content
- **Dynamic data** - Cache computed results when appropriate
- **Resource optimization** - Minimize file system access in callbacks

12.55.13.1.12 Troubleshooting**12.55.13.1.12.1 Common Issues and Solutions**

Troubleshooting Matrix:

Symptom	Possible Cause	Solution
Callback not executing	Registration error beforeFiles setting	Check parameters Verify URL match
Content not displaying	Missing HTML header Socket parameter	Call <code>SendHTMLHeader</code> Check <code>fdprintf</code>
File system conflicts	File naming beforeFiles param	Check html/ Rebuild after changes
Network issues	IP configuration Server startup	Verify device IP Check console

Callback Not Executing

Symptoms:** Expected callback doesn't run Solutions:**

- Verify callback registration parameters
- Check `beforeFiles` setting matches intended behavior
- Ensure URL matches exactly (case-sensitive)
- Confirm no conflicting static files exist

Content Not Displaying

Symptoms:** Blank or incomplete web pages Solutions:**

- Verify `SendHTMLHeader()` called before content
- Check `fdprintf()` syntax and socket parameter
- Ensure callback returns 1 to indicate completion
- Monitor console for error messages

Network Connectivity Issues

Symptoms:** Can't access web interface Solutions:**

- Verify device IP address from console output
- Check network connectivity with ping
- Confirm HTTP server started successfully
- Test with different browsers or clients

12.55.13.1.13 Dependencies

Required NetBurner system libraries:

- `init.h` - System initialization
- `nbrtos.h` - NetBurner RTOS functions
- `system.h` - System utilities and version information
- `http.h` - HTTP server support
- `iosys.h` - I/O system functions

- `htmlfiles.h` - HTML file handling
- `httppost.h` - HTTP POST request handling
- `fdprintf.h` - File descriptor printf functions
- `string.h` - String manipulation functions

12.55.14 HTMLVariables

12.55.14.1 HtmlVariables Example

12.55.14.1.1 Overview

This NetBurner example demonstrates how to create dynamic web content using HTML variables and function calls embedded directly in HTML pages. The application shows how to display real-time system information and execute C++ functions from web pages using special HTML tags.

12.55.14.1.2 Features

- Dynamic variable display using VARIABLE tags
- Function execution from HTML using CPPCALL tags
- Real-time system information display
- Parameter passing from HTML to C++ functions
- Uptime counter that updates on page refresh

12.55.14.1.3 Project Structure

```

HtmlVariables/
├── src/
│   ├── htmlvar.h      # Header file with variable and function declarations
│   ├── main.cpp       # Main application with web server setup
│   └── htmldata.cpp   # Auto-generated file from HTML content
├── html/
│   ├── index.html     # Main web page with dynamic content
│   └── robots.txt     # Web crawler instructions
└── makefile           # Build configuration

```

12.55.14.1.4 Architecture

12.55.14.1.4.1 System Components

12.55.14.1.4.2 Data Flow

12.55.14.1.5 Key Components

12.55.14.1.5.1 Header File (htmlvar.h)

The header file declares global variables accessible from HTML:

```

#ifndef HTMLVARS_H_
#define HTMLVARS_H_

#include <nbrtos.h> // For access to TimeTick

extern int gIntVal;
extern char gStrVal[];

const char *FooWithParameters(int fd, int v);

#endif /*HTMLVARS_H_*/

```

Exported Elements:**

- extern int gIntVal - Integer value displayed on web page
- extern char gStrVal[] - String value displayed on web page
- const char *FooWithParameters(int fd, int v) - Function with parameters

12.55.14.1.5.2 Main Application (main.cpp)

Variable Initialization

```

const char *AppName = "HTML Variable Example";
int gIntVal = 1234;
char gStrVal[] = "Hello World";

```

System Startup

```

void UserMain(void *pd) {
    init(); // Initialize network stack
    EnableSystemDiagnostics(); // Enable debug output
    StartHttp(); // Start web server, default port 80
    WaitForActiveNetwork(); // Wait for DHCP address

    while (1) {
        OSTimeDly(TICKS_PER_SECOND);
    }
}

```

Key Functions:**

- System and network initialization
- HTTP server startup on port 80
- Network activation wait
- Continuous operation loop

12.55.14.1.5.3 Callback Functions

URL Display Function

```

void Foo(int fd, PCSTR pUrl) {
    fdprintf(fd, "The URL value is: %s\r\n", pUrl);
}

```

Purpose:** Displays URL information on the web page

- **fd:** Socket file descriptor from web server
- **pUrl:** URL string from the HTTP request
- **Output:** Writes URL information directly to the web page

Parameterized Function

```
const char *FooWithParameters(int fd, int v) {
    fprintf(fd, "This function was called with parameter v = %d\r\n", v);
    return "\0"; // Return empty string to avoid additional output
}
```

Purpose:** Demonstrates parameter passing from HTML to C++

- **fd:** Socket file descriptor from web server
- **v:** Integer parameter passed from HTML page
- **Return:** Empty string to avoid additional HTML output
- **Output:** Writes parameter information to the web page

12.55.14.1.6 HTML Tag Processing

12.55.14.1.6.1 Tag Types and Usage

HTML Tag Processing Flow:

VARIABLE Tags

Display C++ variables directly in HTML:

```
<!--VARIABLE gIntVal -->
<!--VARIABLE gStrVal -->
<!--VARIABLE TimeTick/TICKS_PER_SECOND -->
```

Features:**

- Direct variable value insertion
- Mathematical expressions (division)
- Real-time value updates

CPPCALL Tags

Execute C++ functions without parameters:

```
<!--CPPCALL Foo -->
```

Features:**

- Function execution with standard parameters (fd, pUrl)
- Direct HTML output from function
- Automatic parameter passing

VARIABLE with Parameters

Call functions with custom parameters:

```
<!--VARIABLE FooWithParameters(fd, gIntVal) -->
```

Features:**

- Custom parameter passing
- Mixed parameter types (file descriptor, variables)
- Function return value handling

12.55.14.1.7 HTML Content Structure

12.55.14.1.7.1 Main Page (index.html)

```
<html>
<body>
<h1>HTML Variable Example</h1>
This example program uses the CPPCALL and VARIABLE tags to create dynamic content<br><br><br>

<h2>VARIABLE Tag</h2>
Number of seconds since system boot: <!--VARIABLE TimeTick/TICKS_PER_SECOND --><br>
The tag is: <pre> &lt;!--VARIABLE TimeTick/TICKS_PER_SECOND --&gt; </pre>
Application integer value: <!--VARIABLE gIntVal --><br>
Application string value: <!--VARIABLE gStrVal --><br>

<h2>Function Call with CPPCALL Tag</h2>
The CPPCALL tag passes the socket file descriptor and URL to a function in your application:<br>
<!--CPPCALL Foo --><br>
The tag is: <pre> &lt;!--CPPCALL Foo --&gt; </pre>

<h2>Function Call with Parameters Using the VARIABLE Tag</h2>
The VARIABLE tag can be used to call a function with a parameter.<br>
Number of time ticks since system boot: <!--VARIABLE FooWithParameters(fd, gIntVal) --><br>
The tag is: <pre> &lt;!--VARIABLE FooWithParameters( fd, gIntVal ) --&gt; </pre>
</body>
</html>
```

Dynamic Elements:**

- System uptime calculation
- Application variable display
- URL information via function call
- Parameterized function demonstration

12.55.14.1.8 Technical Implementation

12.55.14.1.8.1 HTML Tag Processing

HTML File Processing Flow:

Build Process Steps

1. **HTML Collection:** `comhtml` tool processes all files in `html/` directory
2. **Code Generation:** Creates `htмлdata.cpp` with embedded HTML content
3. **Compilation:** Standard C++ compilation includes generated file
4. **Tag Resolution:** Runtime processing replaces tags with dynamic content

12.55.14.1.8.2 Runtime Tag Resolution

Tag Processing Sequence:

When a web request arrives:

1. Web server identifies HTML tags in content
2. VARIABLE tags resolve to variable values or function returns
3. CPPCALL tags execute functions with standard parameters (fd, pUrl)
4. Results are inserted into HTML before sending response

12.55.14.1.8.3 Memory and Performance

Memory Layout:

Performance Characteristics:**

- Static HTML content stored in flash memory
- Dynamic tag processing occurs at request time
- Minimal RAM usage for variable storage
- Fast tag resolution through direct function calls

12.55.14.1.9 Setup Requirements

12.55.14.1.9.1 Include Path Configuration

For NBEclipse users, the auto-generated `htmldata.cpp` file requires access to `htmlvar.h`:

NBEclipse Configuration:

Configuration Steps:**

1. Right-click project and select "Properties"
2. Navigate to "C/C++ Build" options
3. Select "GNU C++ Compiler" > "Directories"
4. Add the project's "HtmlVariables\html" folder to include paths

12.55.14.1.9.2 Build Process

Automated Build Flow:

The build process automatically:

- Processes HTML files with `comphtml` tool
- Generates `htmldata.cpp` from HTML content
- Links HTML content into the application binary

12.55.14.1.10 Web Interface

12.55.14.1.10.1 Dynamic Content Display

Web Page Content Layout:

HTML Variable Example
VARIABLE Tag Section: - System Uptime: [TimeTick/TICKS_PER_SECOND] seconds - Integer Value: [gIntVal = 1234] - String Value: [gStrVal = "Hello World"]
CPPCALL Tag Section: - URL Display: [Output from Foo() function]
Function with Parameters Section: - Parameter Demo: [FooWithParameters(fd, gIntVal)]

The web page displays:

- **System Uptime:** Real-time seconds since boot using `TimeTick/TICKS_PER_SECOND`
- **Application Variables:** Current values of `gIntVal` and `gStrVal`
- **URL Information:** Current request URL via `Foo()` function
- **Parameter Demo:** Function call with `gIntVal` parameter

12.55.14.1.10.2 Page Update Behavior

Update Cycle:

