10 REVISION HISTORY ........................................................................................................................................36
1 Introduction

The idea behind the Mod5213 development kit is to provide an embedded developer everything he or she needs to develop 32-bit embedded applications. The Mod5213 is pre-programmed with a factory demo application you can run right out of the box. The tools installation is quick and easy; just follow the prompts and the IDE, compiler and software will be installed. No configuration is required.

For those developers that are not familiar with the µC/OS real-time operating system (RTOS), do not worry. Use of the RTOS is not required. However, once you see firsthand how easy it is to use in the NetBurner environment, you may see things differently.

1.1 Development Kit Contents

The NetBurner Mod5213 development kit (NDK) includes:

- A Freescale 5213 microprocessor-based module (NetBurner Mod5213)
- A development carrier board for the Mod5213 that includes a power regulator, 4 LEDs, reset switch, RS-232 level shifter, DB9 connectors, CAN transceiver and real-time clock
- Integrated development environment (IDE)
- Real-time operating system (RTOS)
- C/C++ compiler and linker
- Serial cable
- 12 VDC power supply
1.2 The Mod5213

1.2.1 ColdFire 5213 Processor Block Diagram

The NetBurner Mod5213 is based on the Freescale ColdFire 5213 microcontroller. A block diagram of the 5213 is shown below. The signal pins exposed on the Mod5213 come directly from the processor.

![Block Diagram of the Mod5213 Processor](image)

1.2.2 Mod5213 Features

The Mod5213 is based on a 32-bit 66 MHz Freescale ColdFire 5213 processor. Features of this chip include:

- ColdFire® V2 Core
- Temperature range: -40°C to 85°C
- 63 MIPS @ 66 MHz
- MAC module and HW divide
- Low-power optimization
- Standard 40-pin DIP
- 32 kB SRAM
- 256 kB flash
- CAN 2.0B controller with 16 message buffers
- Three UARTs with DMA capability
- Queued serial peripheral interface (QSPI)
- Inter-integrated circuit (I²C) bus controller
- Four 32-bit timer channels with DMA capability
- Four 16-bit timer channels with capture/compare/PWM
- 4-channel/16-bit or 8-channel/8-bit pulse-width modulation (PWM) generator
- Two programmable interrupt timers (PIT)
- 4-channel DMA controller
- 8-channel/12-bit ADC
- Up to 33 general-purpose I/O
- System integration [phase-locked loop (PLL), software watchdog]
- PIN Dimensions: 1.9" x 0.6"
- PCB Dimensions: 2.3" x 0.7"
- 4.5V to 7.5V input to integrated 3.3V regulator
- 3.3V I/O (not 5V tolerant)

### 1.3 Applying Power to the Mod5213

The Mod5213 has two power pins: one is a regulated 3.3 VDC input, and the other is a 4.5–7.5 VDC input. You can power the Mod5213 using either pin, but do not connect power to both at the same time. The development kit carrier board has its own voltage regulator that supplies regulated 3.3 VDC to the 3.3 VDC input power pin.

### 2 Development Kit Setup

This programming guide uses examples based on the Mod5213 and the development kit carrier board. To run the examples, you will need to set up your development hardware by connecting power, the serial port and Mod5213 module, if it isn't mounted already. The diagram below shows the proper connections. The serial cable is connected to serial port 0. The other DB9 is serial port 1. The Mod5213 must be inserted into the socket with the card edge connector facing the center of the board. There is a reset button at the top of the carrier board to the left of the Mod5213.
3 Running the Factory Demo

3.1 Setup

The Mod5213 factory demo is pre-programmed into your Mod5213. The demo uses serial port 0 and the LED display. To run the demo:

- Connect power and the serial port as described in the previous section
- Connect the other end of the serial cable to a serial port on your computer
- Run the NetBurner MTTY program, which can be started from Start → All Programs → NetBurner NNDK → Mttty Serial Terminal, or from NBEclipse → Mtty of the NBEclipse IDE.
- Click on the "Flow Control..." button and verify that the checkboxes for "XON/XOFF Output Control" and "XON/XOFF Input Control" are checked.
- Select the COM port, 115,200 baud, no parity, 8 data bits and 1 stop bit, then click on the "Connect" button in MTTY
- Press the reset button on the carrier board and verify that you see the Mod5213 boot message in the MTTY window. An example of the message is shown below.
- If you do not see the boot message, then check the setup and repeat until the boot message appears.
3.2 Description of the Factory Demo

The factory demo is an example of a simple application that uses the RTOS and GPIO. The GPIO functions are based on the NetBurner Pin Class described later in this document. The application will run two tasks at the same time: one for the carrier board LED display, and the other to process user commands via the serial port. When the application runs, it will display the command menu and the LEDs will begin their display sequence. The source code is well documented, and is an excellent example to illustrate programming of the Mod5213.