Update Characteristics:**

- Content updates on each page refresh
- System uptime increments in real-time
- Function calls execute with each page load
- Variables display current application state

12.55.14.1.11 Build Configuration

12.55.14.1.11.1 Makefile Structure

```

NAME = HtmlVariables

CPP_SRC += src/main.cpp

# Auto-generated targets
CREATEDTARGS += src/htmldata.cpp
CPP_SRC += src/htmldata.cpp
src/htmldata.cpp : $(wildcard html/*.*)

```

```
comphtml html -osrc/htmldata.cpp
include $(NNDK_ROOT)/make/boilerplate.mk
Build Components:**
```

- **NAME:** Project identifier and output binary name
- **CPP_SRC:** C++ source files including generated HTML data
- **CREATEDTARGS:** Files automatically created during build
- **HTML Rule:** Automatic processing of HTML directory contents

12.55.14.1.12 Usage Instructions

12.55.14.1.12.1 Web Interface Testing

Access and Verification

Testing Workflow:

1. Access main page:

- Open browser to `http://<device_ip>/`
- Verify HTML Variable Example page loads

2. Test dynamic content:

- Check system uptime display (should increment)
- Verify integer value shows 1234
- Confirm string value shows "Hello World"
- Observe URL display from Foo() function

3. Verify real-time updates:

- Refresh page multiple times
- Confirm uptime counter increases
- Check that all dynamic content updates properly

12.55.14.1.12.2 Expected Output Examples

Web Page Display

HTML Variable Example

```
VARIABLE Tag
Number of seconds since system boot: 42
Application integer value: 1234
Application string value: Hello World
```

```
Function Call with CPPCALL Tag
The URL value is: /
```

```
Function Call with Parameters Using the VARIABLE Tag
This function was called with parameter v = 1234
```

12.55.14.1.13 Dependencies

Required NetBurner system libraries:

- `init.h` - System initialization
- `nbrtos.h` - NetBurner RTOS functions and timing
- `iosys.h` - I/O system functions
- `netinterface.h` - Network interface management
- `fdprintf.h` - File descriptor printf functions

12.55.14.1.14 Development Notes

12.55.14.1.14.1 Performance Considerations

- Uses NetBurner RTOS timing functions (`TimeTick`, `TICKS_PER_SECOND`)
- Implements standard NetBurner web server initialization
- Application runs in continuous loop with 1-second intervals
- Web server handles automatic HTML tag processing and variable substitution

12.55.14.1.14.2 Production Recommendations

- System diagnostics enabled for development (consider disabling for production)
- Static memory allocation for predictable performance
- Minimal processing overhead for tag resolution
- Flash-based storage for HTML content

12.55.14.1.14.3 Debugging and Monitoring

- Serial console output available at 115200 baud
- System diagnostics provide detailed operational information
- Web server status monitoring through RTOS functions
- Network connectivity verification through standard NetBurner tools

12.55.14.1.15 Learning Objectives

This example teaches:

- **Dynamic HTML content generation:** Creating interactive web pages with embedded C++ integration
- **Tag-based web development:** Using custom HTML tags for dynamic content insertion
- **Real-time data display:** Showing live system information through web interfaces
- **Function integration:** Calling C++ functions directly from HTML pages
- **Parameter passing:** Transferring data between HTML and C++ application layers
- **Web server integration:** Understanding NetBurner HTTP server capabilities

12.55.14.1.16 Advanced Usage Patterns

12.55.14.1.16.1 Custom Variable Types

Extend the system with additional variable types:

```
// In htmlvar.h
extern float gFloatVal;
extern bool gBoolVal;

// In main.cpp
float gFloatVal = 3.14159;
bool gBoolVal = true;
```

12.55.14.1.16.2 Complex Function Parameters

Create functions with multiple parameter types:

```
const char *ComplexFunction(int fd, int intParam, const char *strParam) {
    fdprintf(fd, "Int: %d, String: %s", intParam, strParam);
    return "\0";
}
```

12.55.14.1.16.3 Real-time Data Sources

Integrate with hardware sensors or system monitoring:

```
extern int gTemperature;    // Updated by sensor reading task
extern int gCpuUsage;      // Updated by system monitoring
```

12.55.15 Ping From Web

12.55.15.1 NetBurner Ping From Web Example

12.55.15.1.1 Overview

The Ping From Web Example demonstrates how to create a web-based network diagnostic tool using the NetBurner platform. This example creates a web server that allows users to ping remote hosts (by IP address or DNS name) through a simple HTML form interface, showcasing HTTP POST handling and network diagnostics capabilities.

12.55.15.1.2 Application Description

This embedded web application provides a web-based ping utility that runs on a NetBurner device. Users can enter an IP address or hostname through a web form, and the device will perform a ping operation and display the results. This example demonstrates form handling, DNS resolution, and ICMP ping functionality in an embedded environment.

12.55.15.1.2.1 Key Features

- **Web-Based Interface:** Simple HTML form for entering ping targets
- **DNS Resolution:** Supports both IP addresses and hostnames
- **HTTP POST Handling:** Processes form submissions using NetBurner's HTTP POST framework
- **Network Diagnostics:** Performs ICMP ping operations with response time measurement
- **Real-Time Results:** Displays ping results directly in the web browser
- **Error Handling:** Provides feedback for failed DNS resolution and ping timeouts

12.55.15.1.3 How It Works

12.55.15.1.3.1 Application Flow

1. **Initialization:** The `UserMain()` function initializes the network stack
2. **Diagnostics:** Enables system diagnostics for debugging (should be removed in production)
3. **Web Server:** Starts the HTTP server on port 80

4. **POST Handler:** Registers `PingCallBack` to handle form submissions to "pingpost.html"
5. **Network Wait:** Waits up to 5 seconds for active network connection
6. **Main Loop:** Enters infinite loop with 1-second delays

12.55.15.1.3.2 Ping Process

1. **Form Submission:** User enters IP address or hostname and submits form
2. **Parameter Extraction:** `PingCallBack` extracts the "paddr" parameter from POST data
3. **DNS Resolution:** Uses `GetHostByName()` to resolve hostname to IP address
4. **Ping Execution:** Calls `Ping()` function with 2-second timeout
5. **Result Display:** Shows ping response time or failure message
6. **Return Navigation:** Provides link back to the main ping form

12.55.15.1.3.3 Web Interface

The application serves a simple HTML form (`index.html`) that includes:

- Text input field for IP address or hostname
- Submit button to initiate ping
- Results are displayed on a separate page with navigation back to the form

12.55.15.1.4 Technical Details

12.55.15.1.4.1 Dependencies

- **NBRTOS:** NetBurner Real-Time Operating System
- **Network Stack:** Built-in TCP/IP stack with ICMP support
- **HTTP Server:** Integrated web server with POST handling
- **DNS Client:** Built-in DNS resolution functionality

12.55.15.1.4.2 Key Functions

- `PingCallBack()`: HTTP POST event handler that processes ping requests
- `GetHostByName()`: DNS resolution function
- `Ping()`: ICMP ping function with configurable timeout
- `HtmlPostVariableListCallback`: NetBurner class for handling HTTP POST variables

12.55.15.1.4.3 System Requirements

- NetBurner compatible hardware
- Network connectivity (Ethernet or WiFi depending on platform)
- NNDK (NetBurner Network Development Kit)

12.55.15.1.5 Usage

1. **Compile:** Build the application using the NetBurner development environment
2. **Deploy:** Load the application onto your NetBurner device
3. **Connect:** Ensure the device is connected to your network
4. **Access:** Open a web browser and navigate to the device's IP address
5. **Ping:** Enter an IP address or hostname in the form and click "Ping"
6. **View Results:** The ping results will be displayed with response time or error message

12.55.15.1.6 Example Usage

12.55.15.1.6.1 Successful Ping

```
Enter "google.com" in the form:  
- Address resolved to [142.250.191.46]  
- Ping Responded in 234 Ticks
```

12.55.15.1.6.2 Failed Ping

```
Enter "nonexistent.domain.com" in the form:  
- Failed to resolve address
```

12.55.15.1.7 Development Notes

12.55.15.1.7.1 Production Considerations

- Remove `EnableSystemDiagnostics()` call for production deployments
- Consider adding input validation for the ping target field
- Implement rate limiting to prevent ping flooding
- Add authentication for administrative access
- Consider adding traceroute or other network diagnostic tools

12.55.15.1.7.2 Customization

This example can be extended to include:

- Multiple ping targets in a single request
- Ping history and statistics
- Network topology discovery
- Port scanning capabilities
- Integration with SNMP monitoring
- Automated network health checks

12.55.15.1.7.3 Security Notes

- Ping functionality can be used for network reconnaissance
- Consider restricting ping targets to specific IP ranges in production
- Implement proper input sanitization to prevent injection attacks
- Add logging for audit trails of ping requests

12.55.15.1.8 Console Output

When running, the application displays:

```
Web Application: Ping From Web  
NNDK Revision: [Version Information]
```

12.55.15.1.9 Error Handling

The application handles several error conditions:

- **Empty ping target:** "Ping address empty"
- **DNS resolution failure:** "Failed to resolve address"
- **Ping timeout/failure:** "Ping Failed"
- **Successful ping:** "Ping Responded in X Ticks"

12.55.16 Raw Form Post 2pX

12.55.16.1 Raw Post Callback 2pX

12.55.16.1.1 Overview

This is a NetBurner embedded web server application that demonstrates how to handle **raw** HTTP POST requests. The application creates a web server that can receive and process form data submitted through HTTP POST requests.

12.55.16.1.2 Application Components

12.55.16.1.2.1 Main Application (`main.cpp`)

- **Application Name:** "Raw Post Callback 2pX"
- **Purpose:** Initializes the network stack and starts an HTTP web server
- **Key Features:**
 - Network stack initialization
 - System diagnostics enabled
 - HTTP server startup on default port 80
 - **DHCP** network configuration with 5-second timeout
 - Continuous operation loop

12.55.16.1.2.2 Form Handler (`formcode.cpp`)

- **Purpose:** Handles HTTP POST requests from web forms
- **Key Features:**
 - Raw POST data processing with boundary marker support
 - Real-time data streaming and display
 - HTML response generation
 - Buffer management for large POST data
 - Multipart form data handling capability

12.55.16.1.2.3 Web Interface (`index.html`)

- **Purpose:** Provides a simple web form for user input
- **Features:**
 - NetBurner logo display
 - Single text input field
 - Form submission to `post.html` endpoint
 - Clean HTML table-based layout

12.55.16.1.3 How It Works

1. **Initialization:** The application starts by initializing the network stack and enabling system diagnostics
2. **Web Server:** HTTP server starts on port 80
3. **Network Setup:** Waits for **DHCP** to assign an IP address
4. **Form Display:** Users can access the web interface to see the input form
5. **Data Submission:** When users submit the form, data is sent via POST to `post.html`
6. **Processing:** The `RawPostCallBack` function processes the POST data
7. **Response:** The server responds with an HTML page showing the submitted data

12.55.16.1.4 Technical Details

12.55.16.1.4.1 POST Data Processing

- Uses `ReadSimpleBody()` to read POST data in chunks
- Supports multipart form data with boundary markers
- Handles buffer overflow situations gracefully
- Displays received data in real-time during processing

12.55.16.1.4.2 Buffer Management

- File buffer size: 10,000 bytes
- Streaming data processing to handle large submissions
- Proper memory management for continuous operation

12.55.16.1.4.3 Network Configuration

- Default HTTP port: 80
- **DHCP** network configuration
- 5-second timeout for network activation
- Continuous monitoring loop with 1-second intervals

12.55.16.1.5 Usage

1. Flash the application to a NetBurner device
2. Connect the device to a network with **DHCP**
3. Navigate to the device's IP address in a web browser
4. Enter text in the form field and click "Submit"
5. View the processed POST data in the response page

12.55.16.1.6 Development Environment

- Built for NetBurner 2pX platform
- Uses NetBurner NNDK (NetBurner Network Development Kit)
- Requires NetBurner development tools and libraries

12.55.16.1.7 Files

- `main.cpp` - Main application entry point and initialization
- `formcode.cpp` - HTTP POST request handler and form processing
- `index.html` - Web interface with input form

12.55.16.1.8 Notes

- System diagnostics are enabled for debugging (should be disabled in production)
- The application runs continuously in a loop
- Shows practical implementation of embedded web server POST handling

12.55.17 Remote Web Console for Serial/stdout

12.55.17.1 NetBurner Remote Web Console Example

12.55.17.1.1 Overview

This example demonstrates the **Remote Web Console** feature for NetBurner devices. The Remote Web Console creates a web-based interface that redirects the device's stdout output (normally sent to the USB serial port or DB9) to a webpage accessible at `http://your-device-ip/console.html`. For example, a `printf("↵ Hello Wolrd");` in the application will appear in the web page console window just as it would a serial port terminal.

The Remote Console can be added to any application with:

- `#include <remoteconsole.h>`
- `EnableRemoteConsole();`

This feature is particularly useful for:

- Remote debugging and monitoring
- Accessing device output without physical USB connection
- Web-based device interaction and command input
- Development and troubleshooting in network environments

12.55.17.1.2 Features

- **Web-based Console:** Access device output through any web browser
- **Real-time Output:** Stdout redirected to web interface
- **Interactive Commands:** Simple command processing demonstration
- **Network Accessibility:** Remote access via device IP address

12.55.17.1.3 Files Description

12.55.17.1.3.1 main.cpp

The main application file containing:

- Network stack initialization
- HTTP server startup
- Remote console enablement
- Simple command processing loop
- Periodic status output

12.55.17.1.3.2 ReadMe.txt

Documentation file explaining the Remote Web Console implementation and usage.

12.55.17.1.4 Implementation Details

12.55.17.1.4.1 Key Components

1. Network Initialization

```
init(); // Initialize network stack
StartHttp();
WaitForActiveNetwork(TICKS_PER_SECOND * 5);
```

2. Remote Console Setup

```
#include <remoteconsole.h>
EnableRemoteConsole();
```

3. Command Processing

- Listens for character input
- Responds to 'h' command with "Hello!"
- Provides feedback for unknown commands
- Outputs periodic status dots

12.55.17.1.4.2 Required Headers

- `<init.h>` - Network stack initialization
- `<nbrtos.h>` - NetBurner RTOS functions
- `<system.h>` - System utilities
- `<iosys.h>` - I/O system functions
- `<remoteconsole.h>` - Remote console functionality

12.55.17.1.5 Usage Instructions

12.55.17.1.5.1 Building and Deploying

1. Compile the Application

- Use NetBurner development tools to build the project
- Ensure all required libraries are linked

2. Deploy to Device

- Flash the compiled binary to your NetBurner device
- Connect the device to your network

3. Network Configuration

- Ensure the device obtains an IP address
- Note the device's IP address for web access

12.55.17.1.5.2 Accessing the Web Console

1. Open Web Browser

- Navigate to `http://[device-ip]/console.html`
- Replace `[device-ip]` with your device's actual IP address

2. Interact with Console

- View real-time output from the device
- Send commands through the web interface
- Monitor periodic status updates (dots every second)

12.55.17.1.5.3 Available Commands

- `**h**`: Displays "Hello!" message
- **Other characters**: Shows "Unknown command" message
- **Periodic Output**: Status dots appear every second

12.55.17.1.6 Technical Notes

12.55.17.1.6.1 System Diagnostics

```
EnableSystemDiagnostics();
```

- Enabled for development and debugging
- Consider disabling for production deployments

12.55.17.1.6.2 Timing and Delays

```
OSTimeDly(TICKS_PER_SECOND);
```

- Main loop executes every second
- Provides regular status updates
- Prevents excessive CPU usage

12.55.17.1.6.3 Network Dependencies

- Requires active network connection
- HTTP server must be running
- Device must be accessible via IP address

12.55.17.1.7 Customization Options

12.55.17.1.7.1 Extending Commands

Add more command processing in the main loop:

```
if (c == 'h')
{
    printf("\r\nHello!\r\n");
}
else if (c == 's')
{
    printf("\r\nStatus: Running\r\n");
}
// Add more commands here
```

12.55.17.1.7.2 Modifying Output Frequency

Change the delay value to adjust status update frequency:

```
OSTimeDly(TICKS_PER_SECOND * 2); // 2-second intervals
```

12.55.17.1.7.3 Adding Application Logic

Insert your application-specific code within the main loop while preserving the console functionality.

12.55.17.1.8 Troubleshooting

12.55.17.1.8.1 Common Issues

1. Cannot Access Web Console

- Verify device IP address
- Check network connectivity
- Ensure HTTP server is running
- Confirm firewall settings

2. No Output Visible

- Check if RemoteConsole is enabled
- Verify printf statements are executing
- Ensure web page is properly loaded

3. Commands Not Responding

- Verify character input handling
- Check if `charavail()` is functioning
- Ensure main loop is executing

12.55.17.1.8.2 Debug Steps

1. Monitor USB serial output during development
2. Use network tools to verify device connectivity
3. Check HTTP server status and logs
4. Verify application is running and not stuck

12.55.18 Serial Webserver

12.55.18.1 Serial Webserver

A NetBurner RTOS application that bridges serial communication with HTTP web services, allowing HTTP requests to be received and processed over a serial port connection.

12.55.18.1.1 Overview

The Serial Webserver demonstrates how to create a bidirectional communication bridge between a serial port and TCP/HTTP connections. This application enables HTTP requests to be sent over a serial connection and receive corresponding web responses back through the same serial interface.

It will receive and reply to HTTP requests over a serial port, using the NetBurner web server implementation. The example will display a Hello World message on the device's index page `index.html`.

12.55.18.1.2 Key Features

- **Serial-to-HTTP Bridge:** Receives HTTP requests via serial port and forwards them to the built-in web server
- **Bidirectional Communication:** Splices data between serial and TCP connections in both directions
- **Automatic Connection Management:** Handles TCP connection creation and cleanup automatically
- **Error Recovery:** Automatically reopens serial connections on errors
- **Built-in Web Server:** Serves static content including HTML, CSS, and images

12.55.18.1.3 Technical Specifications

- **Serial Port:** Port 1 at 115200 baud
- **HTTP Port:** Standard port 80
- **Buffer Size:** Uses Ethernet buffer size for data transfer
- **Network Stack:** NetBurner RTOS with TCP/IP support

12.55.18.1.4 Application Architecture

The application follows a simple event-driven architecture:

1. **Initialization:** Sets up network stack, enables diagnostics, and starts HTTP server
2. **Serial Monitoring:** Waits for incoming serial data
3. **Connection Creation:** Establishes TCP connection to local web server when data arrives
4. **Data Splicing:** Uses `select()` to monitor both serial and TCP file descriptors
5. **Bidirectional Transfer:** Forwards data between serial and TCP connections
6. **Error Handling:** Closes and reopens connections on errors

12.55.18.1.5 HTTP Request Format

The application expects standard HTTP requests over the serial connection. A typical request format:

```
GET /INDEX.HTML HTTP/1.1\r\n\r\n
```

Important**: The web server requires a double carriage return line feed (`\r\n\r\n`) to properly parse HTTP requests.