3.3 Factory Demo Commands

The main menu in the MTTY terminal window shows the valid commands:

C to toggle enable/disable LED counting sequence  
+/- to select the Mod5213 pin number  
H/L to set the selected pin High/Low  
Z to set the selected pin to high impedance  
D to enable the drive of the selected pin (opposite of Hiz)  
R to read the selected pin state

The ‘C’ command tells the LED display task whether or not to update the LEDs. Pressing the ‘C’ key will toggle between enabling and disabling LED writes.

The remaining commands let you experiment with the GPIO functions of the Mod5213. Use the '+' / '-' keys to select a pin, then set the pin state to high, low, high impedance (disable drive), enable drive or read the state of the pin as an input. If you disable LED writes with the ‘C’ command, you can write the GPIO states of pins 25, 26, 27 and 28 high and low, which will turn the LEDs on and off.
3.4 Application Source Code

/*
 * This declaration will tell the C++ compiler not to "mangle" the function name
 * so it can be used in a C program. We recommend you make all your file
 * extensions .cpp to take advantage of better error and type checking, even if
 * you write only C code.
 */

extern "C"
{
    void UserMain( void *pd );
}

void LedScan()
{
    static unsigned char position = 0;
    const unsigned char pattern_array[] = { 0x01, 0x02, 0x04, 0x08, 0x04,
                                            0x02 };

    if ( position > 5 )
        position = 0;
    putleds( pattern_array[position++] );
}
/*----------------------------------------------------------------------- 
This will make the LEDs on the carrier board count in binary. 
-----------------------------------------------------------------------*/ 

void LedCount() 
{ 
  static int n = 0;  // Init count value to 0 
  putleds( n++ );  // Write new value to LEDs 
} 

_learning://----------------------------------------------------------------------- 
This is a RTOS task that writes to the LEDs on the carrier board. It will 
switch between two different light sequences. 
-----------------------------------------------------------------------*/ 

void LedTask( void *p ) 
{ 
  static int SequenceCount = 0;  // Counts iterations for each LED seq 
  static BOOL CountSequence = TRUE;  // Selects Count or Scan sequence 
  
  while ( 1 )  // Loop forever 
  { 
    /* 
      Use the RTOS OSTimeDly() to delay between LED writes. This function 
      is a "blocking function", which means it lets lower priority 
      tasks run while it is delaying. This is extremely important in a 
      preemptive OS. Since this task is higher priority than UserMain(), 
      it must block, otherwise UserMain() would never run. 
    */ 
    OSTimeDly( TICKS_PER_SECOND / 8 );  // There are 20 ticks per second 
    if ( bLedSequenceEnable )  // Check enable flag 
    { 
      if ( SequenceCount > 128 )  // Switch to other seq after 128 iterations 
      { 
        SequenceCount = 0; 
        CountSequence = !CountSequence; 
      } 
      SequenceCount++; 
      if ( CountSequence ) 
        LedCount(); 
      else 
        LedScan(); 
    } 
  } 
} 

/*----------------------------------------------------------------------- 
Display the command menu for user commands. 
-----------------------------------------------------------------------*/

return from UserMain().
*/
DisplayCommandMenu();
while ( 1 )
{
    char c = sgetchar( 0 );
    ProcessCommand( c );
}
}
4 Compiling, Downloading and Running an Example Program

Please refer to section four, "Creating a Project for a NetBurner Example Application" and section five, "Downloading Applications to NetBurner Hardware – Creating 'Run' and 'Debug' Configurations" in the "NB Eclipse Getting Started Guide" on how to successfully run a Mod5213 example program. This PDF document can be accessed from the Windows Start menu (assuming a Windows XP environment): Start → All Programs → NetBurner NNDK → NB Eclipse → NB Eclipse Getting Started, or by directly accessing the file in \Nburn\docs\Eclipse.

The NB Eclipse guide provides a full introduction to the NB Eclipse IDE, and describes the steps of creating a project and importing existing example program source files to configuring your Run settings before finally downloading and running an application on the module. The NB Eclipse guide is tailored to help users on how to program any NetBurner device, especially the non-networked Mod5213 module (the Mod5270 prime example in the guide section is used as a reference point for any device). Since the Mod5213 has no support for Ethernet networks, pay attention to parts of the section that draw attention to different options for the Mod5213.