12.55.18.1.6 Expected Response

A successful request to the index page returns:

```
HTTP/1.0 200 OK
Pragma: no-cache
MIME-version: 1.0
Content-Type: text/html
Content-length: 231
```

```
<html>
<head><link rel="stylesheet" type="text/css" href="style.css"></head>
<body>
<a href="http://www.netburner.com"></a>
<h1>Thank you for NetBurning!</h1>
</body>
</html>
```

12.55.18.1.7 Web Content

The application serves the following static files:

- **index.html:** Main page with NetBurner branding and welcome message
- **style.css:** Stylesheet defining Arial font family for the page
- **logo.jpg:** NetBurner logo image (referenced but not included in source)

12.55.18.1.8 Usage

1. Flash the application to your NetBurner device
2. Connect to the device's serial port (Port 1, 115200 baud)
3. Send HTTP requests through the serial connection
4. Receive HTTP responses back through the same serial connection

12.55.18.1.9 Development Notes

- System diagnostics are enabled for development (consider removing for production)
- The application uses blocking I/O operations
- Memory allocation uses `FAST_USER_VAR` for the splice buffer

12.55.18.1.10 Use Cases

This application is ideal for:

- Testing HTTP communication through serial interfaces
- Bridging legacy serial devices to modern web services
- Remote web server access through serial connections

12.55.18.1.11 Build Requirements

- NetBurner NBRTOS development environment
- Standard NetBurner libraries (init, system, iosys, serial, tcp, netinterface)
- Compatible NetBurner hardware platform

12.55.19 Simple HTML

12.55.19.1 NetBurner Simple HTML Example

12.55.19.1.1 Overview

The Simple HTML Example is a basic demonstration of the NetBurner web server implementation and serves as an excellent starting point for custom embedded web applications. This example creates a minimal web server that displays a "Hello World" type message on the device's index page.

12.55.19.1.2 Application Description

This embedded web application initializes a NetBurner device to serve HTML content over HTTP. The application demonstrates the fundamental components needed to create a web-enabled embedded system using the NetBurner Real-Time Operating System (NBRTOS).

12.55.19.1.2.1 Key Features

- **Web Server:** Runs an HTTP server on the default port 80
- **Network Stack:** Initializes the complete network stack for web connectivity
- **System Diagnostics:** Includes optional system diagnostic capabilities
- **Real-Time Operation:** Built on NBRTOS for reliable real-time performance
- **Simple Interface:** Displays a basic HTML page with NetBurner branding

12.55.19.1.3 File Structure

```
/
main.cpp      - Main application entry point
index.html    - Default web page served by the application
style.css     - CSS styling for the web interface
```

12.55.19.1.4 How It Works

12.55.19.1.4.1 Application Flow

1. **Initialization:** The `UserMain()` function initializes the network stack
2. **Diagnostics:** Enables system diagnostics for debugging (should be removed in production)
3. **Web Server:** Starts the HTTP server on port 80
4. **Network Wait:** Waits up to 5 seconds for active network connection
5. **Status Display:** Prints application name and NNDK revision to console
6. **Main Loop:** Enters infinite loop with 1-second delays

12.55.19.1.4.2 Web Content

The application serves a simple HTML page (`index.html`) that includes:

- NetBurner logo and branding
- Basic styling via CSS
- "Thank you for NetBurning!" message
- Link to NetBurner website

12.55.19.1.5 Technical Details

12.55.19.1.5.1 Dependencies

- **NBRTOS:** NetBurner Real-Time Operating System
- **Network Stack:** Built-in TCP/IP stack
- **HTTP Server:** Integrated web server functionality

12.55.19.1.5.2 System Requirements

- NetBurner compatible hardware
- Network connectivity (Ethernet or WiFi depending on platform)
- NNDK (NetBurner Network Development Kit)

12.55.19.1.6 Usage

1. **Compile:** Build the application using the NetBurner development environment
2. **Deploy:** Load the application onto your NetBurner device
3. **Connect:** Ensure the device is connected to your network
4. **Access:** Open a web browser and navigate to the device's IP address
5. **View:** The simple HTML page will be displayed

12.55.19.1.7 Development Notes

12.55.19.1.7.1 Production Considerations

- Remove `EnableSystemDiagnostics()` call for production deployments
- Customize the HTML content in `index.html` for your specific application
- Modify CSS styling in `style.css` to match your branding
- Add additional web pages and functionality as needed

12.55.19.1.7.2 Customization

This example serves as a foundation for more complex web applications. You can:

- Add dynamic content generation
- Implement form handling
- Create RESTful APIs
- Add authentication and security features
- Integrate with sensors and other hardware

12.55.19.1.8 Console Output

When running, the application displays:

```
Web Application: Simple HTML Example  
NNDK Revision: [Version Information]
```

12.55.20 TicTacToe

12.55.20.1 NetBurner TicTacToe Web Application

12.55.20.1.1 Overview

This is a web-based TicTacToe game designed for NetBurner development boards. The application demonstrates embedded web server capabilities, interactive HTML content, and real-time gameplay through a web browser interface.

12.55.20.1.2 Features

12.55.20.1.2.1 Core Functionality

- **Interactive TicTacToe Game:** Play against the computer through a web interface
- **Web Server:** Built-in HTTP server running on port 80
- **LED Manipulation:** Control LEDs on the NetBurner development board (URL encoding example)
- **Request Echo:** View web browser requests sent to the server
- **Auto-Refresh Pages:** Meta tag example for automatically reloading web pages

12.55.20.1.2.2 Technical Capabilities

- **Network Stack:** Full TCP/IP implementation with [DHCP](#) support
- **Serial Console:** Debug interface with command-line utilities
- **Diagnostic Tools:** Network diagnostics, [ARP](#) tables, TCP debugging
- **Real-time Updates:** Dynamic content generation and state management

12.55.20.1.3 Game Rules

- **Player Symbol:** X (Cross)
- **Computer Symbol:** O (Circle)
- **Objective:** Get three symbols in a row (horizontal, vertical, or diagonal)
- **Turn Order:** Player moves first by clicking on empty squares
- **Game State:** Preserved in URL parameters between moves

12.55.20.1.4 File Structure

```

/
main.cpp           # Main application entry point and command processor
tictactoe.cpp      # TicTacToe game logic and web handlers
index.html         # Default homepage with navigation links
tt.htm            # TicTacToe game interface
once.htm          # Single-load counter demonstration
repeat.htm        # Auto-refreshing page example

```

12.55.20.1.5 Web Interface

12.55.20.1.5.1 Available Pages

- / or /index.html: Main navigation page
- /TT.HTM: TicTacToe game interface
- /REPEAT.HTM: Auto-refreshing demonstration page
- /ONCE.HTM: Page load counter example

12.55.20.1.5.2 Game Assets

- CROSS.GIF: X symbol image
- NOT.GIF: O symbol image
- BLANK.GIF: Empty square image

12.55.20.1.6 Command Line Interface

The application provides a serial console interface with the following commands:

Command	Description
A	Show ARP table
C	Show network counters
E	Dump Ethernet statistics
P x.x.x.↵ x.x	Ping specified IP address
W	Display current system time
?	Show help menu

12.55.20.1.6.1 Debug Commands (when _DEBUG is defined)

Command	Description
T	Dump TCP debug information
L	Setup debug log levels
U	Dump OS tasks
S	Dump OS stacks
H	Show task changes

12.55.20.1.7 Technical Implementation

12.55.20.1.7.1 Game Logic

The TicTacToe game uses a bit-encoding system to represent the board state:

Player (X) Positions:**
 0x01 0x04 0x10
 0x40 0x100 0x400
 0x1000 0x4000 0x10000

Computer (O) Positions:**
0x02 0x08 0x20
0x80 0x200 0x800
0x2000 0x8000 0x20000

12.55.20.1.7.2 State Management

- Game state is encoded in URL parameters
- Each move generates a new URL with updated state
- Computer moves are calculated using strategic algorithms
- Win/lose conditions are checked after each move

12.55.20.1.7.3 Web Server Integration

- Uses NetBurner's built-in HTTP server
- Dynamic content generation through function calls
- HTML templates with embedded C++ function calls
- Real-time state updates without page refresh

12.55.20.1.8 Hardware Requirements

- NetBurner development board with network capability
- Ethernet connection for web access
- Serial port for debug console (115200 baud)
- LEDs for visual feedback (board-dependent)

12.55.20.1.9 Network Configuration

- **DHCP**: Automatically obtains IP address
- **Web Server**: Port 80 (HTTP)
- **Serial Console**: Available for diagnostics
- **Ping Support**: Built-in network connectivity testing

12.55.20.1.10 Getting Started

1. **Setup**: Connect NetBurner board to network via Ethernet
2. **Power On**: Board will automatically start and obtain **DHCP** address
3. **Access**: Open web browser and navigate to board's IP address
4. **Play**: Click "Play Tic Tak Toe" to start the game
5. **Debug**: Use serial console for network diagnostics

12.56 Web Client

Web Socket Examples:

- [Earthquake](#)
- [Find My IP](#)
- [Find My IP Task](#)
- [WebClient Http Request Methods](#)
- [Message Passer](#)
- [MessagePasserTask JSON](#)

12.56.1 Earthquake

12.56.1.1 Earthquake Monitor Application

12.56.1.1.1 Overview

This is a simple C++ embedded application that demonstrates real-time earthquake monitoring by retrieving and parsing JSON data from the USGS (United States Geological Survey) earthquake feed. The application fetches information about significant earthquakes (magnitude 4.5 and above) that have occurred in the last 24 hours and displays detailed information about each event.

12.56.1.1.2 Features

- **Real-time Data:** Fetches live earthquake data from USGS API
- **Time Synchronization:** Uses NTP (Network Time Protocol) to set accurate system time
- **JSON Parsing:** Processes earthquake data in GeoJSON format
- **Detailed Reporting:** Shows magnitude, location, and time elapsed since each earthquake
- **Network Stack Integration:** Built for embedded systems with network capabilities

12.56.1.1.3 Data Source

The application retrieves data from:

https://earthquake.usgs.gov/earthquakes/feed/v1.0/summary/4.5_day.geojson

This endpoint provides all earthquakes with magnitude 4.5 or greater from the past day in GeoJSON format.