4.1 Hardware Setup

Before following the NB Eclipse guide, you must make sure that the Mod5213 is connected properly to your computer and have RS-232 serial communications. For example, you can run MTTYTY and verify that you see the boot message when you press the reset button on the Mod5213 carrier board. To start the MTTYTY serial terminal program, select Start → All Programs → NetBurner NNDK → Mtty Serial Terminal.

4.2 Using the .cpp Source Code File Extension

Even if you do not intend to use any C++ source code, it is recommended that you use the .cpp file extensions to take advantage of the enhanced compiler error and type checking. It will also enable you to use NetBurner APIs that do rely on C++.
5 Updating Flash Memory Using a Serial Port

The serial flash download to the Mod5213 is a very useful tool. Your application must include the following line:

```c
#include <SerialUpdate.h>
```

and call the function `EnableSerialUpdate()` in order to enable this capability. The NetBurner application code will listen on any initialized serial ports for incoming updates, and process the update if the proper command sequence is sent. This is a preemptive feature, so a custom application is free to use the serial ports for any purpose.

The SerialLoad application tool or NBEclipse IDE (which in turn calls SerialLoad) will attempt to gain access to a serial port on your PC when executing a serial update. If no running applications are actively utilizing the serial ports, then the serial update process will perform an application download. MTTY has been written to work with the serial update utility, which is also known as "Serial Update Tool" or "SerialLoad". If MTTY is running on a serial port, then the serial update utility will run the update through MTTY, provided that software flow control is enabled. However, if you are using another program or serial terminal (e.g., Microsoft Windows HyperTerminal) to interface with the serial port, then the serial update utility will not be able to use that port.

If polled serial I/O is being used in the custom application, then you need to remember that the serial update will only work if there is a blocking call to a serial input, such as `getchar()` or `read()`. If you are using interrupt-driven I/O, then this is not an issue.

The Mod5213’s boot monitor also supports serial downloads, so if you are developing an application that is repeatedly crashing, then you can abort to the monitor prompt after reset by typing `<Shift> + 'A'` (or just ‘A’ if caps lock is enabled), followed by performing a serial update in the normal manner (by using the "Serial Update Tool" standalone application or by using the NBEclipse IDE).

IMPORTANT: In any cases when sending/receiving binary data on a serial port be sure to call the function: `IRQ_SerialLoad_On_Channel(int port, bool enable);` to disable serial updates on that channel (set the enable parameter to FALSE). Failure to do so can cause a problem if the serial update initiate sequence occurs in the binary data stream.
6 Polled and Interrupt-Driven Serial Port Drivers

6.1 Polled vs. Interrupt-Driven

The NetBurner API provides two types of serial interfaces for the Mod5213 onboard UARTs: polled and interrupt-driven. You can switch between either mode easily just by changing an include file in your application; the application function calls are identical.

Polling means that any time your application attempts a serial read or write, the underlying code will block until a character can be read or written. This is accomplished by polling a status bit in the UART registers. The advantage of polling is that it takes up less SRAM resources than an interrupt-driven scheme since the serial I/O is not buffered.

Interrupt-driven means that the serial I/O is buffered so your application does not have to wait for the actual I/O to occur. It also means the application will not miss any incoming characters when it is busy elsewhere. Unless you are constrained on SRAM space, interrupt-driven serial I/O is recommended.

6.2 Serial Polling and Interrupt-Driven Example Programs

In the AppWizard-generated application below, we can see that it uses interrupt-driven serial I/O, as indicated by the included serialirq.h header file:

```c
#include <stdio.h>
#include <ctype.h>
#include <basictypes.h>
#include <serialirq.h>
#include <system.h>
#include <constants.h>
#include <ucos.h>
#include <SerialUpdate.h>

// Instruct the C++ compiler not to mangle the function name extern "C"
extern "C"
{
  void UserMain( void *pd );
}

// Name for development tools to identify this application
```
const char *AppName = "NewApp5213";

// Main task
void UserMain( void *pd )
{
    OSChangePrio( MAIN_PRIO );
    EnableSerialUpdate();
    SimpleUart( 0, SystemBaud );
    assign_stdio( 0 );
    iprintf( "Application started\r\n" );

    while ( 1 )
    {
        OSTimeDly( TICKS_PER_SECOND );
    }
}

We can convert this to polled serial I/O just by changing the include file. However, if we want the serial flash update utility to work, we need to look (poll) for any incoming characters. The code to do this has been added to the while loop in UserMain() and highlighted in italics:

    /*******************************************************************************
    Application generated by AppWizard
    *******************************************************************************/