12.56.1.1.4 Output Example

```
Application started
Time Set
In the last Day we have had 12 Earthquakes > 4.5
Magnitude : 5.2 at 34km WSW of Ferndale, CA 02:15:32 ago
Magnitude : 4.7 at 89km NNE of Adak, Alaska 05:42:18 ago
Magnitude : 4.9 at South of the Fiji Islands 08:30:45 ago
...
```

12.56.1.1.5 Technical Details

12.56.1.1.5.1 Dependencies

- Network stack initialization ([init.h](#))
- HTTP client functions ([webclient/http_funcs.h](#))
- JSON lexer and parser ([json_lexer.h](#))
- NTP time synchronization ([nbtime.h](#))
- Buffer management ([buffers.h](#))

12.56.1.1.5.2 Key Components

1. **Network Initialization:** Sets up the network stack and waits for [DHCP](#)
2. **Time Synchronization:** Uses NTP to get accurate system time
3. **HTTP Client:** Makes GET requests to the USGS API
4. **JSON Parser:** Processes the GeoJSON response format
5. **Data Display:** Formats and presents earthquake information

12.56.1.1.5.3 Application Flow

1. Initialize network stack and enable diagnostics
2. Wait for active network connection (up to 5 seconds)
3. Synchronize system time using NTP
4. Fetch earthquake data from USGS API
5. Parse JSON response and extract earthquake count
6. Iterate through each earthquake event and display:
 - Magnitude (formatted to 1 decimal place)
 - Location description
 - Time elapsed since the event (if time sync successful)
7. Enter infinite loop with 1-second delays

12.56.1.1.5.4 JSON Data Structure

The application expects GeoJSON format with the following structure:

```
{
  "metadata": {
    "count": number_of_earthquakes
  },
  "features": [
    {
      "properties": {
        "mag": earthquake_magnitude,
        "place": "location_description",
        "time": timestamp_in_milliseconds
      }
    }
  ]
}
```

12.56.1.1.6 Error Handling

- **Network Issues:** Reports "Failed to contact server" if HTTP request fails
- **Parse Errors:** Individual earthquake entries that fail to parse are reported with error messages
- **Time Sync:** Application continues without time information if NTP sync fails

12.56.1.1.7 Usage

This application is designed for embedded systems and runs continuously, fetching earthquake data once at startup and then entering a maintenance loop. It's suitable for:

- Environmental monitoring systems
- Educational demonstrations of web API integration
- Real-time earthquake awareness systems
- JSON parsing examples in embedded contexts

12.56.1.1.8 Configuration

The earthquake magnitude threshold and time period can be modified by changing the API endpoint URL. Available USGS feed options include:

- `all_hour.geojson` - All earthquakes in the past hour
- `2.5_day.geojson` - Magnitude 2.5+ in the past day
- `4.5_week.geojson` - Magnitude 4.5+ in the past week
- `significant_month.geojson` - Significant earthquakes in the past month

12.56.1.1.9 Build Notes

Ensure all required header files and libraries are available in your build environment. The application uses proprietary networking and JSON parsing libraries that must be linked during compilation.

12.56.2 Find My IP

12.56.2.1 FindMyIP Application

12.56.2.1.1 Overview

FindMyIP is a NetBurner embedded application that demonstrates network connectivity by retrieving and displaying the device's public IP address. The application connects to an external web service to determine the IP address that the device appears to have from the internet's perspective.

12.56.2.1.2 Description

This program creates a higher-priority task that performs an HTTP GET request to retrieve network information. Specifically, it connects to <http://httpbin.org/ip> and parses the JSON response to extract the device's public IP address.

12.56.2.1.3 Features

- **Network Connectivity Testing:** Verifies that the device can successfully connect to external web services
- **Public IP Detection:** Retrieves the public-facing IP address of the device
- **JSON Response Parsing:** Demonstrates parsing of JSON data returned from web services
- **System Diagnostics:** Includes diagnostic capabilities for debugging network issues

12.56.2.1.4 How It Works

1. **Initialization:** The application initializes the system and enables diagnostics
2. **Network Wait:** Waits up to 5 seconds for an active network connection ([DHCP](#))
3. **HTTP Request:** Performs a GET request to `httpbin.org/ip`
4. **JSON Parsing:** Extracts the "origin" field from the JSON response
5. **Display Results:** Prints the discovered IP address to the console
6. **Continuous Loop:** Enters an infinite loop with 1-second delays

12.56.2.1.5 Code Structure

12.56.2.1.5.1 Main Components

- **Network Interface:** Uses NetBurner's network stack for HTTP communication
- **JSON Lexer:** Parses JSON responses from the web service
- **HTTP Functions:** Handles web client operations
- **System Initialization:** Sets up the embedded system environment

12.56.2.1.5.2 Key Functions

- `init()`: Initializes the system
- `EnableSystemDiagnostics()`: Enables debugging output
- `WaitForActiveNetwork()`: Waits for network connectivity
- `DoGet()`: Performs HTTP GET request and parses JSON response

12.56.2.1.6 Usage

When the application runs, you will see output similar to:

```
Application started  
My IP address is 203.0.113.42
```

If the connection fails, you will see:

```
Application started  
Failed to contact server
```

12.56.2.1.7 Dependencies

- NetBurner RTOS and network stack
- HTTP client library (`webclient/http_funcs.h`)
- JSON parsing library (`json_lexer.h`)
- Serial communication support

12.56.2.1.8 Configuration

The target URL is configured as a constant:

```
const char *url = "http://httpbin.org/ip";
```

This can be modified to use different IP detection services that return JSON responses.

12.56.2.1.9 Notes

- System diagnostics are enabled by default and should be disabled for production builds
- The application waits 5 seconds for network connectivity before attempting the request
- The main loop includes a 1-second delay to prevent excessive CPU usage
- Error handling is included for network connectivity issues

12.56.3 Find My IP Task

12.56.3.1 Find My IP Application

12.56.3.1.1 Overview

The Find My IP application is a C++ embedded system program that demonstrates web client functionality by retrieving and displaying the external IP address of the device. This application creates a separate, higher-priority task that navigates to a web service and retrieves IP address information.

12.56.3.1.2 Purpose

This program serves as an example of web client implementation on an embedded system, specifically showcasing how to:

- Initialize and configure network stack
- Make HTTP GET requests to external web services
- Parse JSON responses
- Handle network errors gracefully
- Implement task-based architecture with proper priority management

12.56.3.1.3 How It Works

1. **Network Initialization:** The application initializes the network stack and waits for an active network connection (DHCP address assignment)
2. **Web Client Setup:** Configures a web client task with higher priority (MAIN_PRIO - 2) to handle HTTP requests
3. **HTTP Request:** Makes a GET request to <http://httpbin.org/ip> which returns JSON data containing the client's external IP address
4. **JSON Parsing:** Parses the JSON response to extract the "origin" field containing the IP address
5. **Display Results:** Prints the retrieved IP address to the console
6. **Error Handling:** Implements comprehensive error handling with descriptive error messages

12.56.3.1.4 Key Features

- **Asynchronous Operation:** Uses separate tasks for network operations
- **JSON Support:** Built-in JSON parsing capabilities
- **Error Reporting:** Comprehensive error handling and reporting system
- **Network Diagnostics:** Optional system diagnostics for debugging
- **Configurable Timing:** 10-second intervals between operations

12.56.3.1.5 Technical Details

12.56.3.1.5.1 Dependencies

- Network stack initialization ([init.h](#))
- HTTP client functionality ([webclient/http_funcs.h](#), [webclient/web_client.h](#))
- JSON parsing ([json_lexer.h](#))
- Buffer management ([buffers.h](#))

12.56.3.1.5.2 Key Functions

- `UserMain()`: Main application entry point
- `DoActualClientRequest()`: Handles the actual HTTP request and JSON parsing
- `HandleErrorState()`: Processes and displays error conditions

12.56.3.1.5.3 Configuration

- **Target URL:** <http://httpbin.org/ip>
- **Application Name:** "FindMyIp"
- **Network Timeout:** 5 seconds for DHCP acquisition
- **Request Interval:** 10 seconds between requests
- **Task Priority:** MAIN_PRIO - 2 (higher than main task)

12.56.3.1.6 Usage

The application runs continuously once started, making periodic requests to determine the external IP address. This is useful for:

- Network connectivity testing
- IP address monitoring
- Embedded system network diagnostics
- Learning web client implementation patterns

12.56.3.1.7 Output

When successful, the application displays:

```
Application started  
My IP address is [YOUR_EXTERNAL_IP]
```

Error conditions are reported with descriptive messages including error codes and descriptions.

12.56.3.1.8 Notes

- System diagnostics are enabled by default but should be disabled for production code
- The application uses standard HTTP (not HTTPS) for simplicity
- Designed for embedded systems with real-time operating system (RTOS) support
- Requires active internet connection and DNS resolution capability

12.56.4 WebClient Http Request Methods

12.56.4.1 HTTP Methods Test Application

12.56.4.1.1 Overview

This repository contains two complementary networking applications designed for testing and development purposes:

1. **HTTP Methods Test Client** (main.cpp) - A NetBurner embedded C++ application that tests various HTTP methods against a test server
2. **HTTP Echo Server** (main.go) - A Go-based HTTP server that echoes back request details in both HTML and JSON formats

12.56.4.1.2 HTTP Methods Test Client (main.cpp)

12.56.4.1.2.1 Description

The HTTP Methods Test Client is a NetBurner embedded application written in C++ that systematically tests different HTTP methods against a configurable endpoint. The application demonstrates proper usage of NetBurner's HTTP client libraries and JSON handling capabilities.