#include "predef.h"
#include <stdio.h>
#include <ctype.h>
#include <basictypes.h>
#include <serialirq.h>
#include <system.h>
#include <constants.h>
#include <ucos.h>
#include <SerialUpdate.h>

    // Instruct the C++ compiler not to mangle the function name
extern "C"
{
    void UserMain( void *pd );
}

    // Name for development tools to identify this application
const char *AppName = "NewApp5213";

// Main task
void UserMain( void *pd )
{
    OSChangePrio( MAIN_PRIO );
    EnableSerialUpdate();
    SimpleUart( 0, SystemBaud );
    assign_stdio( 0 );
    iprintf( "Application started\r\n" );
while ( 1 )
{
    // Check for I/O on UART 0
    if ( charavail( 0 ) )
        char c = getchar();

    OSTimeDly( TICKS_PER_SECOND );
}
}
6.3 Modifying Interrupt Serial Buffer Values

The serial I/O buffer sizes for the Mod5213 are located in `\Nburn\include\nn\constants.h`, and are shown below (in bytes):

```c
/**
 * Maximum UART buffer sizes.
 */
#define SERIAL0_RX_BUFFER_SIZE   ( 256 )
#define SERIAL0_TX_BUFFER_SIZE   ( 256 )
#define SERIAL1_RX_BUFFER_SIZE   ( 256 )
#define SERIAL1_TX_BUFFER_SIZE   ( 256 )
#define SERIAL2_RX_BUFFER_SIZE   ( 256 )
#define SERIAL2_TX_BUFFER_SIZE   ( 256 )
```

The default transmit and receive buffer size for each of the three UARTs is 256 bytes. The total memory used is: 256 bytes * 6 = 1536 bytes of SRAM. You can change these values to increase or decrease the overall memory usage. After making the modifications, the system library needs to be recompiled in order for the new changes to take effect. This can easily be done in the NBEclipse IDE by going to the top main menu and selecting: NBEclipse → Rebuild system files, followed by recompiling your custom application.

6.4 The NetBurner Serial API

The following sections describe the NetBurner serial API function calls. All the functions can be run in polled or interrupt-driven mode by changing the include file as described earlier in this chapter. Each API function call has the underlying polled and interrupt-driven functions defined.

6.4.1 Open a Serial Port

The following function calls are used to initialize a serial port. The `SimpleUart()` call assumes default values for the most common parameters (used 1 stop bit, 8 data bits and no parity).

```c
int InitUart( int portnum, 
        unsigned int baudrate, // Baud rate: 1200-115,200 bps
        int stop_bits, // Valid values: 1 or 2
        int data_bits, // Valid values: 5, 6, 7 or 8
        parity_mode parity ); // Valid values: eParityNone, eParityOdd, eParityEven or eParityMulti

int SimpleUart( int portnum, // UART port number: 0, 1 or 2
        unsigned int baudrate); // Baud rate: 1200-115,200 bps
```
Return Values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Success</td>
<td>(  0 )</td>
</tr>
<tr>
<td>SERIAL_ERR_NOSUCH_PORT</td>
<td>(-1)</td>
</tr>
<tr>
<td>SERIAL_ERR_PORT_NOTOPEN</td>
<td>(-2)</td>
</tr>
<tr>
<td>SERIAL_ERR_PORT_ALREADYOPEN</td>
<td>(-3)</td>
</tr>
<tr>
<td>SERIAL_ERR_PARAM_ERROR</td>
<td>(-4)</td>
</tr>
</tbody>
</table>

When serialpoll.h is included: InitPolledUart() is called.
When serialirq.h is included: InitIRQUart() is called.

### 6.4.2 Check if a Character is Available to be Read

```c
BOOL charavail( int portnum ); // UART port number: 0, 1 or 2
```

When serialpoll.h is included: polled_charavail() is called.
When serialirq.h is included: IRQ_charavail() is called.

### 6.4.3 Get a Character

This function will block until a character is available to be read.

```c
char sgetchar( int portnum ); // UART port number: 0, 1 or 2
```

When serialpoll.h is included: polled_getchar() is called.
When serialirq.h is included: IRQ_getchar() is called.

**Note:** The polled version does not yield to the RTOS, so no lower priority task can run. The IRQ version will yield to the RTOS until a character is available to be read.

### 6.4.4 Write a Character or String

Both of these functions will block until at least one character can be written.

```c
void writechar( int portnum, char c ); // UART port number: 0, 1 or 2
void writestring( int portnum, const char *s ); // Pointer to a constant string to write
```

When serialpoll.h is included: polled_writechar() / polled_writestring() is called.
When serialirq.h is included: IRQ_writechar() / IRQ_writestring() is called.
6.4.5 Close a Serial Port

```c
void close( int portnum );  // UART port number: 0, 1 or 2
```

When serialpoll.h is included: polled_close() is called.
When serialirq.h is included: IRQ_close() is called.