12.56.4.1.2.2 Features

- **Multiple HTTP Method Testing:** Tests POST, PUT, GET, HEAD, and DELETE methods
- **JSON Request/Response Handling:** Sends structured JSON data and parses responses
- **HTML Content Retrieval:** Can request and display HTML responses
- **Device Information:** Includes MAC address and uptime in requests
- **Automated Testing Loop:** Continuously cycles through different HTTP methods
- **Network Diagnostics:** Optional HTTP debugging output
- **Configurable Target:** Easy to change target URL for different test servers

12.56.4.1.2.3 HTTP Methods Tested

1. **POST** - Sends JSON message with device info and timestamp
2. **PUT** - Sends JSON message with device info and timestamp
3. **GET** - Requests HTML echo response
4. **HEAD** - Requests headers-only response
5. **DELETE** - Sends DELETE request for testing

12.56.4.1.2.4 Configuration

- **Target URL:** Currently set to `http://10.2.0.63:20035/`
- **Request Headers:** Configurable Accept headers (application/json or text/html)
- **Timeout:** 10 seconds per request
- **Test Interval:** 2 seconds between each method test

12.56.4.1.2.5 JSON Request Format

The application sends JSON requests with the following structure:

```
{
  "DEVICEID": "XX:XX:XX:XX:XX:XX",
  "UPTIME": 12345,
  "MESSAGE": "At the tone the time will be: 12345"
}
```

12.56.4.1.2.6 Dependencies

- NetBurner RTOS and libraries
- [init.h](#) - System initialization
- [buffers.h](#) - Buffer management
- [json_lexer.h](#) - JSON parsing
- [webclient/http_funcs.h](#) - HTTP client functions
- [netinterface.h](#) - Network interface management

12.56.4.1.2.7 Usage

1. Configure the target URL in the source code
2. Build and deploy to NetBurner hardware
3. Ensure network connectivity
4. Application will automatically start testing HTTP methods
5. Monitor output via serial console or system diagnostics

12.56.4.1.3 HTTP Echo Server (main.go)

12.56.4.1.3.1 Description

The HTTP Echo Server is a Go-based web server designed to echo back HTTP request details. It serves as a perfect companion for testing HTTP clients by providing detailed information about received requests in both human-readable HTML and machine-readable JSON formats.

12.56.4.1.3.2 Features

- **Content Negotiation:** Returns HTML or JSON based on Accept headers
- **Complete Request Echo:** Displays method, resource, headers, body, and raw request
- **Template-Based Responses:** Uses Go templates for flexible output formatting
- **Configurable Port:** Uses SERVER_PORT environment variable or default port 20035
- **Error Handling:** Proper HTTP error responses for template or processing errors

12.56.4.1.3.3 Response Formats

HTML Response

Provides a formatted web page showing:

- HTTP Method used
- Resource/URI requested
- All request headers with values
- Request body content
- Complete raw HTTP request dump

JSON Response

Returns structured JSON with:

- Method string
- Resource/URI string
- Headers object with arrays for multi-value headers
- Body content as string
- Complete raw request as string

12.56.4.1.3.4 Configuration

- **Default Port:** 20035
- **Environment Variable:** SERVER_PORT overrides default port
- **Content Type Detection:** Automatically detects JSON requests via Accept header

12.56.4.1.3.5 Running the Server

```
# Use default port 20035
go run main.go

# Use custom port via environment variable
SERVER_PORT=8080 go run main.go
```

12.56.4.1.3.6 Template System

The server uses Go's template system with custom functions:

- `set`: Sets a counter value
- `incr`: Increments a counter value

This allows for complex template logic and formatting of response data.

12.56.4.1.4 Integration Testing

These two applications work together to provide a complete HTTP testing environment:

1. **Start the Go echo server** on the target network
2. **Configure the NetBurner client** with the server's IP address and port
3. **Deploy and run the client** - it will automatically begin testing
4. **Monitor responses** via the client's serial output and server logs

12.56.4.1.5 Network Requirements

- Both applications should be on the same network or have routing between them
- Default port 20035 should be available (or configure alternative)
- NetBurner device needs [DHCP](#) or static IP configuration
- Firewall rules should allow HTTP traffic between client and server

12.56.4.1.6 Development Notes

12.56.4.1.6.1 NetBurner Client Development

- Uses NetBurner's RTOS and networking stack
- Requires proper initialization and network waiting
- JSON handling through NetBurner's [ParsedJsonDataSet](#) class
- HTTP operations through DoJsonHttp and DoHttpEx functions

12.56.4.1.6.2 Go Server Development

- Standard Go HTTP server with template system
- Cross-platform compatibility
- Minimal dependencies (standard library only)
- Easy to extend with additional endpoints or features

12.56.4.1.7 Troubleshooting

12.56.4.1.7.1 Common Issues

1. **Network Connectivity:** Ensure both devices can reach each other
2. **Port Conflicts:** Check if port 20035 is available or configure alternative
3. **Timeout Issues:** Adjust timeout values if network is slow
4. **JSON Parsing Errors:** Verify JSON format compatibility
5. **Template Errors:** Check server logs for template parsing issues

12.56.4.1.7.2 Debug Features

- NetBurner client: Enable SetHttpDiag(true) for verbose HTTP debugging
- Go server: Built-in request logging to console
- System diagnostics available on NetBurner platform

12.56.5 Message Passer

12.56.5.1 MessagePasser

A real-time messaging application that periodically sends timestamped messages to a remote server via HTTP POST requests.

12.56.5.1.1 Overview

MessagePasser is an embedded C++ application designed to communicate with a remote web service. The application continuously sends JSON-formatted messages containing device identification, uptime information, and timestamped messages to a specified HTTP endpoint.

12.56.5.1.2 Features

- **Automatic Device Identification:** Uses the device's MAC address as a unique identifier
- **Real-time Communication:** Sends HTTP POST requests with JSON payloads
- **Uptime Tracking:** Reports system uptime with each message
- **Network Integration:** Waits for active network connection ([DHCP](#)) before operation
- **Periodic Messaging:** Sends messages every 10 seconds automatically
- **JSON Response Handling:** Processes server responses and displays success status

12.56.5.1.3 Application Flow

1. **Initialization:** System initialization and diagnostics enablement
2. **Network Setup:** Waits up to 5 seconds for active network connection
3. **Message Loop:** Continuous loop that:
 - Creates timestamped messages
 - Sends JSON data to remote server
 - Processes server responses
 - Waits 10 seconds before next iteration

12.56.5.1.4 Message Format

The application sends JSON messages with the following structure:

```
{
  "DEVICEID": "AABBCCDDEEFF",
  "UPTIME": 12345,
  "MESSAGE": "At the tone the time will be: 12345"
}
```

Where:

- **DEVICEID:** 12-character hexadecimal string representing the device MAC address
- **UPTIME:** Current system uptime in seconds
- **MESSAGE:** Timestamped message string

12.56.5.1.5 Server Endpoints

The application is configured to communicate with:

- Primary: <http://burnedcloud.herokuapp.com/messagehandler>
- Alternative (commented): <http://66.27.60.212:9090/>

12.56.5.1.6 Implementation Details

12.56.5.1.6.1 Key Functions

- `**SendRxMessage(const char *msg)**`: Modern JSON object-based message sending
- `**SendManualRxMessage(const char *msg)**`: Manual JSON string formatting (alternative implementation)
- `**UserMain(void *pd)**`: Main application entry point and message loop

12.56.5.1.6.2 Dependencies

The application requires several system libraries:

- `init.h`: System initialization
- `stdio.h`: Standard I/O operations
- `ctype.h`: Character type functions
- `buffers.h`: Buffer management
- `json_lexer.h`: JSON parsing capabilities
- `webclient/http_funcs.h`: HTTP client functionality
- `netinterface.h`: Network interface management

12.56.5.1.6.3 Network Requirements

- Active network interface with `DHCP` configuration
- Internet connectivity to reach the remote server
- HTTP POST capability

12.56.5.1.7 Configuration

12.56.5.1.7.1 Timing Parameters

- **Network Wait**: 5 seconds maximum for `DHCP` address acquisition
- **Message Interval**: 10 seconds between transmissions
- **HTTP Timeout**: 10 seconds for server response

12.56.5.1.7.2 Customization Options

- Server URL can be modified by changing the `Url` constant
- Message content can be customized in the `UserMain` function
- Timing intervals can be adjusted by modifying the `OSTimeDly` parameters

12.56.5.1.8 Output

The application provides console output including:

- Application startup confirmation
- Success/failure status for each HTTP request
- Server response messages
- Error notifications for failed requests

12.56.5.1.9 Use Cases

This application is suitable for:

- IoT device monitoring and reporting
- Remote system status updates
- Periodic data collection from embedded devices
- Network connectivity testing and validation

12.56.5.1.10 Technical Notes

- Built for embedded systems with real-time OS capabilities
- Uses system ticks for timing (`TICKS_PER_SECOND`)
- Implements proper JSON object building and parsing
- Includes system diagnostics for development/debugging

12.56.6 MessagePasserTask JSON

12.56.6.1 MessagePasserTask Application

12.56.6.1.1 Overview

MessagePasserTask is a NetBurner embedded application that demonstrates JSON-based client-server communication. The application periodically sends status information to a web server via HTTP POST requests and processes the server's responses to control local hardware.

12.56.6.1.2 Purpose

This application serves as an example of how to:

- Implement web client functionality on embedded NetBurner devices
- Send and receive JSON data over HTTP
- Integrate hardware I/O (switches and LEDs) with network communication
- Handle server responses and error conditions

12.56.6.1.3 Key Features

12.56.6.1.3.1 Network Communication

- Makes HTTP POST requests to a configurable server endpoint
- Sends JSON data containing device status information
- Processes JSON responses from the server
- Includes comprehensive error handling for network operations

12.56.6.1.3.2 Hardware Integration

- Reads DIP switch positions to monitor user input
- Controls LEDs based on server responses
- Automatically triggers network requests when switch positions change

12.56.6.1.3.3 Data Exchange

The application sends the following information to the server:

- Device MAC address (as DEVICEID)
- System uptime in seconds
- Current timestamp message
- Student name identifier
- Current switch position values

The server responds with:

- Success flag indicating message processing status
- Current switch value for LED control
- Response message for display

12.56.6.1.4 Configuration

12.56.6.1.4.1 Server URL

The target server URL is configurable via the `Url` config object:

```
static config_string Url(appdata, "http://class.netburner.com/post/", "MessageUrl");
```

12.56.6.1.4.2 Student Identity

Update the student name before deployment:

```
const char *StudentName = "Attendee Name";
```

12.56.6.1.5 Application Flow

1. Initialization

- Initialize NetBurner system and network stack
- Wait for active network connection ([DHCP](#))
- Display IP address information
- Start web client task

2. Main Loop

- Monitor DIP switch positions
- Trigger network request when switches change
- Send periodic status updates every 10 seconds

3. Network Request Process

- Build JSON object with current status
- Send HTTP POST to configured server
- Parse JSON response
- Update LEDs based on server response
- Display status messages

12.56.6.1.6 Error Handling

The application includes robust error handling:

- Network connection timeouts (10 second limit)
- JSON parsing errors
- Server response validation
- Hardware I/O error recovery

Error states are logged to the console with descriptive messages using the `HandleErrorState()` function.

12.56.6.1.7 Hardware Requirements

- NetBurner development board with network capability
- DIP switches for input
- LEDs for status output
- Network connection (Ethernet)

12.56.6.1.8 Build Dependencies

Required NetBurner libraries:

- `init.h` - System initialization
- `webclient/web_client.h` - HTTP client functionality
- `json_lexer.h` - JSON parsing and generation
- `config_obj.h` - Configuration management
- `ipshow.h` - Network diagnostics
- `utils.h` - Hardware I/O utilities

12.56.6.1.9 Usage Notes

- The application automatically starts network communication after initialization
- LED patterns indicate server response status
- Switch changes immediately trigger new server requests
- Console output provides detailed operation logging
- System diagnostics are enabled for debugging (should be disabled in production)

12.56.6.1.10 Troubleshooting

Common issues and solutions:

- **Network timeouts:** Check server availability and network connection
- **JSON parsing errors:** Verify server response format matches expected structure
- **LED not responding:** Check server CURSWITCH value in response
- **No SUCCESS flag:** Server may be rejecting the request format

Enable HTTP diagnostics for detailed network troubleshooting:

```
SetHttpDiag(true);
```

12.56.6.1.11 Development Notes

This application demonstrates best practices for NetBurner embedded web clients and can serve as a foundation for more complex IoT communication scenarios.

12.57 Web Sockets

Web Socket Examples:

- [Web Socket Connect](#)
- [Web Socket Console](#)
- [Web Socket DIP Switch](#)
- [Web Socket Echo](#)
- [HTTPS WebSocket Demo](#)

12.57.1 Web Socket Connect

12.57.1.1 WebSocket Connect Application

12.57.1.1.1 Overview

This application demonstrates a WebSocket client implementation that connects to a server and maintains a persistent connection for real-time communication.

12.57.1.1.2 Features

- **WebSocket Client Connection:** Establishes a connection to a WebSocket server
- **Real-time Data Exchange:** Sends periodic time tick messages to the server
- **Asynchronous Socket Handling:** Uses a dedicated task for reading incoming data
- **Network Stack Integration:** Built on NetBurner's network initialization framework
- **Error Handling:** Monitors socket status and handles connection errors gracefully

12.57.1.1.3 Application Structure

The application consists of two main components:

12.57.1.1.3.1 Main Task (UserMain)

- Initializes the network stack and waits for [DHCP](#)
- Establishes WebSocket connection to the specified server
- Sends periodic "TimeTick" messages every second
- Creates a separate task for handling incoming socket data

12.57.1.1.3.2 Socket Handling Task (UserTask)

- Monitors the WebSocket connection using [select \(\)](#)
- Handles incoming data from the server
- Manages socket errors and connection cleanup
- Echoes received data to stdout

12.57.1.1.4 Configuration

The application is configured with the following default settings:

```
#define SERVER_IP "192.168.1.209"
```

- **Server IP:** 192.168.1.209
- **WebSocket Path:** "/"
- **Port:** 80
- **Message Interval:** 1 second

12.57.1.1.5 Key Functions

12.57.1.1.5.1 Connection Management

- `NB::WebSocket::Connect()`: Establishes WebSocket connection
- `NB::WebSocket::ws_flush()`: Flushes WebSocket buffers

12.57.1.1.5.2 Network Operations

- `select()`: Monitors socket file descriptors for activity
- `read()`: Receives data from the WebSocket
- `writestring()`: Sends string data through the WebSocket
- `writeall()`: Outputs received data to stdout

12.57.1.1.5.3 System Integration

- `init()`: Initializes the NetBurner network stack
- `WaitForActiveNetwork()`: Waits for network connectivity
- `OSSimpleTaskCreatewName()`: Creates the socket handling task

12.57.1.1.6 Message Format

The application sends periodic status messages in the format:

```
TimeTick: [current_tick_value]
```

Where `[current_tick_value]` is the current system tick count, providing a timestamp for each message.

12.57.1.1.7 Error Handling

The application includes robust error handling:

- Socket error detection using `select()` with error file descriptor sets
- Automatic socket cleanup on connection failure
- Graceful task termination when connection is lost

12.57.1.1.8 Build Requirements

- NetBurner development environment
- WebSocket library (`websockets.h`)
- Standard C libraries
- NetBurner initialization framework (`init.h`)

12.57.1.1.9 Usage

1. Configure the `SERVER_IP` define to match your WebSocket server
2. Build and deploy to your NetBurner device
3. The application will automatically:
 - Initialize the network stack
 - Connect to the specified WebSocket server
 - Begin sending periodic time tick messages
 - Display any received messages on the console

12.57.1.1.10 Technical Details

- **Task Priority:** Socket handling task runs at `MAIN_PRIO + 1`
- **Buffer Size:** Uses `ETHER_BUFFER_SIZE` for data reception
- **Timing:** Uses `TICKS_PER_SECOND` for consistent timing intervals
- **Diagnostics:** Includes system diagnostics (should be disabled for production)

12.57.2 Web Socket Console

12.57.2.1 WebSocket Console

A NetBurner NNDK application that provides WebSocket-based access to UART/serial ports and stdio console functionality.

12.57.2.1.1 Overview

This application creates WebSocket endpoints that allow web-based clients to communicate with:

- Standard I/O (stdin/stdout/stderr) via WebSocket
- Up to 10 UART/serial ports with configurable parameters

The application acts as a bridge between WebSocket connections and serial communication interfaces, enabling remote serial console access through a web browser.

12.57.2.1.2 Features

- **WebSocket Console Access:** Connect to the device's standard I/O streams via WebSocket
- **UART Bridging:** Access up to 10 UART ports through individual WebSocket connections
- **Configurable Serial Parameters:** Set baud rate, data bits, parity, and stop bits per UART
- **Real-time Data Transfer:** Bidirectional data flow between WebSocket and serial interfaces
- **Connection Management:** Automatic cleanup on connection errors
- **Status Monitoring:** Built-in diagnostics and connection status reporting

12.57.2.1.3 WebSocket Endpoints

12.57.2.1.3.1 Standard I/O Console

- **Endpoint:** `stdio*`
- **Function:** Redirects stdin, stdout, and stderr to the WebSocket connection
- **Usage:** General console access and debugging

12.57.2.1.3.2 UART Access

- **Endpoint:** `uart*`
- **Function:** Provides WebSocket access to individual UART ports
- **Parameters** (via query string):
 - `uart`: UART port number (0-9)
 - `baud`: Baud rate (1-230400)
 - `data_bits`: Data bits (5-8)
 - `parity`: Parity mode (0-2)
 - `stop_bits`: Stop bits (1-3)

12.57.2.1.4 Configuration Parameters

12.57.2.1.4.1 UART Configuration

- **Port Range:** 0-9 (10 total ports supported)
- **Baud Rate Range:** 1 to 230,400 bps
- **Data Bits:** 5, 6, 7, or 8 bits
- **Parity:** 0 (None), 1 (Odd), 2 (Even)
- **Stop Bits:** 1, 2, or 3 bits

12.57.2.1.4.2 System Settings

- **Buffer Management:** Automatic buffer allocation and cleanup
- **Connection Limit:** One WebSocket connection per UART port
- **Error Handling:** Automatic connection cleanup on errors

12.57.2.1.5 Usage Examples

12.57.2.1.5.1 Connecting to Standard I/O

`ws://device-ip/stdio`

12.57.2.1.5.2 Connecting to UART Port

`ws://device-ip/uart?uart=0&baud=115200&data_bits=8&parity=0&stop_bits=1`

This example connects to UART port 0 with:

- 115,200 bps baud rate
- 8 data bits
- No parity
- 1 stop bit

12.57.2.1.6 Application Architecture

12.57.2.1.6.1 Main Components

1. **WebSocket Handlers:** Process incoming WebSocket connections
2. **UART Management:** Handle serial port configuration and I/O
3. **Data Bridging:** Transfer data between WebSocket and serial interfaces
4. **Connection Monitoring:** Track active connections and handle errors

12.57.2.1.6.2 Key Functions

- `StdioWS()`: Handles stdio WebSocket connections
- `UartWS()`: Processes UART WebSocket requests
- `spliceToWS()`: Transfers data from UART to WebSocket
- `spliceToUart()`: Transfers data from WebSocket to UART
- `ParseUartConfig()`: Validates and parses UART configuration parameters

12.57.2.1.7 Error Handling

The application includes robust error handling for:

- Invalid UART configuration parameters
- Port availability conflicts
- WebSocket connection errors
- Serial port communication failures
- Buffer overflow conditions

12.57.2.1.7.1 HTTP Responses

- **400 Bad Request**: Invalid configuration parameters
- **404 Not Found**: Invalid WebSocket upgrade request
- **503 Not Available**: Port already in use or unavailable

12.57.2.1.8 System Requirements

- NetBurner NNDK (NetBurner Real-Time Operating System)
- Network connectivity (Ethernet with [DHCP](#))
- HTTP server support
- WebSocket protocol support
- Available UART hardware ports

12.57.2.1.9 Compilation Dependencies

- [init.h](#) - System initialization
- [nbrtos.h](#) - NetBurner RTOS functions
- [websockets.h](#) - WebSocket protocol support
- [iosys.h](#) - I/O system functions
- [serial.h](#) - Serial port management
- [dhcpcd.h](#) - [DHCP](#) server functionality

12.57.2.1.10 Status Monitoring

The application provides real-time status information including:

- Active WebSocket connections
- UART port assignments
- Buffer usage statistics
- Connection health monitoring

Status updates are printed to the console every 10 seconds, showing:

- Current socket file descriptors
- UART port mappings
- Memory buffer availability

12.57.2.1.11 Troubleshooting

12.57.2.1.11.1 Common Issues

1. **Port Already in Use:** Ensure UART port is not already connected
2. **Invalid Parameters:** Check baud rate and bit configuration ranges
3. **Connection Dropped:** Monitor network stability and WebSocket client implementation
4. **Buffer Overflow:** Monitor system buffer usage in high-throughput scenarios

12.57.2.1.11.2 Diagnostic Features

- Built-in task stack checking (when `NBRTOS_STACKCHECK` is enabled)
- Connection status reporting
- Buffer usage monitoring
- Automatic error detection and cleanup

12.57.3 Web Socket DIP Switch

Supported Platforms: MODM7AE70, MOD54415, MOD54417

12.57.3.1 Real-Time DIP Switch States via WebSocket

12.57.3.1.1 Overview

This NetBurner application demonstrates real-time monitoring of DIP switch states through a web interface using WebSockets. The application continuously polls DIP switches on the development board and instantly updates a webpage whenever switch positions change, without requiring page refreshes.