6.4.6 Disable Serial Update on a Specific Port

```c
void IRQ_SerialLoad_On_Channel(int portnum, BOOL enable)
```

If a serial port will be receiving binary data you must disable the serial update feature to avoid the possibility of the serial update initiation code appearing in the binary data stream.

For example: IRQ_SerialLoad_On_Channel( 1, FALSE);

6.4.7 Assign a Serial Port as stdio

This function will enable you to use stdio function calls with the specified serial port, such as iprintf(), printf(), iscanf() and scanf().

```c
void assign_stdio( int portnum );  // UART port number: 0, 1 or 2
```

When serialpoll.h is included: polled_assign_stdio() is called.
When serialirq.h is included: IRQ_assign_stdio() is called.

6.4.8 Assign a Serial Port as stderr

This function allows you to use standard error I/O with the specified serial port, such as fprintf( stderr, ... ), fscanf( stderr, ... ), etcetera.

```c
void assign_sterr( int portnum );  // UART port number: 0, 1 or 2
```

When serialpoll.h is included: polled_assign_err() is called.
When serialirq.h is included: IRQ_assign_err() is called.

6.4.9 Create a Serial File Pointer
This creates a FILE-type pointer that can be used to read and write to a serial port with functions that take file pointers as parameters, such as `fprintf()`, `fscanf()`, etcetera.

```c
FILE *fp = create_file( int portnum ); // UART port number: 0, 1 or 2
```

For example:

```c
FILE *fp = create_file( 1 ); // Create a FILE pointer for UART 1
fprintf( fp, "This goes out port 1\r\n" ); // Write string
fclose( fp );
```

When `serialpoll.h` is included: `polled_create_file()` is called.
When `serialirq.h` is included: `IRQ_create_file()` is called.
7 General Purpose I/O and the NetBurner Pin Class

The pins on the two 20-pin headers on the Mod5213 consist mostly of signal pins that can be set to a special function or GPIO, two power pins and a ground pin. Each signal pin can be set to a special function or GPIO. For example, pin 4 can be set to GPIO, I²C Clock, CAN transmit or UART 2 transmit. When using a pin as GPIO, you can configure it as an input, or an output that can be low, high or high impedance. The table below summarizes the functions of each pin.

</tbody>
</table>
Note the supported function names for each pin. They represent the actual definition names that can be used to configure each pin if you choose to use the NetBurner Pin Class. These definitions are located in the header file `\Nburn\MOD5213\include\pinconstant.h`.

### 7.1 Which Pins Can Be Used as GPIO?

The signal pin description chart above specifies in the "Support GPIO?" column whether a pin can be used as GPIO. One exception to this case are the UART 0 receive and transmit signals; despite being configurable for GPIO, you will need these to interface with the Mod5213 system monitor.

### 7.2 What is the NetBurner Pin Class?

As you can see from the signal pin chart, each pin can be used for a variety of functions. However, before it can be made useful, one needs to know what module register needs to be written to and what bits need to be set in the MCF5213 processor in order to configure the signal pin. Rather than make the user read the extensive Freescale ColdFire 5213 reference manual, the Pin Class was created to make configuration and operation much easier. Although the Pin Class is written in C++, you do not need to know much C++ to use it; your application can be written using only C syntax.

Note that you do not need to use the Pin Class. If you prefer to handle the configuration and management yourself, then you are free to do so. If you do not include any Pin Class function calls, then none of the Pin Class code will be linked to your application. The Pin Class is a very efficient implementation with performance that will meet most requirements. It is simple to use – you may want to give it a try for a quick benchmark before writing your own configuration code.
7.3 Pin Class API Summary

To read, write or configure a pin where ‘x’ is the pin number:

\[
\begin{align*}
\text{Pins}[x] &= 0; & \text{Set GPIO output low} \\
\text{Pins}[x] &= 1; & \text{Set GPIO output high} \\
\text{Pins}[x].hiz(); & \text{Set GPIO to high impedance (tri-state)} \\
\text{Pins}[x].drive(); & \text{Turn on GPIO output} \\
\text{int } n &= \text{Pins}[x]; & \text{Read GPIO input and return an int-type value} \\
\text{BOOL } b &= \text{Pins}[x]; & \text{Read GPIO input and return a boolean-type value} \\
\text{Pins}[x].function( \text{FUNCTION} ); & \text{Configure pin for special function}
\end{align*}
\]

The value of "FUNCTION" in the Pins[x].function() call above represents any definition name in the primary or alternate function columns of the signal description chart above. For example, to configure pins 4 and 5 for the CAN interface:

\[
\begin{align*}
\text{Pins}[4].function( \text{PIN4_CANTX} ); \\
\text{Pins}[5].function( \text{PIN5_CANRX} );
\end{align*}
\]

7.4 A Simple Pin Class GPIO Example

The following example illustrates how to read and write signal pins that can be used as GPIO. In this example, pin 25 is used as GPIO output since it is connected to a LED on the MOD-DEV-40 development board. This way, we can see the state of the pin as the LED turns on and off. Pin 4 is used as GPIO input – we cannot automatically change the state of the input pin, so it will always read low (0). The program runs in a loop that toggles the output state each ½ second, and reads the input pin once every second.

\[
\begin{align*}
\text{void } \text{UserMain}( \text{void } *\text{pd} ) \\
\{ \\
\quad \text{SimpleUart}( 0, \text{SystemBaud} ); & \text{Initialize UART 0} \\
\quad \text{EnableSmartTraps}(); & \text{Enable SmartTrap utility} \\
\quad \text{OSChangePrio}( \text{MAIN_PRIO} ); & \text{Set standard main task priority} \\
\quad \text{EnableSerialUpdate}(); & \text{Enable Serial Update utility} \\
\quad \text{assign_stdio}( 0 ); & \text{Use UART 0 for stdio}
\end{align*}
\]

\[
\begin{align*}
\text{printf}( \text{"Starting SimpleGPIO Example\n"} ); \\
\text{while } ( 1 ) \\
\{ \\
\quad \text{// Configure pin 25 as an output and set it to 0. This pin is connected} \\
\quad \text{// to a LED on the Mod5213 carrier board, so you can watch it blink.} \\
\quad \text{Pins}[25] = 0; \\
\quad \text{OSTimeDly( TICKS_PER_SECOND / 2 );}
\end{align*}
\]

\[
\begin{align*}
\text{// Setting pin 25 high (1) lights up the LED} \\
\text{Pins}[25] = 1;
\end{align*}
\]
OSTimeDly( TICKS_PER_SECOND / 2 );

    int n = Pins[4];  // Read the current value of pin 4 as an input
    printf( "Pin[4] input value = %d\r\n", n );
  }
}

7.5 A Simple Pin Class Special Function Example

The following code illustrates how to configure a pin for a special function: \( \text{I}^2\text{C} \). However, this only demonstrates how to handle the pin configuration. The application would still need to implement the \( \text{I}^2\text{C} \) driver.

```c
void UserMain( void *pd )
{
    SimpleUart( 0, SystemBaud );   // Initialize UART 0
    EnableSmartTraps();            // Enable SmartTrap utility
    OSChangePrio( MAIN_PRIO );     // Set standard main task priority
    EnableSerialUpdate();          // Enable Serial Update utility
    assign_stdio( 0 );             // Use UART 0 for stdio

    printf( "Starting SimplePinFunction Example\r\n" );
    Pins[4].function( PIN4_SCL );
    Pins[5].function( PIN5_SDA );

    while ( 1 )
    {
        // Application code goes here
    }
}
```
8 Analog-to-Digital Functions

8.1 Mod5213 A/D Capabilities

The Mod5213 has two separate 12-bit A/D converters, each with their own sample-and-hold circuit. Each converter has four multiplexed analog inputs, providing eight channels of analog input.

The ColdFire 5213 processor’s onboard A/D features include:

- 12-bit resolution
- Maximum ADC clock frequency of 5.33 MHz (period of 187.5 ns)
- Sampling rate up to 1.78 million samples per second (see Footnote 1)
- Single conversion time of 8.5 ADC clock cycles (8.5 * 187.5 ns = 1.595 µs)
- Additional conversion time of 6 ADC clock cycles (6 * 187.5 ns = 1.126 µs)
- Eight conversions in 26.5 ADC clocks (26.5 * 187.5 ns = 4.972 µs) using simultaneous mode
- Ability to simultaneously sample and hold two inputs
- Ability to sequentially scan and store up to eight measurements
- Internal multiplex to select two of eight inputs
- Power saving modes allow automatic shutdown/startup of all or part of ADC
- Inputs that are not selected can tolerate injected/sourced current without affecting ADC performance, supporting operation in noisy industrial environments
- Optional interrupts at the end of a scan if an out-of-range limit is exceeded (high or low), or at zero crossing
- Optional sample correction by subtracting a preprogrammed offset value
- Signed or unsigned result
- Single-ended or differential inputs for all input pins with support for an arbitrary mix of input types

Footnote 1: Once in loop mode, the time between each conversion is six ADC Clock cycles (1.125 µs). Using simultaneous conversion, two samples are captured in 1.126µs, providing an overall sample rate of 1,776,667 samples per second.