The application continuously polls the DIP switches and sends the state of the DIP switches via a websocket to the client. It's not the most efficient implementation when considering CPU utilization but this app demonstrates the capabilities of a WebSocket to allow the server(NetBurner device) to send the state of a variable to the client(webpage) with low latency and minimal packet size. This app also illustrates how to use the NetBurner JSON library to build and send JSON objects from the NetBurner device to the client. In this case, JSON objects are used to pass the state of the DIP switches to the webpage.

12.57.3.1.2 Features

- **Real-time Updates:** DIP switch state changes are immediately reflected on the connected webpage
- **WebSocket Communication:** Low-latency, minimal packet size communication between device and client
- **LED Control:** Interactive LED control through the web interface
- **JSON Data Exchange:** Structured data transfer using NetBurner's JSON library
- **Multi-platform Support:** Compatible with multiple NetBurner platforms

12.57.3.1.3 Supported Platforms

- MODM7AE70
- MOD5441x

12.57.3.1.4 Hardware Requirements

- NetBurner development board (one of the supported platforms)
- MOD-DEV-70CR carrier board
- 8 DIP switches (connected to specific pins)
- 8 LEDs (connected to specific pins)

12.57.3.1.5 Pin Configuration

12.57.3.1.5.1 LED Connections (J2/P2 Connector)

- LED 1: Pin 15
- LED 2: Pin 16
- LED 3: Pin 31
- LED 4: Pin 23
- LED 5: Pin 37
- LED 6: Pin 19
- LED 7: Pin 20
- LED 8: Pin 24

12.57.3.1.5.2 DIP Switch Connections (J2/P2 Connector)

- Switch 1: Pin 8 (A/D channel 7)
- Switch 2: Pin 6 (A/D channel 6)
- Switch 3: Pin 7 (A/D channel 5)
- Switch 4: Pin 10 (A/D channel 3)
- Switch 5: Pin 9 (A/D channel 4)
- Switch 6: Pin 11 (A/D channel 1)
- Switch 7: Pin 12 (A/D channel 0)
- Switch 8: Pin 13 (A/D channel 2)

12.57.3.1.6 How It Works

12.57.3.1.6.1 System Architecture

1. **Main Loop:** Continuously polls DIP switch states
2. **WebSocket Server:** Handles client connections and data transmission
3. **Input Task:** Processes incoming WebSocket messages for LED control
4. **JSON Communication:** Structures data exchange between device and web client

12.57.3.1.6.2 Data Flow

1. Application reads DIP switch positions using analog-to-digital conversion
2. Switch states are converted to JSON format
3. JSON data is transmitted via WebSocket to connected web clients
4. Web interface receives LED control commands and updates hardware accordingly

12.57.3.1.6.3 Switch State Detection

- **MCF5441X Platform:** Uses analog-to-digital conversion to read switch positions
- **Other Platforms:** Uses built-in `getdipsw()` function
- **State Logic:** 0 = switch ON, 1 = switch OFF
- **Change Detection:** Only transmits updates when switch states actually change

12.57.3.1.7 Key Components

12.57.3.1.7.1 WebSocket Endpoint

```
CallBackWSEndPoint ws("data", StartWS);
```

Creates a WebSocket endpoint at `/data` path for client connections.

12.57.3.1.7.2 JSON Data Structure

The application sends DIP switch states in the following JSON format:

```
{
  "dipSwitches": {
    "dip1": "On/Off",
    "dip2": "On/Off",
    ...
    "dip8": "On/Off"
  }
}
```

12.57.3.1.7.3 LED Control

LEDs can be controlled via incoming JSON messages with the format:

```
{
  "ledcb1": true/false,
  "ledcb2": true/false,
  ...
}
```

12.57.3.1.8 Configuration Parameters

- `INCOMING_BUF_SIZE`: 8192 bytes for incoming WebSocket data
- `REPORT_BUF_SIZE`: 512 bytes for outgoing JSON reports
- `NUM_LEDS`: 8 LEDs supported
- `NUM_SWITCHES`: 8 DIP switches supported
- `STATE_BUF_SIZE`: 8 bytes per switch state string

12.57.3.1.9 Usage

1. **Build and Deploy:** Compile and flash the application to your NetBurner device
2. **Network Connection:** Ensure the device is connected to your network
3. **Web Interface:** Connect to the device's web interface through a browser
4. **Real-time Monitoring:** Flip DIP switches to see immediate updates on the webpage
5. **LED Control:** Use the web interface to control individual LEDs

12.57.3.1.10 Performance Considerations

While this implementation continuously polls the DIP switches, it's designed for demonstration purposes rather than optimal CPU utilization. The polling approach clearly shows WebSocket capabilities for real-time data transmission with minimal latency.

12.57.3.1.11 Development Notes

- Uses NetBurner RTOS for task management
- Implements proper WebSocket message parsing with JSON object boundary detection
- Handles WebSocket connection lifecycle (connect/disconnect)
- Includes error handling for socket operations
- Uses semaphores for task synchronization

12.57.4 Web Socket Echo

12.57.4.1 WebSocket Echo Application

12.57.4.1.1 Overview

The WebSocket Echo Application is a real-time communication server that implements a WebSocket endpoint capable of echoing messages back to connected clients. Built for embedded systems or microcontroller environments, this application demonstrates basic WebSocket server functionality using a network stack framework.

12.57.4.1.2 Application Details

Application Name:** WebsocketEcho

12.57.4.1.3 Features

- **WebSocket Server:** Implements a WebSocket endpoint at the pattern "echo*"
- **Real-time Echo:** Receives messages from WebSocket clients and echoes them back
- **Network Stack Integration:** Built on top of a custom network initialization framework
- **HTTP Server:** Includes web server functionality on default port 80
- **Connection Management:** Handles WebSocket connection lifecycle with proper cleanup
- **System Diagnostics:** Optional diagnostic capabilities for development

12.57.4.1.4 Architecture

12.57.4.1.4.1 Core Components

1. **WebSocket Endpoint Handler:** `CallBackWSEndPoint wsep("echo*", WSStart)`

- Registers a WebSocket endpoint that matches URLs starting with "echo"
- Calls `WSStart()` callback when new connections are established

2. **Connection Management:**

- Global WebSocket file descriptor (`ws_fd`)
- Semaphore-based synchronization (`waitingForWS`)
- Select-based I/O multiplexing for non-blocking operations

3. **Echo Logic:**

- Reads incoming WebSocket data
- Writes data to stdout (for logging/debugging)
- Echoes the same data back to the WebSocket client
- Flushes WebSocket buffers to ensure immediate transmission

12.57.4.1.4.2 Application Flow

1. **Initialization Phase:**

- Initialize network stack
- Enable system diagnostics (development feature)
- Start HTTP server on port 80
- Wait for active network connection (5-second timeout)
- Initialize file descriptor sets for `select()` operations

2. **Main Loop:**

- Wait for WebSocket connection using semaphore
- Monitor WebSocket file descriptor for read/error events
- Handle incoming data by echoing it back to the client
- Manage connection cleanup on errors or disconnections
- Implement 1-second delay between connection attempts

12.57.4.1.5 Technical Implementation

12.57.4.1.5.1 Key Functions

- `WSStart(int rv)`: Callback function for new WebSocket connections
- `UserMain(void *pd)`: Main application entry point and event loop

12.57.4.1.5.2 System Dependencies

- Custom network initialization framework (`init.h`)
- WebSocket implementation (`websockets.h`)
- POSIX-style socket operations (`select`, `read`, `write`, `close`)
- Real-time operating system primitives (semaphores, timing)

12.57.4.1.5.3 Buffer Management

- Uses `SMPoolPtr` for memory pool management
- Buffer size defined by `ETHER_BUFFER_SIZE`
- Automatic buffer cleanup and reuse

12.57.4.1.6 Usage

12.57.4.1.6.1 Starting the Application

The application automatically starts when deployed to the target system:

1. Network stack initializes
2. HTTP server starts on port 80
3. WebSocket endpoint becomes available at URLs matching "echo*"
4. Application waits for WebSocket connections

12.57.4.1.6.2 Connecting Clients

WebSocket clients can connect to endpoints such as:

- `ws://[device-ip]/echo`
- `ws://[device-ip]/echo-test`
- `ws://[device-ip]/echo-anything`

12.57.4.1.6.3 Message Flow

1. Client sends WebSocket message
2. Server receives and logs message to stdout
3. Server immediately echoes message back to client
4. Client receives the echoed message

12.57.4.1.7 Development Notes

12.57.4.1.7.1 Production Considerations

- System diagnostics should be disabled in production builds