8.2 The NetBurner Mod5213 A/D API

The Mod5213 API supports automatic continuous sampling of all eight input channels, and a function to read the last sampled value for a particular analog input channel. If you need precise interrupt-driven sampling and control, then you will need to create an A/D driver specific to your application. The Freescale ColdFire 5213 Reference Manual is a good reference on how to configure the A/D system to meet your application requirements.
8.3 Default Sample Rate

The A/D sample rate for a single, active A/D channel is: $33,177,600 \text{ Hz} / (\text{clock}_\text{div} \times 6)$. The sample rate for any one channel must be divided by the number of active channels. For example, if all eight A/D channels are active, and the default value of "clock\_div = 7" is used, then the sample rate per channel is: $33,177,600 \text{ Hz} / (\text{clock}_\text{div} \times 6 \times 8 \text{ active channels}) = 98,742$ samples per second.

8.4 API Functions

Using the A/D functions with the Mod5213 API is very simple: call the function `EnableAD()` to activate the A/D background sampling, and then call `ReadA2DResult()` to read the latest sample. The functions are shown below:

```c
void EnableAD( BYTE clock_div = 7 ); // Default clock divider value is 7
WORD ReadA2DResult( int ch ); // Valid channel numbers: 0 to 7
```

Note that the MCF5213 A/D hardware reports the 12-bit value in a 16-bit format to accommodate the many A/D operating modes. For a single-ended measurement, the count value is stored in the upper 12 bits of a 16-bit word.

8.5 Mod5213 Hardware Configuration

The Mod5213 provides the following connections on the 40-pin header:

- **VDDA**: A/D voltage input
- **VRH**: A/D voltage reference high
- **VRL/VSSA**: A/D voltage reference low and voltage power ground

The A/D on the Mod5213 has its own power and ground connections, as well as a separate A/D voltage reference input in case you want to use a precision voltage reference. The Mod5213 development kit carrier board has two jumpers that can be used for development purposes:

- **JP3**: Connect VDDA to 3.3 VDC
- **JP4**: Connect VRH to 3.3 VDC
8.6 A/D Example

The Mod5213 A/D example is located in \Nburn\examples\MOD5213\a2d. You can view the A/D readings via the serial port in the MTTY terminal window when you run the example. A MTTY screenshot is shown below:
8.7 A/D Example Source Code Listing

```c
#include "predef.h"

#include <a2d.h>
#include <Pins.h>

extern "C"
{
    void UserMain( void *pd );
}

void UserMain( void *pd )
{
    OSChangePrio( MAIN_PRIO );
    EnableSmartTraps();
    EnableSerialUpdate();
    SimpleUart( 0, SystemBaud );
    assign_stdio( 0 );
    // Configure the A2D pins as analog inputs
    Pins[11].function( PIN11_AN2 );
    Pins[12].function( PIN12_AN1 );
    Pins[13].function( PIN13_AN0 );
    Pins[14].function( PIN14_AN3 );
    Pins[15].function( PIN15_AN7 );
    Pins[16].function( PIN16_AN6 );
    Pins[17].function( PIN17_AN5 );
    Pins[18].function( PIN18_AN4 );
    
    /*
     * Enable the A2D. The A2D subsystem will run in the background
     * doing samples at 98.742 KHz per channel. This is all done in
     * hardware with no CPU overhead.
     */
    EnableAD();

    while ( 1 )
    {
        printf( "Hit any key to display A2D readings\r\n" );
        char c = sgetchar( 0 ); // Direct call to serial driver, not stdio
        for ( int i = 0; i < 8; i++ )
        {
            /*
             * Display the A2D readings
             */
            /*
             */
        }
    }
}
```

Mod5213 Programming Guide
The count value returned by ReadA2DResult() is the value stored from the previous sample, at the 98.742KHz sample rate. The number of sample counts is stored as a 16-bit value to accommodate the various configurations of the A/D channels. Since we are doing a simple single ended measurement between 0 and 3.3V, we will left shift the count value so it falls within the 12-bit 4096 count range.

```c
int counts = ReadA2DResult( i ) >> 3;
float volts = ( ( float ) counts / ( 4095.0 ) ) * 3.3;
printf( "AD[%d] = %d counts, %f volts\n", i, counts, volts );
```

iprintf( "\r\n" );
```
9 NetBurner µC/OS RTOS

The µC/OS is a very stable, fast and reliable operating system. The NetBurner implementation takes up very little memory, and it can make applications much easier to code and maintain. In most cases, applications will simply create a few tasks and pass messages between tasks, as in the case with the Mod5213 factory demo application. Even if you only need a single UserMain() task, some of the RTOS functions such as OSTimeDly() and the interrupt-driven serial I/O can come in handy.

The UserMain() function in the application code is equivalent to a standard C-type main() function. If that is all your application requires, then you may not need to use additional RTOS functions. But if you do need advanced features, µC/OS has plenty to offer. For more in-depth information on various RTOS functions, please refer to the "NetBurner's µC/OS RTOS Library" PDF document in \Nburn\docs\NetBurnerRuntimeLibrary\uCOSLibrary.pdf.

9.1 RTOS System Resource Usage

Use of the RTOS will have an impact on system resources. The default values for these resources are located in \Nburn\include_nn\constants.h. You have the option of specifying a non-default value when you call an RTOS function, or you can change the default values in constants.h. Whenever you make a change to a system file in \Nburn\include_nn\.h or \Nburn\system_nn\.c, .cpp), be sure to rebuild the system libraries – either via NBEmclipse or in the Windows command prompt – for the changes to take effect.

9.1.1 Task Stack Size

Each task has its own stack space. If you use the following function:

```c
OSSimpleTaskCreate( TaskName, Priority );
```

the default stack size will be used (1024 bytes). The system idle and UserMain() tasks are created at boot and will use 256 bytes and 1024 bytes respectively. Their values are defined as:

```c
#define IDLE_STK_SIZE            (  256 ) /* Idle task */
#define USER_TASK_STK_SIZE       ( 1024 ) /* User-defined tasks */
```
9.1.2 System Clock Tick

The RTOS system clock uses the MCF5213 Programmable Interrupt Timer (PIT) 0, which is configured with at interrupt request level '1' and priority level '3'. The default number of ticks per second is defined as:

```
#define TICKS_PER_SECOND (20) /* System clock tick */
```

If you need to change the ticks-per-second value, then the recommended values are between 20 and 200. For high resolution timing such a microsecond intervals, the best method is to use another hardware timer in the MCF5213, such as a separate PIT timer channel, or one of the DMA timer channels.

9.1.3 Maximum Number of Tasks

The maximum number of tasks is set at twenty by default. Allowing for reserved tasks, this number can be increased to fifty-six.

```
#define OS_MAX_TASKS (20) /* Maximum number of system tasks */
```

9.1.4 Task Priorities

The convention in µC/OS is that the lower the number, the higher the priority. This means a priority number of 50 is lower priority than 49. In a preemptive RTOS, the highest priority task (lowest priority number) will always run unless a blocking function is called in the higher priority task.

Priorities range from 0 to 63, with 0-3 reserved for future system usage, and 63 reserved for the system idle task. The system idle task is the lowest priority since it is designed to run only when nothing else of higher priority is available. It is just a series of assembly "nop" (no operation) instructions.

The recommended priority for UserMain() is 50. This number is arbitrarily selected so that applications can easily pick lower or higher priorities for other tasks. It also originated from NetBurner network-enabled platforms, where additional system-created tasks occupy priorities between 20 and 30.

```
#define MAIN_PRIO (50) /* UserMain() */
```
9.1.5 Interrupt-Driven Serial Ports

The interrupt-driven serial port drivers also use the RTOS library, specifically the OS semaphore library functions for managing shared resources (i.e., serial receive and transmit buffers): OSSemInit(), OSSemPend() and OSSemPost(). Details on how these functions work can be found in the "NetBurner's µC/OS Library" PDF document. The interrupt-driven serial driver uses the buffers to store receiving and sending data. The default size for both receive and transmit buffers for all UARTs is 256 bytes. This value is defined in \Nburn\include\n\constants.h, and is also mentioned in section 6.3 of this document.

9.1.6 Building Applications Without the RTOS

You can build applications without using the µC/OS RTOS if you want total control of the hardware. To do this, you create a main() function instead of a UserMain() function. An example is shown below:

```c
#include "predef.h"
#include <basictypes.h>     // Include for user-defined types
#include <serialpoll.h>     // Use polled serial driver
#include <SerialUpdate.h>   // Enable support for serial flash update

/*
   The main() function is normally handled by the operating system. You can declare your own if you want to have complete control over the hardware and not use the RTOS.
*/
int main()
{
    SimpleUart( 0, 115200 );
    EnableSerialUpdate();

    writestring( 0, "This application does not use the RTOS\r\n" );

    while( 1 );
}
